xanthines (aminophylline and theophylline): Possibly decreased therapeutic effects of both drugs

FOODS

all food: Increased blood labetalol level

ACTIVITIES

alcohol use: Increased labetalol effects

Adverse Reactions

CNS: Anxiety, confusion, depression, dizziness, drowsiness, fatigue, paresthesia, syncope, vertigo, weakness, yawning

CV: Bradycardia, chest pain, edema, heart block, heart failure, hypotension, orthostatic hypotension, ventricular arrhythmias

EENT: Nasal congestion, taste perversion

GI: Elevated liver function test results, hepatic necrosis, hepatitis, indigestion, nausea, vomiting

GU: Ejaculation failure, impotence

RESP: Dyspnea, wheezing

SKIN: Jaundice, pruritus, rash, scalp tingling

Nursing Considerations

• During I.V. labetalol use, monitor blood

pressure according to facility policy, usually every 5 minutes for 30 minutes, then every 30 minutes for 2 hours, and then every hour for 6 hours.

- Keep patient in supine position for 3 hours after I.V. administration.

WARNING Be aware that labetalol masks common signs of shock.

- Monitor blood glucose level in diabetic patient because labetalol may conceal symptoms of hypoglycemia.
- Be aware that stopping labetalol tablets abruptly after long-term therapy could result in angina, MI, or ventricular arrhythmias. Expect to taper dosage over 2 weeks while monitoring response.

PATIENT TEACHING

- Advise patient to report confusion, difficulty breathing, rash, slow pulse, and swelling in arms or legs.
- Caution patient not to stop drug abruptly because doing so could cause angina and rebound hypertension.
- Suggest that patient minimize effects of orthostatic hypotension by rising slowly, avoiding sudden position changes, and taking labetalol at bedtime, if approved by prescriber.
- Instruct diabetic patient to check blood glucose level often and to be alert for signs and symptoms of hypoglycemia.
- Inform patient that scalp tingling may occur early in treatment but is transient.
- Urge patient to avoid alcohol during labetalol therapy.

lacosamide

Vimpat

Class and Category

Chemical class: Functionalized amino acid

Therapeutic class: Anticonvulsant

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat partial-onset seizures in patients with epilepsy*

TABLETS

Adults and adolescents age 17 and over.

Initial: 50 mg b.i.d., increased by 100 mg/day at weekly intervals based on response and tolerance. *Maintenance:* 200 to 400 mg daily.

I.V. INFUSION

Adults and adolescents age 17 and over.

Initial: 50 mg infused over 30 to 60 min b.i.d., increased by 100 mg/day at weekly intervals. *Maintenance:* 200 to 400 mg daily.

DOSAGE ADJUSTMENT For patients with creatinine clearance of 30 ml/min/1.73 m² or less, maximum is 300 mg daily.

Mechanism of Action

May selectively inactivate voltage-gated sodium channels, which prevents seizure activity by stabilizing hyperexcitable neuronal membranes and inhibiting repetitive neuronal firing in the brain.

Contraindications

Hypersensitivity to lacosamide and its components

Interactions

DRUGS

drugs that may prolong the QT interval:

Possibly further QT-interval prolongation

Adverse Reactions

CNS: Asthenia, ataxia, attention deficit, cerebellar syndrome, confusion, depression, dizziness, feeling drunk, fever, headache, hypoesthesia, impaired balance, irritability, memory impairment, mood alteration, paresthesia, somnolence, suicidal ideation, tremor, vertigo

CV: Palpitations, prolonged QT interval

EENT: Blurred vision, diplopia, dry mouth, nystagmus, oral hypoesthesia, tinnitus

GI: Constipation, diarrhea, dyspepsia, nausea, vomiting

HEME: Anemia, neutropenia

MS: Dysarthria, muscle spasms

SKIN: Pruritus, rash

Other: Delayed multi-organ hypersensitivity reaction; injection site pain, irritation, and erythema

Nursing Considerations

- Use cautiously in patients with conduction problems (such as AV block, sick sinus syndrome) and no pacemaker in place or in patients with severe cardiac disease (such as myocardial ischemia, heart failure). Lacosamide may affect conduction.
- Use cautiously in patients with diabetic neuropathy or cardiovascular disease because drug may predispose them to atrial fibrillation or flutter.

- Watch patient closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times and lead to suicidal ideation.
- Be aware that lacosamide therapy should be discontinued gradually over at least 1 week to minimize seizure frequency.
- Monitor patient closely for hypersensitivity reactions to lacosamide, such as rash, pruritus, and more than one organ abnormality, such as elevated liver enzymes and myocarditis or pancreatitis.

PATIENT TEACHING

- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Encourage patient to carry medical identification that indicates her diagnosis and drug therapy.

lactulose

Acilac (CAN), Cephulac, Cholac, Chronulac, Constilac, Constulose, Duphalac, Enulose, Evalose, Heptalac, Lactulax (CAN), Laxilose (CAN), PMS-Lactulose (CAN), Portalac

Class and Category

Chemical: Synthetic disaccharide sugar
Therapeutic: Ammonia reducer, laxative
Pregnancy category: B

Indications and Dosages

↗ *To treat constipation*

POWDER, SYRUP

Adults. *Initial:* 10 to 20 g daily, increased p.r.n. *Maximum:* 40 g daily.

↗ *To prevent and treat hepatic encephalopathy*

POWDER, SYRUP

Adults. *Initial:* 20 to 30 g t.i.d. or q.i.d. until two or three soft stools occur daily. *Usual:* 60 to 100 g daily in divided doses. For acute episodes, 20 to 30 g every 2 hr initially to achieve rapid laxative effect and then reduced to usual dosage.

RETENTION ENEMA

Adults. 200 g (300 ml) diluted in 700 ml water or normal saline solution and given every 4 to 6 hr, as needed.

Mechanism of Action

Arrives unchanged in the colon, where it breaks down into lactic acid and small amounts of formic and acetic acids, acidifying fecal contents. Acidification leads to increased osmotic pressure in the colon, which, in turn, increases stool water content and softens stool.

Also, lactulose makes intestinal contents more acidic than blood. This prevents ammonia diffusion from intestine into blood, as occurs in hepatic encephalopathy. The trapped ammonia is converted into ammonia ions and, by lactulose's cathartic effect, is expelled in feces with other nitrogenous wastes.

Route	Onset	Peak	Duration
P.O.	24–48 hr	Unknown	Unknown

Contraindications

Hypersensitivity to lactulose or its components, low-galactose diet

Interactions

DRUGS

antacids, antibiotics (especially oral neomycin), other laxatives: Decreased effectiveness of lactulose

Adverse Reactions

GI: Abdominal cramps and distention, diarrhea, flatulence

ENDO: Hyperglycemia

Other: Hyponatremia, hypokalemia, hypovolemia

Nursing Considerations

- When giving lactulose by retention enema, use a rectal tube with a balloon to help patient retain enema for 30 to 60 minutes. If not retained for at least 30 minutes, repeat dose. Be sure to deflate balloon and remove rectal tube after completing administration.
- Expect to periodically check serum electrolyte levels of elderly or debilitated patient who uses oral drug longer than 6 months.
- Monitor blood ammonia level in patient with hepatic encephalopathy. Also watch for dehydration, hyponatremia, and hypokalemia when giving higher lactulose doses to treat this condition.
- Monitor diabetic patient for hypergly-

cemia because lactulose contains galactose and lactose.

- Plan to replace fluids if frequent bowel movements cause hypovolemia.

PATIENT TEACHING

- Advise patient to take lactulose with food or dilute with juice to reduce sweet taste.
- Direct patient not to use other laxatives while taking lactulose.
- Instruct patient to report abdominal distention or severe diarrhea.
- Advise diabetic patient to check blood glucose level often and to report hyperglycemia.
- Instruct patient to increase fluid intake if frequent bowel movements occur.
- Teach patient with chronic constipation the importance of exercising, increasing fiber in diet, and increasing fluid intake.
- Inform patient that because oral lactulose must reach the colon to work, bowel movement may not occur for 24 to 48 hours after taking drug.

lamotrigine

Lamictal

Class and Category

Chemical class: Phenyltriazine

Therapeutic class: Anticonvulsant

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat partial seizures; to treat generalized seizures of Lennox-Gastaut syndrome; to treat primary generalized tonic-clonic seizures*

CHEWABLE TABLETS, TABLETS

Adults and children age 12 and over taking valproate. 25 mg every other day for 2 wk, followed by 25 mg once daily for 2 wk. Increased by 25 to 50 mg every 1 to 2 wk, if needed. *Maintenance:* 100 to 400 mg daily.

Children ages 2 to 12 taking valproate.

0.15 mg/kg daily as a single dose or in divided doses b.i.d. for 2 wk and then 0.3 mg/kg daily as single dose or in divided doses b.i.d. for next 2 wk. Increased by 0.3 mg/kg every 1 to 2 wk, if needed, to reach maintenance dosage. *Maintenance:* 1 to 5 mg/kg daily as single dose or in divided doses b.i.d. *Maximum:* 200 mg daily.

Adults and children age 12 and over taking an antiepileptic drug other than carbamazepine, phenytoin, phenobarbital, primidone, or valproate. 25 mg once daily for 2 wk, followed by 50 mg once daily for 2 wk. Increased by 50 mg every 1 to 2 wk, if needed. *Maintenance:* 225 to 375 mg daily in 2 divided doses b.i.d. *Maximum:* 400 mg daily.

Children ages 2 to 12 taking an antiepileptic drug other than carbamazepine, phenytoin, phenobarbital, primidone, or valproate. 0.3 mg/kg daily in 1 or 2 divided doses for 2 wk; followed by 0.6 mg/kg daily in 2 divided doses for 2 wk. Increased by 0.6 mg/kg daily every 1 to 2 wk, if needed. *Maintenance:* 4.5 to 7.5 mg/kg daily in 2 divided doses. *Maximum:* 300 mg daily

Adults and children age 12 and over taking carbamazepine, phenytoin, phenobarbital, or primidone but not valproate. 50 mg once daily for 2 wk and then 100 mg daily in divided doses b.i.d. for 2 wk. Increased by 100 mg every 1 to 2 wk, if needed. *Maintenance:* 300 to 500 mg daily in divided doses b.i.d. *Maximum:* 700 mg daily in divided doses b.i.d.

Children ages 2 to 12 taking carbamazepine, phenytoin, phenobarbital, or primidone but not valproate. 0.6 mg/kg daily in divided doses b.i.d. for 2 wk and then 1.2 mg/kg daily in divided doses b.i.d. for 2 wk. Increased by 1.2 mg/kg every 1 to 2 wk, if needed to reach maintenance dosage. *Maintenance:* 5 to 15 mg/kg daily in divided doses b.i.d. *Maximum:* 400 mg daily.

↗ *To treat partial seizures after conversion from carbamazepine, phenytoin, phenobarbital, primidone, or valproate*

CHEWABLE TABLETS, TABLETS

Adults and adolescents age 16 and over converting from carbamazepine, phenytoin, phenobarbital, or primidone. 50 mg once daily for 2 wk, followed by 100 mg once daily for next 2 wk. Increased by 100 mg daily every 1 to 2 wk (while continuing to take carbamazepine, phenytoin, phenobarbital, or primidone), until usual maintenance dosage—500 mg daily in divided doses b.i.d.—is achieved. Then carbamazepine, phenytoin, phenobarbital, or primidone dosage tapered in 20% decrements weekly over 4 wk and then discontinued.

Adults and adolescents age 16 and over converting from valproate. 25 mg every other day for 2 wk followed by 25 mg once daily for 2 wk. Then increased by 25 to 50 mg daily every 1 to 2 wk until dosage of 200 mg daily is achieved. At this time valproate dosage decreased to 500 mg daily by decrements no greater than 500 mg daily every wk and then maintained at 500 mg daily for 1 wk. After completion of week, lamotrigine dosage increased to 300 mg daily and maintained for 1 wk while valproate dosage decreased to 250 mg daily and maintained for 1 wk. Then lamotrigine dosage increased by 100 mg daily every wk to achieve maintenance dose of 500 mg daily. Once achieved, valproate therapy is discontinued.

↗ *As maintenance therapy for bipolar 1 disorder to delay occurrence of mood episodes (depression, mania, hypomania, mixed episodes)*

CHEWABLE TABLETS, TABLETS

Adults not taking carbamazepine, phenytoin, phenobarbital, primidone, rifampin, or valproate. 25 mg once daily for 2 wk, followed by 50 mg once daily for 2 wk, followed by 100 mg once daily for 1 wk and then increased to 200 mg once daily as maintenance dose. Maximum: 200 mg daily.

Adults taking valproate. 25 mg every other day for 2 wk, followed by 25 mg once daily for 2 wk, followed by 50 mg once daily for 1 wk, and then increased to 100 mg once daily as maintenance dose.

Adults taking carbamazepine, phenytoin, phenobarbital, primidone, or rifampin, but not valproate. 50 mg once daily for 2 wk followed by 100 mg once daily in divided doses for 2 wk, followed by 200 mg once daily in divided doses for 1 wk and then increased to 300 mg daily in divided doses for 1 wk and then increased to 400 mg daily in divided doses as maintenance dose.

DOSE ADJUSTMENT For patient starting or stopping estrogen-containing oral contraceptives, lamotrigine dosage may need to be adjusted on individual basis. For patient with moderate to severe liver impairment without ascites, dosage reduced by 25%. For patient with severe liver impairment with ascites, dosage reduced by 50%.

Mechanism of Action

May stabilize neuron membranes by blocking their sodium channels and inhibiting release of excitatory neurotransmitters, such as glutamate and aspartate, through these channels. By blocking the release of neurotransmitters, lamotrigine inhibits the spread of seizure activity in the brain and reduces seizure frequency.

Route	Onset	Peak	Duration
P.O.	Days to wks	Unknown	Unknown

Contraindications

Hypersensitivity to lamotrigine or its components

Interactions

DRUGS

acetaminophen (long-term use): Possibly decreased blood lamotrigine level

carbamazepine: Decreased blood lamotrigine level; possibly increased risk of dizziness, diplopia, ataxia, and blurred vision
folate inhibitors, such as co-trimoxazole and methotrexate: Increased blood lamotrigine level

oral contraceptives: Decreased blood lamotrigine level during 3 weeks of active hormonal therapy and increased blood lamotrigine level during 1 week of inactive hormonal therapy; possibly reduced effectiveness of oral contraceptives

oxcarbazepine: Possibly increased risk of headache, dizziness, nausea, and somnolence

phenobarbital, phenytoin, primidone: Decreased blood lamotrigine level, possibly increased CNS depression

topiramate: Increased topiramate level

valproic acid: Increased lamotrigine level, decreased lamotrigine clearance, decreased blood valproic acid level

ACTIVITIES

alcohol use: Possibly increased CNS depression

Adverse Reactions

CNS: Amnesia, anxiety, ataxia, confusion, depression, dizziness, drowsiness, emotional lability, fever, headache, increased seizure activity, lack of coordination, suicidal ideation

CV: Chest pain

EENT: Blurred vision, diplopia, dry mouth, nystagmus

GI: Abdominal pain, anorexia, constipation, diarrhea, hepatic failure, vomiting

HEME: Anemia, aplastic anemia, disseminated intravascular coagulation, eosinophilia, leukopenia, neutropenia, pancytopenia, pure red cell aplasia, thrombocytopenia

SKIN: Petechiae, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Acute multiorgan failure, angioedema, flulike symptoms, lymphadenopathy

Nursing Considerations

- Use cautiously in patients with illnesses that could affect metabolism or elimination of lamotrigine, such as renal, hepatic, or cardiac functional impairment.

WARNING Lamotrigine may cause potentially life-threatening rash. Notify prescriber at first sign, and expect to discontinue drug. Lamotrigine therapy shouldn't be restarted after rash subsides.

- Monitor patient for adverse reactions, especially suicidal thoughts, at start of therapy and with each dosage increase.
- Monitor patient for seizure activity during lamotrigine therapy.
- Stopping lamotrigine abruptly may increase seizure activity. Expect to taper dosage over at least 2 weeks, even for treatment of bipolar disorder.

PATIENT TEACHING

- Advise patient to take lamotrigine exactly as prescribed and not to stop abruptly because seizure activity may increase.
- Advise patient to notify prescriber immediately if rash occurs.
- Instruct patient to report increased seizure activity, vision changes, and vomiting.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to avoid direct sunlight and to wear protective clothing to minimize risk of photosensitivity.
- Instruct patient to wear or carry medical identification stating that she takes an anticonvulsant.
- Caution patient or caregiver about possibility of suicidal thoughts, especially when therapy begins or dosage changes.
- Tell female patient to notify prescriber if she becomes pregnant, is considering

pregnancy, or starts or stops an oral hormonal contraceptive or other female hormonal preparation.

- Urge woman who becomes pregnant while taking lamotrigine to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that registry is collecting information about safety of antiepileptic drugs during pregnancy.

lanreotide

Somatulin Depot

Class and Category

Chemical class: Somatostatin analog

Therapeutic class: Growth inhibitor

Pregnancy category: C

Indications and Dosages

➤ To treat acromegaly in patients with an inadequate response to or who cannot be treated with surgery or radiation

SUBCUTANEOUS INJECTION

Adults. *Initial:* 90 mg every 4 wk for 3 mo; then dosage adjusted according to growth hormone (GH) level. If GH level is less than 1 nanogram/ml, dosage reduced to 60 mg every 4 wk. If GH level is 1 to 2.5 nanograms/ml, dosage is 90 mg every 4 wk. If GH level is above 2.5 nanograms/ml, dosage increased to 120 mg every 4 wk.

DOSAGE ADJUSTMENT For patient with moderate to severe renal or hepatic failure, initial dose reduced to 60 mg every 4 wk for 3 mo; then adjusted according to GH level.

Mechanism of Action

Reduces growth hormone (GH) and insulin growth factor-1 levels, allowing for normalization of these hormones in patients with acromegaly. An octapeptide analog of natural somatostatin, lanreotide has a high affinity for human somatostatin receptors 2 and 5. Activity at these receptors may be responsible for GH inhibition.

Contraindications

Hypersensitivity to lanreotide or its components

Interactions

DRUGS

beta blockers, calcium channel blockers:

Additive depressive effects on heart rate
bromocriptine: Possibly increased action of bromocriptine
cyclosporine: Possibly decreased cyclosporine effectiveness
drugs metabolized by the liver, quinidine, terfenadine: Possibly increased blood levels of these drugs
insulin, oral antidiabetic drugs: Possibly decreased effectiveness of these drugs
oral drugs: Possibly decreased absorption of these drugs

Adverse Reactions

CNS: Headache

CV: Bradycardia, hypertension

ENDO: Hyperglycemia, hypoglycemia

GI: Abdominal pain, cholelithiasis, constipation, diarrhea, flatulence, loose stools, nausea, vomiting

HEME: Anemia

MS: Arthralgia

SKIN: Erythema, pruritus

Other: Injection site reactions (induration, pain, pruritus, redness, swelling), weight loss

Nursing Considerations

- Check patient's blood glucose level before starting lanreotide therapy and whenever dosage changes because drug may cause hypoglycemia or hyperglycemia.
- Inject drug deep into subcutaneous tissue of upper, outer quadrant of buttock. Do not fold the skin. Insert needle perpendicular to the skin, rapidly and to its full length. Alternate between left and right buttocks.
- If patient has underlying cardiovascular disease, watch for changes in heart rate and blood pressure because drug may cause bradycardia or hypertension.
- Monitor patient's GH and insulin growth factor-1 levels, as ordered, to assess lanreotide's effects.

PATIENT TEACHING

- Inform patient that lanreotide will be given as a subcutaneous injection every 4 weeks and that it may cause discomfort at the site.
- Tell patient that periodic blood tests will be needed to monitor lanreotide's effectiveness.
- Instruct diabetic patient to monitor blood glucose level closely.

lansoprazole

Prevacid, Prevacid I.V., Prevacid SoluTab

dexlansoprazole

Kapidex

Class and Category

Chemical class: Substituted benzimidazole

Therapeutic class: Antisecretory, antiulcer

Pregnancy category: B

Indications and Dosages

➤ *To treat duodenal ulcers and maintain healed duodenal ulcers*

DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS

Adults. 15 to 30 mg daily before morning meal for 4 wk. *Maximum:* 30 mg daily.

➤ *To treat gastric ulcers*

DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS

Adults. 15 to 30 mg daily before morning meal for up to 8 wk.

➤ *To treat gastroesophageal reflux disease*

DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS

Adults. 15 mg daily before morning meal for up to 8 wk.

➤ *To treat non-erosive gastroesophageal reflux disease*

CAPSULES (DEXLANSOPRAZOLE)

Adults. 30 mg once daily for 4 wk.

➤ *To heal all grades of erosive esophagitis*

CAPSULES (DEXLANSOPRAZOLE)

Adults. 60 mg once daily for up to 8 wk.

➤ *To maintain healed erosive esophagitis*

CAPSULES (DEXLANSOPRAZOLE)

Adults. 30 mg once daily.

➤ *To treat erosive esophagitis*

DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS

Adults. *Initial:* 30 mg daily before morning meal for up to 8 wk. *Continued* another 8 wk if indicated. *Maintenance:* 15 mg daily.

➤ *To treat erosive esophagitis short-term (up to 7 days) in patients unable to take oral medication*

I.V. INFUSION

Adults. 30 mg daily infused over 30 min for up to 7 days.

↗ *To treat pathological hypersecretory conditions, such as Zollinger-Ellison syndrome*

DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS

Adults. *Initial:* 60 mg daily before morning meal, increased as needed according to patient's condition. Doses exceeding 120 mg/day administered in divided doses. *Maximum:* 180 mg daily.

↗ *To eradicate Helicobacter pylori and reduce risk of duodenal ulcer recurrence*

DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS

Adults. 30 mg plus 1 g amoxicillin and 500 mg clarithromycin every 12 hr before meals for 10 to 14 days. Or, 30 mg plus 1 g amoxicillin t.i.d. before meals for 14 days.

↗ *To treat symptomatic pediatric gastroesophageal reflux disease*

DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS

Children ages 12 to 17. 15 mg daily for up to 8 wk.

Children ages 1 to 11 weighing 30 kg (66 lb) or less. 15 mg daily for up to 12 wk.

Children ages 1 to 11 weighing more than 30 kg. 30 mg daily for up to 12 wk.

↗ *To treat symptomatic pediatric erosive esophagitis*

DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS

Children ages 12 to 17. 30 mg daily for up to 8 wk.

Children ages 1 to 11 weighing 30 kg (66 lb) or less. 15 mg daily for up to 12 wk.

Children ages 1 to 11 weighing more than 30 kg. 30 mg daily for up to 12 wk.

↗ *To treat frequent heartburn*

E.R. CAPSULES (PREVACID 24-HR)

Adults. 1 capsule daily for 14 days. May repeat course every 4 months.

Route	Onset	Peak	Duration
P.O.	1–3 hr	Unknown	Over 24 hr

Mechanism of Action

Binds to and inactivates the hydrogen-

potassium adenosine triphosphate enzyme system (also called the proton pump) in gastric parietal cells. This action blocks the final step of gastric acid production.

Incompatibilities

Don't give any other drugs with parenteral lansoprazole, and dilute only with solutions recommended by manufacturer (sterile water for initial reconstitution and normal saline solution, lactated Ringer's solution, or D₅W for further dilution).

Contraindications

Hypersensitivity to lansoprazole or its components

Interactions

DRUGS

ampicillin, digoxin, iron salts, ketoconazole, other drugs that depend on low gastric pH for bioavailability: Inhibited absorption of these drugs

atazanavir: Decreased blood level and possibly reduced effectiveness of atazanavir

sucralfate: Delayed lansoprazole absorption

theophylline: Slightly decreased blood theophylline level

warfarin: Increased INR and PT with possibly increased risk of serious bleeding

Adverse Reactions

CNS: Dizziness, headache

GI: Abdominal pain, anorexia, diarrhea, elevated liver enzymes, hepatotoxicity, increased appetite, nausea, pancreatitis, pseudomembranous colitis, vomiting

GU: Interstitial nephritis, urine retention

HEME: Agranulocytosis, aplastic anemia, decreased hemoglobin, hemolytic anemia,

leukopenia, neutropenia, pancytopenia, thrombocytopenia, thrombotic thrombocytopenic purpura

MS: Arthralgia, myositis

RESP: Upper respiratory tract infection

SKIN: Erythema multiforme, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, hyperkalemia, injection site reaction

Nursing Considerations

- Give lansoprazole before meals. Antacids may be given as well, if needed.
- If patient is prescribed capsules and has trouble swallowing them, open and sprinkle granules on applesauce, Ensure, pud-

ding, cottage cheese, yogurt, or strained pears. Don't crush granules. Have patient swallow mixture immediately. Or, empty granules into 2 ounces apple, orange, or tomato juice; mix quickly, and have patient swallow immediately. Then add 2 or more ounces of juice to glass and have patient drink immediately to ensure full dose.

- For delayed-release orally disintegrating tablets, place tablet on patient's tongue and let it dissolve, with or without water, until patient can swallow particles.
- For patient with nasogastric tube, don't use oral suspension. Instead use capsules or orally disintegrating tablets. For capsule form, open capsule, mix granules in 40 ml apple juice only, and inject through tube. Then flush tube with apple juice only. For disintegrating tablets, place tablet in syringe and draw up 4 ml (for 15-mg tablet) or 8 ml (for 30-mg tablet) of water. Shake gently, and inject through tube within 15 minutes. Then refill syringe with 5 ml of water, shake gently, and inject through tube.
- For delayed-release oral suspension, empty packet contents into a container with 2 tablespoons water (no other liquids or foods), stir well, and have patient drink immediately. If any particles remain in container, add more water, stir, and have patient drink again immediately.
- Reconstitute parenteral form by injecting 5 ml sterile water into 30-mg drug vial. Mix gently until powder dissolves. Use within 1 hour. After reconstitution, dilute with 50 ml normal saline solution, lactated Ringer's solution, or D₅W. Give within 12 hours if mixed with D₅W or 24 hours if mixed with normal saline solution or lactated Ringer's solution.
- Give parenteral drug with a filter following manufacturer's guidelines. Change filter every 24 hours. Give as I.V. infusion over 30 minutes. Flush line with normal saline solution, lactated Ringer's solution, or D₅W before and after giving lansoprazole.
- Expect to give lansoprazole with antibiotics because decreased gastric acid secretion helps antibiotics eradicate *H. pylori*.
- If lansoprazole is given with antibiotics, watch for diarrhea from possible pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify pre-

scriber and expect to withhold drug and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

PATIENT TEACHING

- Urge patient to take drug exactly as prescribed, usually before a meal (preferably breakfast) to decrease gastric acid output.
- If patient has trouble swallowing dexlansoprazole capsules, tell her to open them and sprinkle granules on 1 tablespoon of applesauce and swallow immediately. If patient has trouble swallowing lansoprazole capsules, tell her to open them and sprinkle granules on applesauce, Ensure, pudding, cottage cheese, yogurt, or strained pears and to swallow immediately without chewing. Or, she may empty granules into 2 ounces of apple, orange, or tomato juice, mix quickly, and swallow immediately. Tell her to refill glass with 2 or more ounces of juice and drink immediately to ensure a full dose.
- If patient was prescribed delayed-release orally disintegrating tablets, tell her to place tablet on tongue, let it dissolve, and then swallow particles with or without water.
- If patient was prescribed delayed-release oral suspension, tell her to empty contents of packet into a container with 2 tablespoons of water (no other liquids or foods), stir well, and drink immediately. If particles remain in container, she should add water, stir, and drink immediately.
- Inform patient that she may take antacids with lansoprazole.
- Advise patient to report severe headache, or worsening of symptoms immediately to prescriber.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.

lanthanum carbonate

Fosrenol

Class and Category

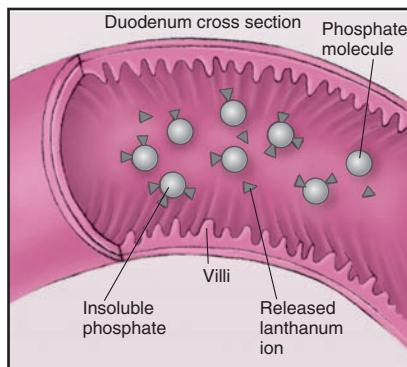

Chemical class: Rare earth element

Mechanism of Action

During digestion, phosphate is released into the upper GI tract (below left) and absorbed into the bloodstream, increasing serum phosphate levels. In patients with end-stage renal disease, however, inefficient phosphate clearance from the blood leads to abnormally elevated levels.

Lanthanum dissociates in the upper GI tract, releasing ions that attach to unbound phosphate to form an insoluble complex (below right). Unabsorbed into the bloodstream, these altered phosphate molecules can't elevate the patient's serum phosphate level.

Therapeutic class: Phosphate binder
Pregnancy category: C

Indications and Dosages

➤ To reduce serum phosphate levels in patients with end-stage renal disease

TABLETS

Adults. *Initial:* 250 to 500 mg t.i.d. with meals; increased, as needed, by 750 mg daily every 2 to 3 wk until acceptable serum phosphate level is reached.

Contraindications

Bowel obstruction, hypersensitivity to lanthanum carbonate or any of its components, hypophosphatemia

Adverse Reactions

CNS: Headache

CV: Hypotension

EENT: Rhinitis

ENDO: Hypercalcemia

GI: Abdominal pain, constipation, diarrhea, nausea, vomiting

GU: Dialysis graft occlusion

RESP: Bronchitis

Nursing Considerations

- Use lanthanum carbonate cautiously in patients with acute peptic ulcer, ulcerative colitis, Crohn's disease, or bowel obstruction

tion because drug effects are unknown in these patients.

- Monitor the patient's serum phosphate levels, as ordered, especially during dosage adjustment, to determine effectiveness of lanthanum carbonate therapy. Serum phosphate levels should fall below 6.0 mg/dl.

PATIENT TEACHING

- Instruct patient to take lanthanum carbonate with or immediately after meals.
- Advise patient to chew each tablet thoroughly before swallowing. If patient has trouble chewing tablets, tell her she may crush them.
- Urge patient to take drug exactly as prescribed, and explain that it may take weeks to reach a desired serum phosphate level.

leflunomide

Arava

Class and Category

Chemical class: Malonitrilamide immunomodulator

Therapeutic class: Antirheumatic

Pregnancy category: X

Indications and Dosages

➤ *To relieve symptoms of active rheumatoid arthritis, improve physical function and slow disease progression*

TABLETS

Adults. *Loading:* 100 mg daily for 3 days. *Maintenance:* 20 mg daily, reduced to 10 mg daily if poorly tolerated. *Maximum:* 20 mg/day.

Mechanism of Action

Inhibits dihydroorotate dehydrogenase, the enzyme in autoimmune process that leads to rheumatoid arthritis. With this action, leflunomide relieves inflammation and prevents alteration of the autoimmune process.

Contraindications

Hypersensitivity to leflunomide or its components, pregnancy

Interactions

DRUGS

activated charcoal, cholestyramine:

Decreased blood leflunomide level

live-virus vaccines: Possibly adverse reactions to vaccines caused by leflunomide-induced immunosuppression

methotrexate: Risk of hepatotoxicity

NSAIDs: Possibly impaired NSAID metabolism

rifampin, tolbutamide: Increased blood leflunomide level

Adverse Reactions

CNS: Anxiety, dizziness, drowsiness, fatigue, fever, headache, paresthesia

CV: Chest pain, hypertension, palpitations, tachycardia

EENT: Blurred vision, conjunctivitis, dry mouth, epistaxis, mouth ulcers, pharyngitis, rhinitis, sinusitis

GI: Abdominal pain, cholestasis, constipation, diarrhea, elevated liver function test results, flatulence, gastritis, gastroenteritis, hepatic failure, hepatitis, nausea, vomiting

GU: UTI

HEME: Agranulocytosis, anemia, pancytopenia, thrombocytopenia

MS: Back pain, synovitis, tendinitis

RESP: Asthma, bronchitis, dyspnea, interstitial lung disease, respiratory tract infection

SKIN: Alopecia (transient), erythematous rash, jaundice, pruritus, urticaria

Other: Sepsis, weight loss

Nursing Considerations

- Leflunomide isn't recommended for patients with severe immunodeficiency, bone marrow dysplasia, or severe, uncontrolled infections because of its immunosuppressant effect.
- Test patient for latent tuberculosis before starting leflunomide. If positive, expect standard medical treatment to be given before leflunomide therapy starts.
- Obtain baseline blood pressure before starting leflunomide, and monitor periodically thereafter because drug may cause hypertension.
- Assess liver enzyme (ALT and AST) levels at start of therapy, monthly during first 6 months, and if stable, every 6 to 8 weeks thereafter, as ordered. Expect to stop drug if hepatic dysfunction develops.
- Obtain platelet count, WBC count, and hemoglobin or hematocrit at start of therapy and every 4 to 8 weeks thereafter, as ordered.
- Notify prescriber if patient develops serious infection because drug may need to be interrupted and cholestyramine or charcoal given to eliminate drug rapidly.

WARNING Monitor patient's respiratory function closely because drug may cause interstitial lung disease that could become life-threatening. If patient develops a cough and dyspnea, notify prescriber; drug may need to be stopped, and patient may need cholestyramine or charcoal to eliminate drug rapidly.

PATIENT TEACHING

- Advise patient that leflunomide doesn't cure arthritis but may relieve its symptoms and improve physical function.
- Inform patient that reversible hair loss may occur.
- Caution woman of childbearing potential not to become pregnant while taking drug because of the high risk of birth defects.
 - Instruct patient to report signs of hepatotoxicity, such as mouth ulcers, unusual bleeding or bruising, and yellow skin or eyes.
- Tell patient to report signs of respiratory dysfunction, such as cough and dyspnea.
- Advise patient to avoid live vaccines during leflunomide therapy.
- Instruct patient to notify prescriber if she develops an infection.

lepirudin

Refludan

Class and Category

Chemical class: Yeast-derived recombinant form of hirudin

Therapeutic class: Anticoagulant

Pregnancy category: B

Indications and Dosages

➤ *To prevent thromboembolic complications in patients with heparin-induced thrombocytopenia and associated thromboembolic disease*

I.V. INFUSION AND INJECTION

Adults. *Initial:* 0.4 mg/kg, but no more than 44 mg, given by bolus over 15 to 20 sec, followed by continuous infusion of 0.15 mg/kg/hr for 2 to 10 days or longer, as indicated. *Maximum:* 0.21 mg/kg/hr.

DOSAGE ADJUSTMENT For patients with renal insufficiency, bolus dose decreased to 0.2 mg/kg and infusion rate adjusted as follows: for creatinine clearance of 45 to 60 ml/min/1.73 m², 50% of standard infusion rate; for clearance of 30 to 44 ml/min/1.73 m², 30% of standard infusion rate; for clearance of 15 to 29 ml/min/1.73 m², 15% of standard infusion rate; for clearance less than 15 ml/min/1.73 m², expect drug to be stopped.

Route	Onset	Peak	Duration
I.V.	Immediate	Unknown	Unknown

Mechanism of Action

Forms a tight bond with thrombin, neutralizing this enzyme's actions, even when the enzyme is trapped within clots. One molecule of lepirudin binds with one molecule of thrombin. Thrombin causes fibrinogen to convert to fibrin, which is essential for clot formation.

Incompatibilities

Don't mix lepirudin in same I.V. line with other drugs.

Contraindications

Hypersensitivity to lepirudin or other hirudins

Interactions

DRUGS

oral anticoagulants, platelet aggregation

inhibitors, thrombolytics: Increased risk of bleeding complications and enhanced effects of lepirudin

Adverse Reactions

CNS: Chills, fever, intracranial hemorrhage

CV: Heart failure

EENT: Epistaxis

GI: GI or rectal bleeding, hepatic dysfunction

GU: Hematuria, vaginal bleeding

HEME: Anemia, easy bruising, hematoma

RESP: Hemoptysis, pneumonia

SKIN: Excessive bleeding from wounds, rash, pruritus, urticaria

Other: Anaphylaxis, injection site bleeding, sepsis

Nursing Considerations

- Be aware that patients with heparin-induced thrombocytopenia have low platelet counts, which can lead to severe bleeding and even death. Lepirudin works to prevent clotting without further reducing platelet count.
- To reconstitute, mix lepirudin with normal saline solution or sterile water for injection. Warm solution to room temperature before giving.
- For I.V. bolus delivery, reconstitute 50 mg drug with 1 ml sterile water for injection or sodium chloride for injection. Then further dilute by withdrawing reconstituted solution into 10-ml syringe and adding enough sterile water for injection, sodium chloride for injection, or D₅W to produce a total volume of 10 ml, or 5 mg of lepirudin/ml. Administer prescribed dose over 15 to 20 seconds.
- For I.V. infusion, reconstitute 2 vials of drug and transfer to infusion bag that contains 250 or 500 ml normal saline solution or D₅W. Concentration will be 0.4 or 0.2 mg/ml.
- Adjust infusion rate as prescribed, according to patient's APTT ratio, which is APTT divided by a control value. Target APTT ratio during treatment is 1.5 to 2.5.
- Expect to obtain first APTT 4 hours after starting infusion and to obtain follow-up APTT daily (more often for patients with hepatic or renal impairment).
- Stop infusion for 2 hours, as ordered, if APTT is above target range. Expect to decrease infusion rate by half when re-

starting. If APTT is below target range, expect to increase rate in 20% increments and recheck APTT in 4 hours.

- Avoid I.M. injections or needle sticks during lepirudin therapy to minimize risk of hematoma.
- Observe I.M. injection sites, I.V. infusion sites, and wounds for bleeding.
- Monitor patient for ecchymoses on arms and legs, epistaxis, hematemesis, hematuria, melena, and vaginal bleeding.
- Be aware that when patient is scheduled to switch to an oral anticoagulant, lepirudin dosage may need to be tapered over a period of days, as ordered, until APTT is just above 1.5, before starting oral anticoagulant. In addition, INR and PT will need to be monitored closely, as ordered, to prevent bleeding adverse effects.

PATIENT TEACHING

- Tell patient to report unexpected bleeding, such as blood in urine, easy bruising, nosebleeds, tarry stools, and vaginal bleeding.
- Advise patient to avoid bumping arms and legs because of the risk of bruising.
- Instruct patient to use electric razor and soft toothbrush to reduce risk of bleeding.

leuprolide acetate

Eligard 7.5 mg, Eligard 22.5 mg, Lupron, Lupron Depot, Lupron Depot-3 Month 11.25 mg, Lupron Depot-3 Month 22.5 mg, Lupron Depot-4 Month 30 mg, Lupron Depot-Ped, Lupron-3 Month SR Depot 22.5 mg

Class and Category

Chemical class: Synthetic peptide gonadotropin-releasing hormone analogue

Therapeutic class: Antianemic, anti-endometriotic agent, antineoplastic, gonadotropin inhibitor

Pregnancy category: X

Indications and Dosages

➤ *To treat prostate cancer*

I.M. INJECTION (LEUPROLIDE ACETATE FOR INJECTION)

Adults. 7.5 mg/mo, 22.5 mg every 3 mo, or 45 mg every 4 mo.

SUBCUTANEOUS INJECTION (LEUPROLIDE ACETATE FOR INJECTABLE SUSPENSION)

Adults. 7.5 mg/mo.

SUBCUTANEOUS INJECTION (LEUPROLIDE ACETATE INJECTION)

Adults. 1 mg daily.

➤ *To provide palliative treatment of advanced prostate cancer*

SUBCUTANEOUS INJECTION (ELIGARD FOR INJECTABLE SUSPENSION)

Adults. 7.5 mg/mo, 22.5 mg every 3 mo, or 45 mg every 6 mo.

➤ *To treat precocious central puberty*

I.M. INJECTION (LEUPROLIDE ACETATE FOR INJECTION)

Children weighing more than 37.5 kg (83 lb). *Initial:* 15 mg every 4 wk.

Maintenance: Dosage increased as needed in increments of 3.75 mg every 4 wk.

Maximum: 15 mg every 4 wk.

Children weighing 25 to 37.5 kg (55 to 83 lb). *Initial:* 11.25 mg every 4 wk.

Maintenance: Dosage increased as needed in increments of 3.75 mg every 4 wk.

Maximum: 15 mg every 4 wk.

Children weighing less than 25 kg. *Initial:*

7.5 mg every 4 wk. *Maintenance:* Dosage increased as needed in increments of

3.75 mg every 4 wk. *Maximum:* 15 mg every 4 wk.

SUBCUTANEOUS INJECTION (LEUPROLIDE ACETATE INJECTION)

Children. 50 mcg/kg daily. Dosage increased in increments of 10 mcg/kg daily.

➤ *To treat endometriosis*

I.M. INJECTION (LEUPROLIDE ACETATE FOR INJECTION)

Adults. 3.75 mg every mo or 11.25 mg every 3 mo for up to 6 mo. *Maximum:* 33.75 mg total dose.

➤ *As adjunct to treat anemia due to uterine leiomyomas*

I.M. INJECTION (LEUPROLIDE ACETATE FOR INJECTION)

Adults. 3.75 mg every mo up to 3 mo or 11.25 mg single dose. *Maximum:* 11.25 mg total dose.

Mechanism of Action

After stimulating follicle-stimulating hormone (FSH) and luteinizing hormone (LH), continuous leuprolide therapy suppresses secretion of gonadotropin-releasing hormone, decreasing testosterone and estradiol levels. In children with central precocious puberty, this stops menses and reproductive organ development.

In adult men, continuous suppression decreases testosterone levels and causes pharmacologic castration, which slows the activity of prostatic neoplastic cells. In women with endometriosis or uterine leiomyomas, leuprolide suppresses ovarian function, inactivating endometrial tissues and resulting in amenorrhea.

Route	Onset	Peak	Duration
I.M., SubQ*	1 wk	Unknown	4–12 wk after therapy
I.M., SubQ†	2–4 wk	After 1– 2 mo	60–90 days after therapy

Contraindications

Women and children (leuprolide acetate injectable suspension); hypersensitivity to benzyl alcohol, gonadorelin, and gonadotropin-releasing hormone analogues, including leuprolide, and their components; pregnancy; undiagnosed abnormal vaginal bleeding

Adverse Reactions

CNS: Depression, dizziness, fatigue, headache, insomnia, lethargy, malaise, memory loss, paresthesia, peripheral neuropathy, rigors, seizures, syncope, weakness; anxiety, mood changes, nervousness (adult women)

CV: Arrhythmias, edema, hypertension, hypotension, palpitations, vasodilation; angina, MI, thrombophlebitis (adult men)

EENT: Blurred vision

ENDO: Amenorrhea, androgenic effects in women, breast tenderness or swelling, decreased testicle size, gynecomastia, hot flashes, hyperglycemia, pituitary apoplexy

GI: Colitis, constipation in adult men, dyspepsia, gastroenteritis, hepatic dysfunction, nausea, vomiting

GU: Bladder spasm, decreased libido, decreased penis size, dysuria, endometriosis flareup, impotence, incontinence, nocturia, prostate cancer flareup, prostate pain, uterine bleeding, vaginal discharge in girls, vaginitis

HEME: Leukopenia

MS: Arthralgia, body pain in children, bone

*Gonadotropin inhibitor.

†Antiendometrial, antineoplastic.

density loss, bone or limb pain, fibromyalgia, myalgia, tenosynovitis

RESP: Asthma, dyspnea, pulmonary embolism

SKIN: Alopecia, clamminess, night sweats, photosensitivity, rash, urticaria

Other: Anaphylaxis; weight gain; injection site abscess, burning, edema, induration, itching, pain, or redness

Nursing Considerations

- Let drug come to room temperature before using. Reconstitute leuprolide acetate depot suspension with diluent provided by manufacturer. Add diluent to powder for suspension and thoroughly shake vials to disperse particles into a uniform milky suspension. Use within 30 minutes after mixing, and discard any unused portion. If using a prefilled dual-chamber syringe, follow manufacturer's instructions to release diluent into chamber containing powder. Shake gently after diluted to disperse particles evenly in solution. No dilution or reconstitution is needed for leuprolide acetate injection for subcutaneous administration. Rotate injection sites.

WARNING Leuprolide acetate for injectable suspension (Eligard) is approved only for use in men for palliative treatment of prostate cancer. Use provided syringes and delivery system, and read and follow instructions carefully to ensure proper mixing of product; shaking alone is inadequate to mix it.

WARNING Monitor patient for possible allergic reaction (erythema and induration) at injection site because leuprolide injections contain benzyl alcohol. Manufacturer recommends that injection be given by physician.

- During first weeks of leuprolide therapy, monitor patient being treated for prostate cancer for initial worsening of symptoms, such as increased bone pain, difficult urination, and paresthesia or paralysis (in patients with vertebral metastasis).
- During treatment for prostate cancer, monitor patient's serum testosterone and PSA levels periodically, as ordered, to determine response to leuprolide therapy.
- Expect to stop drug before age 11 in female patients and age 12 in male

patients treated for precocious central puberty.

- Monitor bone density test results, as ordered, of women at risk for osteoporosis who are receiving leuprolide because of possible drug-induced estrogen loss, which may result in decreased bone density.
- Be aware that therapeutic doses of leuprolide suppress the pituitary-gonadal system and that normal function doesn't return for 4 to 12 weeks after drug is stopped.

WARNING Monitor patient for evidence of pituitary apoplexy, such as sudden headache, vomiting, visual changes, ophthalmoplegia, altered mental status, and possibly cardiovascular collapse. Although rare, it may occur within 2 weeks of first dose, sometimes within the first hour. Notify prescriber immediately and provide supportive care.

PATIENT TEACHING

- Instruct patient who is self-administering leuprolide injection to use syringe provided by manufacturer. If manufacturer's syringe is unavailable, advise her to use only a 0.5-ml disposable, low-dose, U-100 insulin syringe to ensure accurate dosage. Substitution of syringes is not recommended for leuprolide acetate for injectable suspension.
- Advise women to immediately report monthly menses or breakthrough bleeding to prescriber.
- Instruct female patient of childbearing age to use a nonhormonal form of contraception during leuprolide therapy. Advise her to stop taking drug and notify prescriber at once if she becomes pregnant.
- Inform patient with osteoporosis or at risk for developing it that drug may increase bone density loss.
- Inform parents of child being treated for central precocious puberty that they should expect normal gonadal-pituitary function to return 4 to 12 weeks after therapy ends.
- Advise patient to report symptoms of depression or memory problems.
- Caution patient being treated for prostate cancer that drug may initially worsen such symptoms as bone pain and that it may cause new signs or symptoms to occur during first few weeks of treatment. Reassure patient that this is transient.

levalbuterol hydrochloride

Xopenex, Xopenex HFA

Class and Category

Chemical class: Sympathomimetic amine

Therapeutic class: Bronchodilator

Pregnancy category: C

Indications and Dosages

➤ To prevent or treat bronchospasm in reversible obstructive airway disease

INHALATION AEROSOL

Adults and children age 4 and over. 45 or 90 mcg (1 or 2 inhalations) every 4 to 6 hr.

INHALATION SOLUTION

Adults and children age 12 and over.

0.63 to 1.25 mg t.i.d. every 6 to 8 hr.

Maximum: 1.25 mg t.i.d.

Children ages 6 to 11. 0.31 to 0.63 mg t.i.d.

Maximum: 0.63 mg t.i.d.

DOSAGE ADJUSTMENT For elderly patients, dosage limited to 0.63 mg t.i.d. every 6 to 8 hr.

Route	Onset	Peak	Duration
Inhalation	10–17 min	1.5 hr	5–6 hr

Mechanism of Action

Attaches to beta₂ receptors on bronchial cell membranes, which stimulates the intracellular enzyme adenyl cyclase to convert adenosine triphosphate to cAMP. Increased intracellular cAMP level relaxes bronchial smooth muscle and inhibits histamine release from mast cells.

Contraindications

Hypersensitivity to levalbuterol, other sympathomimetic amines, or their components

Interactions

DRUGS

beta blockers: Blocked effects of both drugs

digoxin: Decreased blood digoxin level

loop or thiazide diuretics: Increased risk of hypokalemia

MAO inhibitors, sympathomimetics, tricyclic antidepressants: Increased risk of adverse cardiovascular effects

antidepressants: Increased risk of adverse cardiovascular effects

Adverse Reactions

CNS: Anxiety, chills, dizziness, hypertension,

insomnia, migraine headache, nervousness, paresthesia, syncope, tremor
CV: Chest pain, hypertension, hypotension, tachycardia

EENT: Dry mouth and throat, rhinitis, sinus-itis

GI: Diarrhea, indigestion, nausea, vomiting

MS: Leg cramps, myalgia

RESP: Asthma exacerbation, cough, dyspnea, paradoxical bronchospasm

Other: Flulike symptoms, lymphadenopathy

Nursing Considerations

- Use levalbuterol cautiously in patients with arrhythmias, diabetes mellitus, hypertension, hyperthyroidism, or a history of seizures.
- Give oral solution form only by nebulizer.
- Monitor pulse rate and blood pressure before and after nebulizer treatment.
- Because drug may provoke paradoxical bronchospasm, observe for dyspnea, wheezing, and increased coughing.

PATIENT TEACHING

- Teach patient how to use levalbuterol nebulizer and to measure correct dose.
- Instruct patient to prime inhaler before using it for the first time or when it hasn't been used for more than 3 days by releasing 4 test sprays into the air, aiming it away from her face.
- Show patient how to clean nebulizer or inhaler, and explain the need to do so at least once weekly.
- Instruct patient to notify prescriber if drug fails to work or if she needs more treatments because asthma is worsening.
- Instruct patient not to increase dosage or frequency unless told by prescriber.
- Urge patient to stop drug and call prescriber if she has paradoxical bronchospasm.
- Instruct patient to use inhalation solution within 2 weeks of opening the foil pouch and to protect drug from light and heat.
- Urge patient to consult prescriber before using OTC or other drugs.

levetiracetam

Keppra, Keppra XR

Class and Category

Chemical: Pyrrolidine derivative

Therapeutic: Anticonvulsant

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat partial seizures*

ORAL SOLUTION, TABLETS

Adults and adolescents over age 16. *Initial:* 500 mg b.i.d., increased by 1,000 mg daily every 2 wk if needed. *Maximum:* 3,000 mg daily.

Children ages 4 to 16. *Initial:* 10 mg/kg b.i.d., increased by 20 mg/kg daily every 2 wk until recommended daily dose of 60 mg/kg is reached.

XR TABLETS

Adults and adolescents over age 16.

1,000 mg once daily, increased by 1,000 mg daily every 2 wk until recommended daily dose of 3,000 mg is reached.

I.V. INFUSION

Adults and adolescents over age 16. *Initial:* 500 mg infused over 15 minutes b.i.d., increased by 1,000 mg daily every 2 wk, if needed. *Maximum:* 3,000 mg daily.

↗ *As adjunct to treat myoclonic seizures in patients with juvenile myoclonic epilepsy*

ORAL SOLUTION, TABLETS

Adults and children age 12 and over.

Initial: 500 mg b.i.d., increased by 1,000 mg daily every 2 wk, if needed. *Maximum:* 3,000 mg daily.

↗ *As adjunct to treat primary generalized tonic-clonic seizures in patients with idiopathic generalized epilepsy*

ORAL SOLUTION, TABLETS

Adults and children age 6 and over. *Initial:* 500 mg b.i.d., increased by 1,000 mg daily every 2 wk, as needed. *Maximum:* 3,000 mg daily.

DOSAGE ADJUSTMENT Maximum dosage reduced to 2,000 mg daily for patients with creatinine clearance of 50 to 80 ml/min/1.73 m²; to 1,500 mg daily for clearance of 30 to 49 ml/min/1.73 m²; and to 1,000 mg daily for clearance less than 30 ml/min/1.73 m². For patients with end-stage renal disease who are having dialysis, expect to give another 250 to 500 mg, as prescribed, after each dialysis session. For children who can't tolerate 60 mg/kg daily, dosage reduced to point of tolerance.

Mechanism of Action

May protect against secondary generalized seizure activity by preventing coordination

of epileptiform burst firing. Levetiracetam doesn't seem to involve inhibitory and excitatory neurotransmission.

Contraindications

Hypersensitivity to levetiracetam or its components

Adverse Reactions

CNS: Abnormal gait, aggression, agitation, anger, anxiety, apathy, asthenia, ataxia, behavioral difficulties (children), confusion, coordination difficulties, depersonalization, depression, dizziness, emotional lability, fatigue, hallucinations, headache, hostility, increased reflexes, insomnia, irritability, mental or mood changes, nervousness, neurosis, paresthesia, personality disorder, psychosis, seizures, somnolence, suicidal ideation, vertigo

EENT: Amblyopia, conjunctivitis, diplopia, ear pain, nasopharyngitis, pharyngitis, rhinitis, sinusitis

GI: Anorexia, constipation, diarrhea, elevated liver enzyme levels, gastroenteritis, hepatic failure, hepatitis, pancreatitis, vomiting

GU: Albuminuria

HEME: Decreased hematocrit, hemoglobin, and total mean RBC count; leukopenia; neutropenia; pancytopenia; thrombocytopenia

MS: Neck pain

RESP: Asthma, cough

SKIN: Alopecia, ecchymosis, pruritus, skin discoloration, vesiculobullous rash

Other: Dehydration, facial edema, infection, influenza, weight loss

Nursing Considerations

- Children weighing 20 kg or less should be given only the oral solution form.
- For I.V. use, dilute parenteral levetiracetam in 100 ml of compatible diluent, such as normal saline injection, lactated Ringer's injection, or dextrose 5% injection. Use within 24 hours.
- Assess compliance during first 4 weeks of therapy, when adverse reactions are most common.
- Monitor patient for seizure activity during therapy. As appropriate, implement seizure precautions according to facility policy.
- Stopping drug may increase seizure activity. Expect to taper dosage gradually.

- Certain adverse effects, including somnolence, fatigue, coordination problems, and abnormal behaviors may be more likely in patients taking levetiracetam for partial seizure disorders.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

PATIENT TEACHING

- Caution patient that levetiracetam may cause dizziness and drowsiness, especially during first 4 weeks of therapy.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Caution patient not to stop taking levetiracetam abruptly; inform her that drug dosage should be tapered under prescriber's direction to reduce the risk of breakthrough seizures.
- Explain that levetiracetam may cause mental and behavioral changes, such as aggression, depression, irritability, and rarely psychotic symptoms. Urge her to contact prescriber about any bothersome changes.
- Advise patient to keep taking other anti-convulsants, as ordered, while taking levetiracetam.
- Encourage patient to avoid alcohol during therapy because alcohol can increase incidence of drowsiness and dizziness.
- Instruct patient to see prescriber regularly so that her progress can be monitored.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report concerns immediately.
- Urge woman who becomes pregnant while taking levetiracetam to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that registry is collecting information about safety of antiepileptic drugs during pregnancy.

levocetirizine

Xyzal

Class and Category

Chemical class: H₁-receptor antagonist

Therapeutic class: Antihistamine

Pregnancy category: B

Indications and Dosages

↗ *To treat chronic idiopathic urticaria; to treat allergic rhinitis*

TABLETS, ORAL SOLUTION

Adults and children age 12 and over. 2.5 to 5 mg once daily in evening. *Maximum:* 5 mg daily.

DOSE ADJUSTMENT For patient with mild renal impairment (creatinine clearance 50 to 80 ml/min/1.73 m²), dosage shouldn't exceed 2.5 mg daily. For patient with moderate renal impairment (creatinine clearance 30 to 50 ml/min/1.73 m²), dosage shouldn't exceed 2.5 mg once every other day. For patient with severe renal impairment (creatinine clearance 10 to 30 ml/min/1.73 m²), dosage shouldn't exceed 2.5 mg once every 3 to 4 days.

Children ages 6 to 11. 2.5 mg once daily in evening. *Maximum:* 2.5 mg daily.

Mechanism of Action

Binds to central and peripheral H₁ receptors, competing with histamine for these sites and preventing it from reaching its site of action. By blocking histamine, levocetirizine produces antihistamine effects, inhibiting respiratory, vascular, and GI smooth-muscle contraction; decreasing capillary permeability, which reduces wheals, flares, and itching; and decreasing salivary and lacrimal gland secretions to relieve chronic urticaria and signs and symptoms of allergic rhinitis.

Contraindications

Children ages 6 to 11 with impaired renal function; creatinine clearance less than 10 ml/min/1.73 m²; end-stage renal disease in adults and children age 12 and over; hypersensitivity to levocetirizine, cetirizine or their components; renal failure

Interactions

DRUGS

CNS depressants: Possibly increased CNS depression

MAO inhibitors: Possibly prolonged and intensified anticholinergic effects

ritonavir: Possibly increased risk of adverse effects of levocetirizine

theophylline: Possibly decreased clearance of levocetirizine

ACTIVITIES

alcohol use: Possibly increased CNS depression

Adverse Reactions

CNS: Aggression, agitation, asthenia, fatigue, fever, seizures, somnolence, syncope

CV: Palpitations

EENT: Dry mouth, epistaxis, nasopharyngitis, pharyngitis, visual disturbances

GI: Hepatitis, nausea

MS: Myalgia

RESP: Cough, dyspnea

SKIN: Pruritus, rash, urticaria

Other: Anaphylaxis, angioedema, weight gain

Nursing Considerations

- Expect to stop drug at least 72 hours before skin tests for allergies because drug may inhibit cutaneous histamine response, thus producing false-negative results.

PATIENT TEACHING

- Instruct patient to take drug exactly as prescribed. For oral solution, patient should use appropriate measuring device.
- Urge patient to avoid alcohol while taking levocetirizine
- Advise patient to avoid hazardous activities until drug's CNS effects are known.

levodopa

Dopar, Larodopa

Class and Category

Chemical class: Dihydroxyphenylalanine isomer, metabolic precursor of dopamine

Therapeutic class: Antidyskinetic

Pregnancy category: Not rated

Indications and Dosages

↗ *To manage symptoms of primary Parkinson's disease, postencephalitic parkinsonism, and parkinsonism caused by CNS injury from carbon monoxide or manganese intoxication*

CAPSULES, TABLETS

Adults and children age 12 and over.

Initial: 250 mg daily in divided doses b.i.d. to q.i.d. Increased by 100 to 750 mg every 3 to 7 days, as indicated. *Maximum:* 8 g daily.

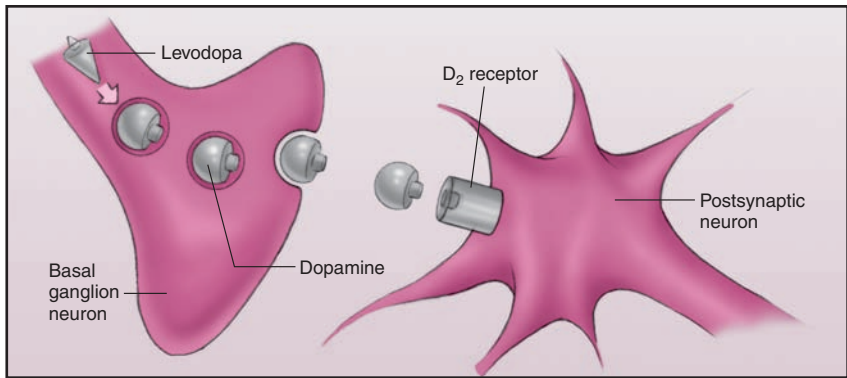

Contraindications

Angle-closure glaucoma, history of melanoma, hypersensitivity to levodopa or its components, suspicious undiagnosed skin

Mechanism of Action

By supplementing a low level of endogenous dopamine, levodopa helps control alterations in voluntary muscle movement (such as tremors and rigidity) in Parkinson's disease. Dopamine, a neurotransmitter synthesized and released by neurons leading from substantia nigra to basal ganglia, is essential for normal motor function. By stimulating peripheral and central dopaminergic (D_2) recep-

tors on postsynaptic cells, dopamine inhibits the firing of striatal neurons (such as cholinergic neurons). In Parkinson's disease, progressive degeneration of these neurons substantially reduces the supply of intrasynaptic dopamine. Levodopa, a dopamine precursor, increases the dopamine supply in neurons, making more available to stimulate dopaminergic receptors.

lesions, use within 14 days of MAO inhibitor therapy

Route	Onset	Peak	Duration
P.O.	14–21 days*	Unknown	5 hr

Interactions

DRUGS

antacids: Increased blood levodopa level
antihypertensives: Risk of orthostatic hypotension
benzodiazepines: Possibly decreased therapeutic effects of levodopa
bromocriptine: Possibly additive effects of levodopa
furazolidone, MAO inhibitors, procarbazine: Risk of severe hypertension
haloperidol, loxapine, molindone, papaverine, phenothiazines, phenytoin, rauwolfia alkaloids: Decreased effects of levodopa
inhaled anesthetics, sympathomimetics: Increased risk of arrhythmias
iron salts: Possibly decreased blood level and effectiveness of levodopa

* With multiple doses.

methyl dopa: Possibly toxic CNS effects
metoclopramide: Possibly worsening of Parkinson's disease and decreased therapeutic effects of metoclopramide
pyridoxine (vitamin B₆): Decreased antidyskinetic effect of levodopa

FOODS

high-protein food: Decreased levodopa absorption

ACTIVITIES

cocaine use: Increased risk of arrhythmias

Adverse Reactions

CNS: Aggressiveness, anxiety, ataxia, confusion, delusions, dizziness, dream disturbances, dyskinesia, dystonia, euphoria, hallucinations, headache, increased tremor, insomnia, malaise, mood changes, severe depression, suicidal tendencies, syncope, weakness

CV: Arrhythmias, hot flashes, orthostatic hypotension, palpitations

EENT: Bitter aftertaste, blurred vision, darkened saliva, diplopia, dry mouth, increased salivation, mydriasis, tooth clenching and grinding

GI: Abdominal pain, anorexia, constipation, diarrhea, flatulence, GI bleeding, hepatotoxicity, hiccups, indigestion, nausea, vomiting

GU: Darkened urine, priapism, urine retention

SKIN: Darkened sweat, diaphoresis, rash

Nursing Considerations

- Expect to discontinue levodopa 6 to 8 hours before surgery to avoid interactions with anesthetics.
- Observe patient for mental or behavioral changes and suicidal tendencies. Notify prescriber immediately if they occur.
- Watch for muscle twitching and blepharospasm (eyelid spasm), which are early signs of levodopa overdose. Report them at once.
- Expect patient to be tested for acromegaly and diabetes during long-term levodopa therapy. Also expect to monitor hematopoietic, hepatic, and renal function.

PATIENT TEACHING

- Advise patient to take levodopa with meals if she experiences adverse GI reactions.
- Because protein impairs drug absorption, instruct patient to avoid high-protein meals during levodopa therapy and to distribute protein intake equally throughout the day.
- Caution patient to avoid excessive use of vitamins and fortified cereals that contain vitamin B₆ or iron, which can reduce levodopa's effects.
- Instruct patient to report fainting, increased muscle tremor, difficult urination, and severe or persistent nausea and vomiting.
- Urge patient to continue taking drug as prescribed even if results of therapy aren't evident immediately.
- Inform patient that saliva, sweat, and urine may darken but that this isn't harmful.
- Direct patient to protect drug from heat, light, and moisture and to discard darkened pills because they have lost their potency.
- Advise patient to change position slowly to minimize orthostatic hypotension.
- Caution male patient about risk of priapism (persistent, painful erection), and urge him to seek medical help immediately if it occurs.

levofloxacin

Levaquin

Class and Category

Chemical class: Fluoroquinolone

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

↗ *To reduce incidence or progression of inhalation anthrax after exposure to aerosolized Bacillus anthracis*

TABLETS, I.V. INFUSION, ORAL SOLUTION

Adults and children weighing more than 50 kg (110 lb). 500 mg (over 60 min for I.V. infusion) daily for 60 days.

Children weighing less than 50 kg. 8 mg/kg (over 60 min for I.V. infusion) every 12 hr for 60 days. *Maximum:* 250 mg/dose.

↗ *To treat acute maxillary sinusitis caused by Haemophilus influenzae, Moraxella catarrhalis, or Streptococcus pneumoniae*

TABLETS, I.V. INFUSION, ORAL SOLUTION

Adults. 500 mg daily (over 60 to 90 min for I.V. infusion) for 10 to 14 days. Or 759 mg daily for 5 days.

↗ *To treat acute exacerbation of chronic bacterial bronchitis caused by H. influenzae, H. parainfluenzae, M. catarrhalis, S. pneumoniae, or Staphylococcus aureus*

TABLETS, I.V. INFUSION, ORAL SOLUTION

Adults. 500 mg daily (over 60 to 90 min for I.V. infusion) for 7 days.

↗ *To treat community-acquired pneumonia caused by Chlamydia pneumoniae, H. influenzae, H. parainfluenzae, Klebsiella pneumoniae, Legionella pneumophila, M. catarrhalis, Mycoplasma pneumoniae, S. aureus, or S. pneumoniae*

TABLETS, I.V. INFUSION, ORAL SOLUTION

Adults. 500 mg daily (over 60 to 90 min for I.V. infusion) for 7 to 14 days. Alternatively, for infection caused by *C. pneumoniae, H. influenzae, H. parainfluenzae, M. pneumoniae, or S. pneumoniae*, 750 mg daily (over 60 to 90 min for I.V. infusion) for 5 days.

↗ *To treat uncomplicated UTI caused by Escherichia coli, K. pneumoniae, or Staphylococcus saprophyticus*

TABLETS, I.V. INFUSION, ORAL SOLUTION

Adults. 250 mg daily (over 60 to 90 min for I.V. infusion) for 3 days.

➤ *To treat complicated UTI caused by Enterococcus faecalis, E. cloacae, E. coli, K. pneumoniae, Proteus mirabilis, or Pseudomonas aeruginosa or acute pyelonephritis caused by E. coli*

TABLETS, I.V. INFUSION, ORAL SOLUTION

Adults. 250 mg daily (over 60 to 90 min for I.V. infusion) for 10 days.

➤ *To treat complicated UTI caused by E. coli, K. pneumoniae, or P. mirabilis or acute pyelonephritis caused by E. coli*

TABLETS, I.V. INFUSION, ORAL SOLUTION

Adults. 750 mg daily (over 90 min for I.V. infusion) for 5 days.

➤ *To treat mild to moderate skin and soft-tissue infections caused by S. aureus or Streptococcus pyogenes*

TABLETS, I.V. INFUSION, ORAL SOLUTION

Adults. 500 mg daily (over 60 to 90 min for I.V. infusion) for 7 to 10 days.

➤ *To treat complicated skin and soft-tissue infections caused by methicillin-sensitive Enterococcus faecalis, Proteus mirabilis, S. aureus, or S. pyogenes; to treat nosocomial pneumonia caused by S. aureus, Pseudomonas aeruginosa, Serratia marcescens, E. coli, K. pneumoniae, H. influenzae, or S. pneumoniae*

TABLETS, I.V. INFUSION, ORAL SOLUTION

Adults. 750 mg daily (over 60 to 90 min for I.V. infusion) for 7 to 14 days.

➤ *To treat chronic bacterial prostatitis caused by E. coli, E. faecalis, or S. epidermidis*

TABLETS, I.V. INFUSION, ORAL SOLUTION

Adults. 500 mg daily (over 60 to 90 min for I.V. infusion) for 28 days.

DOSE ADJUSTMENT For complicated UTI in patients with creatinine clearance of 10 to 19 ml/min/1.73 m², 250 mg initially and then maintenance dosage of 250 mg every 48 hr. For complicated skin and soft-tissue infections and nosocomial pneumonia when creatinine clearance is 19 ml/min/1.73 m² or less, 750 mg initially and then maintenance dosage of 500 mg every 48 hr; when creatinine clearance is 20 to 49 ml/min/1.73 m², 750 mg initially and then maintenance dosage of 750 mg every 48 hr. For all other indications, when creati-

nine clearance is 19 ml/min/1.73 m² or less, 500 mg initially and then maintenance of 250 mg every 48 hr; when creatinine clearance is 20 to 49 ml/min/1.73 m², 500 mg initially and then maintenance dosage of 250 mg every 24 hr.

Mechanism of Action

Interferes with bacterial cell replication by inhibiting the bacterial enzyme DNA gyrase, which is essential for replication and repair of bacterial DNA.

Contraindications

Hypersensitivity to levofloxacin, other fluoroquinolones, or their components

Interactions**DRUGS**

aluminum-, calcium-, or magnesium-containing antacids; didanosine; iron; sucralfate; zinc: Reduced GI absorption of levofloxacin
antineoplastics: Decreased blood levofloxacin level
cimetidine: Increased blood levofloxacin level

cyclosporine: Increased risk of nephrotoxicity
NSAIDs: Possibly increased CNS stimulation and risk of seizures

oral anticoagulants: Increased anticoagulant effect and risk of bleeding

oral antidiabetic drugs: Possibly hyperglycemia or hypoglycemia

theophylline: Increased blood theophylline level and risk of toxicity

ACTIVITIES

sun exposure: Increased risk of photosensitivity

Adverse Reactions

CNS: Anxiety, CNS stimulation, dizziness, fever, headache, increased ICP, insomnia, light-headedness, nervousness, paranoia, peripheral neuropathy, psychosis, seizures, sleep disturbance, suicidal ideation

CV: Arrhythmias, leukocytoclastic vasculitis, prolonged QT interval, torsades de pointes, vasculitis, vasodilation

EENT: Blurred vision, decreased visual acuity, diplopia, dysphonia, scotoma, taste perversion, tinnitus

ENDO: Hyperglycemia, hypoglycemia

GI: Abdominal pain, acute hepatic necrosis or failure, anorexia, constipation, diarrhea, flatulence, hepatitis, hepatotoxicity, indigestion, jaundice, nausea, pseudomembranous

colitis, vomiting

GU: Acute renal failure or insufficiency, crystalluria, interstitial nephritis, vaginal candidiasis

HEME: Agranulocytosis, aplastic anemia, eosinophilia, hemolytic anemia, leukopenia, pancytopenia, thrombocytopenia

MS: Arthralgia, back pain, myalgia, rhabdomyolysis, tendon or muscle rupture

RESP: Allergic pneumonitis

SKIN: Photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, multi-organ failure, serum sickness

Nursing Considerations

- Use levofloxacin cautiously in patients with renal insufficiency. Monitor renal function as appropriate during treatment.
- Use drug cautiously in patients with CNS disorders, such as epilepsy, that may lower the seizure threshold. Also use cautiously in patients taking corticosteroids, especially elderly patients, because of increased risk of tendon rupture.
- Expect to obtain culture and sensitivity tests before levofloxacin treatment begins.
- Avoid giving drug within 2 hours of antacids.
- Give parenteral form over 60 to 90 minutes, depending on dosage, because bolus or rapid I.V. delivery may cause hypotension.

WARNING Stop levofloxacin at first sign of hypersensitivity, including rash and jaundice, because drug may lead to anaphylaxis. Reaction may occur after first dose. Expect to give epinephrine and provide supportive care.

- Monitor blood glucose level, especially in diabetic patient who takes an oral antidiabetic or uses insulin, because levofloxacin may alter blood glucose level. If so, notify prescriber, stop drug immediately if patient has hypoglycemia, and provide prescribed treatment.
- Monitor QT interval if needed. If it lengthens, notify prescriber at once and stop drug. Patients with hypokalemia, significant bradycardia, or cardiomyopathy and those receiving a class IA or III antiarrhythmic shouldn't receive levofloxacin.
- Notify prescriber if patient has symptoms

of peripheral neuropathy (pain; burning; tingling; numbness; weakness; altered sensations of light touch, pain, temperature, position sense, or vibration sense), which could be permanent; or CNS abnormalities (seizures, psychosis, increased ICP or CNS stimulation), which may lead to more serious adverse reactions, such as suicidal ideation. In each case, expect to discontinue levofloxacin.

- Watch for evidence of tendon rupture (inflammation, pain, swelling) during and up to several months after therapy, especially in children, elderly patients, patients receiving corticosteroids, and patients with kidney, heart, and lung transplants. Notify prescriber about suspected tendon rupture, and have patient rest and refrain from exercise until tendon rupture has been ruled out. If present, expect to provide supportive care, as ordered.
- Monitor patient's bowel elimination. If diarrhea develops, obtain stool culture to check for pseudomembranous colitis. If confirmed, expect to stop drug and give fluid, electrolytes, and antibiotics effective against *Clostridium difficile*.

PATIENT TEACHING

- If patient will take oral solution form of levofloxacin, tell him to take it 1 hour before or 2 hours after eating.
- Advise patient to increase fluid intake during therapy to prevent crystalluria.
- Direct patient to take an antacid, didanosine, iron, sucralfate, or zinc at least 2 hours before or after levofloxacin.
- Tell patient to complete the drug as prescribed, even if symptoms subside.
- Urge patient to avoid excessive sun exposure and to wear sunscreen because of increased risk of photosensitivity. Tell patient to notify prescriber at first sign.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Tell patient to stop drug and notify prescriber if he develops tendon pain or inflammation or abnormal changes in motor or sensory function.
- Urge patient to stop drug and tell prescriber about rash or other allergic reaction.
- Advise diabetic patient to monitor blood glucose level and report changes.
- Urge patient to tell prescriber about severe

diarrhea, even if it's more than 2 months after drug therapy ends. Additional treatment may be needed.

- Advise patient to notify prescriber about heart palpitations or loss of consciousness. An ECG may be needed to detect adverse drug effects on the patient's heart.

levorphanol tartrate

Levo-Dromoran

Class, Category, and Schedule

Chemical class: Morphinan derivative

Therapeutic class: Analgesic, anesthesia adjunct

Pregnancy category: Not rated

Controlled substance schedule: II

Indications and Dosages

↗ *To relieve moderate to severe pain*

TABLETS

Adults. 2 mg every 6 to 8 hr, p.r.n. Increased to 3 mg every 6 to 8 hr, if indicated.

I.V. INJECTION

Adults. Up to 1 mg every 3 to 6 hr, p.r.n. *Maximum:* 8 mg daily for non-opioid-dependent patients.

I.M. OR SUBCUTANEOUS INJECTION

Adults. 1 to 2 mg every 6 to 8 hr, p.r.n. *Maximum:* 8 mg daily for non-opioid-dependent patients.

↗ *To provide preoperative sedation*

I.M. OR SUBCUTANEOUS INJECTION

Adults. 1 to 2 mg 60 to 90 min before procedure.

Route	Onset	Peak	Duration
P.O.	10–60 min	90–120 min	4–5 hr
I.V.	Unknown	In 20 min	4–5 hr
I.M.	Unknown	60 min	4–5 hr
SubQ	Unknown	60–90 min	4–5 hr

Mechanism of Action

Decreases intracellular level of cyclic adenosine monophosphate by inhibiting adenylyl cyclase, which regulates release of pain neurotransmitters, such as substance P, gamma-aminobutyric acid, dopamine, acetylcholine, and noradrenaline. Levorphanol also stimulates mu and kappa opioid receptors, altering perception of and emotional response to pain.

Incompatibilities

Don't mix levorphanol tartrate with solutions that contain aminophylline, ammonium chloride, amobarbital sodium, chlorothiazide sodium, heparin sodium, methicillin sodium, nitrofurantoin sodium, novobiacin sodium, pentobarbital sodium, perphenazine, phenobarbital sodium, phenytoin, secobarbital sodium, sodium bicarbonate, sodium iodide, sulfadiazine sodium, sulfisoxazole diethanolamine, or thiopental sodium.

Contraindications

Acute alcoholism, acute or severe asthma, anoxia, hypersensitivity to levorphanol tartrate or its components, increased intracranial pressure, respiratory depression, upper airway obstruction

Interactions

DRUGS

alfentanil, CNS depressants, fentanyl, sufentanil: Possibly increased CNS and respiratory depression and hypotension

anticholinergics: Increased risk of severe constipation

antidiarrheals, such as difenoxin and atropine, kaolin, and loperamide: Increased risk of severe constipation and increased CNS depression

antihypertensives: Increased risk of hypotension

buprenorphine: Possibly decreased therapeutic effects of levorphanol and increased risk of respiratory depression

hydroxyzine: Increased risk of CNS depression and hypotension

metoclopramide: Possibly antagonized effects of metoclopramide

naloxone, naltrexone: Decreased therapeutic effects of levorphanol

neuromuscular blockers: Increased risk of prolonged CNS and respiratory depression

ACTIVITIES

alcohol use: Possibly increased CNS and respiratory depression and hypotension

Adverse Reactions

CNS: Amnesia, coma, confusion, delusions, depression, dizziness, drowsiness, dyskinesia, hypokinesia, insomnia, nervousness, personality disorder, seizures

CV: Bradycardia, cardiac arrest, hypotension, orthostatic hypotension, palpitations, shock, tachycardia

EENT: Abnormal vision, diplopia, dry mouth

GI: Abdominal pain, biliary tract spasm, constipation, hepatic failure, indigestion, nausea, vomiting

GU: Dysuria, urine retention

RESP: Apnea, hyperventilation

SKIN: Cyanosis, pruritus, rash, urticaria

Other: Injection site pain, redness, and swelling; physical and psychological dependence

Nursing Considerations

WARNING Be aware that levorphanol may be habit-forming.

- Give drug with food if GI distress occurs.
- If respiratory depression occurs, expect to administer naloxone to reverse it.
- Monitor supine and standing blood pressure, and notify prescriber of orthostatic hypotension.
- Carefully assess for adverse reactions in elderly patients; they are especially sensitive to drug and are at increased risk for constipation.

PATIENT TEACHING

- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to avoid alcoholic beverages while taking levorphanol.
- Direct patient to change position slowly to minimize orthostatic hypotension.
- Advise patient to notify prescriber if constipation, nausea, or vomiting occurs.
- If patient reports dry mouth, suggest that she use sugarless candy or gum or ice chips.

levothyroxine sodium

(L-thyroxine sodium, T₄, thyroxine sodium)

Eltroxin (CAN), Levo-T, Levothroid, Levoxyl, PMS-Levothyroxine Sodium (CAN), Synthroid, Unithroid

Class and Category

Chemical class: Synthetic thyroxine (T₄)

Therapeutic class: Thyroid hormone replacement

Pregnancy category: A

Indications and Dosages

↗ *To treat mild hypothyroidism*

TABLETS

Adults. *Initial:* 50 mcg daily, increased by 25 to 50 mcg every 2 to 3 wk until desired response occurs or therapeutic blood level is reached. *Maintenance:* 75 to 125 mcg daily.

DOSAGE ADJUSTMENT For elderly patients and those with cardiovascular disease or chronic hypothyroidism, initial dosage usually reduced to 12.5 to 25 mcg daily and then increased by 12.5 to 25 mcg every 3 to 4 wk until desired response occurs. For elderly patients, maintenance dosage is limited to 75 mcg daily.

Children over age 10. 2 to 3 mcg/kg daily. *Usual:* 150 to 200 mcg daily.

Children ages 6 to 10. 4 to 5 mcg/kg daily. *Usual:* 100 to 150 mcg daily.

Children ages 1 to 5. 3 to 5 mcg/kg daily. *Usual:* 75 to 100 mcg daily.

Infants ages 6 to 12 months. 5 to 6 mcg/kg daily. *Usual:* 50 to 75 mcg daily.

Infants under age 6 months. 5 to 6 mcg/kg daily. *Usual:* 25 to 50 mcg daily.

↗ *To treat severe hypothyroidism*

TABLETS

Adults. *Initial:* 12.5 to 25 mcg daily. Increased by 25 mcg every 2 to 3 wk until desired response occurs or therapeutic blood level is reached. *Maintenance:* 75 to 125 mcg daily. *Maximum:* 200 mcg daily.

Children over age 10. 2 to 3 mcg/kg daily. *Usual:* 150 to 200 mcg daily.

Children ages 6 to 10. 4 to 5 mcg/kg daily. *Usual:* 100 to 150 mcg daily.

Children ages 1 to 5. 3 to 5 mcg/kg daily. *Usual:* 75 to 100 mcg daily.

Infants ages 6 to 12 months. 5 to 6 mcg/kg daily. *Usual:* 50 to 75 mcg daily.

Infants under age 6 months. 5 to 6 mcg/kg daily. *Usual:* 25 to 50 mcg daily.

I.V. OR I.M. INJECTION

Adults. 50 to 100 mcg daily until therapeutic blood level is reached.

Children. 75% of usual P.O. dose daily until therapeutic blood level is reached.

↗ *To treat myxedema coma*

I.V. INJECTION

Adults. 200 to 500 mcg on day 1. If no significant improvement, 100 to 300 mcg on day 2. Daily dose continued as prescribed until therapeutic blood level is reached and

P.O. administration is tolerated.

Children. 75% of usual P.O. dose daily until therapeutic blood level is reached and P.O. administration is tolerated.

Route	Onset	Peak	Duration
P.O.	3–5 days	3–4 wk	1–3 wk
I.V.	6–8 hr	24 hr	Unknown
I.M.	Unknown	Unknown	1–3 wk

Mechanism of Action

Replaces endogenous thyroid hormone, which may exert its physiologic effects by controlling DNA transcription and protein synthesis. Levothyroxine has all the following actions of endogenous thyroid hormone. The drug:

- increases energy expenditure
- accelerates the rate of cellular oxidation, which stimulates body tissue growth, maturation, and metabolism
- regulates differentiation and proliferation of stem cells
- aids in myelination of nerves and development of synaptic processes in the nervous system
- regulates growth
- decreases blood and hepatic cholesterol concentrations
- enhances carbohydrate and protein metabolism, increasing gluconeogenesis and protein synthesis.

Contraindications

Acute MI (unless caused or complicated by hyperthyroidism), hypersensitivity to levothyroxine or its components, uncorrected adrenal insufficiency, untreated thyrotoxicosis

Interactions

DRUGS

adrenocorticoids: Possibly adrenocorticoid dosage adjustments as thyroid status changes

aluminum- and magnesium-containing antacids, bile acid sequestrants, calcium carbonate, cation exchange resins, cholestyramine, colestipol, ferrous sulfate, kayexalate, orlistat, sucralfate: Possibly reduced effects of levothyroxine

amiodarone, iodide: Possibly hyperthyroidism

beta blockers: Possibly impaired action of

beta blockers and decreased conversion of T_4 to triiodothyronine (T_3)

cholestyramine, colestipol: Delayed or inhibited levothyroxine absorption

digoxin: Reduced digoxin effects

estrogen, phenylbutazone, phenytoin:

Reduced binding of levothyroxine to protein, possibly requiring increased levothyroxine dosage

insulin, oral antidiabetic drugs: Possibly uncontrolled diabetes mellitus, requiring increased dosage of insulin or oral antidiabetic drug

ketamine: Possibly hypertension and tachycardia

maprotiline: Increased risk of arrhythmias

oral anticoagulants: Altered anticoagulant activity, possibly need for anticoagulant dosage adjustment

selective serotonin reuptake inhibitors, tricyclic and tetracyclic antidepressants:

Increased therapeutic and toxic effects of both drugs

sympathomimetics: Increased risk of coronary insufficiency in patients with coronary artery disease

theophylline: Decreased theophylline clearance

FOODS

dietary fiber, soybean flour (infant formula),

walnuts: Possibly decreased absorption of levothyroxine from GI tract

Adverse Reactions

CNS: Fatigue, headache, insomnia, somnolence

ENDO: Hyperthyroidism (with overdose)

GI: Dysphagia

MS: Muscle weakness, myalgia, slipped capital femoral epiphysis

SKIN: Alopecia (transient), rash, urticaria

Other: Weight gain

Nursing Considerations

• Administer levothyroxine tablets as a single daily dose 30 to 60 minutes before breakfast. If patient has difficulty swallowing, crush tablet and suspend in a small amount of water or food.

• To prevent decreased drug absorption, give oral levothyroxine at least 4 hours before or after aluminum- or magnesium-containing antacids, bile acid sequestrants, calcium carbonate, cation exchange resins, cholestyramine, colestipol, ferrous sulfate,

kayexalate, or sucralfate.

- Expect to give drug I.V. or I.M. if patient can't take tablets. Be aware that drug shouldn't be given subcutaneously.
- For I.V. use, reconstitute drug by adding 5 ml of normal saline solution.
- Monitor PT of patient who is receiving anticoagulants; she may require a dosage adjustment.
- Monitor blood glucose level of diabetic patient. Prescriber may reduce antidiabetic drug dosage as thyroid hormone level enters therapeutic range.
- Expect patient to undergo thyroid function tests regularly during levothyroxine therapy.

PATIENT TEACHING

- Inform patient that levothyroxine replaces a hormone that is normally produced by the thyroid gland and that she'll probably need to take drug for life.
- Instruct patient to take drug at least 30 minutes before breakfast because drug absorption is increased on an empty stomach and evening doses may cause insomnia.
- Stress the need to take levothyroxine with a full glass of water to avoid choking, gagging, having tablet stick in throat, and developing heartburn afterward.
- Instruct patient to separate iron and calcium supplements and antacids by at least 4 hours from levothyroxine doses.
- Inform patient that drug may require a few weeks to take effect.
- Advise patient not to stop drug or change dosage unless instructed by prescriber.
- Instruct patient to report signs of hyperthyroidism, such as diarrhea, excessive sweating, heat intolerance, insomnia, palpitations, weight loss, chest pain, shortness of breath, leg cramps, headache, nervousness, irritability, tremors, changes in appetite, vomiting, fever, and changes in menstrual periods.
- Tell patient to notify prescriber if rash or hives develop during drug use.
- Inform patient that transient hair loss may occur during first few months of levothyroxine therapy.
- Instruct female patient of childbearing age to notify prescriber immediately if she becomes pregnant because levothyroxine dosage may need to be increased.

lidocaine hydrochloride (lignocaine hydrochloride)

Alphacaine (CAN), Anestacon, DermaFlex, Dilocaine, L-Caine, Lidoderm, Xylocaine, Xylocard (CAN), Zingo

Class and Category

Chemical class: Aminoacetamide

Therapeutic class: Class IB antiarrhythmic, local anesthetic

Pregnancy category: B

Indications and Dosages

↗ *To treat ventricular tachycardia or ventricular fibrillation*

I.V. INFUSION AND INJECTION

Adults. *Loading:* 50 to 100 mg (or 1 to 1.5 mg/kg), given at 25 to 50 mg/min. If desired response isn't achieved after 5 to 10 min, second dose of 25 to 50 mg (or 0.5 to 0.75 mg/kg) given every 5 to 10 min until maximum loading dose (300 mg in 1 hr) has been given. *Maintenance:* 20 to 50 mcg/kg/min (1 to 4 mg/min) by continuous infusion. Smaller bolus dose repeated 15 to 20 min after start of infusion if needed to maintain therapeutic blood level.

Maximum: 300 mg (or 3 mg/kg) over 1 hr.

Children. *Loading:* 1 mg/kg. *Maintenance:* 30 mcg/kg/min by continuous infusion.

Maximum: 3 mg/kg.

DOSE ADJUSTMENT For elderly patients receiving I.V. lidocaine to treat arrhythmias and for patients with acute hepatitis or decompensated cirrhosis, loading dose and continuous infusion rate reduced by 50%.

I.M. INJECTION

Adults. 300 mg, repeated after 60 to 90 min, if needed.

↗ *To provide topical anesthesia for skin or mucous membranes*

FILM-FORMING GEL, JELLY, OR OINTMENT

Adults. Thin layer applied to skin or mucous membranes as needed before procedure.

TRANSDERMAL PATCH

Adults. 1 to 3 patches applied over most painful area only once for up to 12 hr with-

in a 24-hr period.

➤ *To provide topical anesthesia before venous access procedures*

POWDER

Children ages 3 to 18. Compressed gas application of powder to selected skin site 1 to 3 minutes before procedure.

Route	Onset	Peak	Duration
I.V.	45–90 sec	Immediate	10–20 min
I.M.	5–15 min	Unknown	60–90 min
Topical	2–5 min	Unknown	0.5–1 hr

Mechanism of Action

Combines with fast sodium channels in myocardial cell membranes, which inhibits sodium influx into cells and decreases ventricular depolarization, automaticity, and excitability during diastole. Lidocaine also blocks nerve impulses by decreasing the permeability of neuronal membranes to sodium, which produces local anesthesia.

Contraindications

Adams-Stokes syndrome; hypersensitivity to lidocaine, amide anesthetics, or their components; severe heart block (without artificial pacemaker); Wolff-Parkinson-White syndrome

Interactions

DRUGS

beta blockers, cimetidine: Increased blood lidocaine level and risk of toxicity

MAO inhibitors, tricyclic antidepressants:

Risk of severe, prolonged hypertension
mexiletine, tocainide: Additive cardiac effects

neuromuscular blockers: Possibly increased neuromuscular blockade

phenytoin, procainamide: Increased cardiac depression

Adverse Reactions

CNS: Anxiety, confusion, difficulty speaking, dizziness, hallucinations, lethargy, paresthesia, seizures

CV: Bradycardia, cardiac arrest, hypotension, new or worsening arrhythmias

EENT: Blurred vision, diplopia, tinnitus

GI: Nausea

MS: Muscle weakness, myalgia

RESP: Respiratory arrest or depression

Other: Hypersensitivity; injection site burning, irritation, petechiae, redness,

stinging, swelling, and tenderness; worsened pain

Nursing Considerations

- Observe for respiratory depression after bolus injection and during I.V. infusion of lidocaine.
- Keep life-support equipment and vasopressors nearby during I.V. use in case of respiratory depression or other reactions.
- Carefully check prefilled syringes before using. Use only syringes labeled “for cardiac arrhythmias” for I.V. administration.
- As ordered, titrate I.V. dose to minimum amount needed to prevent arrhythmias.
- During I.V. administration, place patient on cardiac monitor, as ordered, and closely observe her at all times. Monitor for worsening arrhythmias, widening QRS complex, and prolonged PR interval—possible signs of drug toxicity.
- Check blood drug level, as ordered. Therapeutic level is 2 to 5 mcg/ml.
- If signs of toxicity, such as dizziness, occur, notify prescriber and expect to discontinue or slow infusion.
- Give I.M. injection in deltoid muscle only.
- Apply lidocaine jelly or ointment to gauze or bandage before applying to skin.
- Monitor vital signs as well as BUN and serum creatinine and electrolyte levels during and after therapy.

PATIENT TEACHING

- Inform patient who receives lidocaine as an anesthetic that she’ll feel numbness.
- Advise patient to report difficulty speaking, dizziness, injection site pain, nausea, numbness or tingling, and vision changes.
- Caution patient to keep lidocaine topical preparations and patches out of reach of children and pets.
- Tell patient to wash hands thoroughly after handling lidocaine topical forms or patch and to avoid getting drug in eyes.
- If patient uses patches, tell her to store them in their sealed envelopes until needed and to apply immediately after removing from the envelope. Tell patient to remove patch if irritation or burning occurs at the site and not to reapply until irritation is gone.
- Tell patient to fold used patches so that the adhesive side sticks to itself and discard where children or pets cannot get to them.

lincomycin hydrochloride

Lincocin

Class and Category

Chemical class: Lincosamide

Therapeutic class: Bacteriostatic or bactericidal antibiotic

Pregnancy category: C

Indications and Dosages

➤ *To treat serious respiratory, skin, and soft-tissue infections caused by susceptible strains of streptococci, pneumococci, and staphylococci*

CAPSULES

Adults and adolescents. 500 mg every 6 to 8 hr.

Children over age 1 month. 7.5 to 15 mg/kg every 6 hr; or, 10 to 20 mg/kg every 8 hr.

I.V. INFUSION

Adults. 600 mg to 1 g every 8 to 12 hr.

Maximum: 8 g daily in divided doses for life-threatening infection.

Children over age 1 month. 10 to 20 mg/kg/day in divided doses every 8 to 12 hr, depending on severity of infection.

I.M. INJECTION

Adults and adolescents. 600 mg every 12 to 24 hr.

Children over age 1 month. 10 mg/kg every 12 to 24 hr.

DOSAGE ADJUSTMENT Dosage reduced by 25% to 30% for patients with severely impaired renal function.

Mechanism of Action

Inhibits protein synthesis in susceptible bacteria by binding to 50S subunit of bacterial ribosomes and preventing peptide bond formation, causing bacterial cells to die.

Incompatibilities

Don't give lincomycin with novobiocin or kanamycin.

Contraindications

Hypersensitivity to lincomycin, clindamycin, or their components

Interactions

DRUGS

antimythasthenic drugs: Possibly antagonized effects of these drugs

chloramphenicol, clindamycin, erythromycin: Possibly blocked access of lincomycin to its site of action

hydrocarbon inhalation anesthetics, neuromuscular blockers: Increased neuromuscular blockade, possibly severe respiratory depression

opioid analgesics: Increased risk of prolonged or increased respiratory depression

Adverse Reactions

CNS: Fever, vertigo

CV: Cardiac arrest and hypotension (with rapid administration)

EENT: Glossitis, stomatitis, tinnitus

GI: Abdominal cramps, colitis, diarrhea, nausea, pseudomembranous colitis, rectal candidiasis, vomiting

GU: Vaginal candidiasis

HEME: Agranulocytosis, eosinophilia, leukopenia, neutropenia, thrombocytopenic purpura

SKIN: Erythema multiforme, rash, Stevens-Johnson syndrome, urticaria

Other: Anaphylaxis, angioedema, superinfection

Nursing Considerations

- Expect to obtain a specimen for culture and sensitivity testing before giving first dose of lincomycin.

WARNING Be aware that some lincomycin preparations contain benzyl alcohol, which can cause a fatal toxic syndrome in neonates or premature infants characterized by CNS, respiratory, circulatory, and renal impairment and metabolic acidosis. Because drug enters breast milk, breastfeeding patient may need to stop drug or stop breast-feeding.

- Dilute 600-mg dose in at least 100 ml D₅W, D₁₀W, normal saline solution, dextrose 5% in normal saline solution, or other compatible diluent recommended by manufacturer. Dilute higher doses in 100 ml of a compatible diluent for each gram being given—for example, dilute a 3-g dose in at least 300 ml of diluent. Use diluted solution within 24 hours if stored at room temperature.

WARNING Give lincomycin over at least 1 hour for each gram being administered. For example, infuse 1 g over 1 hour and 3 g over 3 hours. Too-rapid infusion may result in cardiac arrest or hypotension.

WARNING Monitor patient for hypersensitivity reaction, such as rash, pruritus, wheezing, and dysphagia from laryngeal edema. If a reaction occurs, stop infusion and notify prescriber immediately. If anaphylaxis occurs, give epinephrine, antihistamines, oxygen, and corticosteroids, as prescribed. Be aware that patients with a history of asthma or significant allergies are at increased risk of hypersensitivity.

- Observe patient for evidence of superinfection, such as vaginal itching and sore mouth.
- Monitor patient for signs of pseudomembranous colitis, such as watery, loose stools. Patients with a history of GI disease, particularly colitis or regional enteritis, are at increased risk for colitis. In elderly patients, antibiotic-related diarrhea may be more severe and less well tolerated. Notify prescriber if severe or prolonged diarrhea develops; it may indicate pseudomembranous colitis caused by *Clostridium difficile*. Expect to withhold lincomycin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- Monitor results of liver and renal function tests, CBC, and platelet counts periodically during lincomycin therapy.
- Before diluting drug, store it at a controlled room temperature of 68° to 77° F (20° to 25° C).

PATIENT TEACHING

- Advise patient to take lincomycin capsules with a full glass of water on an empty stomach 1 hour before or 2 hours after meals to maximize drug's effectiveness.
- Review with patient possibly serious adverse reactions, such as difficulty breathing, rash, and chest tightness, and tell her to report any that occur.
- Inform patient that yogurt or buttermilk can help maintain intestinal flora and may decrease the risk of diarrhea.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.
- Stress the importance of following dosage regimen and keeping follow-up medical and laboratory appointments.

lindane

Bio-Well, GBH, G-well, Hexit (CAN), Kildane, Kwell, Kwellada (CAN), Kwildane, PMS-Lindane (CAN), Scabene, Thionex

Class and Category

Chemical class: Benzene derivative

Therapeutic class: Pediculicide, scabicide

Pregnancy category: B

Indications and Dosages

↗ *To treat scabies and pediculosis*

CREAM, LOTION

Adults and children. For scabies, thin layer applied once over entire skin surface. For pediculosis, thin layer applied once to affected skin and hair.

SHAMPOO

Adults and children. 30 ml (for short hair) or 45 ml (for long hair) applied to dry hair and worked into lather for 4 to 5 min.

Mechanism of Action

Penetrates parasite skeleton and inhibits neuronal membrane function, causing seizures and death. Lindane also kills parasite eggs.

Contraindications

Hypersensitivity to lindane or its components, prematurity (in neonates), seizure disorders

Interactions

ACTIVITIES

use of oil-based hair products: Possibly increased absorption of lindane

Adverse Reactions

CNS: Dizziness, irritability, nervousness, restlessness, seizures, unsteadiness

SKIN: Erythema, pruritus, rash, urticaria

Nursing Considerations

- Use lindane cautiously in patients at risk for CNS toxicity, such as infants, elderly patients, and patients weighing less than 110 lb (50 kg).
- Wear gloves when applying drug. If another person will apply drug, supply gloves for use.
- For scabies, apply thin layer of preparation to dry skin and rub in thoroughly. Trim patient's nails, and apply under nails with

toothbrush. Apply to body from neck down, including soles. Leave drug on for 8 to 12 hours (usually overnight), and then remove with bath or shower.

- Expect to reduce application time for infants and children to 6 to 8 hours, as prescribed, because of risk of systemic absorption.
- Keep lindane away from mouth and eyes. Don't use on open wounds, cuts, or sores.
- Expect to give topical steroids or oral antihistamines to reduce pruritus, which may continue for several weeks with scabies.
- For hospitalized patients, use special linen-handling precautions until treatment is completed.

WARNING Be aware that lindane may cause seizures or other adverse CNS reactions. Use it only after other treatments have been tried.

- Monitor immunocompromised patients closely because they're at increased risk for adverse reactions.

PATIENT TEACHING

- Inform patient that lindane is for one-time use but may be reapplied after 1 week if she finds live lice or nits (eggs).
- Caution patient to avoid eyes, mucous membranes, and open areas of skin when applying drug and not to inhale vapors.
- Instruct patient (or parents of a child) to wear gloves when applying drug.
- For scabies, instruct patient to shake lotion bottle well before using and to apply lotion or cream in a thin layer all over body from neck down, avoiding face and scalp. Direct her to leave drug on for 8 to 12 hours and then wash it off in the bath or shower. Explain that itching may persist for several weeks after treatment.
- For pubic lice, instruct patient to shake lotion bottle well before using and to apply a thin layer of lotion to pubic hair and skin as well as to groin, thighs, and lower stomach if they're also affected. Direct her to leave lotion on for 12 hours and then thoroughly wash it off in the bath or shower.
- For head lice, instruct patient to shake lotion bottle well before using and to apply lotion to affected areas of head and scalp as well as nearby hairy areas and rub it in well. Tell her to leave lotion on for 12 hours and then thoroughly wash it off.

- For head or pubic lice, instruct patient to wash and dry her hair before applying lindane shampoo, especially if she uses oil-based hair products. Instruct her to shake bottle well before using and then apply shampoo to dry hair, working it in thoroughly and adding a small amount of water if needed to form good lather. Direct her to wait 4 minutes, rinse her hair well, and then dry it with a clean towel. Instruct her to use a fine-toothed comb or tweezers to remove nits or nit shells. Direct patient not to use shampoo again for 7 days and then only if she finds live lice. Caution patient not to use shampoo in the shower to avoid getting it in her eyes and mouth.
- Advise patient to wash lindane off her skin and to contact prescriber if irritation (severe itching, hives, or redness) occurs.
- Explain that if lice come back, the problem is probably reinfestation rather than treatment failure.
- Advise patient to notify family members and sexual contacts about infestation.

linezolid

Zyvox

Class and Category

Chemical class: Oxazolidinone

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

➤ *To treat vancomycin-resistant Enterococcus faecium infections, including bacteremia*

ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults and adolescents. 600 mg every 12 hr for 14 to 28 days.

Infants and children. 10 mg/kg every 8 hr for 14 to 28 days.

➤ *To treat nosocomial pneumonia caused by Staphylococcus aureus (methicillin-susceptible and -resistant strains) or Streptococcus pneumoniae (penicillin-susceptible strains only) and community-acquired pneumonia, including accompanying bacteremia, caused by S. aureus (methicillin-susceptible strains only) or S. pneumoniae (penicillin-susceptible strains only); to treat complicated skin*

Mechanism of Action

Linezolid inhibits bacterial protein synthesis by interfering with translation of ribonucleic acid (RNA) to protein. In bacteria, protein synthesis begins with binding of a 30S ribosomal subunit and a 50S ribosomal subunit to a messenger RNA (mRNA) molecule to form a 70S initiation complex. The 50S ribosomal subunit consists of 23S ribosomal RNA (rRNA) and other ribosomal subunits. Then translation begins. Transfer RNA (tRNA) attaches to the 50S subunit and brings specific amino acids into place. As the tRNA and amino acids fall into place, they are joined together by peptide bonds and elongate to form a polypeptide chain, as shown below left. This chain

eventually combines with other polypeptide chains to form a complete protein molecule. After translation is complete, the ribosomal subunits fall away and are ready to combine with more mRNA to start the translation process over again.

Linezolid binds to a site on the bacterial 23S rRNA of the 50S subunit. This action prevents formation of a functional 70S initiation complex, an essential component of the bacterial translation. Without proper protein production, as shown below right, susceptible bacteria are unable to multiply. Linezolid is bacteriostatic against staphylococci and enterococci and bactericidal against most streptococci.

and soft-tissue infections, including diabetic foot infections without concomitant osteomyelitis, caused by S. aureus (methicillin-susceptible and -resistant strains), Streptococcus pyogenes, or Streptococcus agalactiae

ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults and adolescents. 600 mg every 12 hr for 10 to 14 days.

Infants and children. 10 mg/kg every 8 hr for 10 to 14 days.

➤ *To treat uncomplicated skin and soft-tissue infections caused by S. aureus (methicillin-susceptible strains only) or S. pyogenes*

ORAL SUSPENSION, TABLETS

Adults. 400 mg every 12 hr for 10 to 14 days.

Adolescents. 600 mg every 12 hr for 10 to

14 days.

Children age 5 to 11. 10 mg/kg every 12 hr for 10 to 14 days.

Infants and children to age 5. 10 mg/kg every 8 hr.

Incompatibilities

Don't add other drugs to linezolid solution. Don't infuse linezolid in same I.V. line as amphotericin B, chlorpromazine hydrochloride, co-trimoxazole, diazepam, erythromycin lactobionate, pentamidine isethionate, or phenytoin sodium because these drugs are physically incompatible. Don't infuse linezolid with ceftriaxone sodium because these drugs are chemically incompatible.

Contraindications

Carcinoid syndrome; concurrent therapy

with buspirone, dopaminergic agents, meperidine, sympathomimetic agents, serotonin 5-HT₁ receptor agonists, serotonin reuptake inhibitors, tricyclic antidepressants, or vasopressive agents without careful monitoring; hypersensitivity to linezolid or its components; phenylketonuria; thyrotoxicosis; uncontrolled hypertension; use within 14 days of an MAO inhibitor

Interactions

DRUGS

adrenergics, including pseudoephedrine and phenylpropranolamine: Possibly increased blood pressure

buspirone, meperidine, serotonergics, tricyclic antidepressants: Possibly serotonin syndrome

carbamazepine, phenytoin, phenobarbital, rifampin: Possibly decreased plasma linezolid level

MAO inhibitors: Increased risk of life-threatening adverse effects

FOODS

tyramine-containing foods and beverages: Possibly hypertension

Adverse Reactions

CNS: Dizziness, fever, headache, insomnia, optic and peripheral neuropathy, serotonin syndrome

CV: Hypertension

EENT: Oral candidiasis, tooth or tongue discoloration

GI: Abdominal pain, constipation, diarrhea, indigestion, nausea, pseudomembranous colitis, vomiting

GU: Vaginal candidiasis

HEME: Anemia, leukopenia, pancytopenia, thrombocytopenia

SKIN: Pruritus, rash

Other: Lactic acidosis

Nursing Considerations

- Obtain body tissue and fluid specimens for culture and sensitivity tests, as ordered, before giving first dose of linezolid. Expect to start drug before test results are known.
- Be aware that linezolid shouldn't be used to treat catheter-related bloodstream infections, catheter-site infections, or infections caused by gram-negative bacteria because the risk of death is higher in these infections.
- Infuse I.V. solution over 30 to 120 minutes

with D₅W, normal saline solution, or lactated Ringer's solution.

WARNING Monitor CBC weekly, as ordered, to detect or track worsening myelosuppression in patients who need more than 2 weeks of therapy, who have preexisting myelosuppression and are receiving drugs that produce bone marrow suppression, or who have chronic infection and are receiving or have received antibiotic therapy.

- Notify prescriber if patient develops visual impairment that suggests optic neuropathy, such as changes in visual acuity or color vision, blurred vision, lost vision, or visual field defect. If optic or peripheral neuropathy develops, the drug may need to be stopped.
- If patient takes a dopaminergic agent, sympathomimetic agent, or vasopressive agent, monitor blood pressure closely; if monitoring isn't possible, linezolid shouldn't be prescribed.
- If patient takes buspirone, meperidine, a serotenergic, or a tricyclic antidepressant, watch closely for signs and symptoms of serotonin syndrome; if monitoring isn't possible, linezolid shouldn't be prescribed.
- Assess bowel pattern daily. Also watch for secondary infection, including oral candidiasis and profuse, watery diarrhea.

PATIENT TEACHING

- Caution patient with phenylketonuria that oral suspension contains phenylalanine.
- Advise patient not to take OTC cold remedies without consulting prescriber because medications that contain pseudoephedrine or propanolamine may cause or worsen hypertension.
- Instruct patient to avoid foods and beverages that contain large amounts of tyramine, including aged cheese, fermented or air-dried meats, sauerkraut, soy sauce, tap beers, red wines, and protein-rich foods that have been stored for long periods or poorly refrigerated.
- Instruct patient to notify prescriber at once about severe diarrhea, even up to 2 months after linezolid therapy has ended, because additional treatment may be needed.
- Also tell patient to report vision changes and changes in limb sensation (such as pins and needles, numbness, or tingling) because drug may need to be stopped.

- Reassure patient with tooth discoloration that professional dental cleaning can restore tooth color.

liothyronine sodium (L-triiodothyronine, sodium L-triiodothyronine, T₃, thyronine sodium)

Cytomel, Triostat

Class and Category

Chemical class: Synthetic triiodothyronine (T₃)

Therapeutic class: Thyroid hormone replacement

Pregnancy category: A

Indications and Dosages

↗ *To treat mild hypothyroidism*

TABLETS

Adults. *Initial:* 25 mcg daily. Increased by 12.5 to 25 mcg every 1 to 2 wk until response occurs. *Maintenance:* 25 to 50 mcg daily.

DOSAGE ADJUSTMENT For elderly patients and those with cardiovascular disease, initial dose reduced to 5 mcg daily and then increased by 5 mcg every 2 wk.

↗ *To treat congenital hypothyroidism*

TABLETS

Adults and children. *Initial:* 5 mcg daily. Increased by 5 mcg every 3 to 4 days until desired response occurs. *Maintenance:* Highly individualized.

↗ *To treat simple nontoxic goiter*

TABLETS

Adults. *Initial:* 5 mcg daily. Increased by 5 to 10 mcg every 1 to 2 wk up to 25 mcg daily. Then increased by 12.5 to 25 mcg/wk, as indicated. *Maintenance:* 50 to 100 mcg daily.

↗ *To treat myxedema*

TABLETS

Adults. *Initial:* 2.5 to 5 mcg daily. Increased 5 to 10 mcg every 1 to 2 wk up to 25 mcg daily. Then increased by 12.5 to 25 mcg every 1 to 2 wk, as indicated. *Maintenance:* 25 to 50 mcg daily.

↗ *To treat myxedema coma or premyxedema coma (severe hypothyroidism)*

I.V. INJECTION

Adults. *Initial:* 25 to 50 mcg. Repeated every 4 to 12 hr according to patient's response. Then P.O. therapy is resumed as soon as possible.

DOSAGE ADJUSTMENT When treating myxedema coma in patients with known or suspected cardiovascular disease, initial dose decreased to 10 to 20 mcg.

↗ *To differentiate hyperthyroidism from euthyroidism (T₃ suppression test)*

TABLETS

Adults. 75 to 100 mcg daily for 7 days.

Route	Onset	Peak	Duration
P.O.	24–72 hr	48–72 hr	Up to 72 hr
I.V.	2–4 hr	2 days	Unknown

Mechanism of Action

Replaces endogenous thyroid hormone, which may exert its physiologic effects by controlling DNA transcription and protein synthesis. Like endogenous thyroid hormone, liothyronine:

- increases energy expenditure
- accelerates the rate of cellular oxidation, which stimulates body tissue growth, maturation, and metabolism
- regulates differentiation and proliferation of stem cells
- aids in myelination of nerves and development of synaptic processes in the nervous system
- regulates growth
- decreases blood and hepatic cholesterol concentrations
- enhances carbohydrate and protein metabolism, increasing gluconeogenesis and protein synthesis.

Contraindications

Acute MI (unless caused or complicated by hypothyroidism), hypersensitivity to liothyronine or its components, uncorrected adrenal insufficiency, untreated thyrotoxicosis

Interactions

DRUGS

adrenocorticoids: Possibly need for adrenocorticoid dosage adjustments as thyroid status changes

beta blockers: Possibly impaired action of beta blockers

cholestyramine, colestipol: Decreased liothyronine absorption

digoxin: Reduced therapeutic effects of digoxin

estrogen, phenylbutazone, phenytoin: Reduced binding of liothyronine to protein, possibly requiring increased liothyronine dosage

insulin, oral antidiabetic: Possibly uncontrolled diabetes mellitus, requiring increased dosage of insulin or oral antidiabetic

ketamine: Possibly hypertension and tachycardia

maprotiline: Increased risk of arrhythmias

oral anticoagulants: Altered anticoagulant activity, possibly need for anticoagulant dosage adjustment

sympathomimetics: Increased risk of coronary insufficiency in patients with coronary artery disease

theophylline: Decreased theophylline clearance

tricyclic antidepressants: Increased therapeutic and toxic effects of both drugs

Adverse Reactions

CNS: Insomnia

ENDO: Hyperthyroidism (with overdose)

SKIN: Alopecia (transient), rash, urticaria

Nursing Considerations

- Be aware that liothyronine is used most often for rapid onset or rapidly reversible thyroid hormone replacement.
- Administer tablet as a single daily dose before breakfast.
- Give I.V. injections more than 4 hours but less than 12 hours apart.
- Evaluate response to therapy by monitoring pulse rate and blood pressure.
- Expect patient to undergo regular tests of thyroid function during therapy.
- Monitor PT of patient receiving anticoagulants because she may require a dosage adjustment.
- Frequently monitor blood glucose level of diabetic patient. Prescriber may reduce antidiabetic drug dosage as thyroid hormone level enters therapeutic range.
- Be aware that liothyronine is used in T₃ suppression test to differentiate hyperthyroidism from euthyroidism (normal thyroid function). For this test, ¹³¹I uptake test is performed before and after liothyronine administration. Suppression of ¹³¹I uptake by 50% indicates normal thyroid function.

PATIENT TEACHING

- Inform patient that liothyronine usually is taken for life. Caution her not to discontinue drug or change dosage unless instructed by prescriber.
- Instruct patient to take drug before breakfast; evening doses may cause insomnia.
- Advise patient to report signs of hyperthyroidism, such as chest pain, excessive sweating, heat intolerance, increased pulse rate, nervousness, and palpitations.
- Inform patient that transient hair loss may occur during first few months of therapy.
- Instruct diabetic patient to monitor blood glucose level frequently because antidiabetic drug dosage may need to be reduced.
- Inform patient of need for periodic blood tests to monitor drug effectiveness.

liraglutide

Victoza

Class and Category

Chemical class: Acylated human glucagon-like peptide-1

Therapeutic class: Antidiabetic

Pregnancy category: C

Indications and Dosages

↗ *To improve glycemic control as an adjunct to diet and exercise in patients with type 2 diabetes mellitus*

SUBCUTANEOUS INJECTION

Adults. *Initial*: 0.6 mg daily for 1 wk., then increased to 1.2 mg daily. *Maximum*: 1.8 mg daily.

Route	Onset	Peak	Duration
SubQ	Unknown	8–12 hr	Unknown

Mechanism of Action

Activates the glucagon-like peptide-1 site on pancreatic beta cells, which increases intracellular cyclic AMP, which increases insulin release when blood glucose level is elevated. In addition, because insulin and glucagon levels occur in an inverse relationship to plasma glucose level, increased insulin level will decrease glucagon level, which inhibits glucagon stimulation of the liver that increases plasma glucose level. Although its exact mechanism is unclear,

liraglutide also delays gastric emptying, which helps prevent a sudden rise in plasma glucose level after eating. Together these actions work to lower plasma glucose level.

Contraindications

History or presence of medullary thyroid cancer or multiple endocrine neoplasia syndrome type 2, hypersensitivity to liraglutide or its components, ketoacidosis, type 1 diabetes mellitus

Interactions

DRUGS

oral hypoglycemic agents such as sulfonylureas: Increased risk of hypoglycemia
orally administered drugs: Possibly decreased absorption of these drugs

Adverse Reactions

CNS: Dizziness, fatigue, headache

CV: Hypertension

EENT: Nasopharyngitis, sinusitis

ENDO: Elevated calcitonin levels, thyroid C-cell hyperplasia, thyroid cancer

GI: Anorexia, constipation, diarrhea, dyspepsia, nausea, pancreatitis, slowed gastric emptying, vomiting

GU: UTI

MS: Back pain

RESP: Upper respiratory tract infection

SKIN: Urticaria

Other: Angioedema, anti-liraglutide antibodies, influenza

Nursing Considerations

- Be aware that liraglutide isn't recommended as first-line therapy for patients with type 2 diabetes mellitus not well controlled with diet and exercise. It also isn't a substitute for insulin therapy.
- Liraglutide shouldn't be given to a patient with a history of thyroid C-cell tumors, including medullary thyroid carcinoma, or to patients with multiple endocrine neoplasia syndrome type 2 because drug may stimulate tumor growth.
- Use liraglutide cautiously in patients with a history of pancreatitis because drug can cause pancreatitis and in patients with impaired hepatic or renal function because drug effects in these patients are unknown.
- Dosage of liraglutide given during first week of therapy isn't enough to provide glycemic control but is given to minimize

adverse effects when dosage is increased.

- Monitor patient's serum calcitonin levels, as indicated. Be aware that elevations occur more often when liraglutide dosage is 1.8 mg daily.
- Monitor patient for pancreatitis, especially when therapy starts or dosage increases. Report persistent severe abdominal pain; it may radiate to the back and may be accompanied by vomiting. If pancreatitis is confirmed, expect to stop drug and not restart it after episode has been resolved.
- Monitor patient for hypoglycemia, especially if he takes another antidiabetic, such as a sulfonylurea. Report any episode of hypoglycemia because dosage of other antidiabetic may need adjustment. Treat hypoglycemia with a glucose-containing food or beverage or give glucagons, as ordered, to raise blood glucose level.
- Monitor patient's blood glucose level and hemoglobin A_{1C} regularly, as ordered to assess effectiveness of drug.
- Monitor effectiveness of all other oral drugs because liraglutide slows gastric emptying and may impair their absorption. Alert prescriber to any concerns.

PATIENT TEACHING

- Teach patient how to use prefilled multi-dose pen and how to give a subcutaneous injection. Explain that he'll need to inject drug daily but that he can do it at any time of day, independent of meals. Tell patient to inject drug into his abdomen, thigh, or upper arm and to rotate sites to minimize injection site reactions.
- Advise patient of possible risk of medullary thyroid cancer and need to report any symptoms, such as a neck mass, dysphagia, dyspnea, or persistent hoarseness.
- Stress that liraglutide therapy isn't a substitute for diet and exercise but is used to enhance effectiveness of these measures.

lisdexamfetamine dimesylate

Vyvanse

Class and Category

Chemical class: Sympathomimetic amine

Therapeutic class: CNS stimulant

Pregnancy category: C

Indications and Dosages

➤ *To treat attention deficit hyperactivity disorder (ADHD)*

CAPSULES

Adults and children ages 6 to 12. *Initial:* 30 mg once daily in the morning, increased as needed in increments of 10 or 20 mg daily every wk. *Maximum:* 70 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	Unknown

Mechanism of Action

Produces CNS stimulant effects, probably by facilitating release and blocking reuptake of norepinephrine at adrenergic nerve terminals and by stimulating alpha and beta receptors in peripheral nervous system. The drug also releases and blocks reuptake of dopamine in limbic regions of brain. These actions cause decreased motor restlessness and increased alertness.

Contraindications

Advanced arteriosclerosis; agitation; glaucoma; history of drug abuse, hypersensitivity, or idiosyncratic reaction to lisdexamfetamine, other sympathomimetic amines, or their components; hyperthyroidism; MAO inhibitor therapy within 14 days; moderate to severe hypertension; symptomatic cardiovascular disease; history of seizures

Interactions

DRUGS

adrenergic blockers: Inhibited adrenergic blockade
acetazolamide, alkalizers (such as sodium bicarbonate), some thiazides: Increased blood level and effects of lisdexamfetamine
antihistamines: Possibly reduced sedation from antihistamine
antihypertensives: Possibly decreased antihypertensive effects
chlorpromazine: Inhibited CNS stimulant effects of lisdexamfetamine
ethosuximide: Possibly delayed ethosuximide absorption
GI acidifiers (such as ascorbic acid), reserpine: Decreased amphetamine absorption
guanethine: Decreased antihypertensive effect and decreased lisdexamfetamine absorption

haloperidol: Decreased CNS stimulation
lithium carbonate: Possibly decreased anorectic and stimulant effects of lisdexamfetamine

MAO inhibitors: Potentiated effects of lisdexamfetamine, possibly hypertensive crisis
mepredine: Increased analgesia

methanamine: Increased urine excretion and decreased effects of lisdexamfetamine

norepinephrine: Possibly increased adrenergic effect of norepinephrine

phenobarbital, phenytoin: Synergistic anticonvulsant action

propoxyphene: Increased CNS stimulation, potentially fatal seizures

sympathomimetic drugs: Increased stimulant effect

tricyclic antidepressants: Possibly increased antidepressant effects and decreased lisdexamfetamine effects

urinary acidifiers (such as ammonium chloride and sodium acid phosphate): Increased amphetamine excretion and decreased amphetamine blood level and effects

veratrum alkaloids: Decreased hypotensive effect

Adverse Reactions

CNS: Affect lability, aggression, agitation, anxiety, dizziness, fever, hallucinations, headache, insomnia, irritability, jittery feeling, mania, psychomotor hyperactivity, psychotic episodes, seizures, somnolence, tic, tremor

CV: Hypertension, tachycardia, ventricular hypertrophy

EENT: Blurred vision, dry mouth

GI: Anorexia, diarrhea, nausea, vomiting, upper abdominal pain

GU: Decreased libido, erectile dysfunction

RESP: Dyspnea

SKIN: Diaphoresis, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, physical or psychological dependence, weight loss

Nursing Considerations

WARNING Chest pain or fainting should be reported to prescriber immediately.

WARNING Lisdexamfetamine shouldn't be given to patients with structural cardiac abnormalities, cardiomyopathy, or other serious heart problems or rhythm abnormalities because even usual CNS-

stimulant dosages increase risk of sudden death in patients with these conditions.

- Use lisdexamfetamine cautiously in patients with hypertension, heart failure, recent MI, or ventricular arrhythmia because drug may increase blood pressure and worsen these conditions.
- Monitor patient's blood pressure closely; stimulant drugs such as lisdexamfetamine may increase it.
- Monitor patients with psychosis, bipolar illness, or a history of aggression or hostility; CNS stimulation may worsen symptoms.
- Assess growth pattern in pediatric patients because stimulants such as lisdexamfetamine may suppress growth. If so, notify prescriber and expect therapy to be halted.
- If patient has a history of seizures or EEG abnormality, watch for seizure activity because stimulants may lower seizure threshold. Rarely, lisamfetamine may cause seizures in a patient with no history of them. Take seizure precautions in all patients, and notify prescriber if a seizure occurs. Expect to discontinue lisdexamfetamine, as prescribed.
- Take safety precautions because stimulants may alter accommodation and cause blurred vision. Although these effects haven't been reported with lisdexamfetamine, the drug is a known stimulant.
- Be aware that therapy may be stopped temporarily to assess continued need for it, as evidenced by a return of hyperactivity and attention deficit.

PATIENT TEACHING

WARNING Tell patient with symptoms such as chest pain or fainting to contact prescriber immediately.

- Warn patient or caregiver that drug must be taken exactly as prescribed and dosage increased only at prescriber's instruction because drug can be abused or lead to dependence.
- Instruct patient or caregiver that capsule may be opened and contents dissolved in a glass of water and drunk immediately.
- Tell patient or caregiver that drug should only be taken in the morning because taking it later in the day may cause insomnia.
- Advise patient or caregiver to report any symptoms that suggest heart disease, such as such as exertional chest pain or unex-

plained syncope.

- Urge patient to avoid hazardous activities until drug effects are known.
- Tell female patient of childbearing age to notify prescriber if pregnancy is suspected.

lisinopril

Prinivil, Zestril

Class and Category

Chemical class: Lysine ester of enalaprilat
Therapeutic class: Antihypertensive, vasodilator

Pregnancy category: C (first trimester), D (later trimesters)

Indications and Dosages

➤ *To manage uncomplicated essential hypertension*

TABLETS

Adults. *Initial:* 10 mg daily. *Maintenance:* 20 to 40 mg daily. *Maximum:* 80 mg daily.

DOSAGE ADJUSTMENT For patients with renal failure, initial dosage reduced to 5 mg daily if creatinine clearance is 10 to 30 ml/min/1.73 m² and to 2.5 mg daily if creatinine clearance is less than 10 ml/min/1.73 m². For patients receiving a diuretic, initial dosage reduced to 5 mg daily.

Children age 6 and over with a GFR of at least 30 ml/min/1.73 m². *Initial:* 0.07 mg/kg daily, adjusted according to blood pressure response up to 5 mg daily. *Maximum:* 0.61 mg/kg or 40 mg daily.

➤ *To treat heart failure, along with digoxin and diuretics*

TABLETS

Adults. *Initial:* 5 mg daily. *Maintenance:* 5 to 20 mg daily. *Maximum:* 80 mg daily.

DOSAGE ADJUSTMENT For patients with hyponatremia or creatinine clearance of 30 ml/min/1.73 m² or less, initial dosage reduced to 2.5 mg daily.

➤ *To improve survival in hemodynamically stable patient after acute MI*

TABLETS

Adults. 5 mg within 24 hr after onset of symptoms, followed by 5 mg after 24 hr and 10 mg after 48 hr. *Maintenance:* 10 mg daily for 6 wk. *Maximum:* 80 mg daily.

DOSAGE ADJUSTMENT For patients with baseline systolic blood pressure of 120 mm

Hg or less, initial dosage decreased to 2.5 mg daily for first 3 days after MI. If systolic blood pressure falls to 100 mm Hg or less during therapy, maintenance dosage decreased to 2.5 to 5 mg as tolerated; if systolic blood pressure is 90 mm Hg or less for more than 1 hr, drug is discontinued.

Route	Onset	Peak	Duration
P.O.	1 hr	6–8 hr	24 hr

Mechanism of Action

May reduce blood pressure by inhibiting conversion of angiotensin I to angiotensin II. Angiotensin II is a potent vasoconstrictor that also stimulates adrenal cortex to secrete aldosterone. Lisinopril may also inhibit renal and vascular production of angiotensin II. Decreased release of aldosterone reduces sodium and water reabsorption and increases their excretion, thereby reducing blood pressure.

Contraindications

Hypersensitivity to lisinopril, other ACE inhibitors, or their components; history of angioedema related to previous treatment with an ACE inhibitor; hereditary or idiopathic angioedema

Interactions

DRUGS

allopurinol, bone marrow depressants (such as methotrexate), procainamide, systemic corticosteroids: Increased risk of potentially fatal neutropenia or agranulocytosis
cyclosporine, potassium-sparing diuretics, potassium supplements: Increased risk of hyperkalemia
diuretics, other antihypertensives: Increased hypotensive effect
insulin, oral antidiabetics: Increased risk of hypoglycemia
lithium: Increased blood lithium level and risk of lithium toxicity
NSAIDs: Possibly reduced antihypertensive effect, reduced renal function in patients with preexisting renal dysfunction
sympathomimetics: Possibly reduced antihypertensive effect

FOODS

high-potassium diet, potassium-containing salt substitutes: Increased risk of hyperkalemia

ACTIVITIES

alcohol use: Possibly increased hypotensive effect

Adverse Reactions

CNS: Ataxia, confusion, depression, dizziness, fatigue, headache, mood alterations, nervousness, stroke, syncope, transient ischemic attack, vertigo

CV: Arrhythmias, chest pain, hypotension, MI, orthostatic hypotension, palpitations, peripheral edema, vasculitis

ENDO: Hyperglycemia, syndrome of inappropriate ADH secretion

EENT: Olfactory disturbance

GI: Abdominal pain, anorexia, cholestatic jaundice, diarrhea, elevated liver enzyme levels, fulminant hepatic necrosis, gastritis, hepatitis, indigestion, nausea, pancreatitis, vomiting

GU: Acute renal failure, decreased libido, impotence, pyelonephritis

HEME: Agranulocytosis, anemia, hemolytic anemia, neutropenia, thrombocytopenia

MS: Muscle spasms, myalgia

RESP: Bronchospasm, cough, dyspnea, paroxysmal nocturnal dyspnea, pulmonary embolism and infarction, upper respiratory tract infection

SKIN: Alopecia, cutaneous pseudolymphoma, diaphoresis, erythema, flushing, herpes zoster, infections, pemphigus, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema

Nursing Considerations

- Use lisinopril cautiously in patients with fluid volume deficit, heart failure, impaired renal function, or sodium depletion.
- To prepare pediatric suspension, add 10 ml purified water to a polyethylene terephthalate (PET) bottle containing ten 20-mg tablets and shake for at least 1 minute. Add 30 ml of Bicitra diluent and 160 ml of Ora-Sweet SF to concentrate in PET bottle and shake gently for several seconds. Refrigerate up to 4 weeks. Shake suspension before each use.
- Monitor blood pressure often, especially early in treatment. If excessive hypotension develops, expect to withhold drug for several days.

WARNING If angioedema affects face, glottis, larynx, limbs, lips, mucous mem-

branes, or tongue, notify prescriber immediately and expect to stop lisinopril and start appropriate therapy at once. If airway obstruction threatens, promptly give 0.3 to 0.5 ml of epinephrine 1:1,000 solution subcutaneously, as prescribed.

- Monitor patient for anaphylaxis, especially patient being dialyzed with high-flux membranes and treated with an ACE inhibitor such as lisinopril. If anaphylaxis occurs, stop dialysis immediately and treat aggressively (antihistamines are ineffective in this situation), as ordered. Anaphylaxis has also occurred with some patients undergoing low-density lipoprotein apheresis with dextran sulfate absorption.
- Notify prescriber if patient has persistent, nonproductive cough, a common adverse effect of ACE inhibitors such as lisinopril.
- Monitor for dehydration, which can lead to hypotension. Be aware that diarrhea and vomiting can cause dehydration.
- Monitor patient for hepatic dysfunction because lisinopril, an ACE inhibitor, may rarely cause a syndrome that starts with cholestatic jaundice or hepatitis and progresses to fulminant hepatic necrosis. If patient develops jaundice or a marked elevation in liver enzyme levels, withhold drug and notify prescriber.
- If patient takes insulin or an oral antidiabetic, monitor blood glucose level closely because risk of hypoglycemia increases, especially during first month of therapy.

PATIENT TEACHING

- Explain that lisinopril helps to control but doesn't cure hypertension and that patient may need lifelong therapy.
- Advise patient to take lisinopril at the same time every day.
- Emphasize need to take drug as ordered, even if patient feels well; caution her not to stop drug without consulting prescriber.
- Instruct patient to report dizziness, especially during first few days of therapy.
- Inform patient that persistent, nonproductive cough may develop during lisinopril therapy. Urge her to notify prescriber immediately if cough becomes difficult to tolerate.
- Advise patient to drink adequate fluid and avoid excessive sweating, which can lead to dehydration and hypotension. Make sure

she understands that diarrhea and vomiting also can cause hypotension.

- Caution patient not to use salt substitutes that contain potassium.
- Instruct patient to report signs of infection, such as fever and sore throat, which may indicate neutropenia.
- Advise patient to change position slowly to minimize orthostatic hypotension.
- If patient has diabetes and takes insulin or an oral antidiabetic, urge her to monitor her blood glucose level closely and watch for symptoms of hypoglycemia.
- Caution female patient to notify prescriber immediately if she is or could be pregnant.

lithium carbonate

Carbolith (CAN), Duralith (CAN), Eskalith, Eskalith CR, Lithane, Lithizine (CAN), Lithobid, Lithonate, Lithotabs

lithium citrate

Cibalith-S

Class and Category

Chemical class: Alkaline metal, monovalent cation

Therapeutic class: Antidepressant, antimanic

Pregnancy category: D

Indications and Dosages

➤ *To treat recurrent bipolar affective disorder, to prevent bipolar disorder depression*

CAPSULES, TABLETS

Adults and children age 12 and over. *Initial:* 300 to 600 mg t.i.d. *Maintenance:* 300 mg t.i.d. or q.i.d. *Maximum:* 2,400 g daily.

Children up to age 12. 15 to 20 mg/kg daily in divided doses b.i.d. or t.i.d.

E.R. TABLETS

Adults and children age 12 and over. *Initial:* 900 to 1,800 mg daily in divided doses b.i.d. or t.i.d. *Maintenance:* 450 mg b.i.d. or 300 mg t.i.d. *Maximum:* 2,400 g daily.

SLOW-RELEASE CAPSULES

Adults and children age 12 and over. 600 to 900 mg on day 1, increased to 1,200 to 1,800 mg daily in divided doses t.i.d. *Maintenance:* 900 to 1,200 mg daily in divided doses t.i.d. *Maximum:* 2,400 g daily.

SYRUP (LITHIUM CITRATE)

Adults and children age 12 and over: 8 to 16 mEq (equivalent of 300 to 600 mg of lithium carbonate) t.i.d. **Maintenance:** Equivalent of 300 mg of lithium carbonate t.i.d. or q.i.d. **Maximum:** Equivalent of 2,400 g daily of lithium carbonate.
Children up to age 12: 0.4 to 0.5 mEq (equivalent of 15 to 20 mg of lithium carbonate)/ kg daily in divided doses b.i.d. or t.i.d.

Route	Onset	Peak	Duration
P.O.	1–3 wk	Unknown	Unknown

Mechanism of Action

May increase presynaptic degradation of the catecholamine neurotransmitters serotonin, dopamine, and norepinephrine; inhibit their release at neuronal synapses; and decrease postsynaptic receptor sensitivity. These actions may correct overactive catecholamine systems in patients with mania.

Antidepressant action may result from enhanced serotonergic activity.

Contraindications

Blood dyscrasias, bone marrow depression, brain damage, cerebrovascular disease, coma, coronary artery disease, excessive intake of other CNS depressants, hypersensitivity to lithium or its components, impaired hepatic function, myeloproliferative disorders, severe depression, severe hypertension or hypotension

Interactions**DRUGS**

ACE inhibitors, NSAIDs, piroxicam: Possibly increased blood lithium level and increased risk of toxicity
acetazolamide, sodium bicarbonate, urea, xanthines: Decreased blood lithium level
calcium channel blockers, molindone: Increased risk of neurotoxicity from lithium
calcium iodide, iodinated glycerol, potassium iodide: Possibly increased hypothyroid effects of both drugs
carbamazepine: Possibly increased therapeutic effects of carbamazepine and neurotoxic effect of lithium
chlorpromazine, other phenothiazines: Possibly impaired GI absorption and

decreased blood levels of these drugs; possibly masking of early signs of lithium toxicity
desmopressin, lyspressin, vasopressin: Possibly impaired antidiuretic effects of these drugs
diuretics (loop and osmotic): Increased lithium reabsorption by kidneys, possibly leading to lithium toxicity
fluoxetine, methyl dopa, metronidazole: Increased risk of lithium toxicity from reduced renal clearance of lithium
haloperidol and other antipsychotics: Increased risk of irreversible neurotoxicity and brain damage
neuromuscular blockers: Risk of prolonged paralysis or weakness
norepinephrine: Possibly decreased therapeutic effects of norepinephrine and severe respiratory depression
selective serotonin reuptake inhibitors: Increased risk of adverse effects, such as diarrhea, confusion, dizziness, agitation, and tremor
thyroid hormones: Possibly hypothyroidism
tricyclic antidepressants: Possibly severe mood swings from mania to depression

FOODS

high-sodium foods: Increased excretion and possibly decreased therapeutic effects of lithium

Adverse Reactions

CNS: Ataxia, coma, confusion, depression, dizziness, drowsiness, headache, lethargy, seizures, syncope, tremor (in hands), vertigo
CV: Arrhythmias (including bradycardia and tachycardia), ECG changes, edema
EENT: Dental caries, dry mouth, exophthalmos
ENDO: Diabetes insipidus, euthyroid goiter, hypothyroidism, myxedema
GI: Abdominal distention and pain, anorexia, diarrhea, nausea, thirst
GU: Stress incontinence, urinary frequency
HEME: Leukocytosis
MS: Muscle twitching and weakness
RESP: Dyspnea
SKIN: Acne; alopecia; dry, thin hair; pruritus; rash
Other: Cold sensitivity, weight gain or loss

Nursing Considerations

- Administer lithium after meals to slow absorption from GI tract and reduce adverse reactions. Dilute syrup with juice

or other flavored drink before giving.

- Note that 5 ml of lithium citrate equals 8 mEq of lithium ion or 300 mg of lithium carbonate.
- Expect to monitor blood lithium level two or three times weekly during first month, and then weekly to monthly during maintenance therapy and when starting or stopping NSAID therapy. In uncomplicated cases, plan to monitor lithium level every 2 to 3 months.
- Be aware that lithium has a narrow therapeutic range. Even a slightly high blood level is dangerous, and some patients show signs of toxicity at normal levels.
- Expect prescriber to decrease dosage after acute manic episode is controlled.

WARNING Be aware that lithium affects intracellular and extracellular potassium ion shift, which can cause ECG changes, such as flattened or inverted T waves; it also can increase the risk of cardiac arrest.

• Monitor ECGs, renal and thyroid function test results, and serum electrolyte levels, as appropriate, during lithium treatment.

WARNING Be aware that lithium can cause reversible leukocytosis, which usually peaks within 7 to 10 days of starting therapy; WBC count typically returns to baseline within 10 days after therapy stops.

- Weigh patient daily to detect sudden weight changes.
- Monitor blood glucose level often in diabetic patient because lithium alters glucose tolerance.
- Palpate thyroid gland to detect enlargement because drug may cause goiter.
- Ensure that patient's fluid and sodium intake is adequate during treatment.

PATIENT TEACHING

- Advise patient to take lithium with or after meals to minimize adverse reactions.
- Instruct patient to swallow E.R. or slow-release form whole.
- Direct patient to mix syrup form with juice or other flavored drink before taking.
- Inform patient that frequent urination, nausea, and thirst may occur during the first few days of treatment.
- Caution patient not to stop taking lithium or adjust dosage without first consulting prescriber.
- Instruct patient to report signs of toxicity, such as diarrhea, drowsiness, muscle weak-

ness, tremor, uncoordinated body movements, and vomiting.

- Urge patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to maintain normal fluid and sodium intake.
- Emphasize importance of complying with scheduled checkups and laboratory tests.

lomefloxacin hydrochloride

Maxaquin

Class and Category

Chemical class: Fluoroquinolone

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosage

➤ To treat mild to moderate lower respiratory tract infections caused by susceptible organisms, including *Haemophilus influenzae* and *Moraxella catarrhalis*

TABLETS

Adults. 400 mg daily for 10 days.

➤ To treat uncomplicated cystitis caused by *Escherichia coli*; to treat uncomplicated cystitis caused by *Klebsiella pneumoniae*, *Proteus mirabilis*, or *Staphylococcus saprophyticus*

TABLETS

Adults. 400 mg daily for 3 days.

➤ To treat complicated UTI caused by *Citrobacter diversus*, *Enterobacteriaceae*, *E. coli*, *K. pneumoniae*, *P. mirabilis*, or *Pseudomonas aeruginosa*

TABLETS

Adults. 400 mg daily for 14 days.

➤ To provide prophylaxis for transurethral surgery

TABLETS

Adults. 400 mg as a single dose 2 to 6 hr before surgery.

➤ To provide prophylaxis for transrectal biopsy

TABLETS

Adults. 400 mg as a single dose 1 to 6 hr before surgery.

➤ To treat gonorrhea (as alternative to ciprofloxacin or ofloxacin)

TABLETS

Adults. 400 mg as a single dose.

DOSAGE ADJUSTMENT For patients with creatinine clearance between 11 and 39 ml/min/1.73 m², loading dose of 400 mg given on day 1 and followed by 200 mg daily.

Mechanism of Action

Inhibits the bacterial enzyme DNA gyrase, which normally is responsible for unwinding and supercoiling of bacterial DNA before it replicates. By inhibiting this enzyme, lomefloxacin interferes with bacterial cell replication and causes cell death.

Contraindications

History of tendinitis or tendon rupture, hypersensitivity to lomefloxacin or any quinolone derivative

Interactions

DRUGS

aluminum-, calcium-, or magnesium-containing antacids; iron salts; sucralfate; zinc: Decreased absorption and blood level of lomefloxacin

cyclosporine: Possibly increased blood cyclosporine level, increased nephrotoxicity

probenecid: Decreased lomefloxacin excretion, increased risk of toxicity

warfarin: Possibly increased anticoagulant effect and risk of bleeding

Adverse Reactions

CNS: Ataxia, cerebral thrombosis, dizziness, drowsiness, hallucinations, headache, insomnia, nervousness, peripheral neuropathy, phobia, vertigo

CV: Prolonged QT interval, torsades de pointes, vasculitis

EENT: Diplopia, laryngeal edema, oral candidiasis, painful oral mucosa, taste perversion

GI: Abdominal pain, diarrhea, hepatitis, indigestion, nausea, pseudomembranous colitis, vomiting

GU: Interstitial nephritis, polyuria, renal failure, urine retention, vaginal candidiasis

HEME: Hemolytic anemia

MS: Tendinitis, tendon rupture

RESP: Pulmonary edema

SKIN: Exfoliative dermatitis, hyperpigmentation, photosensitivity, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis

Nursing Considerations

- Know that lomefloxacin shouldn't be

given to patients with QT-interval prolongation or hypokalemia or to patients taking class IA antiarrhythmics (such as quinidine or procainamide) or class III antiarrhythmics (such as amiodarone or sotalol) because of increased risk of torsades de pointes.

- Expect to obtain body fluid or tissue sample for culture and sensitivity testing and to review results, if possible, before lomefloxacin therapy begins.
- If patient's culture test results are positive for gonorrhea, expect to obtain serologic test for syphilis at diagnosis and to repeat test 3 months after lomefloxacin therapy.
- Give drug with meals and a full glass of water.
- Ensure that patient maintains adequate fluid intake during therapy.
- Monitor for evidence of secondary infections, such as sore mouth or vaginal discharge.
- Notify prescriber if patient experiences severe or prolonged diarrhea, which may indicate pseudomembranous colitis.
- Be aware that prolonged use may lead to growth of drug-resistant organisms.
- Notify prescriber and expect to stop lomefloxacin if patient develops symptoms of peripheral neuropathy (pain, burning, tingling, numbness, weakness, or changes in sensations of light touch, pain, temperature, position, or vibration) to prevent an irreversible condition or tendon rupture that requires immediate rest and avoidance of exercise involving affected area.

PATIENT TEACHING

- Advise patient to take lomefloxacin at same time each day with meals and with a full glass of water.
- Caution patient not to take antacids, iron, sucralfate, or zinc 1 hour before or 2 hours after taking lomefloxacin because these preparations impair drug absorption.
- Urge patient to drink plenty of fluids during treatment.
- Instruct patient to complete full course of therapy, even if symptoms subside.
- Advise patient to notify prescriber if symptoms don't improve within a few days after starting lomefloxacin or if severe GI distress or diarrhea develops.
- Instruct patient to notify prescriber and stop taking drug if she has tendon inflam-

mation or pain; advise her to rest until tendinitis and tendon rupture have been ruled out.

- Urge patient to avoid direct sunlight, to wear protective clothing, and to use sun-screen because photosensitivity reactions can occur during therapy and for several days afterward.
- Explain that risk of photosensitivity can be decreased by taking lomefloxacin at least 12 hours before sun exposure. Urge patient to stop drug and notify prescriber at first sign of photosensitivity, such as skin burning, redness, swelling, blisters, rash, itching, or dermatitis.
- Inform patient that an allergic reaction may occur after a single dose. Tell patient to stop lomefloxacin and notify prescriber if rash or other allergic reaction develops.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.

loracarbef

Lorabid

Class and Category

Chemical class: Carbacephem

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

- *To treat acute bronchitis caused by Haemophilus influenzae, Moraxella catarrhalis, or Streptococcus pneumoniae*

CAPSULES, ORAL SUSPENSION

Adults and adolescents. 200 to 400 mg every 12 hr for 7 days.

- *To treat chronic bronchitis exacerbations caused by H. influenzae, M. catarrhalis, or S. pneumoniae*

CAPSULES, ORAL SUSPENSION

Adults and adolescents. 400 mg every 12 hr for 7 days.

- *To treat pneumonia caused by H. influenzae or S. pneumoniae*

CAPSULES, ORAL SUSPENSION

Adults and adolescents. 400 mg every 12 hr for 14 days.

- *To treat pharyngitis, sinusitis, or tonsillitis caused by Streptococcus pyogenes*

CAPSULES, ORAL SUSPENSION

Adults and adolescents. 200 to 400 mg

every 12 hr for 10 days.

Children. 7.5 mg/kg every 12 hr for 10 days.

- *To treat acute otitis media caused by H. influenzae, M. catarrhalis, S. pneumoniae, or S. pyogenes*

ORAL SUSPENSION

Children. 15 mg/kg every 12 hr for 10 days.

- *To treat uncomplicated skin and soft-tissue infections caused by Staphylococcus aureus or S. pyogenes*

CAPSULES, ORAL SUSPENSION

Adults and adolescents. 200 mg every 12 hr for 7 days.

ORAL SUSPENSION

Children. 7.5 mg/kg every 12 hr for 7 days.

- *To treat uncomplicated cystitis caused by Escherichia coli or Staphylococcus saprophyticus*

CAPSULES, ORAL SUSPENSION

Adults and adolescents. 200 mg daily for 7 days.

- *To treat uncomplicated pyelonephritis caused by E. coli*

CAPSULES, ORAL SUSPENSION

Adults and adolescents. 400 mg every 12 hr for 14 days.

DOSAGE ADJUSTMENT If creatinine clearance is 10 to 49 ml/min/1.73 m², 50% of usual dose given at normal interval or usual dose given at twice the normal interval; if clearance is less than 10 ml/min/1.73 m², usual adult dosage given every 3 to 5 days.

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes bacterial cell membrane rigid and protective. Without it, bacterial cells rupture and die.

Contraindications

Hypersensitivity to loracarbef, other cephalosporins, or their components

Interactions

DRUGS

probenecid: Inhibited renal excretion of loracarbef, resulting in increased blood level

FOODS

all foods: Inhibited drug absorption

Adverse Reactions

CNS: Dizziness, drowsiness, headache, insomnia, nervousness, seizures

EENT: Oral candidiasis

GI: Abdominal pain, anorexia, diarrhea, nausea, pseudomembranous colitis, vomiting

GU: Vaginal candidiasis

SKIN: Pruritus, rash, urticaria

Nursing Considerations

- Expect to obtain body fluid or tissue sample for culture and sensitivity testing and to review results, if possible, before giving first dose of lorazepam.
- Be aware that oral suspension is absorbed more rapidly and produces a higher peak plasma level than capsules.
- Monitor patient for signs of secondary infections, such as sore mouth and vaginal discharge.
- Watch for seizures, especially if patient has impaired renal function.

PATIENT TEACHING

- Advise patient to take lorazepam at least 1 hour before or 2 hours after meals.
- Tell patient to complete full course of drug as prescribed, even if symptoms decrease.
- Instruct patient to discard unused oral solution after 14 days.
- Advise patient to report diarrhea, hives, or severe rash to prescriber.

lorazepam

Apo-Lorazepam (CAN), Ativan, Lorazepam Intensol, Novo-Lorazem (CAN), Nu-Loraz (CAN)

Class, Category, and Schedule

Chemical class: Benzodiazepine

Therapeutic class: Amnestic, antianxiety, anticonvulsant, sedative

Pregnancy category: D (parenteral), Not rated (oral)

Controlled substance schedule: IV

Indications and Dosages

↗ *To treat anxiety*

ORAL CONCENTRATE, TABLETS

Adults and adolescents. 1 to 3 mg b.i.d. or t.i.d. *Maximum:* 10 mg daily.

DOSAGE ADJUSTMENT For elderly or debilitated patients, initial dosage may be reduced to 0.5 to 2 mg daily in divided doses.

↗ *To treat insomnia caused by anxiety*

ORAL CONCENTRATE, TABLETS

Adults and adolescents. 2 to 4 mg at bedtime.

DOSAGE ADJUSTMENT Dosage possibly reduced for elderly or debilitated patients.

↗ *To provide preoperative sedation*

I.V. INJECTION

Adults and adolescents. 0.044 mg/kg or 2 mg, whichever is less, given 2 hr before procedure. *Maximum:* 0.05 mg/kg or total of 4 mg.

I.M. INJECTION

Adults and adolescents. 0.05 mg/kg 2 hr before procedure. *Maximum:* 4 mg.

↗ *To treat status epilepticus*

I.V. INJECTION

Adults and adolescents. *Initial:* 4 mg at a rate of 2 mg/min. Repeated in 10 to 15 min if seizures don't subside. *Maximum:* 8 mg/24 hr.

Route	Onset	Peak	Duration
I.V.	5 min	Unknown	12–24 hr
I.M.	15–30 min	Unknown	12–24 hr

Mechanism of Action

May potentiate the effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptors in limbic and cortical areas of CNS. GABA inhibits excitatory stimulation, which helps control emotional behavior. Limbic system contains a highly dense area of benzodiazepine receptors, which may explain drug's antianxiety effects. Also, lorazepam hyperpolarizes neuronal cells, thereby interfering with their ability to generate seizures.

Incompatibilities

Don't mix I.V. lorazepam in same syringe as buprenorphine.

Contraindications

Acute angle-closure glaucoma, hypersensitivity to lorazepam, its components, or benzodiazepines; intra-arterial delivery; psychosis

Interactions

DRUGS

aminophylline, theophylline: Possibly reduced sedative effects of lorazepam
clozapine: Increased risk of marked sedation, excessive salivation, hypotension, ataxia, delirium, and respiratory arrest
CNS depressants: Additive CNS depression, potentially fatal respiratory depression

digoxin: Possibly increased blood digoxin level and risk of digitalis toxicity

fentanyl: Possibly decreased therapeutic effects of fentanyl

probenecid: Possibly increased therapeutic and adverse effects of lorazepam

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Amnesia, anxiety, ataxia, coma, confusion, delusions, depression, dizziness, drowsiness, euphoria, extrapyramidal symptoms, fatigue, headache, hypokinesia, irritability, malaise, nervousness, seizures, slurred speech, suicidal ideation, tremor, unsteadiness, vertigo

CV: Chest pain, palpitations, tachycardia

EENT: Blurred vision, diplopia, dry mouth, increased salivation, photophobia

ENDO: Syndrome of inappropriate ADH

GI: Abdominal pain, constipation, diarrhea, increased liver enzyme levels, jaundice, nausea, thirst, vomiting

GU: Libido changes

HEME: Agranulocytosis, pancytopenia, thrombocytopenia

RESP: Apnea, respiratory depression, worsening of sleep apnea or obstructive pulmonary disease

SKIN: Diaphoresis

Other: Anaphylaxis, injection site pain (I.M.) or phlebitis (I.V.), physical and psychological dependence, withdrawal symptoms

Nursing Considerations

- Before starting lorazepam therapy in a patient with depression, make sure he already takes an antidepressant because of increased risk of suicide in patients with untreated depression.
- Use extreme caution when giving lorazepam to elderly patients, especially those with compromised respiratory function, because drug can cause hypoventilation, sedation, unsteadiness, and respiratory depression.
- Use drug cautiously in patients with a history of alcohol or drug abuse or a personality disorder because of an increased risk of physical and psychological dependence. Also use cautiously in patients with severe hepatic insufficiency or encephalopathy because drug may worsen hepatic

encephalopathy.

- For I.M. use, inject lorazepam deep into large muscle mass, such as gluteus maximus.
- For I.V. use, dilute lorazepam with equal amount of sterile water for injection, sodium chloride for injection, or D₅W. Give diluted lorazepam slowly, at no more than 2 mg/min.
- During I.V. use, monitor patient's respirations every 5 to 15 minutes and keep emergency resuscitation equipment readily available.

WARNING Monitor patient's respiratory status closely because drug may cause life-threatening respiratory depression.

- Because stopping drug abruptly increases risk of withdrawal symptoms, expect to taper dosage gradually, especially in epileptic patients.

PATIENT TEACHING

- Instruct patient to take lorazepam exactly as prescribed and not to stop without consulting prescriber because of risk of withdrawal symptoms.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcohol while taking lorazepam because it increases drug's CNS depressant effects.
- Instruct patient to report excessive drowsiness and nausea.
- Inform pregnant patient that lorazepam therapy will need to be discontinued early in third trimester to avoid possible withdrawal symptoms in newborn.

J
K
L

losartan potassium

Cozaar

Class and Category

Chemical class: Angiotensin II receptor antagonist

Therapeutic class: Antihypertensive

Pregnancy category: C (first trimester), D (later trimesters)

Indications and Dosages

➤ *To manage hypertension*

TABLETS

Adults. *Initial*: 50 mg daily. *Maintenance*: 25 to 100 mg as a single dose or in divided doses b.i.d.

➤ *To treat nephropathy in patients with type 2 diabetes and hypertension*

TABLETS

Adults. *Initial:* 50 mg daily, increased to 100 mg daily, as needed.

➤ *To reduce stroke risk in patients with hypertension and left ventricular hypertrophy*

TABLETS

Adults. *Initial:* 50 mg daily, followed by 12.5 mg hydrochlorothiazide daily. Dosage increased to 100 mg daily, as needed, followed by 25 mg hydrochlorothiazide daily, as needed.

Children age 6 and over. *Initial:* 0.7 mg/kg to a maximum of 50 mg daily. *Maximum:* 1.4 mg/kg or 100 mg daily.

DOSAGE ADJUSTMENT Initial losartan dosage reduced to 25 mg daily for patients with impaired hepatic function or volume depletion.

Route	Onset	Peak	Duration
P.O.	Unknown	6 hr	Over 24 hr

Mechanism of Action

Blocks binding of angiotensin II to receptor sites in many tissues, including vascular smooth muscle and adrenal glands. Angiotensin II is a potent vasoconstrictor that also stimulates the adrenal cortex to secrete aldosterone. The inhibiting effects of angiotensin II reduce blood pressure.

Contraindications

Hypersensitivity to losartan or its components

Interactions

DRUGS

antihypertensives, diuretics: Possibly hypotension

cyclosporine, potassium-sparing diuretics, potassium supplements: Increased risk of hyperkalemia

indomethacin, sympathomimetics: Possibly decreased antihypertensive effect of losartan

NSAIDs: Possibly decreased renal function in patients already compromised; possibly decreased effectiveness of losartan

FOODS

high-potassium diet, potassium-containing salt substitutes: Increased risk of hyperkalemia

Adverse Reactions

CNS: Dizziness, fatigue, headache, insomnia, malaise

CV: Hypotension

EENT: Nasal congestion

GI: Diarrhea, indigestion, nausea, vomiting

HEME: Thrombocytopenia

MS: Back pain, leg pain, muscle spasms

RESP: Cough, upper respiratory tract infection

SKIN: Erythroderma

Other: Angioedema, hyperkalemia, hyponatremia

Nursing Considerations

- In some patients, losartan is more effective when given in two divided doses daily; it may be used with other antihypertensives.
- Know that patients of African descent with hypertension and left ventricular hypertrophy may not benefit from losartan to reduce stroke risk.

WARNING Be aware that patients who have severe heart failure or renal artery stenosis may experience acute renal failure from losartan therapy because losartan inhibits the angiotensin-aldosterone system, on which renal function depends.

- Monitor blood pressure and renal function studies to evaluate drug effectiveness.
- Periodically monitor patient's serum potassium level, as appropriate, to detect hyperkalemia.
- Monitor patient for muscle pain; rarely, rhabdomyolysis develops in patients taking other angiotensin II receptor blockers.

PATIENT TEACHING

- Instruct patient to avoid potassium-containing salt substitutes because they may increase risk of hyperkalemia.
- Advise patient to avoid exercising in hot weather and drinking excessive amounts of alcohol; instruct her to notify prescriber if she has prolonged diarrhea, nausea, or vomiting.

lovastatin (mevinolin)

Altoprev, Mevacor

Class and Category

Chemical class: Mevinic acid derivative

Therapeutic class: Antihyperlipidemic
Pregnancy category: X

Indications and Dosages

↗ *To reduce LDL and total cholesterol levels in patients with primary hypercholesterolemia*

TABLETS

Adults. *Initial:* 20 mg as a single dose with evening meal. *Maintenance:* 20 to 80 mg daily as a single dose or in divided doses with meals. *Maximum:* 80 mg daily.

DOSE ADJUSTMENT For patients who also take immunosuppressants, initial dosage decreased to 10 mg daily and maximum dosage limited to 20 mg daily.

E.R. TABLETS

Adults. *Initial:* 10 mg, 20 mg, 40 mg, or 60 mg as single dose at bedtime, increased, as needed, every 4 wk, up to maximum dose. *Maintenance:* 10 to 60 mg daily as single dose. *Maximum:* 60 mg daily.

↗ *To reduce LDL, total cholesterol, and apolipoprotein B levels in adolescents with heterozygous familial hypercholesterolemia*

TABLETS

Adolescents 1 yr postmenarche (ages 10 to 17). *Initial:* 20 mg daily for LDL reduction of 20% or more, 10 mg daily for LDL reduction of less than 20%; dosage adjusted after at least 4 wk. *Maintenance:* 10 to 40 mg daily. *Maximum:* 40 mg daily.

DOSE ADJUSTMENT For patients who also take amiodarone or verapamil, maximum dosage limited to 40 mg daily. For patients who also take cyclosporine, gemfibrozil or other fibrates, or lipid-lowering drugs such as niacin (1 g or more daily), maximum dosage of lovastatin limited to 20 mg daily. For patients with creatinine clearance less than 30 ml/min/1.73 m², maximum dosage limited to 20 mg daily.

Route	Onset	Peak	Duration
P.O.	In 2 wk	Unknown	4–6 wk

Mechanism of Action

Interferes with the hepatic enzyme hydroxymethylglutaryl-coenzyme A reductase. By doing so, lovastatin reduces formation of mevalonic acid (a cholesterol precursor), thus interrupting the pathway by which cholesterol is synthesized. When cho-

lesterol level declines in hepatic cells, LDLs are consumed, which also reduces amount of circulating total cholesterol and serum triglycerides. The decrease in LDLs may result in decreased level of apolipoprotein B, which is found in each LDL particle.

Contraindications

Acute hepatic disease, breastfeeding, hypersensitivity to lovastatin or its components, pregnancy, unexplained elevated liver function test results

Interactions

DRUGS

amiodarone, clarithromycin, cyclosporine, danazol, erythromycin, fibric acid derivatives, gemfibrozil and other fibrates, HIV protease inhibitors, immunosuppressants, itraconazole, ketoconazole, nefazodone, niacin (1 g daily or more), telithromycin, verapamil:

Increased risk of severe myopathy or rhabdomyolysis

bile acid sequestrants, cholestyramine, colestipol: Decreased bioavailability of lovastatin

isradipine: Increased hepatic clearance of lovastatin

itraconazole, ketoconazole: Increased lovastatin blood level

oral anticoagulants: Increased anticoagulant effect and risk of bleeding

FOODS

all foods: Increased lovastatin absorption

grapefruit juice (more than 1 qt daily):

Increased risk of myopathy or rhabdomyolysis

ACTIVITIES

alcohol use: Increased lovastatin blood level

Adverse Reactions

CNS: Dizziness, fatigue, headache, insomnia

EENT: Blurred vision, cataracts, pharyngitis, rhinitis, sinusitis

GI: Abdominal cramps and pain, constipation, diarrhea, elevated liver function test results, flatulence, indigestion, nausea, vomiting

MS: Arthritis, back pain, myalgia, myopathy, myositis, rhabdomyolysis

RESP: Cough, upper respiratory tract infection

SKIN: Dermatomyositis, erythema multiforme, pruritus, rash, Stevens-Johnson syn-

drome, toxic epidermal necrolysis

Other: Anaphylaxis, angioedema

Nursing Considerations

- Give lovastatin cautiously in patients who have a history of liver disease and patients who consume large amounts of alcohol.
- Monitor liver function test results before and during therapy. If serum transaminase levels rise, expect to measure them more often, as ordered. If AST or ALT level reaches or exceeds three times upper limit of normal and persists at that level, expect to discontinue lovastatin.
- Give drug 1 hour before or 4 hours after bile acid sequestrant, cholestyramine, or colestipol.
- Expect patient to be prescribed a standard low-cholesterol diet during therapy.
- Be aware that drug affects mainly total cholesterol and LDL levels; it has only slight effects on HDL and triglyceride levels.

PATIENT TEACHING

- Tell patient who takes drug once daily to do so with evening meal to enhance absorption.
- Advise patient to report muscle aches, pains, tenderness, or weakness; severe GI distress; and vision changes.
- Urge patient to avoid consuming alcohol or more than 1 quart of grapefruit juice daily while taking drug.
- Direct patient to follow a low-cholesterol diet during therapy. Recommend weight loss and exercise programs as appropriate.
- Stress the importance of periodic eye examinations during therapy.
- Teach female patients appropriate contraceptive methods and the need to report suspected pregnancy immediately.

loxapine hydrochloride

Loxapac (CAN), Loxitane, Loxitane C, Loxitane IM

loxapine succinate

Loxapac (CAN), Loxitane

Class and Category

Chemical class: Dibenzoxazepine derivative

Therapeutic class: Antipsychotic

Pregnancy category: C

Indications and Dosages

↗ *To treat psychotic disorders and schizophrenia*

CAPSULES, ORAL SOLUTION

Adults. *Initial:* 10 mg b.i.d., increased over 7 days. *Maintenance:* 15 to 25 mg b.i.d. to q.i.d. *Maximum:* 250 mg daily.

DOSAGE ADJUSTMENT For elderly patients, dosage reduced to 3 to 5 mg b.i.d.

↗ *To treat acute exacerbations of psychotic disorders*

I.M. INJECTION

Adults. 12.5 to 50 mg every 4 to 6 hr or longer. *Maximum:* 250 mg daily.

Route	Onset	Peak	Duration
P.O.	20–30 min	1.5–3 hr	12 hr

Mechanism of Action

May treat psychotic disorders by blocking dopamine at postsynaptic receptors in the brain. With prolonged use, loxapine enhances antipsychotic effects by causing depolarization blockade of dopamine tracts, resulting in decreased dopamine neurotransmission.

Contraindications

Blood dyscrasias, bone marrow depression, cerebrovascular disease, coma, coronary artery disease, hypersensitivity to loxapine or its components, impaired hepatic function, myeloproliferative disorders, severe drug-induced CNS depression, severe hypertension or hypotension

Interactions

DRUGS

amphetamines, ephedrine: Decreased effects of these drugs

antacids, antidiarrheals (adsorbent): Possibly decreased absorption of oral loxapine

anticholinergics: Possibly increased anticholinergic effects

anticonvulsants: Lowered seizure threshold, increased risk of seizures

antidyskinetics: Possibly antagonized therapeutic effects of these drugs

bromocriptine: Possibly decreased therapeutic effects of bromocriptine

CNS depressants: Increased effects of CNS depression

dopamine: Possibly decreased alpha-adrenergic effects of dopamine

epinephrine: Possibly severe hypotension or tachycardia, decreased epinephrine effects

guanadrel, guanethidine, levodopa: Possibly decreased therapeutic effects of these drugs

MAO inhibitors, tricyclic antidepressants: Possibly increased blood levels of these drugs, increased CNS depressant and anticholinergic effects

metaraminol: Possibly decreased vasopressor effect of metaraminol

methoxamine: Possibly decreased vasopressor effect and methoxamine duration of action

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Confusion, drowsiness, dystonia, involuntary motor activity, neuroleptic malignant syndrome, pseudoparkinsonism, sleep disturbance, tardive dyskinesia

CV: Orthostatic hypotension

EENT: Blurred vision, dry mouth

ENDO: Galactorrhea, gynecomastia

GI: Constipation, ileus, nausea, vomiting

GU: Menstrual irregularities, sexual dysfunction, urine retention

SKIN: Photosensitivity (mild), rash

Other: Weight gain

Nursing Considerations

- Be aware that loxapine's full antipsychotic effect may require weeks.
- Loxapine shouldn't be given to treat dementia-related psychosis in the elderly because of an increased mortality risk.
- Assess for signs of tardive dyskinesia, including involuntary protrusion of tongue and chewing movements. These signs may appear months or years after loxapine therapy begins and may not disappear with dosage reduction.
- Observe for extrapyramidal reactions or parkinsonian symptoms, such as excessive salivation, masklike facies, rigidity, and tremor, especially in first few days of treatment. Prescriber may reduce dosage to control these symptoms.

WARNING Monitor patient for neuroleptic malignant syndrome, a rare but possibly fatal adverse reaction. Early evidence includes altered mental status, arrhythmias, fever, and muscle rigidity.

PATIENT TEACHING

- Instruct patient to dilute loxapine oral solution with orange or grapefruit juice just before taking. Advise her to use calibrated dropper that accompanies solution to ensure correct dosage.
- Tell patient not to take antacids and anti-diarrheals within 2 hours of loxapine.
- Caution patient to avoid alcohol while taking loxapine.
- Advise patient to change position slowly to minimize orthostatic hypotension.
- Urge patient to avoid hazardous activities until CNS effects of loxapine are known.
- Advise patient to avoid prolonged sun exposure and to use sunscreen to minimize risk of photosensitivity.
- Urge patient to have periodic eye examinations during therapy.

lubiprostone

Amitiza

Class and Category

Chemical class: Chloride channel activator

Therapeutic class: Intestinal motility enhancer

Pregnancy category: C

Indications and Dosages

↗ *To treat chronic idiopathic constipation*

CAPSULES

Adults. 24 mcg b.i.d. with food and water.

↗ *To treat irritable bowel syndrome with constipation*

CAPSULES

Adults. 8 mcg b.i.d. with food and water.

Mechanism of Action

Enhances chloride-rich intestinal fluid secretion by locally activating chloride channels. By increasing intestinal fluid secretion, lubiprostone increases intestinal motility, which aids passage of stool, alleviating constipation.

Contraindications

Diarrhea, hypersensitivity to lubiprostone or components, mechanical GI obstruction

Interactions

DRUGS

antidiarrheals: Decreased GI motility

Adverse Reactions

CNS: Asthenia, dizziness, fatigue, headache, malaise

CV: Chest discomfort or pain, edema, increased heart rate

EENT: Dry mouth, throat tightness

GI: Abdominal distention or pain, diarrhea, dyspepsia, flatulence, nausea, vomiting

MS: Muscle cramps or spasms

RESP: Dyspnea

SKIN: Rash

Other: Angioedema

Nursing Considerations

- Be aware that lubiprostone shouldn't be used in patients with severe diarrhea.
- Make sure woman a negative pregnancy test before starting lubiprostone because safety during pregnancy is unknown.
- Watch closely for adverse reactions, particularly dyspnea and especially after first dose.

PATIENT TEACHING

- Advise patient to take drug with food to minimize risk of nausea.
- Tell women to use effective contraception while taking lubiprostone and to notify prescriber if pregnancy is suspected. Drug may need to be discontinued.
- Instruct patient to notify prescriber if severe diarrhea occurs.

lypressin

Diapid

Class and Category

Chemical class: Synthetic vasopressin analogue

Therapeutic class: Antidiuretic

Pregnancy category: C

Indications and Dosages

➤ *To control and prevent dehydration, polydipsia, and polyuria in patients with neurogenic diabetes insipidus that is unresponsive to other therapy*

NASAL SOLUTION

Adults and adolescents. 1 or 2 sprays q.i.d. If more drug is needed, interval between doses is decreased rather than increasing number of sprays/dose.

Mechanism of Action

Increases cellular permeability of collecting ducts in kidneys, leading to increased urine osmolality and decreased urine output.

Contraindications

Hypersensitivity to lypressin or components

Route	Onset	Peak	Duration
Intranasal	In 1 hr	0.5–2 hr	3–4 hr

Interactions**DRUGS**

carbamazepine, chlorpropamide, clofibrate: Possibly increased antidiuretic effect
demeclocycline, lithium, norepinephrine: Decreased antidiuretic effect of lypressin

Adverse Reactions

CNS: Headache

EENT: Conjunctivitis; nasal congestion, irritation, and itching; periorbital edema and itching; rhinorrhea

GI: Abdominal cramps, diarrhea, heartburn (if excessive intranasal use causes dripping into pharynx)

RESP: Cough, transient dyspnea (if drug is accidentally inhaled)

Other: Water intoxication

Nursing Considerations

- Assess patient for nasal congestion or upper respiratory tract infection, which can reduce lypressin absorption and require larger doses or adjunct therapy.
- Administer final spray of drug at bedtime to help control nocturia.

WARNING *Inadvertent inhalation, although rare, may cause chest tightness, continuous cough, and dyspnea.*

- Observe for nasal irritation during long-term therapy.
- Watch for evidence of water intoxication, including coma, confusion, drowsiness, persistent headache, seizures, urine retention, and weight gain.

PATIENT TEACHING

- Teach patient how to administer lypressin correctly by holding head upright and bottle in a vertical position and spraying 1 or 2 sprays in each nostril with each dose.
- Instruct patient to take last dose of day at bedtime to control nocturia.
- Instruct patient to use drug exactly as prescribed.
- Tell patient to report abdominal cramps, heartburn, persistent headache, severe nasal irritation, and shortness of breath.

M

magnesium chloride

(contains 64 mg of elemental magnesium per tablet, 100 mg of elemental magnesium per enteric-coated tablet, 64 mg of elemental magnesium per E.R. tablet, and 200 mg of elemental magnesium per 1 ml of injection)

Chloromag, Mag-L-100, Slow-Mag

magnesium citrate (citrate of magnesia)

(contains 40.5 to 47 mg elemental magnesium per 5 ml oral solution)

Citroma, Citro-Mag (CAN)

magnesium gluconate

(contains 54 mg elemental magnesium per 5 ml oral solution and 27 to 29.3 mg elemental magnesium per tablet)

Almora, Maglucate (CAN), Magonate, Magtrate

magnesium hydroxide (milk of magnesia)

(contains 135 mg elemental magnesium per tablet, 129 to 130 mg elemental magnesium per chewable tablet, and 164 to 328 mg elemental magnesium per 5 ml liquid, liquid concentrate, or oral solution)

Phillips' Chewable Tablets, Phillips' Magnesia Tablets (CAN), Phillips' Milk of Magnesia, Phillips' Milk of Magnesia Concentrate

magnesium lactate

(contains 84 mg elemental magnesium per E.R. tablet)

Mag-Tab SR Caplets

magnesium oxide

(contains 84.5 mg elemental magnesium per capsule and 50 to 302 mg elemental magnesium per tablet)

Mag-200, Mag-Ox 400, Maox, Uro-Mag

magnesium sulfate

(contains 100 to 500 mg elemental magnesium per 1 ml of injection, 1 to 5 g elemental magnesium per 10 ml of injection, and 40 mEq per 5 mg of crystals)

Class and Category

Chemical class: Cation, electrolyte

Therapeutic class: Antacid, antiarrhythmic, anticonvulsant, electrolyte replacement, laxative

Pregnancy category: A (parenteral magnesium sulfate), Not rated (others)

Indications and Dosages

➤ To correct magnesium deficiency caused by alcoholism, magnesium-depleting drugs, malnutrition, or restricted diet; to prevent magnesium deficiency based on U.S. and Canadian recommended daily allowances

CAPSULES, CHEWABLE TABLETS, CRYSTALS, ENTERIC-COATED TABLETS, E.R. TABLETS, LIQUID, LIQUID CONCENTRATE, ORAL SOLUTION, TABLETS (MAGNESIUM CHLORIDE, CITRATE, GLUCONATE, HYDROXIDE, LACTATE [EXCEPT IN CHILDREN], OXIDE, SULFATE)

Dosage individualized based on severity of deficiency and normal recommended daily allowances listed below.

Adult men and children over age 10. 270 to 400 mg daily (Canada: 130 to 250 mg daily).

Adult women and children over age 10. 280 to 300 mg daily (Canada: 135 to 210 mg daily).

Pregnant women. 320 mg daily (Canada: 195 to 245 mg daily).

Breast-feeding women. 340 to 355 mg daily (Canada: 245 to 265 mg daily).

Children ages 7 to 10. 170 mg daily (Canada: 100 to 135 mg daily).

Children ages 4 to 6. 120 mg daily (Canada: 65 mg daily).

Children from birth to age 3. 40 to 80 mg/day (Canada: 20 to 50 mg daily).

➤ To treat mild magnesium deficiency

I.M. INJECTION (MAGNESIUM SULFATE)

Adults and adolescents. 1 g every 6 hr for 4 doses.

↗ *To treat severe hypomagnesemia*

I.V. INFUSION (MAGNESIUM CHLORIDE)

Adults. 4 g diluted in 250 ml D₅W and infused at no more than 3 ml/min.

Maximum: 40 g daily.

I.V. INFUSION (MAGNESIUM SULFATE)

Adults and adolescents. 5 g diluted in 1 L I.V. solution and infused over 3 hr.

↗ *To provide supplemental magnesium in total parenteral nutrition*

I.V. INFUSION (MAGNESIUM SULFATE)

Adults. 1 to 3 g daily.

Children. 0.25 mg to 1.25 g daily.

DOSAGE ADJUSTMENT Adult dosage may be increased to 6 g daily for certain conditions, such as short-bowel syndrome.

I.M. INJECTION (MAGNESIUM SULFATE)

Adults and adolescents. Up to 250 mg/kg every 4 hr, p.r.n.

↗ *To prevent and control seizures in preeclampsia or eclampsia as well as seizures caused by epilepsy, glomerulonephritis, or hypothyroidism*

I.V. INFUSION OR INJECTION (MAGNESIUM SULFATE)

Adults. *Loading:* 4 g diluted in 250 ml compatible solution and infused over 30 min.

Maintenance: 1 to 2 g/hr by continuous infusion.

I.M. INJECTION (MAGNESIUM SULFATE)

Adults. 4 to 5 g every 4 hr, p.r.n.

Children. 20 to 40 mg/kg, repeated p.r.n.

↗ *To relieve indigestion with hyperacidity*

CHEWABLE TABLETS, LIQUID, LIQUID CONCENTRATE, ORAL SOLUTION TABLETS (MAGNESIUM HYDROXIDE)

Adults and adolescents. 400 to 1,200 mg (5 to 15 ml liquid or 2.5 to 7.5 ml liquid concentrate) up to 4 times daily with water, or 622 to 1,244 mg (tablets or chewable tablets) up to 4 times daily.

CAPSULES, TABLETS (MAGNESIUM OXIDE)

Adults and adolescents. 140 mg (capsules) t.i.d. or q.i.d. with water or milk, or 400 to 800 mg daily (tablets).

↗ *To relieve constipation, to evacuate colon for rectal or bowel examination*

LIQUID, LIQUID CONCENTRATE (MAGNESIUM HYDROXIDE)

Adults and children age 12 and over. 2.4 to 4.8 g (30 to 60 ml) daily as single dose or divided doses.

Children ages 6 to 11. 1.2 to 2.4 g (15 to

30 ml)/day as a single dose or in divided doses.

Children ages 2 to 5. 0.4 to 1.2 g (5 to 15 ml) daily as single dose or divided doses.

ORAL SOLUTION (MAGNESIUM CITRATE)

Adults and children age 12 and over. 11 to 25 g daily as single dose or divided doses.

Children ages 6 to 11. 5.5 to 12.5 g daily as single dose or divided doses.

Children ages 2 to 5. 2.7 to 6.25 g daily as single dose or divided doses.

CRYSTALS (MAGNESIUM SULFATE)

Adults and children age 12 and over. 10 to 30 g daily as single dose or divided doses.

DOSAGE ADJUSTMENT Dosage limited to 20 g of magnesium sulfate every 48 hr for patients with severe renal impairment.

Children ages 6 to 11. 5 to 10 g daily as a single dose or in divided doses.

Children ages 2 to 5. 2.5 to 5 g daily as a single dose or in divided doses.

CAPSULES, TABLETS (MAGNESIUM OXIDE)

Adults. 2 to 4 g with a full glass of water or milk, usually at bedtime.

Route	Onset	Peak	Duration
P.O.*	0.5–3 hr	Unknown	Unknown
P.O.†	20 min	Unknown	20–180 min
I.M.‡	1 hr	Unknown	3–4 hr
I.V.‡	Immediate	Unknown	About 30 min

Mechanism of Action

Assists all enzymes involved in phosphate transfer reactions that use adenosine triphosphate (ATP). Magnesium is required for normal function of the ATP-dependent sodium-potassium pump in muscle membranes. It may effectively treat digitalis glycoside-induced arrhythmias because correction of hypomagnesemia improves the sodium-potassium pump's ability to distribute potassium into intracellular spaces and because magnesium decreases calcium uptake and potassium outflow through myocardial cell membranes.

As a laxative, magnesium exerts a hyperosmotic effect in the small intestine. It causes water retention that distends the bowel and causes the duodenum to secrete

* For laxative effect.

† For antacid effect.

‡ For anticonvulsant effect.

cholecystokinin. This substance stimulates fluid secretion and intestinal motility.

As an antacid, magnesium reacts with water, converting magnesium oxide to magnesium hydroxide. Magnesium hydroxide rapidly reacts with gastric acid to form water and magnesium chloride, which increases gastric pH.

As an anticonvulsant, magnesium depresses the CNS and blocks peripheral neuromuscular impulse transmission by decreasing available acetylcholine.

Incompatibilities

Don't combine magnesium sulfate with alkali carbonates and bicarbonates, alkali hydroxides, arsenates, calcium, clindamycin phosphate, dobutamine, fat emulsions, heavy metals, hydrocortisone sodium succinate, phosphates, polymyxin B, procaine hydrochloride, salicylates, sodium bicarbonate, strontium, and tartrates.

Contraindications

Hypersensitivity to magnesium salts or any component of magnesium-containing preparations

For magnesium chloride: Coma, heart disease, renal impairment

For magnesium sulfate: Heart block, MI, preeclampsia 2 hours or less before delivery (I.V. form)

For use as laxative: Acute abdominal problem (as indicated by abdominal pain, nausea, or vomiting), diverticulitis, fecal impaction, intestinal obstruction or perforation, colostomy or ileostomy, severe renal impairment, ulcerative colitis

Interactions

DRUGS

amphotericin B, cisplatin, cyclosporine, gentamicin: Possibly magnesium wasting and need for magnesium dosage adjustment
anticholinergics: Possibly decreased absorption and therapeutic effects of these drugs
calcium salts (I.V.): Possibly neutralization of magnesium sulfate's effects
cellulose sodium phosphate: Possibly binding with magnesium, possibly decreased therapeutic effectiveness of cellulose
CNS depressants: Increased CNS depression
digoxin (I.V.): Possibly heart block and conduction changes, especially when calcium salts are also administered

digoxin, fluoroquinolones, folic acid, H₂-receptor blockers, iron preparations, isoniazid, ketoconazole, penicillamine, phenothiazines, phenytoin, phosphates (oral), tetracyclines: Possibly decreased absorption and blood levels of these drugs

diuretics (loop or thiazide): Possibly hypomagnesemia

edetate sodium, sodium polystyrene sulfonate: Possibly binding with magnesium
enteric-coated drugs: Possibly quicker dissolution of these drugs and increased risk of adverse GI reactions

etidronate (oral): Decreased etidronate absorption

mecamylamine: Possibly prolonged effects of mecamylamine

methenamine, streptomycin, sucralfate, tetracyclines, tobramycin (oral), urinary acidifiers: Possibly decreased therapeutic effects of these drugs

misoprostol: Increased misoprostol-induced diarrhea

neuromuscular blockers: Possibly increased neuromuscular blockade

nifedipine: Possibly increased hypotensive effects when taken with magnesium sulfate

potassium-sparing diuretics: Increased risk of hypermagnesemia

salicylates: Possibly increased excretion and lower blood levels of salicylates

sodium polystyrene sulfonate resin: Possibly metabolic alkalosis

FOODS

high glucose intake: Increased urinary excretion of magnesium

ACTIVITIES

alcohol use: Increased urinary excretion of magnesium

Adverse Reactions

CNS: Confusion, decreased reflexes, dizziness, syncope

CV: Arrhythmias, hypotension

GI: Flatulence, vomiting

MS: Muscle cramps

RESP: Dyspnea, respiratory depression or paralysis

SKIN: Diaphoresis

Other: Allergic reaction, hypermagnesemia, injection site pain or irritation (I.M. form), laxative dependence, magnesium toxicity

Nursing Considerations

- Be aware that magnesium sulfate is the

elemental form of magnesium. Oral preparations aren't all equivalent.

- Be aware that drug isn't metabolized. Drug remaining in the GI tract produces watery stool within 30 minutes to 3 hours.
- Make sure patient chews chewable tablets thoroughly before swallowing.
- Avoid giving other oral drugs within 2 hours of magnesium-containing antacid.
- Before giving drug as laxative, shake oral solution, liquid, or liquid concentrate well and give with a large amount of water.

WARNING Observe for and report early evidence of hypermagnesemia: bradycardia, depressed deep tendon reflexes, diplopia, dyspnea, flushing, hypotension, nausea, slurred speech, vomiting, and weakness.

WARNING Be aware that magnesium may precipitate myasthenic crisis by decreasing patient's sensitivity to acetylcholine.

- Frequently assess cardiac status of patient taking drugs that lower heart rate, such as beta blockers, because magnesium may aggravate symptoms of heart block.

WARNING Magnesium chloride for injection contains the preservative benzyl alcohol, which may cause fatal toxic syndrome in neonates and premature infants.

- Provide adequate diet, exercise, and fluids for patient being treated for constipation.
- Monitor serum electrolyte levels in patients with renal insufficiency because they're at risk for magnesium toxicity.
- Be aware that magnesium salts aren't intended for long-term use.

PATIENT TEACHING

- Advise patient to chew magnesium chewable tablets thoroughly before swallowing then drink a full glass of water. Mention that tablets have a chalky taste.
- Instruct patient to take magnesium-containing antacid between meals and at bedtime. Urge him not to take other drugs within 2 hours of the antacid.
- Tell patient to notify prescriber and avoid using magnesium-containing laxative if he has abdominal pain, nausea, or vomiting.
- Instruct patient to refrigerate magnesium citrate solution.
- Caution patient about risk of dependence with long-term laxative use.
- Teach patient to prevent constipation by increasing dietary fiber and fluid intake and exercising regularly.

- Inform patient that magnesium supplements used to replace electrolytes can cause diarrhea.

mannitol

Osmitrol, Resectisol

Class and Category

Chemical class: Hexahydroxy alcohol

Therapeutic class: Antiglaucoma, diagnostic agent, osmotic diuretic, urinary irrigant

Pregnancy category: B

Indications and Dosages

↗ *To reduce intracranial or intraocular pressure*

I.V. INFUSION

Adults and adolescents. 0.25 to 2 g/kg as 15% to 25% solution given over 30 to 60 min. If used before eye surgery, 1.5 to 2 g/kg 60 to 90 min before procedure. *Maximum:* 6 g/kg daily.

DOSAGE ADJUSTMENT For small or debilitated patients, dosage reduced to 0.5 g/kg.

↗ *To diagnose oliguria or inadequate renal function*

I.V. INFUSION

Adults and adolescents. 200 mg/kg or 12.5 g as 15% to 20% solution given over 3 to 5 min. Second dose given only if patient fails to excrete 30 to 50 ml of urine in 2 to 3 hr. Drug discontinued if no response after second dose. Or, 100 ml of 20% solution diluted in 180 ml normal saline solution (forming 280 ml of 7.2% solution) and infused at 20 ml/min; followed by measurement of urine output. *Maximum:* 6 g/kg daily.

↗ *To prevent oliguria or acute renal failure*

I.V. INFUSION

Adults and adolescents. 50 to 100 g as 5% to 25% solution. *Maximum:* 6 g/kg daily.

↗ *To treat oliguria*

I.V. INFUSION

Adults and adolescents. 50 to 100 g as 15% to 25% solution given over 90 min to several hr. *Maximum:* 6 g/kg daily.

↗ *To promote diuresis in drug toxicity*

I.V. INFUSION

Adults and adolescents. *Loading:* 25 g. *Maintenance:* Up to 200 g as 5% to 25% solution given continuously to maintain

urine output of 100 to 500 ml/hr with positive fluid balance of 1 to 2 L. *Maximum:* 6 g/kg daily.

↗ *To promote diuresis in hemolytic transfusion reaction*

I.V. INFUSION

Adults. 20 g given over 5 min and repeated if needed. *Maximum:* 6 g/kg daily.

↗ *To provide irrigation during transurethral resection of prostate gland*

IRRIGATION SOLUTION

Adults. 2.5% or 5% solution, as needed.

Route	Onset	Peak	Duration
I.V.*	1–3 hr	Unknown	Up to 8 hr
I.V.†	30–60 min	Unknown	4–8 hr
I.V.‡	In 15 min	Unknown	3–8 hr

Mechanism of Action

Elevates plasma osmolality, causing water to flow from tissues, such as brain and eyes, and from CSF, into extracellular fluid, thereby decreasing intracranial and intraocular pressure.

As an osmotic diuretic, mannitol increases the osmolarity of glomerular filtrate, which decreases water reabsorption. This leads to increased excretion of water, sodium, chloride, and toxic substances.

As an irrigant, mannitol minimizes the hemolytic effects of water used as an irrigant and reduces the movement of hemolyzed blood from the urethra to the systemic circulation, which prevents hemoglobinemia and serious renal complications.

Incompatibilities

Don't administer mannitol through same I.V. line as blood or blood products.

Contraindications

Active intracranial bleeding (except during craniotomy), anuria, hepatic failure, hypersensitivity to mannitol or its components, pulmonary edema, severe dehydration, severe heart failure, severe pulmonary congestion, severe renal insufficiency

Interactions

DRUGS

digoxin: Increased risk of digitalis toxicity

* To produce diuresis.

† To decrease intraocular pressure.

‡ To decrease intracranial pressure.

from hypokalemia

diuretics: Possibly increased therapeutic effects of mannitol

Adverse Reactions

CNS: Chills, dizziness, fever, headache, seizures

CV: Chest pain, heart failure, hypertension, tachycardia, thrombophlebitis

EENT: Blurred vision, dry mouth, rhinitis

GI: Diarrhea, nausea, thirst, vomiting

GU: Polyuria, urine retention

RESP: Pulmonary edema

SKIN: Extravasation with edema and tissue necrosis, rash, urticaria

Other: Dehydration, hyperkalemia, hypernatremia, hypervolemia, hypokalemia, hyponatremia (dilutional), metabolic acidosis, water intoxication

Nursing Considerations

- If crystals form in mannitol solution exposed to low temperature, place solution in hot-water bath to redissolve crystals.
- Use a 5-micron in-line filter when administering drug solution of 15% or greater.
- During I.V. infusion of mannitol, monitor vital signs, central venous pressure, and fluid intake and output every hour. Measure urine output with indwelling urinary catheter, as appropriate.
- Check weight and monitor BUN and serum creatinine electrolyte levels daily.
- Provide frequent mouth care to relieve thirst and dry mouth.

PATIENT TEACHING

- Inform patient that he may experience dry mouth and thirst during mannitol therapy.
- Instruct patient to report chest pain, difficulty breathing, or pain at I.V. site.

maprotiline hydrochloride

Ludiomil

Class and Category

Chemical class: Dibenzobicyclooctadiene derivative

Therapeutic class: Antidepressant, tricyclic antidepressant

Pregnancy category: B

Indications and Dosages

↗ *To treat mild to moderate depression*

TABLETS

Adults and adolescents. *Initial:* 75 mg daily in divided doses for 2 wk. Increased in 25-mg increments as needed and tolerated. *Maintenance:* 150 to 225 mg daily in divided doses; for prolonged therapy, possibly 75 to 150 mg daily in divided doses.

↗ *To treat hospitalized patients with severe depression*

TABLETS

Adults and adolescents. *Initial:* 100 to 150 mg daily in divided doses, increased as needed and tolerated. *Maintenance:* 150 to 225 mg daily in divided doses; for prolonged therapy, possibly 75 to 150 mg daily in divided doses.

DOSAGE ADJUSTMENT For patients over age 60, initial dosage reduced to 25 mg daily and then increased by 25 mg/wk up to maintenance dosage of 50 to 75 mg daily in divided doses.

Route	Onset	Peak	Duration
P.O.	1–3 wk	3–6 wk	Unknown

Mechanism of Action

Blocks norepinephrine's reuptake at adrenergic nerve fibers. Normally, when a nerve impulse reaches an adrenergic nerve fiber, norepinephrine is released from storage sites and metabolized in the nerve or at the synapse. Some norepinephrine reaches receptor sites on target organs and tissues, but most is taken back into the nerve and stored by way of reuptake mechanism. By blocking norepinephrine reuptake, maprotiline increases its level at nerve synapses. Elevated norepinephrine level may improve mood and decrease depression.

Contraindications

Hypersensitivity to maprotiline, mirtazapine, or their components; use within 14 days of MAO inhibitor therapy

Interactions

DRUGS

anticholinergics, antihistamines: Increased atropine-like adverse effects, such as blurred vision, constipation, dizziness, and dry mouth

anticonvulsants: Increased risk of CNS depression, possibly lower seizure thresh-

old and increased risk of seizures
bupropion, clozapine, haloperidol, loxapine, molindone, other tricyclic antidepressants, phenothiazines, pimozide, thioxanthenes, trazodone: Possibly increased anticholinergic effects, possibly lowered seizure threshold and increased risk of seizures
cimetidine: Possibly increased blood maprotiline level

clonidine, guanadrel, guanethidine: Possibly decreased antihypertensive effects of these drugs, possibly increased CNS depression (with clonidine)

CNS depressants: Increased risk of CNS depression

estrogens, oral contraceptives containing estrogen: Possibly decreased therapeutic effects and increased adverse effects of maprotiline

MAO inhibitors: Increased risk of hyperpyrexia, hypertensive crisis, severe seizures, or death

sympathomimetics: Increased risk of arrhythmias, hyperpyrexia, hypertension, or tachycardia

thyroid hormones: Increased risk of arrhythmias

ACTIVITIES

alcohol use: Increased risk of CNS depression

Adverse Reactions

CNS: Agitation, dizziness, drowsiness, fatigue, headache, insomnia, seizures, suicidal ideation, tremor, weakness

EENT: Blurred vision, dry mouth, increased intraocular pressure

ENDO: Gynecomastia

GI: Constipation, diarrhea, epigastric distress, increased appetite, nausea, vomiting

GU: Impotence, libido changes, testicular swelling, urinary hesitancy, urine retention

HEME: Agranulocytosis

SKIN: Diaphoresis, photosensitivity, pruritus, rash

Other: Weight loss

Nursing Considerations

- Give largest dose of maprotiline at bedtime if daytime drowsiness occurs.
- Check CBC, as ordered, if fever, sore throat, or other evidence of agranulocytosis develops.
- Take seizure precautions according to facility policy.

- Watch patient (especially children, adolescents, and young adults) closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.
- Expect to taper drug gradually because stopping abruptly may produce withdrawal symptoms.

PATIENT TEACHING

- Advise patient to take maprotiline exactly as prescribed. Caution him not to stop drug abruptly because of risk of withdrawal symptoms, including headache, nausea, nightmares, and vertigo.
- Inform patient that he may not feel drug's effects for several weeks.
- Suggest that patient take drug with food if adverse GI reactions develop.
- Urge patient to report difficulty urinating, excessive drowsiness, fever, or sore throat.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Caution patient to avoid alcohol and other CNS depressants while taking drug.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.

meclizine hydrochloride (meclozine hydrochloride)

Antivert, Bonamine (CAN), Bonine, Dizmiss, Dramamine II, Meclicot, Medivert, Meni-D

Class and Category

Chemical class: Piperazine derivative

Therapeutic class: Antiemetic, antivergigo

Pregnancy category: B

Indications and Dosages

↗ *To prevent and treat vertigo*

CAPSULES, CHEWABLE TABLETS, TABLETS

Adults and adolescents. 25 to 100 mg daily, p.r.n., in divided doses.

↗ *To treat motion sickness*

CAPSULES, TABLETS

Adults. 25 to 50 mg 1 hr before travel and then every 24 hr, p.r.n., for duration of trip.

Route	Onset	Peak	Duration
P.O.	1 hr	Unknown	8–24 hr

Mechanism of Action

May inhibit nausea and vomiting by reducing sensitivity of labyrinthine apparatus and blocking cholinergic synapses in the brain's vomiting center.

Contraindications

Hypersensitivity to meclizine or its components

Interactions

DRUGS

anticholinergics: Possibly potentiated anticholinergic effects

apomorphine: Possibly decreased emetic response to apomorphine

CNS depressants: Possibly potentiated CNS depression

ACTIVITIES

alcohol use: Possibly potentiated CNS depression

Adverse Reactions

CNS: Dizziness, drowsiness, euphoria, excitement, fatigue, hallucinations, headache, insomnia, nervousness, restlessness, vertigo

CV: Hypotension, palpitations, tachycardia

EENT: Blurred vision; diplopia; dry mouth, nose, and throat; tinnitus

GI: Abdominal pain, anorexia, constipation, diarrhea, nausea, vomiting

GU: Urinary frequency and hesitancy, urine retention

RESP: Bronchospasm, thickening of respiratory secretions

SKIN: Jaundice, rash, urticaria

Nursing Considerations

- Use meclizine cautiously in patients with asthma, glaucoma, or prostate gland enlargement.
- Be aware that drug may mask signs of brain tumor, intestinal obstruction, or ototoxicity.

PATIENT TEACHING

- Explain that meclizine works best for motion sickness when taken before travel.
- Instruct patient to chew meclizine chewable tablets thoroughly before swallowing.

- Instruct patient to report blurred vision or drowsiness.
- Urge patient to avoid alcohol while taking drug.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to have regular eye examinations during long-term therapy.

meclofenamate sodium

Meclomen

Class and Category

Chemical class: Fenamate (anthranilic acid) derivative

Therapeutic class: Analgesic, antidysmenorrheal, anti-inflammatory, antirheumatic

Pregnancy category: Not rated

Indications and Dosages

↗ *To relieve pain and inflammation in rheumatoid arthritis and osteoarthritis*

CAPSULES

Adults and adolescents over age 14. 50 to 100 mg every 6 to 8 hr, p.r.n. *Maximum:* 400 mg/day.

↗ *To relieve mild to moderate pain*

CAPSULES

Adults and adolescents over age 14. 50 mg every 4 to 6 hr, p.r.n. Increased to 100 mg every 4 to 6 hr, if needed. *Maximum:* 400 mg daily.

↗ *To treat hypermenorrhea and primary dysmenorrhea*

CAPSULES

Adults and adolescents over age 14. 100 mg t.i.d. for up to 6 days.

Route	Onset	Peak	Duration
P.O.*	1 hr	0.5–2 hr	4–6 hr
P.O.†	Few days	2–3 wk	Unknown

Mechanism of Action

Blocks cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate the inflammatory response and cause local vasodilation, swelling, and pain. By inhibiting prostaglandins, this NSAID reduces

* For analgesic effect.

† For antirheumatic effect.

inflammatory symptoms. It also relieves pain because prostaglandins promote pain transmission from periphery to spinal cord.

Contraindications

Hypersensitivity to aspirin, iodides, meclufenamate, other NSAIDs, or their components

Interactions

DRUGS

acetaminophen: Increased risk of adverse renal effects with long-term use of both drugs

anticoagulants, thrombolytics: Prolonged PT and increased risk of bleeding

antihypertensives: Decreased effectiveness of antihypertensives

beta blockers: Impaired antihypertensive effect of beta blockers

cefamandole, cefoperazone, cefotetan, plicamycin, valproic acid: Hypoprothrombinemia and increased risk of bleeding

cimetidine: Altered meclufenamate level

colchicine, glucocorticoids, potassium supplements: Increased GI irritability and bleeding

cyclosporine, gold compounds, nephrotoxic drugs: Increased risk of nephrotoxicity

digoxin: Increased blood digoxin level

insulin, oral antidiabetic drugs: Decreased effectiveness of these drugs

lithium: Increased risk of lithium toxicity

loop diuretics: Decreased effects of these drugs

methotrexate: Increased risk of methotrexate toxicity

NSAIDs, salicylates: Increased GI irritability and risk of bleeding, decreased meclufenamate effectiveness

phenytoin: Increased blood phenytoin level

probenecid: Increased risk of meclufenamate toxicity

ACTIVITIES

alcohol use: Increased GI irritability and bleeding

Adverse Reactions

CNS: Dizziness, drowsiness, fatigue, headache, insomnia, seizures, stroke

CV: Hypertension, MI, peripheral edema, tachycardia

EENT: Stomatitis, tinnitus

GI: Abdominal pain; anorexia; constipation; diarrhea; diverticulitis; dyspepsia; dysphagia; elevated liver function test results; esophagitis; flatulence; gastritis; gastroen-

teritis; gastroesophageal reflux disease; GI bleeding, perforation, and ulceration; hepatic failure; indigestion; jaundice; melena; nausea; perforation of stomach or intestines; stomatitis; vomiting

GU: Acute renal failure, dysuria, elevated BUN and serum creatinine levels

HEME: Agranulocytosis, anemia, easy bruising, hemolytic anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia

RESP: Asthma, respiratory depression

SKIN: Erythema multiforme, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema

Nursing Considerations

- Use meclufenamate with extreme caution in patients with a history of ulcer disease or GI bleeding because NSAIDs such as meclufenamate increase risk of GI bleeding and ulceration. Expect to use drug for shortest time possible in these patients.
- Be aware that serious GI tract ulceration, bleeding, and perforation may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food and a full glass of water. If GI distress occurs, withhold drug and notify prescriber immediately.
- Use meclufenamate cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

WARNING Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

- Monitor patient—especially if he's elderly or taking meclufenamate long-term—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver function test results because, rarely, elevations may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure.
- Monitor BUN and serum creatinine levels in elderly patients, patients taking diuretics or ACE inhibitors, and patients with heart failure, impaired renal function, or

hepatic dysfunction; drug may cause renal failure.

- Monitor CBC for decreased hemoglobin and hematocrit because drug may worsen anemia.

WARNING If patient has bone marrow suppression or is receiving an antineoplastic drug, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of meclufenamate may mask signs and symptoms, such as fever and pain.

- Assess patient's skin regularly for rash or other hypersensitivity reaction because meclufenamate is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID sensitivity. At first sign of reaction, stop drug and notify prescriber.
- Expect lower doses of meclufenamate to be used for long-term therapy.

PATIENT TEACHING

- Tell patient to take drug with a full glass of water to keep it from lodging in esophagus and causing irritation. Suggest taking drug with food or milk to avoid GI distress.
- Instruct patient to report itching, rash, severe diarrhea, and swelling in ankles or fingers.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Caution pregnant patient not to take NSAIDs such as meclufenamate during last trimester because they may cause premature closure of fetal ductus arteriosus.
- Explain that meclufenamate may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, weakness, or slurring of speech.
- Explain that meclufenamate may increase risk of serious adverse GI reactions; stress importance of seeking immediate medical attention for such signs and symptoms as epigastric or abdominal pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions to meclufenamate. Urge him to seek immediate medical attention for rash, blisters, itching, fever, or other indications of hypersensitivity.

meloxicam

Mobic

Class and Category

Chemical class: Oxicam derivative

Therapeutic class: Anti-inflammatory

Pregnancy category: C

Indications and Dosages

↗ *To relieve signs and symptoms of osteoarthritis and rheumatoid arthritis*

ORAL SUSPENSION, TABLETS

Adults. 7.5 mg daily. *Maximum:* 15 mg daily.

↗ *To relieve pauciarticular or polyarticular signs and symptoms of juvenile rheumatoid arthritis*

ORAL SUSPENSION, TABLETS

Children age 2 and over. 0.125 mg/kg daily. *Maximum:* 7.5 mg daily.

Mechanism of Action

Blocks cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate the inflammatory response and cause local vasodilation, swelling, and pain. By inhibiting prostaglandins, the NSAID meloxicam reduces inflammatory symptoms. It also relieves pain because prostaglandins promote pain transmission from the periphery to the spinal cord.

Contraindications

Angioedema, asthma, bronchospasm, nasal polyps, rhinitis, or urticaria induced by hypersensitivity to aspirin, meloxicam, other NSAIDs, or their components

Interactions

DRUGS

ACE inhibitors: Decreased antihypertensive effect, increased risk of renal failure

aspirin: Increased risk of GI ulceration

furosemide: Decreased diuretic effect of furosemide, possibly renal impairment

lithium: Elevated blood lithium level, possibly lithium toxicity

oral anticoagulants, warfarin: Increased risk of bleeding

ACTIVITIES

alcohol use, smoking: Increased risk of GI bleeding

Adverse Reactions

CNS: Confusion, dizziness, fever, headache,

insomnia, mood alteration, seizures, stroke

CV: Chest pain, edema, heart failure, hypertension, MI, tachycardia, vasculitis

EENT: Laryngitis, pharyngitis, sinusitis

GI: Abdominal pain, anorexia, colitis, constipation, diarrhea, diverticulitis, dyspepsia, dysphagia, elevated liver function test results, esophagitis, flatulence, gastritis, gastroenteritis, gastroesophageal reflux disease, GI bleeding and ulceration, hepatic failure, hepatitis, indigestion, melena, nausea, pancreatitis, perforation of stomach or intestines, stomatitis, vomiting

GU: Acute renal failure, acute urine retention (children), urinary frequency, UTI

HEME: Agranulocytosis, anemia, easy bruising, hemolytic anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia

MS: Arthralgia; back pain; joint crepitation, effusion, or swelling; muscle spasms; myalgia

RESP: Asthma, bronchospasm, cough, dyspnea, respiratory depression, upper respiratory tract infection

SKIN: Erythema multiforme, exfoliative dermatitis, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, angioedema, flulike symptoms

Nursing Considerations

- Use meloxicam with extreme caution in patients with history of ulcer disease or GI bleeding because NSAIDs such as meloxicam increase risk of GI bleeding and ulceration. Expect to use drug for shortest time possible in these patients.
- Be aware that serious GI tract ulceration, bleeding, and perforation may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food and a full glass of water. If GI distress occurs, withhold drug and notify prescriber immediately.
- Use meloxicam cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

WARNING Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

- Monitor patient—especially if elderly or taking meloxicam long-term—for less

- common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver function test results because, rarely, elevations may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure.
 - Monitor BUN and serum creatinine levels in elderly patients; patients taking diuretics, angiotensin II receptor antagonists, or ACE inhibitors; and patients with heart failure, impaired renal function, or hepatic dysfunction; drug may cause renal failure.
 - Monitor CBC for decreased hemoglobin and hematocrit. Drug may worsen anemia.

WARNING If patient has bone marrow suppression or is receiving an antineoplastic drug, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of meloxicam may mask signs and symptoms, such as fever and pain.

- Assess patient's skin regularly for rash or other hypersensitivity reaction because meloxicam is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID sensitivity. At first sign of reaction, stop drug and notify prescriber.
- Monitor patient for adequate hydration before beginning meloxicam therapy to decrease risk of renal dysfunction.

PATIENT TEACHING

- Instruct patient to take meloxicam with food or after meals if he has stomach upset.
- For oral suspension, tell patient to shake container gently before use.
- Caution patient to avoid using other NSAIDs, aspirin, or products containing aspirin while taking meloxicam.
- Advise patient to refrain from smoking and alcohol use because these activities may increase risk of adverse GI reactions.
- Instruct patient to notify prescriber if he develops signs or symptoms of hepatic dysfunction, such as dark yellow or brown urine, fatigue, fever, itching, lethargy, nausea, or yellowing of eyes or skin.
- Advise patient, especially if he's taking an oral anticoagulant such as warfarin, to

report immediately signs of bleeding, such as easy bruising, stomach pain, blood in urine, or black tarry stools.

- Caution pregnant patient not to take NSAIDs such as meloxicam during the last trimester because they may cause premature closure of ductus arteriosus.
- Explain that meloxicam may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, weakness, and slurring of speech.
- Explain that meloxicam may increase risk of serious adverse GI reactions; stress importance of seeking immediate medical attention for such signs and symptoms as epigastric or abdominal pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions. Urge him to seek immediate medical attention for rash, blisters, itching, fever, or other indications of hypersensitivity.

memantine hydrochloride

Namenda

M

Class and Category

Chemical class: N-methyl-D-aspartate (NMDA) receptor antagonist

Therapeutic class: Antidementia agent

Pregnancy category: B

Indications and Dosages

↗ To treat moderate-to-severe dementia of the Alzheimer's type

TABLETS

Adults. *Initial:* 5 mg daily P.O., increased by 5 mg/wk, as needed, to 10 mg daily in two divided doses; then 15 mg daily with one 5-mg and one 10-mg dose daily; then 20 mg daily in two divided doses. *Maintenance:* 20 mg daily.

DOSAGE ADJUSTMENT Dosage reduction probable for patients with renal impairment.

Contraindications

Hypersensitivity to memantine, amantadine, or their components

Mechanism of Action

Memantine blocks the excitatory amino acid glutamate on N-methyl-D-aspartate (NMDA) receptor cells in the CNS. In Alzheimer's disease, glutamate levels are abnormally high when brain cells are both at rest and active. Normally, when certain brain cells are resting, magnesium ions block NMDA receptors and prevent influx of sodium and calcium ions and outflow of potassium ions. When learning and memory cells in the brain are active, glutamate engages with NMDA receptors, magnesium ions are removed from NMDA receptors, and cells are depolarized. During depolarization, sodium and calcium ions enter brain cells, and potas-

sium ions leave. In Alzheimer's disease, excessive circulating glutamate permanently removes magnesium ions and opens ion channels. Excessive influx of calcium may damage brain cells and play a major role in Alzheimer's disease. What's more, dying brain cells release additional glutamate, worsening the cycle of brain cell destruction.

Memantine replaces magnesium on NMDA receptors of brain cells, closing ion channels and preventing calcium influx and the resulting damage to brain cells. By preventing excessive brain cell death, memantine slows progression of Alzheimer's disease.

Interactions

DRUGS

amantadine, dextromethorphan, ketamine: Possibly additive effects
carbonic anhydrase inhibitors, sodium bicarbonate: Decreased memantine clearance, leading to increased blood drug levels and risk of adverse effects
cimetidine, hydrochlorothiazide, metformin, nicotinic acid, quinidine, ranitidine, tri-arterene: Possibly increased blood levels of both agents

Adverse Reactions

CNS: Abnormal gait, agitation, akathisia, anxiety, confusion, delirium, delusions, depression, dizziness, drowsiness, dyskinesia, fatigue, hallucinations, headache, hyperexcitability, insomnia, neuroleptic malig-

nant syndrome, psychosis, restlessness, seizures, somnolence, stroke, tardive dyskinesia

CV: AV block, chest pain, hypertension, peripheral edema, prolonged QT interval, supraventricular tachycardia, tachycardia

ENDO: Hypoglycemia

GI: Acute pancreatitis, anorexia, colitis, constipation, diarrhea, hepatic failure, ileus, nausea, vomiting

GU: Acute renal failure, impotence, urinary incontinence, UTI

HEME: Thrombocytopenia

MS: Arthralgia, back pain

RESP: Bronchitis, cough, dyspnea, upper respiratory tract infection

SKIN: Stevens-Johnson syndrome

Other: Generalized pain, flulike symptoms

Nursing Considerations

- Use meperidine cautiously in patients with renal tubular acidosis or severe UTI because these conditions make urine alkaline, reducing meperidine excretion and increasing the risk of adverse reactions.
- Use cautiously in patients with severe hepatic impairment because drug undergoes partial hepatic metabolism, which may increase risk of adverse reactions.
- Monitor patient's response to meperidine, and notify prescriber if serious or bothersome adverse reactions occur.

PATIENT TEACHING

- Advise patient to avoid a diet excessively high in fruits and vegetables because these foods contribute to alkaline urine, which can alter meperidine clearance and increase adverse reactions.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.

meperidine hydrochloride (pethidine hydrochloride)

Demerol

Class, Category, and Schedule

Chemical class: Phenylpiperidine derivative opioid

Therapeutic class: Analgesic

Pregnancy category: C

Controlled substance schedule: II

Indications and Dosages

➤ *To relieve moderate to severe pain*

SYRUP, TABLETS, I.M. OR SUBCUTANEOUS INJECTION

Adults. 50 to 150 mg every 3 to 4 hr, p.r.n.

Children. 1.1 to 1.8 mg/kg every 3 to 4 hr, p.r.n.

➤ *To provide preoperative sedation*

I.V. INJECTION

Adults. 15 to 35 mg/hr, p.r.n.

I.M. OR SUBCUTANEOUS INJECTION

Adults. 50 to 100 mg 30 to 90 min before surgery.

Children. 1 to 2 mg/kg 30 to 90 min before surgery. *Maximum:* 100 mg every 3 to 4 hr.

➤ *As adjunct to anesthesia*

I.V. INFUSION OR INJECTION

Adults. Individualized. Repeated slow injections of 10 mg/ml solution or continuous infusion of dilute solution (1 mg/ml) titrated as needed.

➤ *To provide obstetric analgesia*

I.M. OR SUBCUTANEOUS INJECTION

Adults. 50 to 100 mg given with regular, painful contractions; repeated every 1 to 3 hr.

DOSAGE ADJUSTMENT For patients with creatinine clearance of 10 to 50 ml/min/1.73 m², 75% of usual dose is used; with creatinine clearance of less than 10 ml/min/1.73 m², 50% of usual dose is used.

Route	Onset	Peak	Duration
P.O.	15 min	1–1.5 hr	2–4 hr
I.V.	1 min	5–7 min	2–4 hr
I.M.,	10–15	30–50	2–4 hr
SubQ	min	min	

Mechanism of Action

Binds with opiate receptors in the spinal cord and higher levels of the CNS. In this way, meperidine stimulates mu and kappa receptors, which alters the perception of and emotional response to pain.

Incompatibilities

Don't mix meperidine in same syringe with aminophylline, barbiturates, heparin, iodides, methicillin, morphine sulfate, phenytoin, sodium bicarbonate, sulfadiazole, or sulfoxazole.

Contraindications

Acute asthma; hypersensitivity to meperidine, opioids, or their components; increased intracranial pressure; severe respiratory depression; upper respiratory tract obstruction; use within 14 days of MAO inhibitor therapy

Interactions

DRUGS

acyclovir, ritonavir: Possibly increased blood meperidine level

alfentanil, CNS depressants, fentanyl, sufentanil: Increased risk of CNS and respiratory depression and hypotension

amphetamines, MAO inhibitors: Risk of increased CNS excitation or depression with possibly fatal reactions

anticholinergics: Increased risk of severe constipation

antidiarrheals (such as loperamide and difenoxin and atropine): Increased risk of severe constipation and increased CNS depression

antihypertensives: Increased risk of hypotension

buprenorphine: Possibly decreased therapeutic effects of meperidine and increased risk of respiratory depression

cimetidine: Reduced clearance and volume of distribution of meperidine

hydroxyzine: Increased risk of CNS depression and hypotension

metoclopramide: Possibly decreased effects of metoclopramide

naloxone, naltrexone: Decreased pharmacologic effects of meperidine

neuromuscular blockers: Increased risk of prolonged respiratory and CNS depression

oral anticoagulants: Possibly increased anticoagulant effect and risk of bleeding

phenytoin: Possibly enhanced hepatic metabolism of meperidine

ACTIVITIES

alcohol use: Possibly increased CNS and respiratory depression and hypotension

Adverse Reactions

CNS: Confusion, depression, dizziness, drowsiness, euphoria, headache, increased intracranial pressure, lack of coordination, malaise, nervousness, nightmares, restlessness, seizures, syncope, tremor

CV: Hypotension, orthostatic hypotension, tachycardia

EENT: Blurred vision, diplopia, dry mouth

GI: Abdominal cramps or pain, anorexia, constipation, ileus, nausea, vomiting

GU: Dysuria, urinary frequency, urine retention

RESP: Dyspnea, respiratory arrest or depression, wheezing

SKIN: Diaphoresis, flushing, pruritus, rash, urticaria

Other: Anaphylaxis, injection site pain, redness, and swelling; physical and psychological dependence

Nursing Considerations

- Use meperidine with extreme caution in patients with acute abdominal conditions, hepatic or renal disorders, hypothyroidism, prostatic hyperplasia, seizures, or supraventricular tachycardia.
- To minimize local anesthetic effect, dilute

meperidine syrup with water before use.

- Give I.V. dose slowly by direct injection or as a slow continuous infusion. Mix with D₅W, normal saline solution, or Ringer's or lactated Ringer's solution.
- Keep naloxone available when giving I.V. meperidine.
- Be aware that subcutaneous injection is painful and isn't recommended.
- Be aware that oral form of meperidine is less than half as effective as parenteral meperidine. Give I.M. form when possible, and expect to increase dosage when switching patient to oral form.
- Monitor patient's respiratory and cardiovascular status during treatment. Notify prescriber immediately and expect to discontinue drug if respiratory rate falls to less than 12 breaths/minute or if respiratory depth decreases.
- Monitor patient's bowel function to detect constipation, and assess the need for stool softeners.
- Assess for signs of physical dependence and abuse.
- Expect withdrawal symptoms to occur if drug is abruptly withdrawn after long-term use.

PATIENT TEACHING

- Inform patient that meperidine is a controlled substance and that he'll need identification to purchase it.
- Advise patient to take drug exactly as prescribed.
- Instruct patient to report constipation, severe nausea, and shortness or breath.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to prevent postoperative atelectasis by turning, coughing, and deep-breathing.
- Urge patient to avoid alcohol, sedatives, and tranquilizers during therapy.

mephentermine sulfate

Wyamine

Class and Category

Chemical class: Sympathomimetic amine

Therapeutic class: Vasopressor

Pregnancy category: C

Indications and Dosages

↗ *To treat hypotension secondary to spinal anesthesia*

I.V. INJECTION

Adults. 30 to 45 mg (15 mg for obstetric patients); may be repeated, as needed, to maintain blood pressure.

I.V. INFUSION

Adults. Dosage individualized based on patient response to therapy. Average dose is 1 to 5 mg/min.

Route	Onset	Peak	Duration
I.V.	Almost immediate	Unknown	15–30 min

Mechanism of Action

Stimulates alpha-adrenergic receptors directly and indirectly, resulting in positive inotropic and chronotropic effects. Indirect stimulation occurs by release of norepinephrine from its storage sites in the heart and other tissues. By enhancing cardiac contraction, mephentermine improves cardiac output, thereby increasing blood pressure. Increased peripheral resistance from peripheral vasoconstriction may also contribute to increased blood pressure. Drug can affect heart rate but change is variable, based on vagal tone. It also may stimulate beta-adrenergic receptors.

Contraindications

Hypersensitivity to mephentermine, phenothiazine-induced hypotension, use within 14 days of MAO inhibitor therapy

Interactions

DRUGS

alpha blockers and other drugs with alpha-blocking effects: Possibly decreased peripheral vasoconstrictive and hypertensive effects of mephentermine

beta blockers (ophthalmic): Decreased effects of mephentermine; increased risk of bronchospasm, wheezing, decreased pulmonary function, and respiratory failure

beta blockers (systemic): Increased risk of bronchospasm and decreased effects of both drugs

diuretics and other antihypertensives:

Possibly reduced effectiveness of these drugs

doxapram: Possibly increased vasopressor effects of either drug

ergot alkaloids: Increased vasopressor effects

guanadrel, guanethidine, mecamlamine, methyldopa, reserpine: Possibly decreased effects of these drugs and increased risk of adverse effects

hydrocarbon inhalation anesthetics:

Increased risk of atrial and ventricular arrhythmias

MAO inhibitors: Increased, lengthened cardiac stimulation and vasopressor effects, and possibly severe headache and hypertensive crisis

maprotiline, tricyclic antidepressants:

Increased vasopressor response; increased risk of prolonged QTc interval, arrhythmias, hypertension, and hyperpyrexia

methylphenidate: Possibly increased vasopressor effect of mephentermine

nitrates: Possibly reduced antianginal effects of nitrates and decreased vasopressor effect

other sympathomimetics (such as dopamine): Possibly increased cardiac effects and adverse reactions

oxytocin: Possibly severe hypertension

thyroid hormones: Increased effects of both drugs, increased risk of coronary insufficiency in patients with coronary artery disease

Adverse Reactions

CNS: Anxiety, dizziness, drowsiness, euphoria, headache, incoherence, nervousness, psychosis, restlessness, seizures, weakness

CV: Angina, arrhythmias (including bradycardia, tachycardia, and ventricular arrhythmias), hypertension, hypotension, palpitations, peripheral vasoconstriction

GI: Nausea, vomiting

RESP: Dyspnea

SKIN: Peripheral necrosis

Nursing Considerations

- Before giving mephentermine, expect to intervene, as ordered, to correct hemorrhage, hypovolemia, metabolic acidosis, or hypoxia.
- Discard vial if you observe discoloration or precipitate.
- Using D₅W or normal saline solution, prepare a 1-mg/ml solution for infusion.
- Administer drug using an infusion pump to provide a controlled rate.
- Monitor blood pressure, cardiac rate and

rhythm, central venous pressure (if appropriate), and urine output during administration. Adjust infusion rate according to patient response, as ordered. Be aware that patients with a history of cardiovascular disease (including hypertension) or hyperthyroidism and chronically ill patients are at increased risk for mephentermine's adverse cardiovascular effects.

- Assess patients with angle-closure glaucoma for signs of an exacerbation, such as eye pain or blurred vision.
- Assess circulation in patients with a history of occlusive vascular disease, such as atherosclerosis and Raynaud's disease, because mephentermine may cause decreased circulation and increase risk of necrosis or gangrene. Inspect I.V. site periodically for signs of extravasation.

WARNING Be aware that weeping, excitability, seizures, and hallucinations are some of the symptoms of mephentermine overdose. Contact prescriber immediately if patient has such symptoms, and expect to provide supportive treatment.

- Be aware that mephentermine can increase contractions in pregnant women, especially during third trimester. Expect drug to be prescribed only when benefits outweigh potential adverse effects.
- Store drug at 59° to 86° F (15° to 30° C); don't freeze.

PATIENT TEACHING

- Instruct patient receiving mephentermine to report adverse reactions, including chest pain, difficulty breathing, dizziness, irregular heartbeat, headache, and weakness.

mephenytoin

Mesantoin

Class and Category

Chemical class: Hydantoin derivative

Therapeutic class: Anticonvulsant

Pregnancy category: Not rated

Indications and Dosages

↗ *To control generalized tonic-clonic, focal, and jacksonian seizures when other drugs are ineffective*

TABLETS

Adults. *Initial:* 50 to 100 mg daily during first wk. Increased by 50 to 100 mg at 1-wk

intervals until desired response is reached.

Maintenance: 200 to 600 mg daily in equally divided doses. *Maximum:* 1.2 g daily.

Children. *Initial:* 20 to 50 mg daily.

Increased by 25 to 50 mg at 1-wk intervals until desired response occurs. *Maintenance:* 100 to 400 mg daily in equally divided doses. *Maximum:* 400 mg daily.

↗ *To replace other anticonvulsants*

TABLETS

Adults. 50 to 100 mg daily during first wk. Dosage gradually increased while decreasing dosage of other drug over 3 to 6 wk.

Route	Onset	Peak	Duration
P.O.	30 min	Unknown	24–48 hr

Mechanism of Action

Limits spread of seizure activity and start of new seizures by:

- regulating voltage-dependent sodium and calcium channels in neurons
- inhibiting calcium movement across neuronal membranes
- enhancing sodium-potassium adenosine triphosphatase activity in neurons and glial cells.

These actions may reflect a slowed recovery rate of inactivated sodium channels.

Contraindications

Hypersensitivity to mephenytoin, phenytoin, other hydantoins, or their components

Interactions

DRUGS

acetaminophen: Increased risk of hepatotoxicity with long-term acetaminophen use

amiodarone: Possibly increased blood mephenytoin level and risk of toxicity

antacids: Possibly decreased mephenytoin effectiveness

antineoplastics: Increased mephenytoin metabolism

bupropion, clozapine, loxapine, MAO inhibitors, maprotiline, phenothiazines, pimozide, thioxanthenes: Possibly lowered seizure

threshold and decreased therapeutic effects of mephenytoin, possibly intensified CNS depressant effects of these drugs

calcium channel blockers, fluconazole, itraconazole, ketoconazole, miconazole, omeprazole: Possibly increased phenytoin level

carbamazepine: Decreased blood carbamazepine level, possibly increased blood phen-

ytoin level and risk of toxicity
chloramphenicol, cimetidine, disulfiram, isoniazid, methylphenidate, metronidazole, phenylbutazone, ranitidine, salicylates, sulfonamides, trimethoprim: Possibly impaired metabolism of these drugs and increased risk of mephenytoin toxicity
corticosteroids, cyclosporine, digoxin, disopyramide, doxycycline, furosemide, levodopa, mexiletine, quinidine: Decreased therapeutic effects of these drugs
diazoxide: Possibly decreased therapeutic effects of both drugs
estrogens, progestins: Decreased therapeutic effects of these drugs, increased blood phenytoin level
felbamate: Possibly impaired metabolism and increased blood level of phenytoin
fluoxetine: Possibly increased blood phenytoin level and risk of toxicity
folic acid: Increased mephenytoin metabolism, decreased seizure control
haloperidol: Possibly lowered seizure threshold and decreased therapeutic effects of mephenytoin; possibly decreased blood haloperidol level
insulin, oral antidiabetic drugs: Possibly increased blood glucose level and decreased therapeutic effects of these drugs
lamotrigine: Possibly decreased therapeutic effects of lamotrigine
lithium: Increased risk of lithium toxicity
methadone: Possibly increased methadone metabolism and withdrawal symptoms
molindone: Possibly lowered seizure threshold, impaired absorption, and decreased therapeutic effects of mephenytoin
oral anticoagulants: Possibly impaired metabolism of these drugs and increased risk of mephenytoin toxicity; possibly increased anticoagulant effect initially, but decreased effect with prolonged therapy
oral contraceptives containing estrogen and progestin: Possibly breakthrough bleeding and decreased contraceptive effectiveness
rifampin: Possibly decreased therapeutic effects of mephenytoin
streptozocin: Possibly decreased therapeutic effects of streptozocin
sucralfate: Possibly decreased mephenytoin absorption
tricyclic antidepressants: Possibly lowered seizure threshold and decreased therapeutic effects of mephenytoin; possibly decreased

blood level of tricyclic antidepressants
valproic acid: Decreased blood phenytoin level, increased blood valproic acid level
vitamin D analogues: Decreased vitamin D analogue activity, risk of anticonvulsant-induced rickets and osteomalacia
xanthines: Possibly inhibited mephenytoin absorption and increased clearance of xanthines
zaleplon: Increased clearance and decreased effectiveness of zaleplon

ACTIVITIES

alcohol use: Possibly decreased mephenytoin effectiveness

Adverse Reactions

CNS: Ataxia, choreoathetoid movements, confusion, dizziness, drowsiness, excitement, fatigue, fever, headache, peripheral neuropathy, sedation, slurred speech, stuttering, tremor

EENT: Gingival hyperplasia, nystagmus

GI: Constipation, diarrhea, nausea, vomiting

HEME: Agranulocytosis, leukopenia, thrombocytopenia

MS: Muscle twitching

SKIN: Rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Lymphadenopathy, systemic lupus erythematosus

Nursing Considerations

- Because of mephenytoin's potentially dangerous adverse effects, expect to use it only when other drugs are ineffective.
- Keep in mind that mephenytoin doesn't control absence seizures.

WARNING Be aware that drug shouldn't be discontinued abruptly because doing so may cause status epilepticus. Plan to reduce dosage gradually or substitute another drug, as prescribed.

- Obtain CBC and differential before treatment, after 2 weeks, and then monthly during first year of treatment, as ordered.
- If patient has depressed blood counts, enlarged lymph nodes, or rash, notify prescriber immediately and expect to stop mephenytoin and substitute another drug.

PATIENT TEACHING

- Urge patient to take mephenytoin exactly as prescribed and not to stop abruptly.
- Advise patient to take drug with food to enhance absorption and reduce adverse GI reactions.

- Caution patient on once-a-day therapy to be especially careful not to miss a dose.
- Advise patient to report impaired coordination, persistent headache, rash, severe GI distress, swollen gums or lymph nodes, or unusual bleeding or bruising.
- Encourage patient to maintain good oral hygiene and to have regular dental check-ups to reduce risk of gum disease.
- Instruct patient to keep medical appointments to monitor drug effectiveness and check for adverse reactions. Explain the need for periodic laboratory tests.
- Advise patient to wear medical identification stating that he has epilepsy and takes mephenytoin to prevent seizures.

mephobarbital

Mebaral

Class, Category, and Schedule

Chemical class: Barbiturate derivative

Therapeutic class: Anticonvulsant, sedative

Pregnancy category: D

Controlled substance schedule: IV

Indications and Dosages

↗ *To treat seizures*

TABLETS

Adults. 400 to 600 mg daily as a single dose or in divided doses, usually beginning with low dose and increasing over 4 to 5 days until optimum dosage is determined.

Children over age 5. 32 to 64 mg t.i.d. or q.i.d.

Children under age 5. 16 to 32 mg t.i.d. or q.i.d.

↗ *To provide sedation*

TABLETS

Adults. 32 to 100 mg t.i.d. or q.i.d.

Children. 16 to 32 mg t.i.d. or q.i.d.

Route	Onset	Peak	Duration
P.O.	30–60 min	Unknown	10–16 hr

Mechanism of Action

May reduce seizure activity by reducing transmission of monosynaptic and polysynaptic nerve impulses, which decreases excitability in nerve cells. As a sedative, mephobarbital inhibits upward conduction of nerve impulses to the reticular formation

of the brain, which disrupts impulse transmission to the cortex. As a result, mephobarbital depresses the CNS and produces drowsiness, hypnosis, and sedation.

Contraindications

Hepatic disease or failure; history of addiction to sedatives or hypnotics; hypersensitivity to mephobarbital, other barbiturates, or their components; nephritis; porphyria; severe respiratory disease with obstruction or dyspnea

Interactions

DRUGS

acetaminophen: Possibly decreased effects of acetaminophen (with long-term mephobarbital use)

anesthetics (halogenated hydrocarbon):

Increased risk of hepatotoxicity (with long-term mephobarbital use)

carbamazepine, chloramphenicol, corticosteroids, cyclosporine, dacarbazine, digoxin, disopyramide, doxycycline, griseofulvin,

metronidazole, oral contraceptives, phenylbutazone, quinidine, theophyllines, vitamin D: Decreased effectiveness of these drugs

CNS depressants: Increased CNS depression

divalproex sodium, valproic acid: Increased risk of CNS depression and neurotoxicity

guanadrel, guanethidine: Increased risk of orthostatic hypotension

haloperidol: Possibly decreased blood haloperidol level and change in seizure pattern

hydantoins: Possibly interference with hydantoin metabolism

leucovorin: Possibly decreased anticonvulsant effect of mephobarbital

maprotiline: Possibly increased CNS depression and decreased therapeutic effects of mephobarbital

mexiletine: Possibly decreased blood mexiletine level

oral anticoagulants: Possibly decreased therapeutic effects of anticoagulants, possibly increased risk of bleeding when mephobarbital is discontinued

tricyclic antidepressants: Possibly decreased therapeutic effects of tricyclic antidepressants

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Agitation, anxiety, ataxia, confusion,

delusions, depression, dizziness, drowsiness, fever, hallucinations, headache, insomnia, irritability, nervousness, nightmares, paradoxical stimulation, seizures, syncope, tremor

CV: Orthostatic hypotension

EENT: Vision changes

GI: Anorexia, constipation, hepatic dysfunction, nausea, vomiting

HEME: Agranulocytosis

MS: Arthralgia, bone pain, muscle twitching or weakness

RESP: Respiratory depression

SKIN: Exfoliative dermatitis, rash, Stevens-Johnson syndrome

Other: Physical and psychological dependence, weight loss

Nursing Considerations

- Observe patient for signs of physical and psychological dependence, especially with prolonged use at high doses.
- Observe for signs of chronic barbiturate intoxication, including confusion, insomnia, poor judgment, slurred speech, and unsteady gait.
- Assess for paradoxical stimulation in patient who receives drug for acute or chronic pain.

WARNING Expect to taper mephobarbital gradually when discontinuing. Be aware that withdrawal symptoms can be severe and may cause death. Mild signs and symptoms may include anxiety, muscle twitching, nausea, orthostatic hypotension, and progressive weakness and may appear 8 to 12 hours after last dose. More severe signs include delirium and seizures.

PATIENT TEACHING

- Advise patient to take mephobarbital exactly as prescribed. Caution him not to stop taking drug abruptly because of possible withdrawal symptoms and, for epileptic patients, seizures.
- Instruct patient to avoid alcohol, sleeping pills, and other sedatives while taking mephobarbital because of the risk of increased CNS depression.
- Advise patient to avoid hazardous activities until CNS effects of drug are known.
- Advise patient to change position slowly to minimize orthostatic hypotension.
- Urge patient to report confusion, fever, rash, or severe dizziness.

meprobamate

Apo-Meprobamate (CAN), Equanil, MB-Tab, Meprospan, Miltown, Neuramate

Class, Category, and Schedule

Chemical class: Carbamate derivative

Therapeutic class: Antianxiety

Pregnancy category: Not rated

Controlled substance schedule: IV

Indications and Dosages

↗ *To treat anxiety*

S.R. CAPSULES

Adults and adolescents. 400 to 800 mg every morning and bedtime. *Maximum:* 2,400 mg daily.

Children ages 6 to 12. 200 mg every morning and bedtime.

TABLETS

Adults and adolescents. 1,200 to 1,600 mg/day in divided doses t.i.d. or q.i.d.

Maximum: 2,400 mg daily.

DOSAGE ADJUSTMENT For patients with creatinine clearance of 10 to 50 ml/min/1.73 m², drug given every 12 hr; with creatinine clearance less than 10 ml/min/1.73 m², drug given every 18 hr.

Children ages 6 to 12. 200 to 600 mg daily in divided doses b.i.d. or t.i.d.

Route	Onset	Peak	Duration
P.O.	1 hr	Unknown	Unknown

Mechanism of Action

May act at multiple sites in CNS, including thalamus and limbic system. Meprobamate inhibits spinal reflexes, causing CNS relaxation; its sedative effects may account for its anticonvulsant action. It also has muscle relaxant properties.

Contraindications

Hypersensitivity to meprobamate or related drugs, such as carisoprodol; porphyria

Interactions

DRUGS

CNS depressants: Increased CNS depression

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Ataxia, dizziness, drowsiness, euphoria, headache, paradoxical stimulation,

paresthesia, slurred speech, syncope, vertigo, weakness

CV: Arrhythmias, including tachycardia; hypotension; palpitations

EENT: Impaired visual accommodation

GI: Diarrhea, nausea, vomiting

SKIN: Erythematous maculopapular rash, pruritus, urticaria

Other: Physical dependence

Nursing Considerations

- Use meprobamate cautiously in patients with impaired hepatic or renal function, seizure disorders, or suicidal tendencies.
- Also use drug cautiously in patients with history of drug dependence or abuse because meprobamate use can lead to physical dependence and abuse.
- Observe for evidence of chronic drug intoxication, such as ataxia, slurred speech, and vertigo.

WARNING When stopping therapy, expect to taper dosage over 2 weeks because stopping abruptly can worsen previous symptoms, such as anxiety, or cause withdrawal symptoms, such as confusion, hallucinations, muscle twitching, tremor, and vomiting.

PATIENT TEACHING

- Instruct patient to take meprobamate exactly as directed and not to stop taking it abruptly.
- Advise patient not to crush or chew S.R. capsules.
- Instruct patient to avoid hazardous activities until drug's CNS effects are known.
- Direct patient to avoid alcohol, sedatives, and other CNS depressants while taking meprobamate.
- Inform patient that drug may become less effective after several months of treatment.
- Instruct patient to report rash.

meropenem

Merrem I.V.

Class and Category

Chemical class: Carbapenem

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ *To treat complicated appendicitis and*

peritonitis caused by susceptible strains of alpha-hemolytic streptococci, Bacteroides fragilis, Bacteroides thetaio-tomicron, Escherichia coli, Klebsiella pneumoniae, Peptostreptococcus species, or Pseudomonas aeruginosa

I.V. INFUSION OR INJECTION

Adults and children weighing more than 50 kg (110 lb). 1 g every 8 hr infused over 15 to 30 min or given as a bolus over 3 to 5 min.

Children over age 3 months weighing less than 50 kg. 20 mg/kg every 8 hr infused over 15 to 30 min or given as bolus over 3 to 5 min. *Maximum:* 1 g every 8 hr.

DOSAGE ADJUSTMENT For patients with creatinine clearance of 26 to 50 ml/min/1.73 m², dosage reduced to 1 g every 12 hr. For those with clearance of 10 to 25 ml/min/1.73 m², dosage reduced to 500 mg every 12 hr. For those with clearance less than 10 ml/min/1.73 m², dosage reduced to 500 mg every 24 hr.

↗ *To treat complicated skin and skin structure infections caused by Staphylococcus aureus, Streptococcus agalactiae, Streptococcus pyogenes, viridans group streptococci, Enterococcus faecalis (excluding vancomycin-resistant isolates), Pseudomonas aeruginosa, Escherichia coli, Proteus mirabilis, Bacteroides fragilis, and Peptostreptococcus species*

I.V. INFUSION

Adults and children weighing more than 50 kg (110 lb). 500 mg every 8 hr infused over 15 to 30 min.

Children over age 3 months weighing less than 50 kg. 10 mg/kg every 8 hr infused over 15 to 30 min. *Maximum:* 500 mg every 8 hr.

DOSAGE ADJUSTMENT For patients with creatinine clearance of 26 to 50 ml/min/1.73 m², dosage reduced to 500 mg every 12 hr. For those with clearance of 10 to 25 ml/min/1.73 m², dosage reduced to 250 mg every 12 hr. For those with clearance less than 10 ml/min/1.73 m², dosage reduced to 250 mg every 24 hr.

↗ *To treat bacterial meningitis caused by Haemophilus influenzae, Neisseria meningitidis, or Streptococcus pneumoniae in children*

I.V. INFUSION OR INJECTION

Children weighing more than 50 kg. 2 g every 8 hr infused over 15 to 30 min or given as a bolus over 3 to 5 min.

Children over age 3 months weighing less than 50 kg. 40 mg/kg every 8 hr infused over 15 to 30 min or given as bolus over 3 to 5 min. *Maximum:* 2 g every 8 hr.

Mechanism of Action

Penetrates cell walls of most gram-negative and gram-positive bacteria, inactivating penicillin-binding proteins. This action inhibits bacterial cell wall synthesis and causes cell death.

Incompatibilities

Don't mix meropenem in same solution with other drugs.

Contraindications

Hypersensitivity to meropenem, other carbapenem drugs, beta lactams, or their components

Interactions

DRUGS

probenecid: Inhibited renal excretion of meropenem

valproic acid: Possibly reduced blood level of valproic acid to subtherapeutic level

Adverse Reactions

CNS: Headache, seizures

CV: Shock

EENT: Epistaxis, glossitis, oral candidiasis

GI: Anorexia, constipation, diarrhea, elevated liver function test results, nausea, pseudomembranous colitis, vomiting

GU: Elevated BUN and serum creatinine levels, hematuria, renal failure

HEME: Agranulocytosis, hemolytic anemia, leukopenia, neutropenia, positive Coombs' test

RESP: Apnea, dyspnea

SKIN: Diaper rash from candidiasis (children), erythema multiforme, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis; angioedema; injection site inflammation, pain, phlebitis, or thrombophlebitis; sepsis

Nursing Considerations

- Obtain body fluid and tissue samples, as ordered, for culture and sensitivity testing. Expect to review test results, if possible, before giving first dose of meropenem.

- For I.V. bolus, add 10 ml sterile water for injection to 500 mg/20-ml vial, or 20 ml diluent to 1 g/30-ml vial of drug. Shake to dissolve.

WARNING Be aware that fatal hypersensitivity reactions have occurred with meropenem use. Determine whether patient has had previous reactions to antibiotics or other allergens. Monitor patient closely and stop drug immediately if signs and symptoms of anaphylaxis occur. Notify prescriber, and expect to provide supportive emergency care that may include epinephrine and I.V. steroid administration, oxygen, and airway management.

- Monitor patient closely for diarrhea, which may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold meropenem and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- Take seizure precautions according to facility policy, especially for patients with bacterial meningitis or CNS or renal disorders because of an increased risk of seizures with meropenem.
- Monitor patient with creatinine clearance of 10 to 26 ml/min/1.73 m² for signs and symptoms of seizures, heart failure, renal failure, or shock.

PATIENT TEACHING

- Tell patient to report trouble breathing, injection site pain, and sore mouth.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.

mesalamine

Asacol, Canasa, Lialda, Mesasal (CAN), Pentasa, Rowasa, Salofalk (CAN)

Class and Category

Chemical class: 5-Aminosalicylic acid derivative

Therapeutic class: Anti-inflammatory

Pregnancy category: B

Indications and Dosages

➤ To treat and maintain remission of

*ulcerative colitis***DELAYED-RELEASE TABLETS (ASACOL)****Adults.** *Initial:* 0.8 g t.i.d. for 6 wk.*Maintenance:* 1.6 g daily in divided doses.**DELAYED-RELEASE TABLETS (MESASAL)****Adults.** 1.5 to 3 g daily in divided doses for 6 wk.**DELAYED-RELEASE TABLETS (SALOFALK)****Adults.** 1 g t.i.d. or q.i.d. for 6 wk.**E.R. CAPSULES****Adults.** 1 g q.i.d. for up to 8 wk.

↗ *To treat mild to moderate distal ulcerative colitis, proctitis, and proctosigmoiditis*

RECTAL SUSPENSION**Adults.** 4 g (60 ml) daily at bedtime for 3 to 6 wk.

↗ *To treat active ulcerative proctitis*

SUPPOSITORIES (CANASA)**Adults.** 0.5 g b.i.d. or t.i.d. for 3 to 6 wk. Or 1 g at bedtime for 3 to 6 wk.

↗ *To induce remission in patients with active mild to moderate ulcerative colitis.*

TABLETS**Adults.** 2.4 or 4.8 g once daily with a meal for up to 8 wk.**Mechanism of Action**

May reduce inflammation by inhibiting the enzyme cyclooxygenase and decreasing production of arachidonic acid metabolites, which may be increased in patients with inflammatory bowel disease. Cyclooxygenase is needed to form prostaglandins from arachidonic acid. Prostaglandins mediate inflammatory activity and produce signs and symptoms of inflammation. Mesalamine also may reduce inflammation by interfering with leukotriene synthesis and inhibiting the enzyme lipoxygenase, both of which take part in inflammatory response.

Contraindications

Hypersensitivity to mesalamine, salicylates, or their components

Interactions**DRUGS**

digoxin: Possibly decreased absorption and bioavailability of digoxin

lactulose: Possibly interference with delayed-release tablets or E.R. capsules

omeprazole: Increased mesalamine absorption

Adverse Reactions

CNS: Chills, confusion, depression, dizzi-

ness, emotional lability, fatigue, fever, headache (severe), somnolence, tremor, vertigo, weakness

CV: Myocarditis, pericarditis

EENT: Blurred vision, dry mouth, rhinitis, taste perversion, tinnitus

GI: Abdominal cramps or pain (severe), anorexia, bloody diarrhea, cholecystitis, colitis, diarrhea, elevated liver function test results, flatulence, gastritis, hepatotoxicity, hepatitis, indigestion, nausea, pancreatitis, rectal pain, vomiting

GU: Acute or chronic renal failure, interstitial nephritis, nephrotoxicity

HEME: Agranulocytosis, anemia including aplastic anemia, eosinophilia, granulocytopenia, leukopenia, lymphadenopathy, thrombocytopenia

MS: Back pain, dysarthria, gout

RESP: Allergic alveolitis, asthma exacerbation, fibrosing alveolitis, pleuritis, pneumonitis

SKIN: Acne, alopecia, dryness, erythema nodosum, pruritus, rash, urticaria

Other: Angioedema, drug fever, systemic lupus erythematosus

Nursing Considerations

- Use mesalamine cautiously in patients with sulfite sensitivity. Some drug formulations contain sulfites, which may cause hypersensitivity reactions in these patients.
- Use mesalamine cautiously in patients with liver disease because hepatic dysfunction may occur.
- Ensure that suppository is firm before inserting it. If it's too soft, chill in refrigerator for 30 minutes or run under cold water before removing wrapper. Moisten with water-soluble lubricant or tap water before insertion. Have patient retain suppository for 1 to 3 hours, as directed.
- Give rectal suspension at bedtime, and have patient retain for prescribed time—about 8 hours, if possible. Retention time ranges from 3.5 to 12 hours.
- Be aware that rectal suspension may darken slightly over time but that this change doesn't affect potency. Discard rectal suspension that turns dark brown.
- Assess patient for evidence of acute intolerance similar to flare-up of inflammatory bowel disease: acute abdominal cramps and pain, bloody diarrhea, and, possibly, fever, headache, and rash.

- For patients with impaired renal function, expect to monitor renal function test results periodically during long-term therapy because drug may cause nephrotoxicity.
- Monitor patient's CBC with differential for eosinophilia, which may indicate an allergic reaction.

PATIENT TEACHING

- Instruct patient taking oral drug to swallow tablets or capsules whole and not to break outer coating by cutting or chewing.
- Tell patient taking extended-release product to take it with a meal.
- Teach patient how to use rectal suspension or suppositories correctly. Stress shaking suspension bottle well before using.
- Advise patient to notify prescriber immediately about abdominal cramps or pain, bloody diarrhea, fever, headache, or rash.

mesoridazine besylate

Serentil

Class and Category

Chemical class: Alkylpiperidine phenothiazine derivative

Therapeutic class: Antipsychotic

Pregnancy category: Not rated

Indications and Dosages

➤ *To treat schizophrenia in patients who failed to respond to other antipsychotic drugs, either because they were ineffective or because intolerable adverse effects prevented attainment of effective dose*

ORAL SOLUTION, TABLETS

Adults and adolescents. 50 mg t.i.d., increased as needed and tolerated.

Maximum: 400 mg daily.

I.M. INJECTION

Adults and adolescents. 25 mg, repeated in 30 to 60 min, as needed. *Maximum:* 200 mg/day.

Route	Onset	Peak	Duration
P.O., I.M.	Up to several wk	6 wk–6 mo	4–8 hr

Mechanism of Action

Depresses brain areas that control activity

and aggression—including cerebral cortex, hypothalamus, and limbic system—by an unknown mechanism.

Contraindications

Blood dyscrasias; bone marrow depression; cerebral arteriosclerosis; coma; concurrent use of high doses of CNS depressants; concurrent use of other drugs that prolong QTc interval, such as disopyramide, procainamide, and quinidine; congenital long-QT syndrome; coronary artery disease; hepatic dysfunction; history of arrhythmias; hypersensitivity to mesoridazine, other phenothiazines, or their components; myeloproliferative disorders; severe CNS depression; severe hypertension or hypotension; subcortical brain damage

Interactions

DRUGS

aluminum- or magnesium-containing antacids, antidiarrheals (adsorbent): Decreased mesoridazine absorption

amantadine, anticholinergics: Increased anticholinergic effects, possibly decreased therapeutic effects of mesoridazine

aminoglycosides, ototoxic drugs: Masked symptoms of ototoxicity, such as dizziness, tinnitus, and vertigo

anticonvulsants: Possibly lowered seizure threshold

antithyroid drugs: Increased risk of agranulocytosis

appetite suppressants: Possibly antagonized anorectic effect

astemizole, cisapride, disopyramide, erythromycin, pimozide, probucof, procainamide, quinidine: Increased risk of prolonged QT interval and life-threatening arrhythmias

beta blockers: Increased blood levels of both drugs, possibly resulting in additive hypotension, retinopathy, arrhythmias, and tardive dyskinesia

CNS depressants, general anesthetics:

Increased CNS depression

dextroamphetamine: Possibly interference with action of either drug

levodopa: Possibly inhibited levodopa effects

lithium: Possibly decreased absorption of mesoridazine

opioid analgesics: Possibly decreased mesoridazine effects; increased CNS and respiratory depression and orthostatic hypotension; increased risk of severe constipation

oral anticoagulants: Possibly decreased therapeutic effects of anticoagulants

sympathomimetics: Possibly decreased therapeutic effects of these drugs and increased risk of hypotension

thiazide diuretics: Possibly orthostatic hypotension, hyponatremia, and water intoxication

tricyclic antidepressants: Increased tricyclic antidepressant levels, inhibited mesoridazine metabolism, increased risk of neuroleptic malignant syndrome

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Ataxia, dizziness, drowsiness, extrapyramidal reactions (tardive dyskinesia, pseudoparkinsonism), fever, neuroleptic malignant syndrome, restlessness, seizures, slurred speech, syncope, tremor, weakness

CV: Hypotension, orthostatic hypotension, prolonged QTc interval, torsades de pointes

EENT: Blurred vision, dry mouth, hypertrophic papillae of tongue, increased salivation, photophobia

ENDO: Galactorrhea, gynecomastia

GI: Constipation, hepatotoxicity, nausea, vomiting

GU: Dysuria, ejaculation disorders, impotence, menstrual irregularities, priapism

HEME: Agranulocytosis, leukopenia, thrombocytopenia

SKIN: Contact dermatitis, decreased sweating, jaundice, photosensitivity, rash

Other: Injection site pain, weight gain

Nursing Considerations

- Before starting mesoridazine, expect to obtain a 12-lead ECG to detect prolonged QTc interval. If patient's QTc interval is greater than 450 milliseconds (msec), expect to withhold drug because of risk of life-threatening torsades de pointes.
- Wear gloves when working with liquid and parenteral forms of mesoridazine, and avoid contact with clothing or skin; drug may cause contact dermatitis.
- Discard injection solution if it's frankly discolored or contains precipitate; slightly yellow color is acceptable.
- Inject I.M. drug deep into upper outer quadrant of buttocks; massage area afterward to prevent sterile abscess.
- Implement continuous ECG monitoring,

as ordered, to detect arrhythmias. Expect to discontinue mesoridazine if the QTc interval exceeds 500 msec.

- Monitor serum potassium level before and during therapy, and administer potassium supplements as prescribed.
 - Assess patient for hypotension and orthostatic hypotension, especially during I.M. use. Notify prescriber if either develops.
- WARNING** Monitor patient for neuroleptic malignant syndrome, a potentially fatal reaction to antipsychotic drugs, and notify prescriber about such early signs as altered mental status, fever, hypertension or hypotension, muscle rigidity, and tachycardia.
- Assess patient for signs of blood dyscrasias, including cellulitis, fever, and pharyngitis. If they develop, expect to stop drug.
 - Monitor patient for signs of tardive dyskinesia, even after treatment stops. Notify prescriber if they develop.
 - Expect to taper drug dosage before discontinuation to avoid adverse reactions, such as dizziness, nausea, tremor, and vomiting.

PATIENT TEACHING

- Instruct patient to take drug exactly as prescribed and not to stop abruptly.
- Explain that I.M. injection may be painful.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to change position slowly to minimize orthostatic hypotension.
- Tell patient to report fever, involuntary facial movements, sore throat, unusual bleeding or bruising, and yellowing of eyes or skin.
- Urge patient to avoid alcohol and prolonged sun exposure during therapy.
- If patient need long-term therapy, explain the risk of tardive dyskinesia. Also advise him to have regular eye examinations.

metaproterenol sulfate

Alupent, Arm-a-Med Metaproterenol, Dey-Lute Metaproterenol

Class and Category

Chemical class: Sympathomimetic amine

Therapeutic class: Antiasthmatic, bronchodilator

Pregnancy category: C

Indications and Dosages

↗ *To treat bronchospasm*

SYRUP, TABLETS

Adults and children age 9 or over weighing more than 27 kg (59 lb). 20 mg every 6 to 8 hr.

Children ages 6 to 9 weighing 27 kg or less. 10 mg every 6 to 8 hr.

INHALATION AEROSOL

Adults and adolescents. 2 to 3 inhalations (1.3 to 1.95 mg) every 3 to 4 hr. *Maximum:* 12 inhalations daily.

Children ages 6 to 12. 1 to 3 inhalations (0.65 to 1.95 mg) every 3 to 4 hr.

Maximum: 12 inhalations daily.

INHALATION NEBULIZER

Adults and adolescents. 0.2 to 0.3 ml of 5% solution diluted in 2.5 ml normal saline solution t.i.d. or q.i.d., p.r.n., but no more than every 4 hr.

Children ages 6 to 12. 0.1 to 0.2 ml of 5% solution diluted in normal saline solution to a total volume of 3 ml t.i.d. or q.i.d., p.r.n., but no more than every 4 hr.

Route	Onset	Peak	Duration
P.O.	15 min	1 hr	4 hr or longer
Inhalation (aerosol)	1 min	1 hr	4 hr or longer
Inhalation (nebulizer)	5–30 min	Unknown	4 hr or longer

Mechanism of Action

Attaches to beta₂ receptors on bronchial cell membranes, which stimulates intracellular enzyme adenyl cyclase to convert adenosine triphosphate to cyclic adenosine monophosphate (cAMP). Increased intracellular cAMP level relaxes bronchial smooth-muscle cells and inhibits histamine release.

Contraindications

Angina, cerebral arteriosclerosis, dilated heart failure, heart block from digitalis toxicity, hypersensitivity to metaproterenol or its components, labor, local anesthesia, organic brain damage, tachyarrhythmias

Interactions

DRUGS

beta blockers: Increased risk of bronchospasm
MAO inhibitors, tricyclic antidepressants:

Possibly potentiated cardiovascular effects of metaproterenol
other sympathomimetics: Possibly additive effects of both drugs and risk of toxicity
theophylline: Increased risk of arrhythmias

Adverse Reactions

CNS: Dizziness, fatigue, headache, insomnia, malaise, nervousness, tremor

CV: ECG changes, hypertension, palpitations, tachycardia

EENT: Dry mouth, pharyngitis, taste perversion

GI: Diarrhea, nausea, vomiting

RESP: Asthma exacerbation, cough

Nursing Considerations

- Anticipate that a single dose of nebulized metaproterenol may not completely stop an acute asthma attack.
- Monitor for adverse reactions and signs of toxicity, especially if patient uses tablets and aerosol. Notify prescriber if they develop.
- Be aware that tolerance may occur with continued use.

PATIENT TEACHING

- Caution patient not to use metaproterenol inhaler or nebulizer more often than prescribed.
- Teach patient to use metaproterenol inhaler correctly, to hold breath during second half of inhalation, and to wait 2 minutes between inhalations.
- Instruct parents to use spacer with their child's metered-dose inhaler.
- Advise patient to use metaproterenol 5 minutes before using corticosteroid inhaler, if prescribed, to maximize airway opening and drug effects.
- Instruct patient to immediately report diarrhea, increased shortness of breath, insomnia, or irregular heartbeat.
- Instruct patient to notify prescriber if drug becomes less effective.

metaxalone

Skelaxin

Class and Category

Chemical class: Oxazolidinone derivative

Therapeutic class: Skeletal muscle relaxant

Pregnancy category: Not rated

Indications and Dosages

↗ *To relieve discomfort caused by acute, painful musculoskeletal conditions*

TABLETS

Adults and children over age 12. 800 mg t.i.d. or q.i.d.

Route	Onset	Peak	Duration
P.O.	Usually in 1 hr	Unknown	4–6 hr

Mechanism of Action

May depress CNS, causing sedation, which in turn may reduce skeletal muscle spasms to provide pain relief. Metaxalone doesn't directly relax tense skeletal muscles.

Contraindications

Hypersensitivity to metaxalone or its components, significant renal or hepatic disease, tendency to develop drug-induced, hemolytic, or other anemias

Interactions**DRUGS**

CNS depressants: Increased CNS depression

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Dizziness, drowsiness, excitement, general CNS depression, headache, insomnia, irritability, nervousness, restlessness

GI: Abdominal cramps or pain, GI upset, jaundice, hepatotoxicity, nausea, vomiting

HEME: Hemolytic anemia, leukopenia

SKIN: Pruritus, rash

Nursing Considerations

- Metaxalone may not be prescribed for women who are or may become pregnant unless potential benefits outweigh risks because drug's effect on fetus is unknown.
- Expect to avoid giving metaxalone with food because food may increase CNS depression, especially in elderly patients.
- Monitor patient for excessive drowsiness, which may lead to respiratory depression.
- Caution patient to consult prescriber before taking other drugs, such as sleeping pills, cold or allergy preparations, opioid analgesics, and antidepressants.
- Monitor liver function test results for elevations, especially in patients with preexisting hepatic disease.
- Monitor renal function test results, as pre-

scribed, for signs of impaired renal function because drug is excreted by kidneys.

- Provide rest and other pain-relief measures.
- Store drug at 59° to 86° F (15° to 30° C).

PATIENT TEACHING

- Advise patient to take metaxalone tablets exactly as prescribed and not to increase dosage or frequency.
- Instruct patient to take metaxalone tablets on an empty stomach.
- Caution patient to avoid hazardous activities, such as driving or operating machinery, until drug's CNS effects are known.
- Instruct patient to avoid alcohol and other CNS depressants during therapy.
- Urge patient to notify prescriber if he notices a rash or itching, which may signify a hypersensitivity reaction, or if he develops signs of hepatotoxicity, such as tiredness, nausea, yellow skin, or flulike symptoms.

metformin hydrochloride

Fortamet, Gen-Metformin (CAN), Glucophage, Glucophage XR, Glumetza, Glycon (CAN), Novo-Metformin (CAN), Riomet

Class and Category

Chemical class: Dimethylbiguanide

Therapeutic class: Antidiabetic

Pregnancy category: B

Indications and Dosages

↗ *To reduce blood glucose level in type 2 diabetes mellitus*

ORAL SOLUTION, TABLETS

Adults and children age 10 and over.

Initial: 500 mg b.i.d. or 850 mg daily, increased as prescribed by 500 mg/wk or by 850 mg every 2 wk until desired response occurs. *Usual:* 500 to 850 mg b.i.d. or t.i.d. *Maximum:* 2,550 mg daily (adults and adolescents age 17 and over); 2,000 mg daily (children ages 10 to 16).

DOSAGE ADJUSTMENT If patient uses insulin, initial dosage reduced to 500 mg daily and then increased as prescribed by 500 mg weekly until blood glucose level is controlled.

E.R. TABLETS (GLUCOPHAGE XR, GLUMETZA)

Adults and adolescents age 18 and over.

Initial: 500 mg daily (Glucophage XR) or 1,000 mg daily (Glumetza) with evening meal. Increased as prescribed by 500 mg/wk. *Maximum:* 2,000 mg daily.

DOSE ADJUSTMENT If control isn't achieved with maximum once-daily E.R. dosage, regimen may be changed to 1,000 mg b.i.d. If control isn't achieved after 4 wk of maximum dosage, an oral sulfonylurea may be prescribed.

E.R. TABLETS (FORTAMET)**Adults and adolescents age 17 and over.**

Initial: 500 to 1,000 mg once daily in evening. Increased in increments of 500 mg weekly, as needed. *Maximum:* 2,500 mg daily. If control isn't achieved after 4 wk at maximum dosage, an oral sulfonylurea may be prescribed.

↗ *As adjunct to insulin therapy in type 2 diabetes mellitus*

ORAL SOLUTION, TABLETS, E.R. TABLETS

Adults. *Initial:* 500 mg (Glucophage, Glucophage XR, Fortamet) or 1,000 mg (Glumetza) daily in addition to current dose of insulin. Increased by 500 mg/wk, as needed. *Maximum:* 2,000 mg for Glucophage XR and Glumetza; 2,500 mg for Glucophage and Fortamet.

DOSE ADJUSTMENT If fasting blood glucose level drops below 120 mg/dl, insulin dosage decreased by 10% to 25%. Subsequent insulin dosage decrease may be needed based upon patient's continued response.

Route	Onset	Peak	Duration
P.O. (tablets)	Unknown	Up to 2 wk	2 wk after drug dis- continued

Mechanism of Action

May promote storage of excess glucose as glycogen in the liver, which reduces glucose production. Metformin also may improve glucose use by skeletal muscle and adipose tissue by increasing glucose transport across cell membranes. This drug also may increase the number of insulin receptors on cell membranes and make them more sensitive to insulin. In addition, metformin modestly decreases blood triglyceride and total cholesterol levels.

Contraindications

Hypersensitivity to metformin or its components, impaired renal function, metabolic acidosis, use of iodinated contrast media within preceding 48 hours

Interactions**DRUGS**

calcium channel blockers, corticosteroids, estrogens, isoniazid, nicotinic acid, oral contraceptives, phenothiazines, phenytoin, sympathomimetics, thiazide and other diuretics, thyroid drugs: Possibly hyperglycemia
cationic drugs (such as amiloride, cimetidine, digoxin, morphine, procainamide, quinidine, quinine, ranitidine, triamterene, trimethoprim, vancomycin), nifedipine: Increased blood metformin level
clofibrate, MAO inhibitors, probenecid, propranolol, rifabutin, rifampin, salicylates, sulfonamides, sulfonylureas: Increased risk of hypoglycemia

FOODS

all foods: Possibly delayed metformin absorption

ACTIVITIES

alcohol use: Increased risk of hypoglycemia and lactate formation

Adverse Reactions

CNS: Headache

EENT: Metallic taste

ENDO: Hypoglycemia

GI: Abdominal distention, anorexia, constipation, diarrhea, flatulence, indigestion, nausea, vomiting

HEME: Aplastic anemia, megaloblastic anemia, thrombocytopenia

SKIN: Photosensitivity, rash

Other: Lactic acidosis, weight loss

Nursing Considerations

- Give metformin tablets with food, which decreases and slightly delays absorption, thus reducing risk of adverse GI reactions. Give E.R. tablets with evening meal; don't break or crush them.
- Expect prescriber to alter dosage if patient has a condition that decreases or delays gastric emptying, such as diarrhea, gastroparesis, GI obstruction, ileus, or vomiting.
- Expect to assess BUN and serum creatinine level before and during long-term therapy in those at increased risk for lactic acidosis.

- Monitor patient's hepatic function, as ordered, because impaired hepatic function may significantly reduce the liver's ability to clear lactate, predisposing the patient to lactic acidosis.
- Monitor patient's blood glucose level to evaluate drug effectiveness. Assess for hyperglycemia and the need for insulin during times of increased stress, such as infection and surgery.
- Withhold drug, as ordered, if patient becomes dehydrated or develops hypoxemia or sepsis because these conditions increase the risk of lactic acidosis.
- Iodinated contrast media used in radiographic studies increases risk of renal failure and lactic acidosis during metformin therapy. Expect to withhold drug for 48 hours before and after testing.

PATIENT TEACHING

- Instruct patient to take metformin tablet at breakfast if taking drug once a day or at breakfast and dinner if taking drug twice a day. Instruct him to take E.R. tablets once daily with evening meal and to swallow them whole without crushing or chewing.
- Direct patient to take drug exactly as prescribed and not to change the dosage or frequency unless instructed.
- Stress importance of following prescribed diet, exercising regularly, controlling weight, and checking blood glucose level.
- Teach patient how to measure blood glucose level and recognize hyperglycemia and hypoglycemia. Urge him to notify prescriber of abnormal blood glucose level.
- Caution patient to avoid alcohol, which can increase the risk of hypoglycemia.
- Instruct patient to report early signs of lactic acidosis, including drowsiness, hyperventilation, malaise, and muscle pain.
- Advise patient to expect laboratory testing of glycosylated hemoglobin every 3 months until blood glucose is controlled.

methadone hydrochloride

Dolophine, Methadose

Class, Category, and Schedule

Chemical class: Phenylheptylamine

Therapeutic class: Synthetic opiate agonist

Pregnancy category: C

Controlled substance schedule: II

Indications and Dosages

➤ *To manage opioid detoxification*

DISPERSIBLE TABLETS, ORAL CONCENTRATE, I.M. OR SUBCUTANEOUS INJECTION

Adults. *Initial:* 15 to 40 mg daily or as needed. *Usual:* Dosage individualized based on clinical response. *Maximum:* 120 mg daily.

Children. Dosage individualized based on age and size. *Maximum:* 120 mg daily.

➤ *To maintain opioid abstinence*

DISPERSIBLE TABLETS, ORAL CONCENTRATE

Adults. Dosage individualized based on clinical response. *Maximum:* 120 mg daily.

Children. Dosage individualized based on age and size. *Maximum:* 120 mg daily.

➤ *To treat severe or chronic pain*

ORAL CONCENTRATE, ORAL SOLUTION

Adults. 5 to 20 mg every 4 to 8 hr. Dosage increased or dosing interval decreased, as prescribed and as needed. *Maximum:* 120 mg/day.

Children. Dosage individualized based on age and size.

TABLETS, I.M. OR SUBCUTANEOUS INJECTION

Adults. 2.5 to 10 mg every 3 to 4 hr as needed. For chronic pain, dosage and dosing interval may be adjusted, as prescribed and as needed.

Children. Dosage individualized based on age and size.

DOSAGE ADJUSTMENT Elderly patients, debilitated patients, and patients with severe hepatic or renal dysfunction, hypothyroidism, Addison's disease, prostatic hyperplasia, or urethral stricture need individualized reduced dosages.

Route	Onset	Peak	Duration
P.O.	30–60 min	1.5–2 hr	4–6 hr
I.M.	10–20 min	1–2 hr	4–5 hr

Mechanism of Action

Binds with and activates opioid receptors (primarily mu receptors) in spinal cord and higher levels of CNS to produce analgesia and euphoric effects.

Contraindications

Acute or postoperative pain, acute or severe asthma, chronic respiratory disease, diar-

rhea related to pseudomembranous colitis or poisoning, hypersensitivity to methadone or its components, respiratory depression, severe inflammatory bowel disease

Interactions

DRUGS

ammonium chloride, ascorbic acid, potassium, sodium phosphate: May precipitate methadone withdrawal symptoms
amitriptyline, chloripramine, nortriptyline: Increased CNS and respiratory depression
anticholinergics: Possibly severe constipation leading to ileus; urine retention
antiemetics, general anesthetics, hypnotics, phenothiazines, sedatives, tranquilizers: Possibly coma, hypotension, respiratory depression, and severe sedation
antihistamines, choral hydrate, glutethimide, MAO inhibitors, methocarbamol: Increased CNS and respiratory depressant effects of methadone
antihypertensives, hypotension-producing drugs: Increased hypotension, risk of orthostatic hypotension
azole antifungals, macrolide antibiotics: Increased or prolonged opioid effect
buprenorphine: Decreased therapeutic effect of methadone, increased respiratory depression, possibly withdrawal symptoms
calcium channel blockers, class IA and class III antiarrhythmics, diuretics, laxatives, mineralocorticoid hormones, neuroleptics, tricyclic antidepressants: Increased risk of electrolyte disturbances and prolonged QT interval
carbamazepine, phenobarbital, St. John's wort: Possibly precipitation of withdrawal symptoms
cimetidine: Increased analgesic and CNS and respiratory depressant effects of methadone
desipramine: Increased plasma desipramine level
didanosine, stavudine: Decreased plasma levels of these drugs
diuretics: Decreased diuresis
efavirenz, nevirapine, ritonavir, ritonavir and lopinavir: Decreased blood methadone level
hydroxyzine: Increased analgesic, CNS depressant, and hypotensive effects of methadone
loperamide, paregoric: Increased CNS depression, possibly severe constipation
MAO inhibitors: Possibly increased risk of

severe adverse reactions
metoclopramide: Possibly antagonized metoclopramide effects on GI motility
mixed agonist-antagonist analgesics: Possibly withdrawal symptoms
naloxone: Antagonized analgesic and CNS and respiratory depressant effects of methadone, and possibly withdrawal symptoms
naltrexone: Possibly induction or worsening of withdrawal symptoms if methadone given within 7 days before naltrexone
neuromuscular blockers: Increased or prolonged respiratory depression
opioid analgesics (such as alfentanil and sufentanil): Increased CNS and respiratory depression, increased hypotension
phenytoin, rifampin: May precipitate withdrawal symptoms
selective serotonin reuptake inhibitors: Possibly increased blood methadone levels and increased risk of methadone toxicity
zidovudine: Increased blood zidovudine level and risk of toxicity

ACTIVITIES

alcohol use: Increased CNS and respiratory depression, possibly hypotension

Adverse Reactions

CNS: Agitation, amnesia, anxiety, asthenia, coma, confusion, decreased concentration, delirium, delusions, depression, dizziness, drowsiness, euphoria, fever, hallucinations, headache, insomnia, lethargy, light-headedness, malaise, psychosis, restlessness, sedation, seizures, syncope, tremor

CV: Bradycardia, cardiac arrest, cardiomyopathy, edema, heart failure, hypotension, orthostatic hypotension, palpitations, phlebitis, prolonged QT interval, shock, tachycardia, torsades de pointes, T-wave inversion on ECG, ventricular fibrillation or tachycardia

EENT: Blurred vision, diplopia, dry mouth, glossitis, laryngeal edema or laryngospasm (allergic), miosis, nystagmus, rhinitis

GI: Abdominal cramps or pain, anorexia, biliary tract spasm, constipation, diarrhea, dysphagia, elevated liver function test results, gastroesophageal reflux, hiccups, ileus and toxic megacolon (in patients with inflammatory bowel disease), indigestion, nausea, vomiting

GU: Amenorrhea, decreased ejaculate potency, decreased libido, difficult ejaculation, impotence, prolonged labor, urinary

hesitancy, urine retention

HEME: Anemia, leukopenia, thrombocytopenia

MS: Arthralgia

RESP: Apnea, asthma exacerbation, atelectasis, bronchospasm, depressed cough reflex, hypoventilation, pulmonary edema, respiratory arrest and depression, wheezing
SKIN: Diaphoresis, flushing

Other: Allergic reaction; facial edema; hypokalemia; hypomagnesemia; injection site edema, pain, rash, or redness; physical and psychological dependence; weight gain; withdrawal symptoms

Nursing Considerations

- Before giving methadone, make sure opioid antagonist and equipment for administering oxygen and controlling respiration are nearby.
- Before therapy begins, assess patient's current drug use, including all prescription and OTC drugs.

WARNING Give drug cautiously to patients at risk for a prolonged QT interval, such as those with cardiac hypertrophy, hypokalemia, or hypomagnesemia; those with a history of cardiac conduction abnormalities; and those taking diuretics or medications that affect cardiac conduction.

- Dilute oral concentrate with water or another liquid to volume of at least 30 ml, but preferably to 90 ml or more, before administration. Dissolve dispersible tablets in water or another liquid before giving.
- Monitor patient for expected excessive drowsiness, unsteadiness, or confusion during first 3 to 5 days of therapy, and notify prescriber if effects continue to worsen or persist beyond this time.

WARNING Monitor respiratory and circulatory status carefully and often during methadone therapy because respiratory depression, circulatory depression, respiratory arrest, shock, hypotension, and cardiac arrest are risks. Monitor children often for respiratory depression and paradoxical CNS excitation because of their increased sensitivity to drug. Assess patient for excessive or persistent sedation; dosage may need to be adjusted.

- Watch for drug tolerance, especially in patients with a history of chronic drug abuse, because methadone can cause phys-

ical and psychological dependence.

- Monitor patient for pain because maintenance dosage doesn't provide pain relief; patients with tolerance to opiate agonists, including those with chronic cancer pain, may require a higher dosage.
- Monitor patients who are pregnant or who have liver or renal impairment for increased adverse effects from methadone because drug may have a prolonged duration and cumulative effect in these patients. Methadone may prolong labor by reducing strength, duration, and frequency of uterine contractions, so expect dosage to be tapered before third trimester of pregnancy. Breast-feeding mothers on maintenance therapy put their infants at risk of withdrawal symptoms if they abruptly stop breast-feeding or discontinue methadone therapy. Methadone also accumulates in CNS tissue, increasing the risk of seizures in infants.
- Check plasma amylase and lipase levels in patients who develop biliary tract spasms because levels may increase up to 15 times normal. Notify prescriber immediately of any significant or sustained increase.
- Monitor patients who have head injuries or other conditions that may increase intracranial pressure (ICP) because methadone may further increase ICP.
- Assess patient for withdrawal symptoms and tolerance to therapy because physiologic dependence can occur with long-term methadone use. Avoid abrupt discontinuation because withdrawal symptoms will occur within 3 to 4 days after last dose.
- Monitor patients, especially the elderly, for cardiac arrhythmias, hypotension, hypovolemia, orthostatic hypotension, and vasovagal syncope because methadone may produce cholinergic effects in patients with cardiac disease, resulting in bradycardia and peripheral vasodilation; dosage decrease may be indicated.
- Monitor patients with prostatic hypertrophy, urethral stricture, or renal disease for urine retention and oliguria because methadone can increase tension of detrusor muscle.
- Be prepared to treat patient's symptoms of anxiety, and be aware that anxiety may be confused with symptoms of opioid absti-

nence and that methadone doesn't have anti-anxiety effects.

PATIENT TEACHING

- Instruct patient taking oral concentrate form of methadone to dilute it with water or another liquid to a volume of at least 30 ml and preferably to 90 ml or more before administration.
- Instruct patient to dissolve dispersible tablets in water or other liquid before administration.
- Advise patient to notify prescriber of all other drugs he's currently taking and to avoid alcohol and other depressants, such as sleeping pills and tranquilizers, because they may increase drug's CNS depressant effects.
- Instruct patient to take drug only as prescribed and not to change dosage without prescriber approval. Inform patient that abrupt cessation of methadone therapy can precipitate withdrawal symptoms. Urge him to notify prescriber if he develops any concerns over therapy.
- Urge patient to notify prescriber if he experiences palpitations, dizziness, light-headedness, or syncope, which may be caused by methadone-induced arrhythmias.
- Instruct patient to avoid potentially hazardous activities or those that require mental alertness because methadone therapy may cause drowsiness or sleepiness.
- Teach patient to change positions slowly to minimize the effects of orthostatic hypotension.
- Instruct patient to notify prescriber of worsening or breakthrough pain because dosage may need to be adjusted.
- Inform parents that a child on methadone maintenance therapy may become unusually excited or restless; advise them to notify prescriber of changes in child's behavior.
- Instruct female patient to notify prescriber immediately if she becomes pregnant during methadone therapy because drug may cause physical dependence in fetus and withdrawal symptoms in neonate.
- Caution patient who is breast-feeding not to stop doing so abruptly and not to stop taking methadone without prescriber's approval because infant may experience withdrawal symptoms.

methamphetamine hydrochloride

Desoxyn, Desoxyn Gradumet

Class, Category, and Schedule

Chemical class: Amphetamine

Therapeutic class: CNS stimulant

Pregnancy category: C

Controlled substance schedule: II

Indications and Dosages

↗ *To treat attention-deficit hyperactivity disorder (ADHD)*

E.R. TABLETS

Children age 6 and over. 20 to 25 mg daily.

TABLETS

Children age 6 and over. *Initial:* 5 mg once or twice daily. Increased by 5 mg every wk. *Maintenance:* 20 to 25 mg daily in divided doses b.i.d.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	6–24 hr

Mechanism of Action

May produce CNS stimulation by facilitating release and blocking reuptake of norepinephrine at adrenergic nerve terminals and by stimulating alpha and beta receptors in the peripheral nervous system. Methamphetamine also promotes dopamine release and blocks its reuptake in the brain's limbic regions. It appears to act mainly in cerebral cortex and, possibly, reticular activating system. Its actions decrease motor restlessness, increase alertness, and reduce drowsiness and fatigue. Peripheral actions include increased blood pressure and mild bronchodilation and respiratory stimulation.

Contraindications

Advanced arteriosclerosis; glaucoma; hypersensitivity to methamphetamine, sympathomimetic amines, or their components; hyperthyroidism; history of drug abuse; moderate to severe hypertension; severe agitation; symptomatic cardiovascular disease; use within 14 days of MAO inhibitor

Interactions

DRUGS

ascorbic acid: Decreased methamphetamine

absorption and therapeutic effect

beta blockers: Increased risk of heart block, hypotension, and severe bradycardia

CNS stimulants: Increased CNS stimulation and risk of adverse reactions

digoxin, levodopa: Increased risk of arrhythmias

diuretics, other antihypertensives: Possibly decreased antihypertensive effect

ethosuximide, phenobarbital, phenytoin:

Possibly delayed absorption of these drugs

haloperidol, phenothiazines: Possibly interference with effects of these drugs and with methamphetamine's CNS stimulant effects

inhalation anesthetics: Increased risk of ventricular arrhythmias

insulin: Altered insulin requirements

lithium: Possibly antagonized CNS stimulant effects of methamphetamine

MAO inhibitors: Possibly severe hypertension, risk of hypertensive crisis, increased vasopressor effect of methamphetamine

mepheridine: Increased risk of hypotension and life-threatening interactions, such as severe respiratory depression and coma

metrizamide (intrathecal): Increased risk of seizures

thyroid hormones: Enhanced effects of both drugs

tricyclic antidepressants: Increased risk of arrhythmias and severe hypertension

urinary acidifiers: Increased metabolism and shortened pharmacologic effects of methamphetamine

urinary alkalinizers: Decreased metabolism and prolonged pharmacologic effects of methamphetamine

FOODS

caffeine: Increased methamphetamine effects

Adverse Reactions

CNS: Dizziness, euphoria, headache, hyperactivity, insomnia, irritability, mania, nervousness, psychotic episodes, restlessness, stroke, talkativeness, tremor

CV: Arrhythmias, chest pain, hypertension, hypotension, MI, palpitations, tachycardia

EENT: Accommodation abnormality, blurred vision, dry mouth, taste perversion

ENDO: Stunted growth

GI: Abdominal cramps, anorexia, constipation, diarrhea, nausea, vomiting

GU: Impotence, libido changes

SKIN: Diaphoresis, urticaria

Other: Physical and psychological dependence

Nursing Considerations

- Methamphetamine shouldn't be used in a patient (especially a child or an adolescent) with a serious heart condition, such as a structural heart defect, cardiomyopathy, or a serious heart rhythm abnormality.
- Use methamphetamine cautiously in patients with a history of psychiatric problems or suicidal or homicidal tendencies.
- Assess for seizures in patients with a history of seizure disorders because drug may lower seizure threshold.
- Observe patient for evidence of drug tolerance and, possibly, extreme dependence, which may develop after a few weeks. Be aware that methamphetamine abuse may occur.
- Expect treatment for ADHD to include psychological, educational, and social measures in addition to drug therapy.
- Monitor child's growth pattern. If growth appears to be delayed, notify prescriber because methamphetamine therapy may need to be interrupted temporarily.
- Watch for signs of chronic methamphetamine intoxication, including hyperactivity, insomnia, irritability, and personality changes. Notify prescriber if they occur.
- Monitor patient for exertional chest pain, unexplained syncope, and other evidence that could suggest heart disease. If present, notify prescriber. A cardiac evaluation will be needed, and therapy may need to stop.

PATIENT TEACHING

- Instruct parent of patient to give methamphetamine at least 6 hours before bedtime to prevent insomnia.
- Explain high risk of abuse with this drug. Instruct parent of patient not to increase dosage unless advised by prescriber and not to give drug to prevent fatigue.

WARNING Advise patient to take methamphetamine exactly as prescribed because misuse may cause serious heart effects or even death.

- Caution parent that patient should not crush or chew E.R. tablets.
- Advise parent that patient should avoid caffeine, which increases drug's effects.
- Instruct parent of patient to report signs of overstimulation, such as diarrhea, hyperactivity, insomnia, and irritability.

methazolamide

MZM, Neptazane

Class and Category

Chemical class: Sulfonamide derivative

Therapeutic class: Antiglaucoma

Pregnancy category: C

Indications and Dosages

↗ *To treat open-angle glaucoma*

TABLETS

Adults. 50 to 100 mg b.i.d. or t.i.d.

Route	Onset	Peak	Duration
P.O.	2–4 hr	6–8 hr	10–18 hr

Mechanism of Action

Inhibits the enzyme carbonic anhydrase, which normally appears in renal proximal tubule cells, choroid plexus of the brain, and ciliary processes of the eye. By inhibiting this enzyme in the eyes, methazolamide decreases aqueous humor secretion, which reduces intraocular pressure.

Contraindications

Cirrhosis; hyperchloremic acidosis; hypersensitivity to methazolamide, other carbonic anhydrase inhibitors, or their components; hypokalemia; hyponatremia; severe adrenocortical, hepatic, or renal impairment

Interactions

DRUGS

amphetamines, anticholinergics, mecamlamine, procainamide, quinidine: Decreased renal clearance of these drugs, increased risk of toxicity

amphotericin B, corticosteroids: Increased risk of severe hypokalemia

barbiturates, carbamazepine, phenytoin,

primidone: Increased risk of osteopenia

digoxin: Increased risk of hypokalemia and digitalis toxicity

ephedrine: Possibly prolonged duration of action of ephedrine

insulin, oral antidiabetic drugs: Increased risk of glycosuria and hyperglycemia

lithium: Increased lithium excretion

mannitol: Increased diuresis and further reduction of intraocular pressure

methenamine compounds: Decreased methenamine effectiveness

mexiletine: Possibly impaired renal excretion

of mexiletine

neuromuscular blockers: Possibly prolonged duration of action of blockers from methazolamide-induced hypokalemia, increased risk of prolonged respiratory paralysis and depression

salicylates: Possibly CNS depression and metabolic acidosis, increased risk of methazolamide toxicity

Adverse Reactions

CNS: Confusion, depression, drowsiness, fatigue, fever, malaise, paresthesia, seizures, weakness

EENT: Hearing loss, myopia (transient), taste perversion, tinnitus

GI: Anorexia, diarrhea, nausea, vomiting

GU: Crystalluria, nephrotoxicity, renal calculi

SKIN: Photosensitivity, pruritus, rash, Stevens-Johnson syndrome, urticaria

Other: Metabolic acidosis

Nursing Considerations

- Use methazolamide cautiously in patients with obstructive pulmonary disease.
- Monitor fluid intake and output, weight, and serum electrolyte levels during methazolamide therapy.

PATIENT TEACHING

- Direct patient to take methazolamide exactly as prescribed because increasing dosage may lead to metabolic acidosis.
- Advise patient to take drug with food if GI distress occurs.
- Instruct patient to report if rash develops.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Emphasize need to have regular eye examinations during methazolamide therapy.

methenamine hippurate

Hiprex, Urex

methenamine mandelate

Mandelamine

Class and Category

Chemical class: Formaldehyde precursor,

hexamethylenetetramine
Therapeutic class: Antibiotic
Pregnancy category: C

Indications and Dosages

➤ *To prevent or suppress frequently recurring UTI caused by a wide variety of gram-negative and gram-positive bacteria (including enterococci, Escherichia coli, Micrococcus pyogenes, and staphylococci) in intermittently catheterized patients with neurogenic bladder*

ENTERIC-COATED TABLETS, ORAL SUSPENSION (METHENAMINE MANDELATE)

Adults and adolescents. 1 g q.i.d. before meals and at bedtime.

Children ages 6 to 12. 500 mg q.i.d., or 50 mg/kg daily in divided doses.

Children under age 6. 18.4 mg/kg q.i.d.

TABLETS (METHENAMINE HIPPURATE)

Adults and adolescents. 1 g b.i.d.

Children ages 6 to 12. 0.5 to 1 g every 12 hr.

Mechanism of Action

Hydrolyzes to formaldehyde and ammonia in an acidic environment, such as urine, producing greater amounts of formaldehyde as pH decreases. Formaldehyde has bactericidal action, possibly by denaturing proteins. To facilitate hydrolysis, methenamine is formulated with weak organic acid, such as hippuric acid or mandelic acid.

Contraindications

Concurrent therapy with sulfonamides, hypersensitivity to methenamine, renal insufficiency, severe dehydration, severe hepatic disease

Interactions

DRUGS

bicarbonate-containing antacids, urinary alkalinizers: Decreased methenamine effect
sulfonamides, such as sulfamethizole:

Possibly formation of insoluble precipitate in urine

FOODS

milk, milk products, most fruits: Possibly decreased effectiveness of methenamine

Adverse Reactions

CNS: Headache

CV: Edema

EENT: Stomatitis

GI: Abdominal cramps, anorexia, diarrhea, nausea, vomiting

GU: Bladder irritation, crystalluria, dysuria,

hematuria, proteinuria, urinary frequency
RESP: Pulmonary hypersensitivity (dyspnea, pneumonitis)

SKIN: Pruritus, rash, urticaria

Nursing Considerations

- Be aware that methenamine is used for prophylaxis; it isn't recommended as primary treatment for UTI.
- Drug shouldn't be given to patients with creatinine clearance less than 50 ml/min/1.73 m².
- Before giving first dose, expect to obtain urine specimen for culture and sensitivity tests and to review test results if available.
- Plan to give methenamine mandelate around the clock to maintain a therapeutic blood level.
- Make sure patient receives adequate fluids.
- Expect to repeat culture and sensitivity tests if patient fails to improve.

PATIENT TEACHING

- Instruct patient to take methenamine with food to avoid GI distress.
- Direct patient to drink extra fluids; avoid alkaline foods, such as milk, milk products, and most fruits; and avoid antacids that contain sodium bicarbonate or carbonate during methenamine therapy.
- Instruct patient to report painful urination, rash, or severe GI distress.
- Urge patient to comply with urine testing before and during long-term therapy.

methicillin sodium

Staphicillin

Class and Category

Chemical: Penicillinase-resistant penicillin

Therapeutic: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat general infections, such as sepsis, sinusitis, and skin and soft-tissue infections, caused by susceptible organisms (including penicillinase-producing and non-penicillinase-producing strains of Staphylococcus epidermidis, Staphylococcus saprophyticus, and Streptococcus pneumoniae)*

I.V. INFUSION, I.M. INJECTION

Adults and children weighing 40 kg (88 lb)

or more. 1 g every 4 to 6 hr (I.M.) or 1 g every 6 hr (I.V.). *Maximum:* 24 g daily.

Children weighing less than 40 kg. 25 mg/kg every 6 hr.

DOSAJE ADJUSTMENT For adults and children with cystic fibrosis, dosage adjusted to 50 mg/kg every 6 hr.

➤ **To treat bacterial meningitis**

I.V. INFUSION, I.M. INJECTION

Neonates weighing 2 kg (4.4 lb) or more.

50 mg/kg every 8 hr for first wk after birth and then 50 mg/kg every 6 hr.

Neonates weighing less than 2 kg. 25 to 50 mg/kg every 12 hr for first wk after birth and then 50 mg/kg every 8 hr.

Mechanism of Action

Kills bacteria by inhibiting cell wall synthesis. In susceptible bacteria, the rigid, cross-linked cell wall is assembled in several steps. In final stage of cross-linking, methicillin binds with and inactivates penicillin-binding proteins (enzymes responsible for linking cell wall strands), resulting in bacterial cell lysis and death. *Staphylococcus aureus* has developed resistance to methicillin by altering its penicillin-binding proteins.

Incompatibilities

Don't mix methicillin in same syringe or I.V. solution with other drugs. Don't mix methicillin with dextrose solutions because their low acidity may damage drug. Give methicillin at least 1 hour before or after aminoglycosides and at different sites; otherwise, mutual inactivation can occur.

Contraindications

Hypersensitivity to methicillin sodium, other penicillins, or their components

Interactions

DRUGS

aminoglycosides: Substantial aminoglycoside inactivation

chloramphenicol, erythromycins, sulfonamides, tetracyclines: Possibly decreased therapeutic effects of methicillin

methotrexate: Increased risk of methotrexate toxicity

probenecid: Possibly decreased renal clearance, increased blood level, and increased risk of toxicity of methicillin

Adverse Reactions

CNS: Aggressiveness, agitation, anxiety,

confusion, depression, headache, seizures

EENT: Oral candidiasis

GI: Abdominal pain, diarrhea, hepatotoxicity, nausea, pseudomembranous colitis, vomiting

GU: Interstitial nephritis, vaginitis

HEME: Leukopenia, neutropenia, thrombocytopenia

SKIN: Exfoliative dermatitis, pruritus, rash, urticaria

Other: Anaphylaxis; infusion site redness, swelling, and tenderness; injection site pain, redness, and swelling; serum sicknesslike reaction

Nursing Considerations

WARNING Be aware that methicillin isn't a first-line treatment for the indications above because of the prevalence of methicillin-resistant *Staphylococcus aureus*.

- Before giving first dose, obtain appropriate body fluid or tissue specimens for culture and sensitivity tests, as ordered, and review test results if available.
- Inject I.M. form deep into gluteal muscle.
- In I.V. use, observe infusion site closely for redness, swelling, and tenderness.
- Monitor fluid intake and output and renal function test results during therapy.
- Observe for signs of superinfection, such as diarrhea, vaginal itching, and white patches or sores in mouth or on tongue. Notify prescriber if they occur.
- Closely monitor renal function test results, including serum creatinine level; about one-third of patients have interstitial nephritis after 10 days of methicillin therapy.
- Monitor liver function test results, and report evidence of hepatotoxicity, such as fever and nausea.

PATIENT TEACHING

- Explain that I.M. injection may be painful.
- Unless contraindicated, instruct patient to drink extra fluids during therapy.
- Advise patient to report diarrhea, injection site pain, mouth sores, or rash.

methimazole

Tapazole

Class and Category

Chemical class: Thioimidazole derivative

Therapeutic class: Antithyroid
Pregnancy category: D

Indications and Dosages

➤ To treat mild hyperthyroidism

TABLETS

Adults and adolescents. *Initial:* 15 mg daily as a single dose or in divided doses b.i.d. for 6 to 8 wk or until euthyroid level is reached.

Maintenance: 5 to 30 mg daily as a single dose or in divided doses b.i.d.

Children. *Initial:* 0.4 mg/kg daily as a single dose or in divided doses b.i.d. *Maintenance:* 0.2 mg/kg daily as a single dose or in divided doses b.i.d.

➤ To treat moderate hyperthyroidism

TABLETS

Adults and adolescents. *Initial:* 30 to 40 mg/day as a single dose or in divided doses b.i.d. for 6 to 8 wk or until euthyroid level is reached. *Maintenance:* 5 to 30 mg daily as a single dose or in divided doses b.i.d.

Children. *Initial:* 0.4 mg/kg daily as a single dose or in divided doses b.i.d. *Maintenance:* 0.2 mg/kg daily as a single dose or in divided doses b.i.d.

➤ To treat severe hyperthyroidism

TABLETS

Adults and adolescents. *Initial:* 60 mg daily as a single dose or in divided doses b.i.d. for 6 to 8 wk or until euthyroid level is reached. *Maintenance:* 5 to 30 mg daily as a single dose or in divided doses b.i.d.

Children. *Initial:* 0.4 mg/kg daily as a single dose or in divided doses b.i.d. *Maintenance:* 0.2 mg/kg daily as a single dose or in divided doses b.i.d.

➤ As adjunct to treat thyrotoxicosis

SUPPOSITORIES

Adults and adolescents. 15 to 20 mg every 4 hr on first day and then adjusted based on patient response.

Children. 0.4 mg/kg daily as a single dose or in divided doses b.i.d.

Route	Onset	Peak	Duration
P.O.	5 days	7 wk	Unknown

Mechanism of Action

Directly interferes with thyroid hormone synthesis in the thyroid gland by inhibiting iodide incorporation into thyroglobulin. Iodination of thyroglobulin is an important step in synthesizing the thyroid hormones

thyroxine and triiodothyronine. Eventually, thyroglobulin is depleted and the circulating thyroid hormone level drops.

Contraindications

Breast-feeding; hypersensitivity to methimazole, other antithyroid drugs, or their components

Interactions

DRUGS

amiodarone, iodine, potassium iodide:

Decreased response to methimazole

digoxin: Possibly increased blood digoxin level

oral anticoagulants: Possibly a need for altered anticoagulant dosage

Adverse Reactions

CNS: Drowsiness, headache, paresthesia, vertigo

CV: Edema

EENT: Loss of taste

ENDO: Hypothyroidism

GI: Diarrhea, indigestion, nausea, vomiting

HEME: Agranulocytosis, aplastic anemia, leukopenia, thrombocytopenia

MS: Arthralgia, myalgia

SKIN: Alopecia, jaundice, pruritus, rash, skin discoloration, urticaria

Other: Lupus-like symptoms, lymphadenopathy

Nursing Considerations

- Closely monitor thyroid function test results during methimazole therapy.
- Check CBC results to detect abnormalities caused by inhibition of myelopoiesis.
- Watch for signs and symptoms of hypothyroidism, such as cold intolerance, depression, and edema.
- Be aware that hyperthyroidism may increase metabolic clearance of beta blockers and theophylline and that dosages of these drugs may need to be reduced as the patient's thyroid condition becomes corrected.

PATIENT TEACHING

- Instruct patient to take drug with meals to avoid adverse GI reactions.
- Explain about possible hair loss or thinning during and for months after therapy.
- Instruct patient to notify prescriber immediately about cold intolerance, fever, sore throat, tiredness, and unusual bleeding or bruising.

methocarbamol

Carbacot, Robaxin, Robaxin 750, Skelex

Class and Category

Chemical class: Carbamate derivative of guaifenesin

Therapeutic class: Skeletal muscle relaxant

Pregnancy category: C

Indications and Dosages

↗ *To relieve discomfort caused by acute, painful musculoskeletal conditions*

TABLETS

Adults and adolescents. *Initial:* 1,500 mg q.i.d. for 2 to 3 days; for severe discomfort, 8,000 mg daily. *Maintenance:* 750 mg every 4 hr, 1,000 mg q.i.d., or 1,500 mg t.i.d.

I.V. INJECTION (100 MG/ML)

Adults and adolescents. Up to 3,000 mg daily administered at 8-hr intervals for 3 consecutive days. Regimen repeated as prescribed after patient is drug-free for 48 hr.

I.M. INJECTION (100 MG/ML)

Adults and adolescents. 1,000 to 3,000 mg/day administered at 8-hr intervals for 3 consecutive days. Regimen repeated as prescribed after patient is drug-free for 48 hr.

↗ *To provide supportive therapy for tetanus*

TABLETS

Adults and adolescents. 24,000 mg daily given by NG tube.

I.V. INFUSION OR INJECTION (100 MG/ML)

Adults and adolescents. 1,000 to 3,000 mg by infusion or 1,000 to 2,000 mg by direct injection every 6 hr. *Maximum:* 300 mg (3 ml)/min.

Children. 15 mg/kg every 6 hr.

Route	Onset	Peak	Duration
P.O.	30 min	Unknown	Unknown
I.V.	Immediate	Unknown	Unknown

Mechanism of Action

May depress CNS, which leads to sedation and reduced skeletal muscle spasms. Methocarbamol also alters perception of pain.

Contraindications

Hypersensitivity to methocarbamol or its components, renal disease (injectable form)

Interactions

DRUGS

CNS depressants: Increased CNS depression

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Dizziness, drowsiness, fever, headache, light-headedness, seizures (I.V.), syncope, vertigo, weakness

CV: Bradycardia, hypotension, and thrombophlebitis (parenteral)

EENT: Blurred vision, conjunctivitis, diplopia, metallic taste, nasal congestion, nystagmus

GI: Nausea

GU: Black, brown, or green urine

SKIN: Flushing, pruritus, rash, urticaria

Other: Anaphylaxis (parenteral), angioedema, injection site irritation or pain (I.M.), injection site sloughing (I.V.)

Nursing Considerations

- If needed, crush methocarbamol tablets and mix with water for administration by NG tube.
 - Give I.V. form directly through infusion line at 3 ml/min. To prepare solution, add 10 ml to no more than 250 ml D₅W or normal saline solution. Infuse at no more than 300 mg (3 ml)/min to avoid hypotension and seizures.
 - Keep patient recumbent during I.V. administration and for at least 15 minutes afterward. Then have him rise slowly.
 - Monitor I.V. site regularly for signs of phlebitis.
 - Inject I.M. form deep into large muscle, such as the gluteus. Give no more than 5 ml/dose every 8 hours. One dose is usually adequate.
 - Don't give methocarbamol by subcutaneous route.
 - Keep epinephrine, antihistamines, and corticosteroids available in case patient experiences anaphylactic reaction.
 - Be aware that the parenteral dosage form shouldn't be used in patients with renal dysfunction because the polyethylene glycol 300 vehicle is nephrotoxic.
- #### PATIENT TEACHING
- Tell patient to take drug exactly as prescribed.
 - Advise patient to take drug with food or milk to avoid nausea.
 - Inform patient that urine may turn green, black, or brown until methocarbamol is

- discontinued.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to avoid alcohol and other CNS depressants during therapy.

methotrexate (amethopterin)

Rheumatrex

methotrexate sodium

Folex, Folex PFS, Mexate, Mexate-AQ

Class and Category

Chemical class: Folic acid analogue

Therapeutic class: Antipsoriatic, anti-rheumatic

Pregnancy category: X

Indications and Dosages

↗ *To treat severe psoriasis unresponsive to other therapy*

TABLETS (METHOTREXATE)

Adults. 2.5 to 5 mg every 12 hr for 3 doses/wk, increased as ordered by 2.5 mg/wk.

Maximum: 20 mg/wk.

I.V. OR I.M. INJECTION (METHOTREXATE SODIUM)

Adults. 10 mg/wk. *Maximum:* 25 mg/wk.

↗ *To treat severe rheumatoid arthritis unresponsive to other therapy*

TABLETS (METHOTREXATE)

Adults. 2.5 to 5 mg every 12 hr for 3 doses/wk, increased as ordered by 2.5 mg/wk.

Maximum: 20 mg/wk.

Route	Onset	Peak	Duration
P.O., I.V., I.M.	3–6 wk	Unknown	Unknown

Mechanism of Action

May exert immunosuppressive effects by inhibiting replication and function of T and possibly B lymphocytes. Methotrexate also slows rapidly growing cells, such as epithelial skin cells in psoriasis. This action may result from the drug's inhibition of dihydrofolate reductase, the enzyme that reduces folic acid to tetrahydrofolic acid. Inhibition of tetrahydrofolic acid interferes

with DNA synthesis and cell reproduction in rapidly proliferating cells.

Contraindications

Breast-feeding, hypersensitivity to methotrexate or its components, pregnancy

Interactions

DRUGS

bone marrow depressants: Possibly increased bone marrow depression

co-trimoxazole: Possibly increased bone marrow suppression

folic acid: Possibly decreased effectiveness of methotrexate

hepatotoxic drugs: Increased risk of hepatotoxicity

chloramphenicol, neomycin, tetracycline:

Possibly decreased methotrexate absorption

NSAIDs, penicillins, phenylbutazone, phenytoin, probenecid, salicylates, sulfonamides:

Increased risk of methotrexate toxicity

oral anticoagulants: Increased bleeding risk

sulfonamides: Increased risk of hepatotoxicity

theophylline: Possibly increased risk of theophylline toxicity

vaccines: Risk of disseminated infection

with live-virus vaccines, risk of suppressed response to killed-virus vaccines

ACTIVITIES

alcohol use: Increased risk of hepatotoxicity

Adverse Reactions

CNS: Aphasia, cerebral thrombosis, chills, dizziness, drowsiness, fatigue, fever, headache, hemiparesis, leukoencephalopathy, malaise, paresis, seizures

CV: Chest pain, deep vein thrombosis, hypotension, pericardial effusion, pericarditis, thromboembolism

ENDO: Gynecomastia

EENT: Blurred vision, conjunctivitis, gingivitis, glossitis, pharyngitis, stomatitis, transient blindness, tinnitus

GI: Abdominal pain, anorexia, cirrhosis, diarrhea, elevated liver function test results, enteritis, GI bleeding and ulceration, hepatitis, hepatotoxicity, nausea, pancreatitis, vomiting

GU: Cystitis, hematuria, infertility, menstrual dysfunction, nephropathy, renal failure, tubular necrosis, vaginal discharge

HEME: Anemia, aplastic anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia

MS: Arthralgia, dysarthria, myalgia, stress fracture

RESP: Dry nonproductive cough, dyspnea, interstitial pneumonitis, pneumonia, pulmonary fibrosis or failure, pulmonary infiltrates

SKIN: Acne, alopecia, altered skin pigmentation, ecchymosis, erythema multiforme, exfoliative dermatitis, furunculosis, necrosis, photosensitivity, pruritus, psoriatic lesions, rash, Stevens-Johnson syndrome, telangiectasia, toxic epidermal necrolysis, ulceration, urticaria

Other: Anaphylaxis, increased risk of infection, lymphadenopathy, lymphoproliferative disease

Nursing Considerations

- Follow facility policy for preparing and handling drug; parenteral form poses a risk of carcinogenicity, mutagenicity, and teratogenicity. Avoid skin contact.
 - Monitor results of CBC, chest X-ray, liver and renal function tests, and urinalysis before and during treatment.
 - Unless contraindicated, increase patient's fluid intake to 2 to 3 L daily to reduce the risk of adverse GU reactions.
 - Assess patient for bleeding and infection.
- WARNING** Expect renal impairment to severely alter drug elimination.
- Be aware that high doses of methotrexate can impair renal elimination by forming crystals that obstruct urine flow. To prevent drug precipitation, alkalize patient's urine with sodium bicarbonate tablets, as ordered.
 - Follow standard precautions because drug can cause immunosuppression.
 - If patient becomes dehydrated from vomiting, notify prescriber and expect to withhold drug until patient recovers.
 - If patient receives high doses of drug, keep leucovorin readily available as antidote.
 - Be aware that methotrexate resistance may develop with prolonged use.

PATIENT TEACHING

- Prepare a calendar of treatment days for patient, and stress importance of following instructions exactly.
- Instruct patient to avoid alcohol during methotrexate therapy.
- Encourage frequent mouth care to reduce the risk of mouth sores.

- Instruct patient to use sunblock when exposed to sunlight.
- Advise patient to notify prescriber about bruising, chills, cough, fever, dark or bloody urine, mouth sores, shortness of breath, sore throat, and yellow skin or eyes.
- Urge women of childbearing age to use reliable contraception during methotrexate therapy.

methoxypolyethylene glycol-epoetin beta

Mircera

Class and Category

Chemical class: Continuous erythropoietin receptor activator

Therapeutic class: Antianemic

Pregnancy category: C

Indications and Dosages

↗ *To treat anemia associated with chronic renal failure in dialysis-dependent and dialysis-independent patients*

I.V. INJECTION, SUBCUTANEOUS INJECTION

Adults not currently being treated with an erythropoiesis-stimulating agent. *Initial:*

0.6 mcg/kg every 2 wk, increased or decreased by 25% monthly as needed.

Maintenance: 1.2 mcg/kg every 4 wk.

Adults stabilized on less than 8,000 units/wk of epoetin alfa or 40 mcg/wk of darbepoetin alfa. 60 mcg every 2 wk or 120 mcg every 4 wk.

Adults stabilized on 8,000 to 16,000 units/wk of epoetin alfa or 40 to 80 mcg/wk of darbepoetin alfa. 100 mcg every 2 wk or 200 mcg every 4 wk.

Adults stabilized on more than 16,000 units/wk of epoetin alfa or more than 80 mcg/wk of darbepoetin alfa. 180 mcg every 2 wk or 360 mcg every 4 wk.

DOSAGE ADJUSTMENT If hemoglobin increase is greater than 1 g/dl during any 2-wk period or hemoglobin is increasing and approaching 12 g/dl, dosage reduced by 25%. If hemoglobin continues to increase despite this reduction, drug discontinued until hemoglobin begins to decrease; then drug restarted at a dose 25% less than previously given. If hemoglobin doesn't

increase by 1 g/dl after 4 wk of therapy, dosage increased by 25%.

Route	Onset	Peak	Duration
I.V., SubQ	7–15 days	72 hr	4 wk

Mechanism of Action

Stimulates release of reticulocytes from bone marrow into the bloodstream, where they develop into mature RBCs.

Incompatibilities

Don't mix methoxypolyethylene glycol-epoetin beta with any other drug.

Contraindications

Hemoglobin greater than 12 g/dl, hypersensitivity to methoxypolyethylene glycol-epoetin beta or its components, red cell aplasia, uncontrolled hypertension

Adverse Reactions

CNS: Headache, seizures, stroke

CV: Chest pain, congestive heart failure, deep vein thrombosis, hypertension, hypotension, MI, tachycardia, vascular access thrombosis

EENT: Nasopharyngitis

GI: Constipation, diarrhea, GI bleeding, vomiting

GU: UTI

HEME: Pure red cell aplasia, severe anemia

MS: Back or limb pain, muscle spasms

RESP: Cough, upper respiratory tract infection

SKIN: Erythema, pruritus, rash

Other: Anaphylaxis, antibody formation to drug

Nursing Considerations

- Use drug cautiously in patients who have conditions that could decrease or delay response to drug, such as aluminum intoxication, folic acid deficiency, hemolysis, infection, inflammation, iron deficiency, malignant neoplasm, osteitis (birrosa cystica), or vitamin B₁₂ deficiency.
- Also use drug cautiously in patients with a cardiovascular disorder caused by hypertension, a history of seizures, vascular disease, or a hematologic disorder, such as hypercoagulation, myelodysplastic syndrome or sickle cell disease.
- Be aware that if patient's blood pressure is

difficult to control even with drug therapy or dietary measures, dose of methoxypolyethylene glycol-epoetin beta should be reduced or drug withheld until blood pressure is controlled.

- Don't shake vial during preparation to avoid denaturing glycoprotein, inactivating drug. Protect vials and prefilled syringes from light by storing in original cartons.
 - Discard unused portion of single-dose vial because it contains no preservatives.
- WARNING** Target hemoglobin shouldn't exceed 12 g/dl because it increases risk of life-threatening adverse cardiovascular effects.
- Monitor drug effectiveness by checking hemoglobin every 2 weeks until stabilized at 10 to 12 g/dl and maintenance dose has been established. Then expect hemoglobin to be monitored at least monthly unless dosage adjustment is needed.
 - Expect to give an iron supplement because iron requirements rise when erythropoiesis consumes existing iron stores.
 - Notify prescriber if patient has sudden loss of response to drug, evidenced by severe anemia and a low reticulocyte count. Anti-erythropoietin antibody-related anemia may be present, which requires stopping drug and any other erythropoietic proteins.
 - Take seizure precautions, especially during the first couple months of therapy.
 - Risk of hypertensive or thrombotic complications increases if hemoglobin rises more than 1 g/dl over 2 weeks.

PATIENT TEACHING

- Teach patient how to administer drug and how to dispose of needles properly. Caution against reusing needles.
- Stress importance of complying with dosage regimen and keeping follow-up medical and laboratory appointments.
- Review possible adverse reactions, and urge patient to notify prescriber about chest pain, headache, hives, rapid heart-beat, rash, seizures, shortness of breath, or swelling.
- Advise patient that the risk of seizures is highest during the first couple of months of methoxypolyethylene glycol-epoetin beta therapy. Urge him to avoid hazardous activities during this time.
- Encourage patient to eat iron-rich foods.

methscopolamine bromide

Pamine, Pamine Forte

Class and Category

Chemical class: Quaternary ammonium derivative of scopolamine

Therapeutic class: Anticholinergic

Pregnancy category: C

Indications and Dosages

➤ *As adjunct to treat peptic ulcer*

TABLETS

Adults. For mild to moderate symptoms, 2.5 mg 30 min before meals and 2.5 to 5 mg at bedtime; for severe symptoms, 5 mg 30 min. before meals and at bedtime.

Route	Onset	Peak	Duration
P.O.	1 hr	Unknown	4–6 hr

Mechanism of Action

Reduces volume and total acid content of gastric secretions, which may have a beneficial effect in treating peptic ulcer. Drug also reduces GI motility and inhibits salivation, which may have additional benefits.

Contraindications

Glaucoma, hypersensitivity to methscopolamine bromide or its components, intestinal atony (elderly or debilitated patients), myasthenia gravis, obstructive disease of GI or GU tract, paralytic ileus, severe ulcerative colitis, toxic megacolon complicating ulcerative colitis, unstable cardiovascular status in acute hemorrhage

Interactions

DRUGS

antacids: Possibly decreased methscopolamine absorption

anticholinergics, antipsychotics, tricyclic antidepressants: Possibly increased anticholinergic effects

Adverse Reactions

CNS: Confusion, dizziness, drowsiness, headache, insomnia, nervousness, weakness

CV: Palpitations, tachycardia

EENT: Blurred vision, cycloplegia, dry mouth, increased intraocular pressure, loss of taste, pupil dilation

ENDO: Suppression of lactation

GI: Bloating, constipation, nausea, vomiting

GU: Impotence, urinary hesitancy, urine retention

SKIN: Decreased sweating, urticaria

Other: Anaphylaxis

Nursing Considerations

- Use with caution in elderly patients and in patients with autonomic neuropathy, congestive heart failure, coronary artery disease, hepatic or renal disease, hypertension, hyperthyroidism, prostatic hypertrophy, tachycardia, or ulcerative colitis.
- Notify prescriber if diarrhea occurs because it may be an early sign of incomplete intestinal obstruction.

PATIENT TEACHING

- Advise patient to avoid excessive exposure to heat to reduce the risk of heat prostration and heatstroke because methscopolamine decreases sweating.
- Caution patient to avoid antacids because they may interfere with drug's absorption.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.

methsuximide

Celontin

M

Class and Category

Chemical class: Succinimide derivative

Therapeutic class: Anticonvulsant

Pregnancy category: Not rated

Indications and Dosages

➤ *To treat absence seizures unresponsive to other drugs*

CAPSULES

Adults and children. *Initial:* 300 mg daily. Increased by 150 to 300 mg daily every 1 to 2 wk until control is achieved with minimal adverse reactions. *Maximum:* 1.2 g daily in divided doses.

Mechanism of Action

Elevates seizure threshold and reduces frequency of seizures by depressing motor cortex and elevating threshold of CNS response to convulsive stimuli. Methsuximide is metabolized to active metabolite N-demethylmethsuximide, which may add to the anticonvulsant effects of the drug.

Contraindications

Hypersensitivity to methsuximide, succinimides, or their components

Interactions**DRUGS**

carbamazepine, phenobarbital, phenytoin, primidone: Possibly decreased blood methsuximide level

CNS depressants: Possibly increased CNS depression

haloperidol: Altered seizure pattern; possibly decreased blood haloperidol level

loxapine, MAO inhibitors, maprotiline, molindone, phenothiazines, pimozide, thioxanthenes, tricyclic antidepressants: Possibly lowered seizure threshold and reduced therapeutic effect of methsuximide

ACTIVITIES

alcohol use: Possibly increased CNS depression

Adverse Reactions

CNS: Aggressiveness, ataxia, decreased concentration, dizziness, drowsiness, fatigue, fever, headache, insomnia, irritability, mental depression, nightmares, seizures, suicidal ideation

EENT: Periorbital edema, pharyngitis

GI: Abdominal and epigastric pain, abdominal cramps, abnormal liver function test results, anorexia, diarrhea, hiccups, nausea, vomiting

GU: Microscopic hematuria, proteinuria

HEME: Agranulocytosis, aplastic anemia, eosinophilia, leukopenia, pancytopenia

MS: Muscle pain

SKIN: Erythematous and pruritic rash, Stevens-Johnson syndrome, systemic lupus erythematosus, urticaria

Other: Lymphadenopathy

Nursing Considerations

- Monitor CBC and platelet count and assess patient for signs of infection, such as cough, fever, and pharyngitis, because methsuximide may cause blood dyscrasias.
- Monitor liver function test results and urinalysis results in patients with a history of hepatic or renal disease; methsuximide may cause functional changes in liver and kidneys.
- When giving drug to patient with a history of mixed-type epilepsy, institute seizure precautions because drug may increase

risk of generalized tonic-clonic seizures.

- Expect the dosage to be carefully and slowly adjusted according to patient's response and needs and withdrawn slowly to avoid precipitating seizures.
- Plan to use 150-mg capsule when making dosage adjustments for small children.
- Notify prescriber if patient develops depression or aggressiveness.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

PATIENT TEACHING

- Advise patient to take a missed dose as soon as he remembers unless it's nearly time for the next dose. Warn him not to double the dose.
- Instruct patient to take drug with milk or food to reduce gastric irritation.
- Advise patient to notify prescriber if he develops cough, fever, or pharyngitis.
- Urge patient to avoid alcohol because of increased risk of CNS depression.
- Instruct patient to avoid hazardous activities until drug's adverse effects are known.
- Caution patient not to stop taking drug abruptly to avoid risk of absence seizures.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report concerns immediately.
- Urge woman who becomes pregnant while taking methsuximide to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that this registry is collecting information about the safety of antiepileptic drugs during pregnancy.

methyl dopa

Aldomet, Apo-Methyl dopa (CAN), Dopamet (CAN), Nu-Medopa (CAN)

methyl dopate hydrochloride

Aldomet

Class and Category

Chemical class: 3,4-dihydroxyphenylalanine (DOPA) analogue

Therapeutic class: Antihypertensive

Pregnancy category: B (oral form), C (parenteral form)

Indications and Dosages

↗ *To manage hypertension, to treat hypertensive crisis*

ORAL SUSPENSION, TABLETS (METHYLDOPA)

Adults. *Initial:* 250 mg b.i.d. or t.i.d. for first 48 hr, increased as ordered after 2 days. *Maintenance:* 500 to 2,000 mg daily in divided doses b.i.d. to q.i.d. *Maximum:* 3,000 mg daily.

Children. *Initial:* 10 mg/kg daily in divided doses b.i.d. to q.i.d. for first 48 hr, increased as ordered after 2 days. *Maximum:* 65 mg/kg or 3,000 mg daily.

I.V. INFUSION (METHYLDOPATE HYDROCHLORIDE)

Adults. 250 to 500 mg diluted in D₅W and infused over 30 to 60 min every 6 hr. *Maximum:* 1,000 mg every 6 hr.

Children. 20 to 40 mg/kg infused over 30 to 60 min every 6 hr. *Maximum:* 65 mg/kg or 3,000 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	4–6 hr*	12–24 hr†
I.V.	Unknown	4–6 hr	10–16 hr

Mechanism of Action

Is decarboxylated in the body to produce alpha-methylnorepinephrine, a metabolite that stimulates central inhibitory alpha-adrenergic receptors. This action may reduce blood pressure by decreasing sympathetic stimulation of heart and peripheral vascular system.

Incompatibilities

Don't administer methyldopa through same I.V. line as barbiturates or sulfonamides.

Contraindications

Active hepatic disease, hypersensitivity to methyldopa or its components, impaired hepatic function from previous methyldopa therapy, use within 14 days of MAO inhibitor

Interactions

DRUGS

antihypertensives: Increased hypotension
appetite suppressants, NSAIDs, tricyclic anti-

* For single dose; 2 to 3 days for multiple doses.

† For single dose; 24 to 48 hr for multiple doses.

depressants: Possibly decreased therapeutic effects of methyldopa

central anesthetics: Possibly need for reduced anesthetic dosage

CNS depressants: Possibly increased CNS depression

haloperidol: Increased risk of adverse CNS effects

levodopa: Possibly decreased therapeutic effects of levodopa and increased risk of adverse CNS effects

lithium: Increased risk of lithium toxicity

MAO inhibitors: Possibly hallucinations, headaches, hyperexcitability, and severe hypertension

oral anticoagulants: Possibly increased therapeutic effects of anticoagulants

sympathomimetics: Possibly decreased therapeutic effects of methyldopa and increased vasopressor effects of sympathomimetics

ACTIVITIES

alcohol use: Possibly increased CNS depression

Adverse Reactions

CNS: Decreased concentration, depression, dizziness, drowsiness, fever, headache, involuntary motor activity, memory loss (transient), nightmares, paresthesia, parkinsonism, sedation, vertigo, weakness

CV: Angina, bradycardia, edema, heart failure, myocarditis, orthostatic hypotension

EENT: Black or sore tongue, dry mouth, nasal congestion

ENDO: Gynecomastia

GI: Constipation, diarrhea, flatulence, hepatic necrosis, hepatitis, nausea, pancreatitis, vomiting

GU: Decreased libido, impotence

HEME: Agranulocytosis, hemolytic anemia, leukopenia, positive Coombs' test, positive tests for ANA and rheumatoid factor, thrombocytopenia

SKIN: Eczema, rash, urticaria

Other: Weight gain

Nursing Considerations

- For I.V. infusion, add methyldopate to 100 ml of D₅W and administer over 30 to 60 minutes.
- Expect to monitor CBC and differential results before and periodically during methyldopa therapy.
- Monitor blood pressure regularly during therapy.

- Monitor results of Coombs' test; a positive result after several months of treatment indicates that patient has hemolytic anemia. Expect to discontinue drug.
- Assess for weight gain and edema. If they develop, give a diuretic, as prescribed.
- Notify prescriber if patient has signs of heart failure (dyspnea, edema, hypertension) or involuntary, rapid, jerky movements.
- Be aware that hypertension may return within 48 hours after stopping drug.

PATIENT TEACHING

- Instruct patient to take methylaltraxone exactly as prescribed and not to skip a dose. Explain that hypertension can return within 48 hours after stopping drug.
- Suggest that patient take drug at bedtime to minimize daytime drowsiness.
- Instruct patient to weigh himself daily and to report a gain of more than 5 lb (2.3 kg) in 2 days.
- Advise patient to change position slowly to minimize orthostatic hypotension.
- Direct patient to notify prescriber about bruising, chest pain, fever, involuntary jerky movements, prolonged dizziness, rash, and yellow eyes or skin.
- Caution patient not to stop drug abruptly; doing so may cause withdrawal symptoms, such as headache, hypertension, increased sweating, nausea, and tremor.

methylaltraxone bromide

Relistor

Class and Category

Chemical class: Noroxymorphone methobromide

Therapeutic class: Peripheral mu-opioid receptor antagonist

Pregnancy category: B

Indications and Dosages

➤ *To treat opioid-induced constipation in patients receiving palliative care and not responsive to laxative therapy.*

SUBCUTANEOUS INJECTION

Adults weighing more than 114 kg (251 lb): 0.15 mg/kg every other day as needed. *Maximum:* 0.15 mg/kg daily.

Adults weighing 62 to 114 kg (136 to 251 lb): 12 mg every other day as needed. *Maximum:* 12 mg daily.

Adults weighing 38 to less than 62 kg (84 to less than 136 lb): 8 mg every other day as needed. *Maximum:* 8 mg daily.

Adults weighing less than 38 kg: 0.15 mg/kg every other day as needed. *Maximum:* 0.15 mg/kg daily.

DOSAGE ADJUSTMENT For patients with severe renal failure (creatinine clearance less than 30 ml/min/1.73 m²), dosage reduced by half.

Route	Onset	Peak	Duration
SubQ	Unknown	0.5 hr	Unknown

Mechanism of Action

Binds to peripherally acting mu-opioid receptors in the GI tract, preventing opioid-induced slowing of GI transit time and motility. When transit time and motility is restored to normal, constipation is relieved.

Contraindications

Hypersensitivity to methylaltraxone bromide or its components, I.V. administration, mechanical GI obstruction

Adverse Reactions

CNS: Dizziness

GI: Abdominal pain, diarrhea, flatulence, nausea

Skin: Diaphoresis

Nursing Considerations

- To determine volume of drug to give patients who weigh more than 114 kg (251 lb) or less than 38 kg (84 lb), multiply patient's weight in pounds by 0.0034 and round up to the nearest 0.1 ml. Or, multiply patient's weight in kilograms by 0.0075 and round up to the nearest 0.1 ml. For patients who weigh 62 to 114 kg (136 to 251 lb), injection volume administered should be 0.6 ml. For patients who weigh 38 to less than 62 kg (84 to less than 136 lb), injection volume administered should be 0.4 ml.
- Inspect vial before giving drug to make sure solution is clear and colorless to pale yellow.
- Give drug only as subcutaneous injection into patient's upper arm, abdomen, or thigh and no more than once in 24 hours.

Make sure to rotate injection sites.

- Once drug is drawn into syringe, it should be given immediately. However, if needed, it may be stored at room temperature for up to 24 hours.
- Notify prescriber about severe or persistent diarrhea, and expect drug to be discontinued.

PATIENT TEACHING

- Teach patient or caregiver how to prepare and give methylphenidate subcutaneous-ly. Stress need to rotate injection sites.
- Inform patient that a bowel movement may occur within 30 minutes after drug has been administered.
- Advise patient that if severe or persistent diarrhea occurs, prescriber should be notified and drug discontinued.
- Reassure patient that drug is not a controlled substance.
- Tell patient to stop taking methylphenidate if she stops taking opioid pain medication.

methylphenidate hydrochloride

Concerta, Daytrana Ritalin LA, Metadate, Metadate CD, Metadate ER, Methylin, Methylin ER, PMS-Methylphenidate (CAN), Riphenidate (CAN), Ritalin, Ritalin-LA, Ritalin SR (CAN), Ritalin-SR

Class, Category, and Schedule

Chemical class: Piperidine derivative

Therapeutic class: CNS stimulant

Pregnancy category: C

Controlled substance schedule: II

Indications and Dosages

↗ *To treat attention-deficit hyperactivity disorder (ADHD)*

CAPSULES, E.R. TABLETS, ORAL SOLUTION,

S.R. TABLETS, TABLETS

Adults and adolescents. 5 to 20 mg b.i.d. or t.i.d. *Maximum:* 90 mg daily.

Children ages 6 to 12. 5 mg b.i.d. before breakfast and lunch; increased by 5 to 10 mg daily at 1-wk intervals. *Maximum:* 60 mg daily.

E.R. ONCE-DAILY TABLETS (CONCERTA)

Adults and adolescents. 18 mg daily;

increased in 18-mg increments at 1-wk intervals. *Maximum:* 72 mg daily, not to exceed 2 mg/kg daily.

Children ages 6 to 12. 18 mg daily.

Maximum: 54 mg daily.

E.R. ONCE-DAILY CAPSULES (METADATE CD)

Children age 6 and over. 20 mg daily.

Dosage titrated to 40 or 60 mg daily based on individual response. *Maximum:* 60 mg daily.

DOSAGE ADJUSTMENT Dosage reduced or drug stopped if no improvement in 1 mo. When maintenance dosage is achieved with tablets, may be switched to E.R. or S.R. tablets.

TRANSDERMAL PATCH

Children ages 6 to 12. *Initial:* 10-mg (12.5-cm²) patch worn 9 hr daily; after 1 wk, increased to 15-mg (18.75-cm²) patch worn 9 hr daily; after 1 more wk, increased to 20-mg (25-cm²) patch worn 9 hr daily; after 1 more wk, increased to 30-mg (37.5-cm²) patch worn 9 hr daily. *Maximum:* 30-mg (37.5-cm²) patch worn 9 hr daily.

↗ *To treat narcolepsy*

ORAL SOLUTION, TABLETS

Adults and adolescents. 5 to 20 mg b.i.d. or t.i.d. *Maximum:* 90 mg daily.

Route	Onset	Peak	Duration
P.O. (tablets)	Unknown	Unknown	3–6 hr
P.O. (E.R., S.R.)	Unknown	Unknown	About 8 hr
P.O. (E.R. once-daily)	Unknown	Unknown	About 12 hr

Mechanism of Action

Blocks the reuptake mechanism of dopaminergic neurons in the cerebral cortex and subcortical structures of the brain, including the thalamus, decreasing motor restlessness and improving concentration.

Methylphenidate also may trigger sympathomimetic activity. This action produces increased motor activity, alertness, mild euphoria, and decreased fatigue in patients with narcolepsy.

Contraindications

Angina pectoris, anxiety, cardiac arrhythmias, depression, fructose intolerance, glau-

coma, glucose-galactose malabsorption, heart failure, hypersensitivity to methylphenidate or its components, hyperthyroidism, motor tics, recent MI, severe agitation, severe hypertension, sucrase-isomaltase insufficiency, tension, thyrotoxicosis, Tourette's syndrome or family history of it, use of halogenated anesthetics, use within 14 days of an MAO inhibitor

Interactions

DRUGS

anticholinergics: Possibly increased anticholinergic effects of both drugs

anticonvulsants, oral anticoagulants, phenylbutazone, tricyclic antidepressants:

Inhibited metabolism and increased blood levels of these drugs

diuretics, antihypertensives: Decreased therapeutic effects of these drugs

halogenated anesthetics: Possibly sudden decrease in blood pressure during surgery
MAO inhibitors: Possibly increased adverse effects of methylphenidate, possibly severe hypertension

FOODS

caffeine: Increased methylphenidate effects

Adverse Reactions

CNS: Agitation, aggressiveness, anxiety, confusion, depression, dizziness, dyskinesia, emotional lability, fever, hallucinations, headache, hyperactivity, insomnia, irritability, ischemic neurologic defects (reversible), mania, migraine, motor tics, nervousness, obsessive-compulsive disorder, paresthesia, psychosis, sedation, seizures, stroke, suicidal ideation, transient mood depression, tension, tremor, Tourette's syndrome, vertigo

CV: Angina, arrhythmias, bradycardia, cardiac arrest, chest pain, extrasystoles, hypertension, hypotension, MI, palpitations, Raynaud's phenomenon, sudden death, tachycardia

EENT: Accommodation abnormality, blurred vision, diplopia, dry mouth or throat, mydriasis, pharyngitis, rhinitis, sinusitis, vision changes

ENDO: Dysmenorrhea, growth suppression in children with long-term use

GI: Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, hepatotoxicity, nausea, vomiting

GU: Decreased libido

HEME: Anemia, decreased platelet count,

leukopenia, pancytopenia, thrombocytopenia, thrombocytopenic purpura

MS: Arthralgia, myalgia, muscle tightness or twitching

RESP: Increased cough, upper respiratory tract infection

SKIN: Allergic contact dermatitis, alopecia, application site reactions (transdermal patch), diaphoresis, erythema multiforme, exfoliative dermatitis, pruritus, rash, urticaria

Other: Anaphylaxis, angioedema, physical and psychological dependence, weight loss

Nursing Considerations

WARNING Be aware that methylphenidate may induce CNS stimulation and psychosis and may worsen behavior disturbances and thought disorders in patients who already have psychosis. Use drug cautiously in patients with psychosis.

- Keep in mind that, when signs and symptoms of ADHD occur with acute stress reactions or with pre-existing structural cardiac abnormalities or other serious heart problems, methylphenidate usually isn't indicated because of possible worsened reaction or sudden death.
- Monitor children and adolescents for first-time psychotic or manic symptoms. If present, notify prescriber and expect drug to be discontinued.

WARNING Know that the E.R. tablet form (Concerta) shouldn't be given to patients with esophageal motility disorders; drug may cause GI obstruction because tablet doesn't change shape in GI tract.

- Monitor blood pressure and pulse rate to detect hypertension and excessive stimulation. Notify prescriber if present. For patient with hypertension, expect to increase antihypertensive dosage or add another antihypertensive to regimen.

WARNING Watch for signs of physical or psychological dependence. Methylphenidate's abuse potential is similar to that of amphetamines; use cautiously in patients with a history of drug abuse.

- Stopping drug abruptly after long-term use may unmask dysphoria, paranoia, severe depression, or suicidal thoughts.
- Monitor growth in children. Report failure to grow or gain weight, and expect to stop drug.

- Watch closely (especially children, adolescents, and young adults), for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.
- Monitor transdermal patch application site for erythema. If more intense reactions occur with erythema, such as local edema or papule or vesicle formation that don't improve within 48 hours after patch is removed from irritated site or that spread beyond the patch site, expect further diagnostic testing to determine presence of allergic contact dermatitis.
- Patients with allergic contact dermatitis from transdermal patch may develop systemic allergy reaction if methylphenidate is taken by another route, such as by mouth. Monitor patient closely if route of administration changes, and report any evidence of flare-up of previous dermatitis or positive patch-test sites, generalized skin eruptions in previously unaffected skin, headache, fever, malaise, arthralgia, diarrhea, or vomiting because drug may need to be discontinued.

PATIENT TEACHING

- Stress need to take drug exactly as prescribed because misuse may cause serious adverse cardiovascular reactions, including sudden death.
- For transdermal form, teach patient to apply patch to a clean, dry location in his hip area 2 hours before effect is needed and to remove it 9 hours after application.
- Caution patient to avoid applying patch to skin that's oily, damaged, or irritated and to avoid the waistline, where clothing may dislodge the patch. Tell patient to rotate application sites between hips.
- Instruct patient to apply patch immediately after opening pouch and removing protective liner. Tell him to press patch firmly in place with palm of his hand for about 30 seconds. Reassure patient that exposing site to water shouldn't cause patch to fall off. If a patch does fall off, explain that a new patch may be applied but that the total exposure time for the day shouldn't exceed 9 hours.
- Urge patient not to chew or crush E.R. tablets.
- Tell patient to take tablets at least 6 hours

- before bedtime to avoid insomnia and to take E.R. once-daily tablets in the morning.
- Advise patient taking E.R. once-daily tablets (Concerta) that he may see intact tablet in stool. Explain that drug is slowly released from nonabsorbable tablet shell.
- Tell patient taking capsule form to swallow it whole or sprinkle contents onto a tablespoon of applesauce and take immediately, followed by a liquid such as water.
- Direct patient to notify prescriber about excessive nervousness, fever, insomnia, palpitations, rash, or vomiting.
- Warn patient with seizure disorder that drug may cause seizures.
- Inform parents of children on long-term therapy that drug may delay growth.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.

methylprednisolone

Medrol, Meprolone

methylprednisolone acetate

depMedalone, Depoject, Depo-Medrol, Depopred, Depo-Predate, Methylcotolone

methylprednisolone sodium succinate

A-methaPred, Solu-Medrol

Class and Category

Chemical class: Synthetic glucocorticoid

Therapeutic class: Anti-inflammatory, immunosuppressant

Pregnancy category: C

Indications and Dosages

➤ *To treat ulcerative colitis*

I.V. INFUSION (METHYLPREDNISOLONE SODIUM SUCCINATE)

Adults. 40 to 120 mg 3 to 7 times/wk for 2 or more wk. Later doses given I.V. or I.M., based on patient's condition and response.

Children. 0.14 to 0.84 mg/kg daily in divid-

ed doses every 12 to 24 hr.

➤ *To treat a wide range of immune and inflammatory disorders, including allergic rhinitis, asthma, Crohn's disease, and systemic lupus erythematosus*

TABLETS (METHYLPREDNISOLONE)

Adults. 4 to 48 mg daily as a single dose or in divided doses.

Children. 0.42 to 1.67 mg/kg daily in divided doses t.i.d. or q.i.d.

I.V. INFUSION, I.M. INJECTION

(METHYLPREDNISOLONE SODIUM SUCCINATE)

Adults. *Initial:* 10 to 40 mg infused over several min. Later doses given I.V. or I.M., based on patient's condition and response.

Children. 0.14 to 0.84 mg/kg every 12 to 24 hr.

I.M. INJECTION (METHYLPREDNISOLONE ACETATE)

Adults. 40 to 120 mg daily to every 2 wk, according to clinical response.

Children. 0.14 to 0.84 mg/kg every 12 to 24 hr.

INTRA-ARTICULAR, INTRALESIONAL, OR SOFT-TISSUE INJECTION (METHYLPREDNISOLONE ACETATE)

Adults. 4 to 80 mg every 1 to 5 wk, according to clinical response.

➤ *To treat adrenal hyperplasia*

I.M. INJECTION (METHYLPREDNISOLONE ACETATE)

Adults. 40 mg every 2 wk.

Children. 0.14 to 0.84 mg/kg every 12 to 24 hr.

➤ *To treat acute exacerbations of multiple sclerosis*

TABLETS (METHYLPREDNISOLONE)

Adults. 160 mg daily for 7 days followed by 64 mg every other day for 1 mo.

I.V. OR I.M. INJECTION (METHYLPREDNISOLONE ACETATE, METHYLPREDNISOLONE SODIUM SUCCINATE)

Adults. 160 mg daily for 1 wk followed by 64 mg every other day for 1 mo.

➤ *To treat adrenocortical insufficiency*

TABLETS (METHYLPREDNISOLONE), I.M. INJECTION (METHYLPREDNISOLONE SODIUM SUCCINATE)

Children. 0.18 mg/kg daily in divided doses t.i.d.

I.M. INJECTION (METHYLPREDNISOLONE ACETATE)

Children. 0.12 mg/kg every 3 days or 0.039 to 0.059 mg/kg daily.

Mechanism of Action

Binds to intracellular glucocorticoid receptors and suppresses inflammatory and

immune responses by inhibiting accumulation of neutrophils and monocytes at inflammation sites, stabilizing lysosomal membranes, suppressing the antigen response of macrophages and helper T cells, and inhibiting the synthesis of inflammatory response mediators, such as cytokines, interleukins, and prostaglandins.

Route	Onset	Peak	Duration
P.O.	In 60 min	1–2 hr	1.25–1.5 days
I.V.	Rapid	30 min	Unknown
I.M.	6–48 hr	4–8 days	1–4 wk

Incompatibilities

Don't mix methylprednisolone with any drug without first consulting pharmacist. Don't dilute methylprednisolone acetate with any other drug.

Contraindications

Fungal infection, hypersensitivity to methylprednisolone or its components, idiopathic thrombocytopenic purpura (I.M.)

Interactions

DRUGS

acetaminophen: Increased risk of hepatotoxicity

aminoglutethimide: Possibly loss of methylprednisolone-induced adrenal suppression

amphotericin B, carbonic anhydrase inhibitors: Possibly severe hypokalemia

anabolic steroids, androgens: Increased risk of edema and worsening of acne

anticholinergics: Possibly increased intraocular pressure

asparaginase: Increased risk of hyperglycemia and toxicity

aspirin, NSAIDs: Increased risk of adverse GI effects and bleeding

barbiturates, carbamazepine, phenytoin, rifampin: Decreased blood methylprednisolone level

cholestyramine: Possibly increased methylprednisolone clearance

cyclosporine: Increased risk of seizures

digoxin: Possibly hypokalemia-induced arrhythmias and digitalis toxicity

estrogens, oral contraceptives: Possibly increased therapeutic and toxic effects of methylprednisolone

insulin, oral antidiabetic drugs: Possibly

increased blood glucose level
isoniazid: Possibly decreased therapeutic effects of isoniazid

ketoconazole, macrolide antibiotics such as erythromycin and troleandomycin:

Decreased methylprednisolone clearance and increased risk of adverse effects
mexiletine: Possibly decreased blood mexiletine level

neuromuscular blockers: Possibly increased neuromuscular blockade, causing respiratory depression or apnea

oral anticoagulants, thrombolytics: Increased risk of GI ulceration and hemorrhage, possibly decreased therapeutic effects of these drugs

potassium supplements: Possibly decreased effects of these supplements

somatrem, somatropin: Possibly decreased therapeutic effects of these drugs

streptozocin: Increased risk of hyperglycemia

troleandomycin: Increased blood methylprednisolone level

vaccines: Decreased antibody response and increased risk of neurologic complications

ACTIVITIES

alcohol use: Increased risk of adverse GI effects and bleeding

Adverse Reactions

CNS: Ataxia, behavioral changes, depression, dizziness, euphoria, fatigue, headache, increased intracranial pressure with papilledema, insomnia, malaise, mood changes, neuropathy, paresthesia, restlessness, seizures, steroid psychosis, syncope, vertigo

CV: Arrhythmias (from hypokalemia), cardiac arrest, edema, fat embolism, heart failure, hypertension, hypertrophic cardiomyopathy (premature infants), hypotension, myocardial rupture following recent MI, tachycardia, thromboembolism, thrombophlebitis

EENT: Exophthalmos, glaucoma, increased intraocular pressure, nystagmus, posterior subcapsular cataracts

ENDO: Adrenal insufficiency, cushingoid symptoms (moon face, buffalo hump, central obesity, supraclavicular fat pad enlargement), diabetes mellitus, growth suppression in children, hyperglycemia, negative nitrogen balance from protein catabolism

GI: Abdominal distention, elevated liver enzymes, hepatomegaly, hiccups, increased

appetite, melena, nausea, pancreatitis, peptic ulcer, ulcerative esophagitis, vomiting
GU: Amenorrhea, glycosuria, menstrual irregularities, perineal burning or tingling

HEME: Easy bruising, leukocytosis

MS: Arthralgia; aseptic necrosis of femoral and humeral heads; Charcot-like arthropathy; compression fractures; muscle atrophy, twitching, or weakness; myalgia; osteoporosis; spontaneous fractures; steroid myopathy; tendon rupture

RESP: Pulmonary edema

SKIN: Acne; allergic dermatitis; altered skin pigmentation; diaphoresis; dry, scaly skin; erythema; hirsutism; necrotizing vasculitis; petechiae; purpura; rash; scarring; sterile abscess; striae; subcutaneous fat atrophy; thin, fragile skin; urticaria

Other: Activation of latent infections, anaphylaxis, angioedema, exacerbation of systemic fungal infections, hypernatremia, hypocalcemia, hypokalemia, hypokalemic alkalosis, impaired wound healing, masking of signs of infection, metabolic alkalosis, suppressed skin test reaction, weight gain

Nursing Considerations

- Use cautiously in patients with congestive heart failure or renal insufficiency because sodium retention and edema can occur in patients taking a corticosteroid. Also use cautiously in patients with peptic ulcer, diverticulitis, fresh intestinal anastomoses, or nonspecific ulcerative colitis; these conditions increase risk of perforation during corticosteroid therapy.
- Give methylprednisolone tablets with food to minimize indigestion and GI irritation. For once-daily dosing, give in the morning to coincide with normal cortisol secretion. Expect prescriber to add an anticid or H₂-receptor antagonist to regimen.
- Discard parenteral products that are discolored or contain particles. Discard any remaining Depo-Medrol suspension after prescribed dose is drawn from vial.
- Inject I.M. form deep into gluteal muscle. Avoid injecting into deltoid muscle because of risk of subcutaneous atrophy.
- Arrange for low-sodium diet with added potassium, as prescribed.
- Protect patient from falling, especially elderly patient at risk for fractures from osteoporosis.

- Closely monitor patient for signs of infection because drug may mask them or may worsen systemic fungal infections or active latent disease. Be aware that chickenpox and measles can become life-threatening in patients taking a corticosteroid.
- Assess for possible depression or psychotic episodes during therapy.
- Monitor blood glucose level; dosage of insulin or oral antidiabetic drug may need to be adjusted in diabetic patient.

WARNING To avoid possibly fatal acute adrenocortical insufficiency, expect to taper long-term therapy when discontinuing it, but expect dosage to be increased during times of stress.

- Be aware that changes in thyroid function such as development of hypothyroidism or hyperthyroidism may require dosage adjustment in chronic therapy because metabolic clearance of methylprednisolone is affected by thyroid activity.
- Avoid skin testing during methylprednisolone therapy because drug may suppress reaction.

PATIENT TEACHING

- Caution patient not to stop taking methylprednisolone abruptly or to change dosage without consulting prescriber.
- Tell patient to take a missed dose as soon as he remembers unless it's nearly time for the next dose. Caution against double-dosing.
- Urge patient to notify prescriber immediately about dark or tarry stools; signs of impending adrenocortical insufficiency, such as anorexia, dizziness, fainting, fatigue, fever, joint pain, muscle weakness, or nausea; and sudden weight gain or swelling.
- Instruct patient not to obtain vaccinations unless approved by prescriber.
- Urge patient to take vitamin D, calcium supplements, or both if recommended by prescriber.
- Inform patient that insomnia and restlessness usually resolve after 1 to 3 weeks.
- Caution patient to avoid people with contagious diseases.
- Explain the need for regular exercise or physical therapy to maintain muscle mass.
- Advise patient to carry medical identification that documents his need for long-term corticosteroid therapy.

metoclopramide hydrochloride

Apo-Metoclop (CAN), Maxeran (CAN), Metoclopramide Intensol, Octamide, PMS-Metoclopramide (CAN), Reglan

Class and Category

Chemical class: Benzamide

Therapeutic class: Antiemetic, upper GI stimulant

Pregnancy category: B

Indications and Dosages

↗ To treat diabetic gastroparesis

ORAL SOLUTION, ORAL SOLUTION CONCENTRATE, TABLETS

Adults and adolescents. 10 mg 30 min before meals and at bedtime up to q.i.d.

I.V. OR I.M. INJECTION

Adults and adolescents. 10 mg t.i.d. or q.i.d. for severe symptoms; dosage adjusted as needed.

↗ To treat gastroesophageal reflux disease

ORAL SOLUTION, ORAL SOLUTION CONCENTRATE, TABLETS

Adults and adolescents. 10 to 15 mg 30 min before meals and at bedtime.

↗ To prevent chemotherapy-induced vomiting

I.V. INFUSION

Adults and adolescents. 3 mg/kg before chemotherapy and then 0.5 mg/kg/hr for 8 hr.

I.V. INJECTION

Adults and adolescents. 1 to 2 mg/kg 30 min before chemotherapy and then repeated every 2 to 3 hr, as needed.

Children. 1 mg/kg as a single dose, repeated in 1 hr. *Maximum:* 2 mg/kg.

↗ To prevent postoperative nausea and vomiting

I.M. INJECTION

Adults and adolescents. 10 to 20 mg near end of procedure.

DOSAGE ADJUSTMENT Reduced by half if creatinine clearance is less than 40 ml/min/1.73 m².

Mechanism of Action

Antagonizes the inhibitory effect of dopamine on GI smooth muscle. This causes gastric contraction, which promotes gas-

tric emptying and peristalsis, thus reducing gastroesophageal reflux. Metoclopramide also blocks dopaminergic receptors in the chemoreceptor trigger zone, preventing nausea and vomiting.

Route	Onset	Peak	Duration
P.O.	30–60 min	Unknown	1–2 hr
I.V.	1–3 min	Unknown	1–2 hr
I.M.	10–15 min	Unknown	1–2 hr

Incompatibilities

Don't administer metoclopramide through same I.V. line as calcium gluconate, cephalothin sodium, chloramphenicol sodium, cisplatin, erythromycin lactobionate, furosemide, methotrexate, penicillin G potassium, or sodium bicarbonate.

Contraindications

Concurrent use of butyrophenones, phenothiazines, or other drugs that may cause extrapyramidal reactions; GI hemorrhage, mechanical obstruction, or perforation; hypersensitivity to metoclopramide or its components; pheochromocytoma; seizure disorders

Interactions

DRUGS

anticholinergics, opioid analgesics: Possibly decreased metoclopramide effects

apomorphine: Possibly decreased antiemetic effect of apomorphine, possibly increased CNS depression

bromocriptine, pergolide: Possibly decreased therapeutic effects of these drugs

cimetidine: Possibly decreased absorption and therapeutic effects of cimetidine

CNS depressants: Possibly increased CNS depression

cyclosporine: Increased cyclosporine level

digoxin: Decreased gastric digoxin absorption

levodopa: Possibly decreased levodopa effects

MAO inhibitors: Increased risk of severe hypertension if patient has essential hypertension

mexiletine: Possibly faster mexiletine absorption

succinylcholine: Possibly prolonged therapeutic action of succinylcholine

ACTIVITIES

alcohol use: Risk of excessive sedation

Adverse Reactions

CNS: Agitation, anxiety, depression, dizziness, drowsiness, extrapyramidal reactions (motor restlessness, parkinsonism, tardive dyskinesia), fatigue, headache, insomnia, irritability, lassitude, neuroleptic malignant syndrome, panic reaction, restlessness

CV: AV block, fluid retention, heart failure, hypertension, hypotension, supraventricular tachycardia

EENT: Dry mouth

ENDO: Galactorrhea, gynecomastia

GI: Constipation, diarrhea, nausea

GU: Menstrual irregularities

HEME: Agranulocytosis

SKIN: Rash

Other: Restless leg syndrome

Nursing Considerations

- Use metoclopramide cautiously in patients with hypertension because it may increase catecholamine levels.

WARNING Watch closely for tardive dyskinesia, especially in the elderly, women, and patients with diabetes, because this serious adverse effect is often irreversible even after therapy stops. Therapy lasting longer than 12 weeks isn't recommended because risk of tardive dyskinesia increases the longer the patient takes metoclopramide. Risk also has been linked to total cumulative dose so prescriber must take this into account when setting dosage. At first sign of involuntary movements of face, tongue, or limbs, notify prescriber and expect to discontinue drug.

- Monitor patient with NADH-cytochrome b5 reductase deficiency because metoclopramide increases risk of methemoglobinemia and sulfhemoglobinemia, and patient can't receive methylene blue.
- Assess patient for signs of intestinal obstruction, such as abnormal bowel sounds, diarrhea, nausea, and vomiting, before administering metoclopramide. Notify prescriber if you detect them.
- For I.V. use, you need not dilute doses of 10 mg or less. Give drug over 1 to 2 minutes. For doses larger than 10 mg, dilute in 50 ml normal saline solution, half-normal (0.45) saline solution, D₅W, or lactated Ringer's solution and infuse over at least 15 minutes.
- Avoid rapid I.V. delivery because it may cause anxiety, restlessness, and drowsiness.

WARNING Notify prescriber if patient shows signs of toxicity, such as disorientation, drowsiness, and extrapyramidal reactions.

- Monitor patient, especially one with heart failure or cirrhosis, for possible fluid retention or volume overload due to transient increase in plasma aldosterone level.
- Monitor patient closely for neuroleptic malignant syndrome, a rare but potentially fatal disorder characterized by hyperthermia, muscle rigidity, altered level of consciousness, irregular pulse or blood pressure, tachycardia, diaphoresis, and arrhythmias.
- Store drug in a light-resistant container; discard if discolored or contains particulate.

PATIENT TEACHING

- Advise against activities that require alertness for about 2 hours after each dose.
- Urge patient to avoid alcohol and CNS depressants while taking metoclopramide. They may increase CNS depression.
- Tell patient to immediately report involuntary movements of face, eyes, tongue, or hands, including lip smacking, chewing, puckering of mouth, frowning, scowling, sticking out tongue, blinking, moving eyes, or shaking arms and legs.
- Explain that stopping metoclopramide may cause withdrawal symptoms that include dizziness, nervousness, and headache.

metolazone

Diulo, Mykrox, Zaroxolyn

Class and Category

Chemical class: Quinazoline derivative
Therapeutic class: Antihypertensive, diuretic
Pregnancy category: B

Indications and Dosages

➤ *To manage mild to moderate hypertension*

EXTENDED TABLETS

Adults. 2.5 to 5 mg daily.

PROMPT TABLETS (MYKROX)

Adults. 0.5 mg daily. *Maintenance:* 0.5 to 1 mg daily. *Maximum:* 1 mg daily.

➤ *To manage edema from heart failure or renal disease*

EXTENDED TABLETS

Adults. 5 to 20 mg daily.

Mechanism of Action

Promotes renal excretion of water and sodium by inhibiting their reabsorption in distal convoluted tubules. The resulting reduction in plasma and extracellular fluid volume reduces blood pressure. Metolazone also helps reduce blood pressure by decreasing peripheral vascular resistance.

Route	Onset	Peak	Duration
P.O.	1 hr	2 hr	12–24 hr

Contraindications

Anuria; hepatic coma; hypersensitivity to metolazone, other sulfonamide derivatives, quinethazones, thiazides, or their components; renal failure

Interactions

DRUGS

allopurinol: Increased risk of hypersensitivity to allopurinol

amiodarone: Increased risk of arrhythmias from hypokalemia

amphotericin B: Increased risk of electrolyte imbalances

anesthetics: Increased effects of anesthetics

antigout drugs: Increased blood uric acid level and risk of gout attack

antihypertensives: Increased hypotension

antineoplastics: Prolonged antineoplastic-induced leukopenia

calcium salts: Increased risk of hypercalcemia
cholestyramine, colestipol: Decreased metolazone absorption

diazoxide: Increased risk of hyperglycemia

digoxin: Increased risk of electrolyte imbalances and digoxin-induced arrhythmias

diuretics: Additive effects of both drugs, possibly leading to severe hypovolemia and electrolyte imbalances

dopamine: Increased diuretic effect

insulin, oral antidiabetic drugs: Decreased effectiveness of these drugs, increased risk of hyperglycemia

lithium: Increased risk of lithium toxicity

methenamine: Decreased metolazone effectiveness from urinary alkalization

methylglucamine: Possibly hemolytic anemia

neuromuscular blockers: Increased risk of hypokalemia and neuromuscular blockade, increased risk of respiratory depression

NSAIDs, sympathomimetics: Possibly decreased metolazone effectiveness

oral anticoagulants: Decreased anticoagulation

vitamin D: Increased vitamin D action, increased risk of hypercalcemia

Adverse Reactions

CNS: Anxiety, chills, depression, dizziness, drowsiness, headache, insomnia, neuropathy, paresthesia, restlessness, syncope, weakness

CV: Chest pain, cold extremities, orthostatic hypotension, palpitations, peripheral edema, vasculitis, venous thrombosis

EENT: Bitter taste, blurred vision, dry mouth, epistaxis, pharyngitis, sinus congestion, tinnitus

ENDO: Hyperglycemia

GI: Abdominal pain, anorexia, cholecystitis, constipation, diarrhea, hepatic dysfunction, hepatitis, indigestion, nausea, pancreatitis, vomiting

GU: Decreased libido, glycosuria, impotence

HEME: Agranulocytosis, aplastic anemia, leukopenia, thrombocytopenia

MS: Arthralgia, gout, myalgia

RESP: Cough

SKIN: Dry skin, necrosis, petechiae, photosensitivity, pruritus, rash, urticaria

Other: Hypochloremia, hypokalemia, hyponatremia, hypovolemia, metabolic alkalosis

Nursing Considerations

WARNING Be aware that Mykrox prompt tablets shouldn't be substituted for Diulo or Zaroxolyn extended tablets because they aren't equivalent.

- Anticipate giving metolazone with a loop diuretic if patient responds poorly to loop diuretic alone.
- To monitor drug's diuretic effect, measure fluid intake and output and daily weight.
- If response to 1 mg of Mykrox is inadequate, expect to add another drug rather than increase dosage.
- Monitor blood chemistry test results and assess for evidence of hypochloremia, hypokalemia, and, possibly, mild metabolic alkalosis.
- Monitor serum calcium and uric acid levels, especially if patient has a history of gout or renal calculi. Metolazone may slightly increase calcium reabsorption and decrease uric acid excretion.

PATIENT TEACHING

- Inform patient that metolazone controls

but doesn't cure hypertension. Discuss possible need for lifelong therapy and consequences of uncontrolled hypertension.

- Instruct patient to take drug at the same time each day.
- Direct patient to take drug with food or milk to minimize adverse GI reactions.
- Advise patient to change position slowly to minimize orthostatic hypotension.
- Urge patient to notify prescriber about persistent, severe diarrhea, nausea, or vomiting, which can cause dehydration and orthostatic hypotension.
- Stress the importance of weight and diet control, especially limiting sodium intake.
- Inform diabetic patient that metolazone may increase blood glucose level and that he should check his level often.

metoprolol succinate

Toprol-XL

metoprolol tartrate

Apo-Metoprolol (CAN), Betaloc (CAN), Betaloc Durules (CAN), Lopresor (CAN), Lopresor SR (CAN), Lopressor, Novometoprol (CAN)

Class and Category

Chemical class: Beta₁-adrenergic antagonist

Therapeutic class: Antianginal, antihypertensive, MI prophylaxis and treatment

Pregnancy category: C

Indications and Dosages

↗ To manage hypertension, alone or with other antihypertensives

E.R. TABLETS (METOPROLOL SUCCINATE)

Adults. *Initial*: 25 to 100 mg daily, adjusted weekly as prescribed. *Maximum*: 400 mg daily.

E.R. TABLETS (METOPROLOL TARTRATE)

Adults. *Maintenance*: 100 to 400 mg daily to maintain blood pressure control after therapeutic level has been achieved with immediate-release tablets.

TABLETS (METOPROLOL TARTRATE)

Adults. *Initial*: 100 mg daily, adjusted weekly as prescribed. *Maximum*: 450 mg daily as a single dose or in divided doses.

➤ **To treat acute MI or evolving acute MI TABLETS (METOPROLOL TARTRATE), I.V. INJECTION (METOPROLOL TARTRATE)**

Adults. *Initial:* 5 mg by I.V. bolus every 2 min for 3 doses followed by 50 mg P.O. for patients who tolerate total I.V. dose (25 to 50 mg P.O. for patients who can't tolerate total I.V. dose) every 6 hr for 48 hr, starting 15 min after final I.V. dose; after 48 hr, 100 mg b.i.d. followed by maintenance dosage. *Maintenance:* 100 mg P.O. b.i.d. for at least 3 mo.

➤ **To treat angina pectoris and chronic stable angina**

E.R. TABLETS (METOPROLOL SUCCINATE)

Adults. 100 mg daily, increased weekly as prescribed. *Maximum:* 400 mg daily as a single dose or in divided doses.

E.R. TABLETS (METOPROLOL TARTRATE)

Adults. *Initial:* 100 mg daily, adjusted weekly as prescribed. *Maximum:* 450 mg daily.

TABLETS (METOPROLOL TARTRATE)

Adults. *Initial:* 50 mg b.i.d., adjusted weekly as prescribed. *Maximum:* 450 mg daily.

➤ **To treat stable, symptomatic (New York Heart Association [NYHA] Class II or III), ischemic, hypertensive, or cardiomyopathic heart failure**

E.R. TABLETS (METOPROLOL SUCCINATE)

Adults. *Initial:* 25 mg daily (NYHA Class II) or 12.5 mg daily (NYHA Class III or more severe heart failure) for 2 wk. Then dosage doubled every 2 wk as tolerated. *Maximum:* 200 mg daily.

Route	Onset	Peak	Duration
P.O.	60 min	1–2 hr	Unknown
P.O. (E.R.)	Unknown	6–12 hr	Unknown
I.V.	Unknown	20 min	Unknown

Mechanism of Action

Inhibits stimulation of beta₁-receptor sites, located mainly in the heart, resulting in decreased cardiac excitability, cardiac output, and myocardial oxygen demand. These effects help relieve angina. Metoprolol also helps reduce blood pressure by decreasing renal release of renin.

Contraindications

Acute heart failure; pulse less than 45 beats/minute; cardiogenic shock; hypersensitivity to metoprolol, its components, or other beta blockers; pheochromocytoma; second-

or third-degree AV block; severe peripheral arterial disorders; sick sinus syndrome

Interactions

DRUGS

aluminum salts, barbiturates, calcium salts, cholestyramine, colestipol, NSAIDs, rifampin, salicylates, sulfonpyrazone: Decreased therapeutic effects of metoprolol

amiodarone, digoxin, diltiazem, verapamil:

Increased risk of complete AV block

calcium channel blockers: Increased risk of heart failure and increased effects of both drugs

cimetidine: Increased metoprolol level

clonidine: Increased risk of hypotension;

increased risk of rebound hypertension

when clonidine is discontinued

digoxin: Decreased heart rate and slowed

atrioventricular conduction

estrogens: Possibly decreased antihypertensive effect of metoprolol

general anesthetics: Increased risk of hypotension and heart failure

insulin, oral antidiabetic drugs: Decreased blood glucose control, possibly masking of signs and symptoms of hypoglycemia (by metoprolol)

lidocaine: Increased risk of lidocaine toxicity

MAO inhibitors: Risk of hypertension

neuromuscular blockers: Possibly enhanced

and prolonged neuromuscular blockade

other antihypertensives: Additive hypotensive effect

phenothiazines: Possibly increased blood levels of both drugs

propafenone: Increased blood level and half-life of metoprolol

sympathomimetics, xanthines: Possibly decreased therapeutic effects of both drugs

FOODS

all foods: Increased bioavailability of metoprolol

Adverse Reactions

CNS: Anxiety, confusion, depression, dizziness, drowsiness, fatigue, hallucinations, headache, insomnia, weakness

CV: Angina, arrhythmias (including AV

block and bradycardia), chest pain,

decreased HDL level, increased triglyceride

levels, gangrene of extremity, heart failure,

hypertension, orthostatic hypotension

EENT: Nasal congestion, rhinitis, taste disturbance

GI: Constipation, diarrhea, hepatitis, nausea, vomiting

GU: Impotence

HEME: Leukopenia, thrombocytopenia

MS: Arthralgia, back pain, myalgia

RESP: Bronchospasm, dyspnea

SKIN: Diaphoresis, photosensitivity, rash, urticaria, worsening of psoriasis

Nursing Considerations

- Use metoprolol with extreme caution in patients with bronchospastic disease who don't respond to or can't tolerate other antihypertensives. Expect to give smaller doses more often to avoid the higher plasma levels in longer dosage intervals.
- Use cautiously in patients with hypertension or angina who have congestive heart failure because beta blockers such as metoprolol can further depress myocardial contractility, worsening heart failure.
- For patient with acute MI who can't tolerate initial dosage or who delays treatment, start with maintenance dosage, as prescribed and tolerated.
- Before starting therapy for heart failure, expect to give a diuretic, an ACE inhibitor, and digoxin to stabilize patient.
- If patient has pheochromocytoma, alpha blocker therapy should start first, followed by metoprolol to prevent paradoxical increase in blood pressure from attenuation of beta-mediated vasodilation in skeletal muscle.
- Be aware that metoprolol dosage for heart failure is highly individualized. Monitor patient for evidence of worsening heart failure during dosage increases. If heart failure worsens, expect to increase diuretic dosage and possibly decrease metoprolol dosage or temporarily discontinue drug, as prescribed. Metoprolol dosage shouldn't be increased until worsening heart failure has been stabilized.
- If patient with heart failure develops symptomatic bradycardia, expect to decrease the metoprolol dosage.

WARNING If dosage exceeds 400 mg daily, monitor patient for bronchospasm and dyspnea because metoprolol competitively blocks beta₂-adrenergic receptors in bronchial and vascular smooth muscles.

WARNING When substituting metoprolol for clonidine, expect to gradually reduce clonidine and increase metoprolol dosage

over several days. Given together, these drugs have additive hypotensive effects.

- Patients who take metoprolol may be at risk for AV block. If AV block results from depressed AV node conduction, prepare to give appropriate drug, as ordered, or assist with insertion of temporary pacemaker.
- Check for signs of poor glucose control in patient with diabetes mellitus. Metoprolol may interfere with therapeutic effects of insulin and oral antidiabetic drugs. It also may mask evidence of hypoglycemia, such as palpitations, tachycardia, and tremor.
- Monitor patient with peripheral vascular disease for evidence of arterial insufficiency (pain, pallor, and coldness in affected extremity) Metoprolol can precipitate or aggravate peripheral vascular disease.

WARNING Expect to taper dosage over 1 to 2 weeks when drug is discontinued; stopping abruptly can cause myocardial ischemia, MI, ventricular arrhythmias, or severe hypertension, especially in patients with cardiac disease. Abrupt withdrawal also may cause thyroid storm in a patient with hyperthyroidism or thyrotoxicosis.

PATIENT TEACHING

- Instruct patient to take metoprolol with food at the same time each day—once daily for E.R. tablets. Explain that he may halve tablets but not chew or crush them.
- Advise patient to notify prescriber if pulse rate falls below 60 beats/minute or is significantly lower than usual.
- Urge diabetic patient to check blood glucose level often during therapy.
- Caution patient not to stop drug abruptly.

metronidazole

Apo-Metronidazole (CAN), Flagyl, Flagyl I.V. RTU, Metric 21, MetroGel, MetroGel-Vaginal, Nidagel (CAN), Novonidazol (CAN), Protostat, Trikacide (CAN)

metronidazole hydrochloride

Flagyl I.V.

Class and Category

Chemical class: Nitroimidazole derivative

Therapeutic class: Antibiotic, antiprotozoal
Pregnancy category: B

Indications and Dosages

➤ *To treat systemic anaerobic infections caused by Bacteroides fragilis, Clostridium difficile, Clostridium perfringens, Eubacterium, Fusobacterium, Peptococcus, Peptostreptococcus, and Veillonella species*

CAPSULES, TABLETS

Adults and adolescents. 7.5 mg/kg up to 1,000 mg every 6 hr for 7 days or longer.
Maximum: 4,000 mg daily.

Children. 7.5 mg/kg every 6 hr or 10 mg/kg every 8 hr.

I.V. INFUSION

Adults and adolescents. *Initial:* 15 mg/kg and then 7.5 mg/kg up to 1,000 mg every 6 hr for 7 days or longer. *Maximum:* 4,000 mg daily.

Children. 7.5 mg/kg every 6 hr or 10 mg/kg every 8 hr.

➤ *To treat amebiasis (Entamoeba histolytica)*

CAPSULES, TABLETS

Adults. 500 to 750 mg t.i.d. for 5 to 10 days.

Children. 11.6 to 16.7 mg/kg t.i.d. for 10 days.

➤ *To treat trichomoniasis (Trichomonas vaginalis)*

CAPSULES, TABLETS

Adults. 2,000 mg as a single dose, 1,000 mg b.i.d. for 24 hr, or 250 mg t.i.d. for 7 days.

Children. 5 mg/kg t.i.d. for 7 days.

➤ *To prevent perioperative bowel infection*

I.V. INFUSION

Adults and adolescents. 15 mg/kg 1 hr before surgery and then 7.5 mg/kg 6 and 12 hr after initial dose.

➤ *To treat acne in patients with rosacea*

TOPICAL GEL

Adults. Thin film applied to affected area b.i.d. for 9 wk.

➤ *To treat bacterial vaginosis*

VAGINAL CREAM

Adults. 500 mg (1 applicatorful) once or twice daily for 10 to 20 days.

VAGINAL GEL

Adults. 37.5 mg (1 applicatorful) once or twice daily for 5 days.

VAGINAL TABLETS

Adults. 500 mg at bedtime for 10 to 20 days.

Mechanism of Action

Undergoes intracellular chemical reduction during anaerobic metabolism. After metronidazole is reduced, it damages DNA's helical structure and breaks its strands, which inhibits bacterial nucleic acid synthesis and causes cell death.

Incompatibilities

Don't administer I.V. metronidazole with aluminum needles or hubs or through same I.V. line as other drugs.

Contraindications

Breast-feeding, hypersensitivity to metronidazole or its components, trichomoniasis during first trimester of pregnancy

Interactions

DRUGS

cimetidine: Possibly delayed elimination and increased blood level of metronidazole

disulfiram: Possibly combined toxicity, with confusion and psychotic reactions
neurotoxic drugs: Increased risk of neurotoxicity

oral anticoagulants: Possibly increased anticoagulant effect

phenobarbital: Increased metabolism and decreased blood level and half-life of metronidazole

phenytoin: Decreased phenytoin clearance

ACTIVITIES

alcohol use: Possibly disulfiram-like effects

Adverse Reactions

CNS: Aseptic meningitis (parenteral form), ataxia, confusion, dizziness, encephalopathy, fever, headache, incoordination, insomnia, irritability, light-headedness, peripheral neuropathy, seizures (high doses), syncope, weakness, vertigo

EENT: Dry mouth, lacrimation (topical form), metallic taste, nasal congestion, optic neuropathy, pharyngitis

GI: Abdominal cramps or pain, anorexia, diarrhea, nausea, pancreatitis, vomiting

GU: Dark urine, vaginal candidiasis (oral, parenteral, and topical forms); burning or irritation of sexual partner's penis, candidal cervicitis or vaginitis, dysuria, dryness of vagina or vulva, urinary frequency, vulvitis (vaginal form)

HEME: Leukopenia

MS: Back pain, dysarthria

SKIN: Burning or stinging sensation, dry

skin (topical form); erythema, flushing, pruritus, rash, Stevens Johnson syndrome, urticaria (oral and parenteral forms)

Other: Injection site edema, pain, or tenderness

Nursing Considerations

- Give I.V. drug by slow infusion over 1 hour; don't give by direct I.V. injection.
- Discontinue primary I.V. infusion during metronidazole infusion.

WARNING If patient has adverse CNS reactions, such as seizures or peripheral neuropathy, tell prescriber and stop drug immediately.

- Monitor patient with severe liver disease because slowed metronidazole metabolism may cause drug to accumulate in body and increase the risk of adverse effects.
- If skin irritation occurs, apply topical metronidazole gel less frequently or discontinue it, as ordered.
- Monitor CBC and culture and sensitivity tests if therapy lasts longer than 10 days or if second course of treatment is needed.

PATIENT TEACHING

- Instruct female patient to notify prescriber if she is pregnant, intends to get pregnant, or is breast-feeding.
- Urge patient to take metronidazole at evenly spaced intervals day and with food to minimize adverse GI reactions.
- Urge patient to complete the entire course of therapy.
- Caution patient to avoid alcohol during therapy and for at least 3 days afterward.
- Advise patient to avoid hazardous activities until drug's CNS effects are known and to report any abnormal neurologic signs or symptoms, such as weakness, numbness, seizures, or vision changes.
- If patient reports dry mouth, suggest ice chips or sugarless hard candy or gum; suggest a dental visit if dryness lasts longer than 2 weeks.
- Instruct patient to notify prescriber if no improvement occurs within a few days of taking tablets or capsules.
- Direct patient using topical gel to wash hands and affected area with a mild, non-irritating cleaner; to rinse well and pat dry; and then to apply a thin film of drug and wash hands again.
- Advise patient with rosacea to keep topical

gel away from his eyes. If drug gets into his eyes, urge him to wash them immediately with large amounts of cool tap water and to call prescriber if eyes continue to hurt or burn.

- Instruct patient with rosacea to notify prescriber if no improvement occurs after 3 weeks of topical use; full therapeutic effect may take 9 weeks.
- Teach patient how to fill, insert, and clean vaginal cream or gel applicator after use. Instruct her to wash her hands before and after administration.
- To help vaginal tablets dissolve, instruct patient to run tap water over unwrapped tablet for a few seconds before insertion.
- Inform patient with trichomoniasis that her male sexual partners should wear condoms during her treatment and that they may need treatment themselves to prevent reinfection.
- Caution patient that vaginal cream and tablets (not gel) may contain oils that damage latex condoms.
- Urge patient to follow up with prescriber to make sure infection is gone.

metyrosine

Demser

Class and Category

Chemical class: Alpha-methyl tyrosine

Therapeutic class: Antipheochromocytoma agent

Pregnancy category: C

Indications and Dosages

↗ *To control hypertension and related symptoms until pheochromocytectomy is performed, to treat chronic malignant pheochromocytoma*

CAPSULES

Adults and adolescents. *Initial:* 250 mg q.i.d., increased as ordered by 250 to 500 mg daily. *Maintenance:* 2,000 to 3,000 mg daily in divided doses q.i.d. Preoperative dosage given for at least 7 days. *Maximum:* 4,000 mg daily in divided doses.

Mechanism of Action

Blocks activity of tyrosine hydroxylase, the enzyme that controls rate of catecholamine synthesis. This action decreases production

of the catecholamines epinephrine and norepinephrine, which, in patients with pheochromocytoma, are produced in excessive amounts.

Contraindications

Hypersensitivity to metyrosine or its components

Interactions

DRUGS

CNS depressants: Increased sedation
haloperidol, phenothiazines: Increased extrapyramidal effects

ACTIVITIES

alcohol use: Increased sedation

Adverse Reactions

CNS: Anxiety, confusion, depression, disorientation, extrapyramidal reactions (difficulty speaking, drooling, parkinsonism, tremor, trismus), hallucinations, headache, sedation

CV: Peripheral edema

EENT: Dry mouth, nasal congestion, pharyngeal edema

ENDO: Galactorrhea, gynecomastia

GI: Abdominal pain, diarrhea, elevated serum AST level, nausea, vomiting

GU: Crystalluria, dysuria (transient), ejaculation failure, hematuria, impotence, urolithiasis

HEME: Anemia, eosinophilia, thrombocytopenia, thrombocytosis

SKIN: Urticaria

Nursing Considerations

- Expect patient taking metyrosine to experience moderate to severe sedation at low and high dosages. Sedation begins during first 24 hours, peaks after 2 to 3 days, and tends to wane during next few days. It usually subsides after 1 week unless dosage is increased or exceeds 2 g daily.
- Obtain urine specimens as ordered to check for crystalluria and urolithiasis. If crystalluria develops, increase fluid intake to achieve daily urine output of 2,000 ml or more with doses above 2 g daily. If crystalluria persists, reduce dosage or stop drug, as ordered.
- Expect to adjust dosage, as prescribed, based on clinical response and urine catecholamine level.
- If signs and symptoms aren't adequately controlled by metyrosine, expect to add an

alpha-adrenergic blocker, such as phenoxylbenzamine, as prescribed.

PATIENT TEACHING

- Inform patient about metyrosine's sedative effects. Advise him to avoid alcohol and CNS depressants, which may increase sedation.
- Instruct patient to increase fluid intake, as appropriate.
- Urge patient to report drooling, severe diarrhea, trembling and shaking of hands and fingers, or trouble speaking.
- Inform patient that he may experience changes in sleep pattern for 2 to 3 days after stopping drug.
- Advise patient to keep regular visits with prescriber to monitor progress.

mexiletine hydrochloride

Mexitil

Class and Category

Chemical class: Lidocaine analogue

Therapeutic class: Class IB antiarrhythmic

Pregnancy category: C

Indications and Dosages

↗ *To treat life-threatening ventricular arrhythmias*

CAPSULES

Adults. *Initial:* 200 mg every 8 hr, adjusted, as ordered, by 50 to 100 mg/dose every 2 to 3 days, as tolerated. If patient tolerates 300 mg or less every 8 hr, total dosage may be divided and given every 12 hr. If patient continues to experience arrhythmias, dosage frequency may be changed to q.i.d. *Maximum:* 1,200 mg daily when given every 8 hr (400 mg/dose); 900 mg daily when given every 12 hr (450 mg/dose).

↗ *To rapidly control life-threatening ventricular arrhythmias*

CAPSULES

Adults. *Initial:* 400 mg followed by 200 mg after 8 hr. *Maintenance:* 200 mg every 8 hr, adjusted, as ordered, by 50 to 100 mg/dose every 2 to 3 days, as tolerated. If patient tolerates 300 mg or less every 8 hr, total dosage may be divided and given every 12 hr. If patient continues to experience arrhythmias, dosage frequency may be

changed to q.i.d.

DOSE ADJUSTMENT For patients with severe hepatic disease or heart failure, dosage reduced and adjusted every 2 or 3 days.

Route	Onset	Peak	Duration
P.O.	0.5–2 hr	2–3 hr	8–12 hr

Mechanism of Action

Produces antiarrhythmic effect by inhibiting fast sodium channels in myocardial cell membranes, especially in the His-Purkinje system. This action decreases duration of action potential and effective refractory period of His-Purkinje system. The myocardium, which becomes refractory again after resting membrane potential is restored, is less likely to generate and respond to ectopic ventricular impulses.

Contraindications

Cardiogenic shock, second- or third-degree AV block without a pacemaker

Interactions

DRUGS

aluminum- or magnesium-containing antacids: Delayed mexiletine absorption
antiarrhythmics: Increased cardiac effects
cimetidine: Possibly increased or decreased blood mexiletine level

hepatic enzyme inducers: Accelerated metabolism and decreased level of mexiletine
metoclopramide: Accelerated mexiletine absorption

rifampin: Decreased blood mexiletine level

theophylline: Increased theophylline level

urine acidifiers: Accelerated renal excretion of mexiletine

urine alkalizers: Delayed mexiletine excretion

FOODS

caffeine: Possibly decreased clearance and increased effects of caffeine

foods that may acidify urine (such as cheese, cranberries, eggs, fish, grains, meats, plums, poultry, and prunes): Accelerated renal excretion of mexiletine

foods that may alkalize urine (such as milk and all vegetables and fruits except cranberries, plums, and prunes): Delayed renal excretion of mexiletine

ACTIVITIES

smoking: Reduced mexiletine half-life

Adverse Reactions

CNS: Confusion, dizziness, fatigue, headache, lack of coordination, light-headedness, nervousness, paresthesia, seizures, sleep disturbance, syncope, tremor, weakness

CV: Atrial arrhythmias, AV conduction disorders, bradycardia, cardiogenic shock, chest pain, heart failure, hypotension, palpitations, PVCs, ventricular arrhythmias (increased)

EENT: Blurred vision, dry mouth, tinnitus

GI: Constipation, diarrhea, heartburn, nausea, vomiting

HEME: Agranulocytosis, leukopenia, thrombocytopenia

RESP: Dyspnea

SKIN: Rash

Nursing Considerations

- If mexiletine is replacing another antiarrhythmic, expect to give first dose 6 to 12 hours after last dose of quinidine sulfate or disopyramide, 3 to 6 hours after last dose of procainamide, or 8 to 12 hours after last dose of tocainide, as prescribed.
- If mexiletine is replacing parenteral lidocaine, expect to reduce or withdraw lidocaine 1 to 2 hours after starting mexiletine, as prescribed.
- Monitor continuous ECG and serum mexiletine level.
- Assess patient for thrombocytopenia, which may occur within a few days after mexiletine therapy starts. Expect platelet count to return to normal within 1 month after mexiletine therapy stops.

PATIENT TEACHING

- Instruct patient to take mexiletine at evenly spaced intervals, to avoid missing doses, and to take drug as prescribed, even if he's feeling well.
- Advise patient to take drug with food to reduce adverse GI reactions.
- Inform patient that nausea and vomiting may occur within 2 hours after dose but tend to lessen as treatment continues.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Teach patient to take his pulse, and advise him to contact prescriber if rate is below 50 beats/minute or rhythm is irregular.
- Urge patient to notify prescriber immediately about chest pain, chills, fast or irregular heartbeat, fever, shortness of breath,

- and unusual bleeding or bruising.
- Advise patient to avoid greatly increasing intake of foods that may acidify urine (cheese, cranberries, eggs, fish, grains, meats, plums, poultry, prunes) or alkalize urine (milk, all vegetables, all fruits except cranberries, plums, and prunes).
- Encourage patient to keep regular visits with prescriber to monitor progress.

mezlocillin sodium

Mezlin

Class and Category

Chemical class: Acyclaminopenicillin

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

- *To treat moderate to severe infections, including bacteremia, bone and joint infections, gynecologic infections (such as endometritis, pelvic cellulitis, and pelvic inflammatory disease), intra-abdominal infections (such as cholangitis, cholecystitis, hepatic abscess, intra-abdominal abscess, and peritonitis), lower respiratory tract infections (such as pneumonia and lung abscess), meningitis, septicemia caused by susceptible bacteria, or skin and soft-tissue infections (such as cellulitis and diabetic foot ulcer); to manage febrile neutropenia*

I.V. INFUSION, I.M. INJECTION

Adults and adolescents. 3 g every 4 hr or 4 g every 6 hr.

- *To treat life-threatening infections of the types listed above*

I.V. INFUSION, I.M. INJECTION

Adults and adolescents. Up to 350 mg/kg daily. *Maximum:* 24,000 mg daily.

Children and infants. 50 mg/kg every 4 hr (or infused over 30 min every 4 hr).

Neonates over age 7 days weighing 2,000 g (4.4 lb) or less. 75 mg/kg I.V. every 8 hr.

Neonates age 7 days or less weighing 2,000 g or less. 75 mg/kg I.V. every 12 hr.

Neonates age 7 days or less weighing more than 2,000 g. 75 mg/kg I.V. every 6 hr.

- *To treat uncomplicated UTI*

I.V. INFUSION, I.M. INJECTION

Adults. 1.5 to 2 g every 6 hr.

- *To treat complicated UTI*

I.V. INFUSION

Adults. 3 g every 6 hr.

DOSAGE ADJUSTMENT Dosing interval extended to 6 to 8 hr if needed for patients with creatinine clearance of 10 to 30 ml/min/1.73 m². Dosing interval extended and dosage reduced to 1.5 to 2 g for patients with creatinine clearance below 10 ml/min/1.73 m².

- *To treat uncomplicated gonorrhea caused by susceptible strains of Neisseria gonorrhoeae*

I.V. INFUSION, I.M. INJECTION

Adults. 1 to 2 g as a single dose given with 1 g of probenecid P.O. (or probenecid given up to 30 min before mezlocillin).

- *To prevent infection from potentially contaminated surgical procedures*

I.V. INFUSION

Adults. 4 g 30 min before surgery and then 4 g every 6 hr for 2 more doses.

- *To prevent infection in cesarean section*

I.V. INFUSION

Adults. 4 g as soon as umbilical cord is clamped; then 4 g every 4 hr for 2 more doses, starting 4 hr after initial dose.

Mechanism of Action

Inhibits bacterial cell wall synthesis. In susceptible bacteria, the rigid, cross-linked cell wall is assembled in several stages. Mezlocillin affects final stage of cross-linking process by binding with and inactivating penicillin-binding proteins (enzymes responsible for linking cell wall strands). This causes bacterial cell lysis and death.

Incompatibilities

Administer mezlocillin at separate sites and at least 1 hour before or after administering aminoglycosides. Don't mix mezlocillin in the same I.V. bag, bottle, or tubing with other drugs.

Contraindications

Hypersensitivity to mezlocillin, other penicillins, or their components

Interactions

DRUGS

aminoglycosides: Substantial aminoglycoside inactivation
chloramphenicol, erythromycins, sulfonamides, tetracyclines: Possibly decreased therapeutic effects of mezlocillin

methotrexate: Increased risk of methotrexate toxicity

probenecid: Increased blood level and prolonged half-life of mezlocillin

Adverse Reactions

CNS: Depression, headache, seizures

EENT: Oral candidiasis

GI: Abdominal pain, diarrhea, pseudomembranous colitis, nausea, vomiting

GU: Vaginitis

HEME: Leukopenia, neutropenia

SKIN: Exfoliative dermatitis, pruritus, rash, urticaria

Other: Anaphylaxis; hypokalemia; injection site pain, redness, and swelling; serum sicknesslike reaction

Nursing Considerations

WARNING Before starting mezlocillin, make sure patient has had no previous hypersensitivity reactions to penicillins.

- Anticipate that mezlocillin therapy will last for at least 2 days after signs and symptoms have resolved—typically 7 to 10 days, depending on severity of infection. Complicated infections may need longer treatment. Group A beta-hemolytic streptococcal infections usually are treated for at least 10 days to reduce risk of rheumatic fever or glomerulonephritis.
- For I.M. injection, reconstitute each gram of mezlocillin with 3 to 4 ml sterile water for injection and shake vigorously. Inject no more than 2 g into a large muscle, such as the gluteus maximus, over 12 to 15 seconds to minimize discomfort.
- Although drug may be given I.M., expect to use intermittent I.V. infusion, as directed, for serious infections.
- For I.V. use, reconstitute each gram of mezlocillin with 9 to 10 ml sterile water for injection, D₅W, or sodium chloride for injection and shake vigorously. Inject directly into I.V. tubing over 3 to 5 minutes.
- For intermittent infusion, further dilute to desired volume (50 to 100 ml) with an appropriate I.V. solution and administer over 30 minutes. Discontinue other infusions during mezlocillin administration.
- Be aware that mezlocillin powder and reconstituted solution may darken slightly but that potency isn't affected.
- Periodically monitor serum potassium level during long-term therapy, as ordered.

- During long-term therapy, watch for signs and symptoms of superinfection, such as oral candidiasis and vaginitis.

PATIENT TEACHING

- Instruct patient taking mezlocillin to notify prescriber immediately about increased bruising or other bleeding tendencies.
- Advise patient to report diarrhea and to check with prescriber before taking an antidiarrheal medicine because of the risk of masking pseudomembranous colitis.

micafungin sodium

Mycamine

Class and Category

Chemical class: Semisynthetic lipopeptide echinocandin

Therapeutic class: Antifungal

Pregnancy category: C

Indications and Dosages

➤ *To treat esophageal candidiasis*

I.V. INFUSION

Adults. 150 mg infused over 1 hr daily.

➤ *To prevent Candida infection in patients undergoing hematopoietic stem cell transplantation*

I.V. INFUSION

Adults. 50 mg infused over 1 hr daily.

➤ *To treat candidemia, acute disseminated candidiasis, and Candida peritonitis and abscesses*

I.V. INFUSION

Adults. 100 mg infused over 1 hr daily.

Mechanism of Action

Inhibits synthesis of 1,3-beta-D-glucan, which is an essential component of the *Candida* fungal cell wall. Without 1,3-beta-D-glucan, the fungal cell dies.

Contraindications

Hypersensitivity to micafungin, its components, or other echinocandins

Incompatibilities

Mixing or infusing with other drugs may cause micafungin to precipitate.

Interactions

DRUGS

immunosuppressants: Possibly additive adverse hematologic effects

itraconazole, nifedipine, sirolimus: Increased plasma levels of these drugs

Adverse Reactions

CNS: Anxiety, delirium, dizziness, dysgeusia, fatigue, fever, headache, insomnia, intracranial hemorrhage, rigors, seizures, somnolence

CV: Arrhythmia, atrial fibrillation, bradycardia, cardiac arrest, deep venous thrombosis, hypertension, hypotension, MI, peripheral edema, phlebitis, tachycardia, shock, vasodilation

EENT: Epistaxis, mucosal inflammation

ENDO: Hypoglycemia, hyperglycemia

GI: Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, elevated liver enzyme levels, hepatic dysfunction, hiccups, hyperbilirubinemia, jaundice, nausea, vomiting

GU: Acute renal failure, anuria, elevated serum creatinine and blood urea levels, oliguria, renal tubular necrosis

HEME: Anemia, coagulopathy, eosinophilia, hemolytic anemia, leukopenia, lymphopenia, neutropenia, pancytopenia, thrombocytopenia

MS: Arthralgia, back pain

RESP: Apnea, cough, cyanosis, dyspnea, hypoxia, pneumonia, pulmonary embolism

SKIN: Erythema, erythema multiforme, flushing, necrosis, pruritus, rash, urticaria

Other: Acidosis, anaphylaxis, angioedema, bacteremia, hyperkalemia, hypernatremia, hypocalcemia, hypokalemia, hypomagnesemia, hyponatremia, hypophosphatemia, injection site reactions including phlebitis and thrombophlebitis, sepsis

Nursing Considerations

- Use cautiously in patients with hepatic or renal insufficiency.
- Reconstitute miconazole by adding 5 ml normal saline solution to each 50-mg vial being used (to yield 10 mg miconazole/ml) or 5 ml normal saline solution to each 100-mg vial (to yield 20 mg miconazole/ml). Swirl vial gently to minimize excessive foaming. Add reconstituted solution to 100 ml normal saline solution, and give solution over 1 hour. Protect diluted solution from light, although you need not cover the infusion drip chamber or tubing.
- Always flush an existing intravenous line with normal saline solution before administering miconazole through that line.

- Monitor infusion rate carefully because infusions that took less than 1 hour to infuse have been associated with more frequent hypersensitivity reactions.

WARNING Monitor patient closely for hypersensitivity reactions including anaphylaxis and angioedema. Stop infusion immediately if present, notify prescriber, and provide supportive care, as prescribed.

- Monitor patient's liver and renal function closely throughout therapy because liver and renal abnormalities may occur in patients receiving miconazole.

- Monitor hematologic status closely because hematologic abnormalities may occur. If they do, monitor patient closely. If patient's condition worsens, expect miconazole to be discontinued.

PATIENT TEACHING

- Instruct patient to report any infusion site discomfort immediately.
- Tell patient to report any unusual or persistent signs and symptoms to prescriber.

midazolam hydrochloride

Versed

Class, Category, and Schedule

Chemical class: Benzodiazepine

Therapeutic class: Sedative-hypnotic

Pregnancy category: D

Controlled substance schedule: IV

Indications and Dosages

➤ *To induce preoperative sedation or amnesia, to control preoperative anxiety*

ORAL SOLUTION

Children ages 6 months to 16 years.

0.25 to 0.5 mg/kg as a single dose 30 to 45 min before surgery. *Usual:* 0.5 mg/kg. *Maximum:* 20 mg.

I.V. INJECTION

Adults age 60 and over. 1.5 mg over 2 min immediately before procedure. After 2-min waiting period, dosage adjusted to desired level in 25% increments, as ordered.

Maximum: 1 mg in 2 min.

Adults under age 60 and adolescents. Up to 2.5 mg over 2 min immediately before procedure. After 2-min waiting period, dosage adjusted to desired level in 25%

increments, as ordered. *Maximum:* 5 mg.

Children ages 6 to 12. Initial: 0.025 to 0.05 mg/kg, up to 0.4 mg/kg, if needed.

Maximum: 10 mg.

Children ages 6 months to 5 years. Initial: 0.05 to 0.1 mg/kg, up to 0.6 mg/kg, if needed. *Maximum:* 6 mg.

I.M. INJECTION

Adults age 60 and over. 0.02 to 0.05 mg/kg as a single dose 30 to 60 min before surgery.

Adults under age 60 and adolescents.

0.07 to 0.08 mg/kg as a single dose 30 to 60 min before surgery.

Children ages 6 months to 12 years. 0.1 to 0.15 mg/kg, up to 0.5 mg/kg for more anxious patients. *Maximum:* 10 mg.

↗ *To relieve agitation and anxiety in mechanically ventilated patients*

I.V. INFUSION

Adults. Initial: 0.01 to 0.05 mg/kg infused over several min, repeated at 10- to 15-min intervals until adequate sedation occurs.

Maintenance: 0.02 to 0.1 mg/kg/hr initially, adjusted to desired level in 25% to 50% increments, as ordered. After achieving desired level of sedation, infusion rate decreased by 10% to 25% every few hr, as ordered, until minimum effective infusion rate is determined.

Children. Initial: 50 to 200 mcg/kg over 2 to 3 min followed by 1 to 2 mcg/kg/min by continuous infusion. *Maintenance:* 0.4 to 6 mcg/kg/min.

Infants over age 32 weeks. 1 mcg/kg/min by continuous infusion.

Infants under age 32 weeks. 0.5 mcg/kg/min by continuous infusion.

Route	Onset	Peak	Duration
I.V.*	1.5–5 min	Rapid	2–6 hr
I.M.*	5–15 min	15–60 min	2–6 hr
I.M.†	30–60 min	Unknown	Unknown

Mechanism of Action

May exert sedating effect by increasing activity of gamma-aminobutyric acid, a major inhibitory neurotransmitter in the brain. As a result, midazolam produces a calming effect, relaxes skeletal muscles, and—at high doses—induces sleep.

* For sedation.

† For amnesia.

Contraindications

Acute angle-closure glaucoma; alcohol intoxication; coma; hypersensitivity to midazolam, other benzodiazepines, or their components; shock

Interactions

DRUGS

antihypertensives: Increased risk of hypotension

cimetidine, diltiazem, erythromycin, fluconazole, indinavir, itraconazole, ketoconazole, ranitidine, ritonavir, saquinavir, verapamil:

Intense and prolonged sedation caused by reduced midazolam metabolism

CNS depressants: Possibly increased CNS and respiratory depression and hypotension

rifampin: Decreased blood midazolam level

FOODS

grapefruit, grapefruit juice: Possibly increased blood midazolam level and risk of toxicity

ACTIVITIES

alcohol use: Possibly intense, prolonged sedative effect and increased respiratory depression and hypotension

Adverse Reactions

CNS: Agitation, delirium, or dreaming during emergence from anesthesia; anxiety; ataxia; chills; combativeness; confusion; dizziness; drowsiness; euphoria; excessive sedation; headache; insomnia; lethargy; nervousness; nightmares; paresthesia; prolonged emergence from anesthesia; restlessness; retrograde amnesia; sleep disturbance; slurred speech; weakness; yawning

CV: Cardiac arrest, hypotension, nodal rhythm, PVCs, tachycardia, vasovagal episodes

EENT: Blurred vision, diplopia, or other vision changes; increased salivation; laryngospasm; miosis; nystagmus; toothache

GI: Hiccups, nausea, retching, vomiting

RESP: Airway obstruction, bradypnea, bronchospasm, coughing, decreased tidal volume, dyspnea, hyperventilation, respiratory arrest, shallow breathing, tachypnea, wheezing

SKIN: Pruritus, rash, urticaria

Other: Injection site burning, edema, induration, pain, redness, and tenderness

Nursing Considerations

• Before giving midazolam, determine whether patient consumes alcohol or takes

antihypertensives, antibiotics, or protease inhibitors because these substances can produce an intense and prolonged sedative effect when taken with midazolam.

WARNING I.V. midazolam is given only in hospital or ambulatory care settings that allow continuous monitoring of respiratory and cardiac function. Keep resuscitative drugs and equipment at hand.

- As needed, combine midazolam injection with D₅W, normal saline solution, or lactated Ringer's solution. With D₅W and normal saline, solution is stable 24 hours. With lactated Ringer's, solution is stable 4 hours.
- As needed, mix injection in same syringe with atropine sulfate, meperidine hydrochloride, morphine sulfate, or scopolamine hydrobromide. The resulting solution is stable for 30 minutes.
- Assess level of consciousness frequently because the range between sedation and unconsciousness or disorientation is narrow with midazolam.
- Be aware that recovery time is usually 2 hours but may be up to 6 hours.

PATIENT TEACHING

- Inform patient that he may not remember procedure because midazolam produces amnesia.
- Advise patient to avoid hazardous activities until drug's adverse CNS effects, such as dizziness and drowsiness, have worn off.
- Instruct patient to avoid alcohol and other CNS depressants for 24 hours after receiving drug, as directed by prescriber.

midodrine hydrochloride

ProAmatine

Class and Category

Chemical class: Desglymidodrine prodrug

Therapeutic class: Antihypotensive, vasopressor

Pregnancy category: C

Indications and Dosages

↗ *To treat symptomatic orthostatic hypotension*

TABLETS

Adults. 10 mg t.i.d. in 3- to 4-hr intervals.

DOSAGE ADJUSTMENT Initial dose possibly reduced to 2.5 mg for patients with renal impairment.

Route	Onset	Peak	Duration
P.O.	Unknown	30 min	2–3 hr

Mechanism of Action

Is broken down into the active metabolite desglymidodrine. Desglymidodrine directly stimulates alpha-adrenergic receptors in arteries and veins. This action increases total peripheral vascular resistance, which in turn increases systolic and diastolic blood pressure.

Contraindications

Acute renal disease, hypersensitivity to midodrine or its components, initial supine systolic pressure above 180 mm Hg, persistent and excessive supine hypertension, pheo-chromocytoma, severe heart disease, thyrotoxicosis, urine retention

Interactions

DRUGS

beta blockers, digoxin: Enhanced or precipitated bradycardia, AV block, arrhythmias
cimetidine, flecainide, metformin, procainamide, quinidine, ranitidine, triamterene: Possibly decreased renal clearance of these drugs

dihydroergotamine, ephedrine, phenylephrine, phenylpropanolamine, pseudoephedrine: Increased vasopressor effects

doxazosin, prazosin, terazosin: Antagonized midodrine effects

fludrocortisone acetate: Increased risk of supine hypertension

Adverse Reactions

CNS: Anxiety, asthenia, chills, confusion, delusions, dizziness, feeling of pressure or fullness in head, headache, hyperesthesia, insomnia, nervousness, paresthesia, somnolence

CV: Hypertension (sitting and supine), vasodilation

EENT: Canker sore, dry mouth, vision changes

GI: Flatulence, indigestion, nausea

GU: Dysuria, urinary frequency and urgency, urine retention

MS: Back pain, leg cramps

SKIN: Dry skin, erythema multiforme,

facial flushing, piloerection, rash, scalp pruritus

Nursing Considerations

- Monitor hepatic and renal function, as ordered, before and during midodrine therapy.
- Give drug at 3- to 4-hour intervals, if ordered and needed to control symptoms. Don't give after evening meal, less than 4 hours before bed, or more often than every 3 hours.

WARNING Monitor for severe, persistent systolic supine hypertension, which may develop with single doses up to 20 mg.

- Avoid placing patient flat in bed for any length of time. Elevate head of bed when patient is supine.
- Monitor supine and sitting blood pressure often during midodrine therapy.

PATIENT TEACHING

- Instruct patient to take midodrine every 3 to 4 hours during daytime but not to take final dose after evening meal or within 4 hours of going to bed.
- Advise patient to elevate head of bed when he lies supine. Caution him not to remain flat for any length of time.
- Direct patient to notify prescriber immediately about headache, increased dizziness, urine retention, or vision changes.
- Encourage patient to keep follow-up appointments to monitor blood pressure and hepatic and renal function.

miglitol

Glyset

Class and Category

Chemical class: Desoxynojirimycin derivative

Therapeutic class: Alpha-glucosidase inhibitor, antidiabetic drug

Pregnancy category: B

Indications and Dosages

↗ *To manage type 2 diabetes mellitus*

TABLETS

Adults. *Initial:* 25 mg t.i.d. with first bite of each meal. Or, 25 mg daily, increased gradually to 25 mg t.i.d. *Maximum:* 100 mg t.i.d.

DOSE ADJUSTMENT After 4 to 8 wk, dosage increased, if ordered, to 50 mg t.i.d.

for about 3 mo; then dosage adjusted based on glycosylated hemoglobin (HbA_{1C}) level.

Route	Onset	Peak	Duration
P.O.	Rapid	2–3 hr	Unknown

Mechanism of Action

Inhibits intestinal glucoside hydrolase enzymes, which normally hydrolyze oligosaccharides and disaccharides to glucose and other monosaccharides. This action delays carbohydrate digestion and absorption and reduces postprandial blood glucose level.

Contraindications

Acute or chronic bowel disorder, diabetic ketoacidosis, hypersensitivity to miglitol or its components

Interactions

DRUGS

digestive enzyme preparations, intestinal adsorbents (activated charcoal): Decreased miglitol effects

digoxin: Decreased blood digoxin level
propranolol, ranitidine: Decreased bioavailability of these drugs

Adverse Reactions

GI: Abdominal pain, diarrhea, flatulence, hepatotoxicity

HEME: Low serum iron level

SKIN: Rash (transient)

Nursing Considerations

- Use miglitol cautiously in patient with serum creatinine level above 2 mg/dl.
- Be aware that some patients with type 2 diabetes also may receive a sulfonylurea as an adjunct to miglitol therapy.
- Give miglitol with first bite of each meal. Drug must have arrived at site of enzymatic action when carbohydrates reach small intestine.
- Review patient's HbA_{1C} level, as appropriate, to monitor long-term glucose control.
- Monitor patient for evidence of overdose, such as transient increases in abdominal discomfort, diarrhea, and flatulence (but not hypoglycemia).

PATIENT TEACHING

- Explain that miglitol is an adjunct to diet, which is the primary treatment for type 2 diabetes mellitus.

- Instruct patient to take drug with first bite of each meal.
- Describe signs and symptoms of hypoglycemia and pathophysiology of diabetes to patient and family members.
- If miglitol is the only drug patient takes to control blood glucose level, explain that it won't cause hypoglycemia.
- If patient takes a sulfonylurea or insulin with miglitol, recommend that he keep a source of glucose readily available to reverse hypoglycemia.
- Explain importance of monitoring blood and urine glucose levels.
- Explain that adverse GI reactions usually decrease in frequency and intensity over time.
- Teach obese patient about weight loss, calorie restriction, diet, and regular exercise, as indicated.

milnacipran hydrochloride

Savella

Class and Category

Chemical class: Selective norepinephrine and serotonin reuptake inhibitor

Therapeutic class: Anti-fibromyalgia

Pregnancy category: C

Indications and Dosages

➤ *To manage fibromyalgia*

TABLETS

Adults and adolescents age 17 and over.

Initial: 12.5 mg on day one; 12.5 mg b.i.d. on days 2 and 3; 25 mg b.i.d. on days 4 through 7; and then 50 mg b.i.d., increased, if needed to 100 mg b.i.d.

Maximum: 100 mg b.i.d.

DOSAGE ADJUSTMENT For patients with severe renal impairment (creatinine clearance of 5 to 29 ml/min/1.73 m²), maintenance dosage reduced by half.

Route	Onset	Peak	Duration
P.O.	Unknown	2–4 hr	Unknown

Mechanism of Action

Inhibits reuptake of norepinephrine and serotonin by CNS neurons without affect-

ing uptake of dopamine or other neurotransmitters, thereby increasing amount of norepinephrine and serotonin available in nerve synapses. Elevated norepinephrine and serotonin levels may improve symptoms of fibromyalgia, including by central analgesic effect.

Contraindications

Hypersensitivity to milnacipran or its components, uncontrolled narrow-angle glaucoma, use within 14 days of MAO inhibitor

Interactions

DRUGS

aspirin, NSAIDs, warfarin: Increased risk of bleeding

clomipramine: Increased risk of euphoria and postural hypotension

clonidine: Possibly inhibited antihypertensive effect

CNS-active drugs: Possibly increased CNS effects

digoxin (I.V.): Possibly increased risk of postural hypotension and tachycardia

epinephrine, norepinephrine: Increased risk of arrhythmias and paroxysmal hypertension

lithium: Increased risk of serotonin syndrome

MAO inhibitors: Possibly hyperpyretic episodes, hypertensive crisis, serotonin syndrome, and severe seizures

serotonergic drugs such as SSRIs, triptans, and tramadol: Increased risk of hypertension and coronary artery vasoconstriction

ACTIVITIES

alcohol use: Increased risk of liver impairment

Adverse Reactions

CNS: Anxiety, chills, delirium, depression, dizziness, fatigue, fever, hallucinations, headache, hypoesthesia, insomnia, irritability, loss of consciousness, migraine, neuroleptic malignant syndrome, parkinsonism, paresthesia, seizures, serotonin syndrome, suicidal ideation, tremor

CV: Chest pain, hypercholesterolemia, hypertension, hypertensive crisis, increased heart rate, palpitations, peripheral edema, somnolence, supraventricular tachycardia, tachycardia

EENT: Accommodation abnormality, blurred vision, dry mouth, mydriasis

ENDO: Hot flashes, hyperprolactinemia

GI: Abdominal distention or pain, anorexia, constipation, diarrhea, dyspepsia, elevated liver enzymes, gastroesophageal reflux, flatulence, hepatitis, jaundice, liver dysfunction, nausea, vomiting

GU: Acute renal failure, cystitis, decreased libido, dysuria, ejaculation disorder, erectile dysfunction, prostatitis, scrotal or testicular pain, testicular swelling, urinary hesitation, urine retention, urethral pain, UTI

HEME: Leukopenia, neutropenia, thrombocytopenia

MS: Rhabdomyolysis

RESP: Dyspnea, upper respiratory infection

SKIN: Erythema multiforme, flushing, hyperhidrosis, night sweats, pruritus, rash, Stevens-Johnson syndrome

Other: Hyponatremia, weight gain or loss

Nursing Considerations

- Because milnacipran may aggravate liver disease, it shouldn't be given to patients with alcohol addiction or chronic liver disease.
- Use cautiously in patients with mild to moderate renal impairment and patients with significant hypertension or cardiac disease. Also use cautiously in patients with a history of dysuria, especially men with prostatic hypertrophy, prostatitis, and other lower urinary tract obstructive disorders.
- At least 14 days should elapse between stopping an MAO inhibitor and starting milnacipran. At least 5 days should elapse between stopping milnacipran and starting an MAO inhibitor.
- Measure patient's blood pressure and heart rate before starting and periodically during milnacipran therapy because drug can raise blood pressure and heart rate. If hypertension or tachycardia occurs and persists, notify prescriber and expect to reduce dosage or discontinue drug.
- Watch closely for suicidal tendencies, especially when therapy starts and dosage changes.

WARNING Monitor patient closely for serotonin syndrome, a rare but serious adverse effect of selective serotonin reuptake inhibitors such as milnacipran. Signs and symptoms include agitation, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness,

shaking, talking or acting with uncontrolled excitement, tremor, and twitching. If symptoms occur, notify prescriber immediately, expect to discontinue drug, and provide supportive care.

- Monitor patient's liver function. If jaundice or signs and symptoms of liver dysfunction occur, notify prescriber and expect drug to be discontinued.
- Watch for hypersensitivity reactions, especially in patients with aspirin sensitivity, because drug contains the yellow dye tartrazine.
- Check patient's serum sodium level, as ordered, because drug may cause hyponatremia, especially in elderly patients, patients taking diuretics, and patients who are volume depleted.
- Expect to taper drug when no longer needed, as ordered, to minimize adverse reactions.

PATIENT TEACHING

- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Caution patient against stopping drug abruptly because serious adverse effects may result.
- Instruct patient to alert all prescribers that he takes milnacipran.
- Tell patient to have his blood pressure monitored regularly throughout milnacipran therapy.
- Advise patient to avoid activities, such as driving, that require alertness until the CNS effects of milnacipran are known.
- Caution patient to avoid aspirin and NSAIDs, if possible, while taking milnacipran.

milrinone lactate

Primacor

Class and Category

Chemical class: Bipyridine derivative

Therapeutic class: Inotropic, vasodilator

Pregnancy category: C

Indications and Dosages

↗ To provide short-term treatment of acute heart failure

I.V. INFUSION

Adults. Loading: 50 mcg/kg over 10 min (at

Mechanism of Action

An inotropic drug, milrinone increases the force of myocardial contraction—and cardiac output—by blocking the enzyme phosphodiesterase. Normally, this enzyme is activated by hormones binding to cell membrane receptors. As shown below left, phosphodiesterase normally degrades intracellular cAMP, which restricts calcium movement into myocar-

dial cells. By inhibiting phosphodiesterase, as shown below right, milrinone slows the rate of cAMP degradation, increasing the intracellular cAMP level and the amount of calcium that enters myocardial cells. In blood vessels, increased cAMP causes smooth-muscle relaxation, which improves cardiac output by reducing preload and afterload.

least 0.375 mcg/kg/min). *Usual:* 0.375 to 0.75 mcg/kg/min. *Maximum:* 1.13 mg/kg daily.

DOSE ADJUSTMENT Dosage adjusted according to cardiac output, pulmonary artery wedge pressure (PAWP), and clinical response. If creatinine clearance is 30 to 39 ml/min/1.73 m², infusion rate reduced to 0.33 mcg/kg/min; if 20 to 29 ml/min/1.73 m², to 0.28 mcg/kg/min; if 10 to 19 ml/min/1.73 m², to 0.23 mcg/kg/min; and if less than 9 ml/min/1.73 m², to 0.2 mcg/kg/min.

Route	Onset	Peak	Duration
I.V.	5–15 min	Unknown	3–6 hr

Incompatibilities

Don't administer milrinone through same I.V. line as furosemide because precipitate will form. Don't add other drugs to pre-mixed milrinone flexible containers.

Contraindications

Hypersensitivity to milrinone or its components

Interactions

DRUGS

antihypertensives: Possibly hypotension

Adverse Reactions

CNS: Headache, tremor

CV: Angina, hypotension, supraventricular arrhythmias, ventricular ectopic activity, ventricular fibrillation, ventricular tachycardia, torsades de pointes

GI: Liver function test abnormalities

HEME: Thrombocytopenia

RESP: Bronchospasm

SKIN: Rash

Other: Anaphylactic shock, hypokalemia, infusion site reactions (pain, swelling, redness)

Nursing Considerations

- Make sure ECG equipment is available for continuous monitoring during milrinone therapy.
- Discard drug if it's discolored or contains particles.
- For loading dose, infuse undiluted drug directly into I.V. line with compatible infusing solution. For continuous infu-

sion, dilute drug with half-normal (0.45) saline solution, normal saline solution, or D₅W. Dilution isn't needed when using premixed milrinone flexible containers.

- Check platelet count before and periodically during infusion, as ordered. Expect to discontinue drug if platelet count falls below 150,000/mm³.
- Give loading dose using a controlled-rate infusion device. For continuous infusion, use a calibrated electronic infusion device.
- Monitor cardiac output, pulmonary artery wedge pressure, blood pressure, heart rate, weight, and fluid status during therapy to determine drug effectiveness.
- Monitor renal and liver function test results and serum electrolyte levels. Notify prescriber of abnormalities.
- If severe hypotension develops, notify prescriber at once and expect to stop drug.
- Expect patient to receive digoxin before starting milrinone, which can increase ventricular response rate.

PATIENT TEACHING

- Reassure patient that you will be present and that he will be monitored constantly during therapy.

minocycline

Minocin

minocycline hydrochloride

Alti-Minocycline (CAN), Apo-Minocycline (CAN), Dynacin, Gen-Minocycline (CAN), Minocin, Novo-Minocycline (CAN), Solodyn, Vectrin

Class and Category

Chemical class: Tetracycline

Therapeutic class: Antibiotic, antiprotozoal

Pregnancy category: D

Indications and Dosages

- *To treat bartonellosis, brucellosis, chancroid, granuloma inguinale, inclusion conjunctivitis, lymphogranuloma venereum, nongonococcal urethritis, plague, psittacosis, Q fever, relapsing fever, respiratory tract infections (including pneumonia), rickettsial pox, Rocky Mountain spotted fever, tulare-*

mia, typhus, and UTI caused by gram-negative organisms (including Bartonella bacilliformis, Brucella species, Haemophilus ducreyi, Haemophilus influenzae, Vibrio cholerae, and Yersinia pestis), susceptible gram-positive organisms (including certain strains of Streptococcus pneumoniae), and other organisms (including Actinomyces species, Bacillus anthracis, Borrelia recurrentis, Chlamydia species, Mycoplasma pneumoniae, and Rickettsiae); as adjunct to treat intestinal amebiasis and as alternative to treat listeriosis caused by Listeria monocytogenes, syphilis caused by Treponema pallidum, and yaws caused by Treponema pertenue for nonpregnant patients allergic to penicillin

CAPSULES, ORAL SUSPENSION

Adults and adolescents. *Initial:* 200 mg. *Maintenance:* 100 mg every 12 hr. Or 100 to 200 mg initially followed by 50 mg every 6 hr.

Children over age 8. *Initial:* 4 mg/kg.

Maintenance: 2 mg/kg every 12 hr.

I.V. INJECTION

Adults and adolescents. *Initial:* 200 mg.

Maintenance: 100 mg every 12 hr.

Maximum: 400 mg daily.

Children over age 8. *Initial:* 4 mg/kg.

Maintenance: 2 mg/kg every 12 hr.

DOSAGE ADJUSTMENT If patient has renal impairment, don't exceed 200 mg daily.

- *As adjunct to treat inflammatory acne vulgaris that's unresponsive to oral tetracycline or erythromycin*

CAPSULES, ORAL SUSPENSION

Adults and adolescents. 50 mg once daily to t.i.d.

- *To treat inflammatory lesions of non-nodular moderate to severe acne vulgaris*

E.R. TABLETS

Adults and adolescents. 1 mg/kg once daily for 12 weeks.

DOSAGE ADJUSTMENT For patient with renal impairment, dosage reduced or time interval between doses extended.

- *To treat uncomplicated gonorrhea from Neisseria gonorrhoeae in nonpregnant patients allergic to penicillin*

CAPSULES, ORAL SUSPENSION

Adults and adolescents. *Initial:* 200 mg.

Maintenance: 100 mg every 12 hr for at least 4 days.

↗ *To treat uncomplicated gonococcal urethritis in men*

CAPSULES, ORAL SUSPENSION

Adults and adolescents. 100 mg b.i.d. for 5 days.

↗ *To treat asymptomatic meningococcal carriers with Neisseria meningitidis in nasopharynx*

CAPSULES, ORAL SUSPENSION

Adults and adolescents. 100 mg every 12 hr for 5 days.

Children over age 8. Initial: 4 mg/kg.

Maintenance: 2 mg/kg every 12 hr for 5 days.

↗ *To treat infections caused by Mycobacterium marinum*

CAPSULES, ORAL SUSPENSION

Adults. 100 mg every 12 hr for 6 to 8 wk.

Route	Onset	Peak	Duration
P.O.	Unknown	2–4 hr	6–12 hr
I.V.	Unknown	Unknown	6–12 hr

Mechanism of Action

Inhibits bacterial protein synthesis by competitively binding to the 30S ribosomal sub-unit of the mRNA-ribosome complex of certain organisms.

Incompatibilities

Don't mix minocycline in same syringe with solution that contains calcium because precipitate will form.

Contraindications

Hypersensitivity to minocycline, other tetracyclines, or their components

Interactions

DRUGS

aluminum-, calcium-, or magnesium-containing antacids; calcium supplements; choline and magnesium salicylates; iron-containing preparations; magnesium-containing laxatives; sodium bicarbonate: Possibly formation of nonabsorbable complex, impaired minocycline absorption
cholestyramine, colestipol: Possibly impaired cholestyramine or colestipol absorption
cimetidine: Possibly decreased GI absorption and effectiveness of minocycline
digoxin: Possibly increased blood digoxin level and risk of digitalis toxicity
insulin: Possibly decreased need for insulin

iron salts: Possibly decreased GI absorption and antimicrobial effect of minocycline
lithium: Possibly increased or decreased blood lithium level

methoxyflurane: Increased risk of nephrotoxicity

oral anticoagulants: Possibly potentiated anticoagulant effects

oral contraceptives containing estrogen:

Decreased contraceptive effectiveness, increased risk of breakthrough bleeding

penicillin: Interference with bactericidal action of penicillin

vitamin A: Possibly benign intracranial hypertension

Adverse Reactions

CNS: Dizziness, fever, headache, light-headedness, unsteadiness, vertigo

CV: Pericarditis

EENT: Blurred vision, darkened or discolored tongue, glossitis, papilledema, tooth discoloration, vision changes

GI: Abdominal cramps or pain, anorexia, diarrhea, dysphagia, enterocolitis, esophageal irritation and ulceration, hepatitis, hepatotoxicity, indigestion, nausea, pancreatitis, pseudomembranous colitis, vomiting

GU: Genital candidiasis, nephrotoxicity

HEME: Eosinophilia, hemolytic anemia, neutropenia, thrombocytopenia, thrombocytopenic purpura

MS: Arthralgia, myopathy (transient)

RESP: Pulmonary infiltrates (with eosinophilia)

SKIN: Erythema multiforme, exfoliative dermatitis, brown pigmentation of skin and mucous membranes, erythematous and maculopapular rash, jaundice, onycholysis, photosensitivity, pruritus, purpura (anaphylactoid), Stevens-Johnson syndrome, urticaria

Other: Anaphylaxis, angioedema, serum sicknesslike reaction, systemic lupus erythematosus exacerbation

Nursing Considerations

- Use minocycline cautiously in patients with renal or hepatic dysfunction and in those taking other hepatotoxic drugs because drug may cause nephrotoxicity or hepatotoxicity.

WARNING Notify prescriber if patient is breast-feeding because drug appears in breast milk and may have toxic effects.

- Monitor blood, renal, and hepatic tests before and during long-term therapy.
- Shake oral suspension well before use.
- To prepare drug for I.V. use, reconstitute each 100-mg vial with 5 to 10 ml sterile water for injection. Further dilute in 500 to 1,000 ml normal saline solution, D₅W, dextrose 5% in normal saline solution, or Ringer's or lactated Ringer's solution. Administer final dilution immediately, but avoid rapid administration.
- Store reconstituted drug at room temperature and use within 24 hours.
- Assess patient for signs of superinfection; if they appear, notify prescriber, discontinue minocycline, and start appropriate therapy, as ordered.
- Monitor patient for development of foul smelling diarrhea, which suggests *Clostridium difficile*. If present, notify prescriber, obtain stool culture, and expect to withhold minocycline and provide supportive care, as indicated and ordered.
- Monitor PT in patient who also takes an anticoagulant during minocycline therapy.

PATIENT TEACHING

- Instruct patient to shake oral suspension well and to use calibrated measuring device.
- Advise patient to take minocycline with a full glass of water, with food or milk, and in an upright position to minimize esophageal and GI irritation.
- Direct patient to take a missed dose as soon as he remembers unless it's nearly time for the next dose. Caution against double-dosing.
- Instruct patient not to take minocycline within 2 hours of an antacid or 3 hours of an iron preparation.
- Urge patient to complete full course of treatment even if he feels better before finishing.
- Instruct patient to notify prescriber if no improvement occurs in a few days.
- Advise patient to avoid prolonged exposure to sun or sunlamps during therapy.
- Counsel female patient to avoid becoming pregnant because minocycline should be avoided, if possible, during tooth development (last half of gestation up to age 8). Drug may permanently turn teeth yellow, gray, or brown and cause enamel hypoplasia. It also may slow skeletal growth and

cause congenital anomalies, including limb reduction.

- Encourage patient who uses an oral contraceptive to use additional contraceptive method during minocycline therapy.
- Instruct patient to notify prescriber immediately about blurred vision, dizziness, headache, known or suspected pregnancy, and unsteadiness.
- Explain that diarrhea may occur up to 2 months after completing therapy; urge patient to notify prescriber if it occurs.

minoxidil (oral)

Loniten

minoxidil (topical)

Apo-Gain (CAN), Gen-Minoxidil (CAN), Minox (CAN), Minoxigaine (CAN), Rogaine (CAN), Rogaine ES for Men, Rogaine for Men, Rogaine for Women

Class and Category

Chemical class: Piperidinopyrimidine derivative

Therapeutic class: Antihypertensive (oral), hair-growth stimulant (topical)

Pregnancy category: C

Indications and Dosages

↗ *To manage severe symptomatic hypertension or hypertension with target organ damage that's unresponsive to other treatment*

TABLETS

Adults and adolescents. *Initial:* 5 mg as a single dose or divided doses b.i.d. Increased, as directed, after at least 3 days. *Maintenance:* 10 to 40 mg daily. *Maximum:* 100 mg daily.

Children. *Initial:* 0.2 mg/kg daily. Increased, as directed, after at least 3 days. *Maintenance:* 0.25 to 1 mg/kg daily as a single dose or in divided doses b.i.d. *Maximum:* 50-mg starting dose, 50 mg daily.

DOSE ADJUSTMENT Dosage possibly reduced for elderly patients and those who have renal failure or are having dialysis.

↗ *To treat alopecia*

TOPICAL 2%

Adults up to age 65. 1 ml applied b.i.d. to

area of desired hair growth.

TOPICAL 5%

Adult men up to age 65. 1 ml applied b.i.d. to area of desired hair growth.

Route	Onset	Peak	Duration
P.O.	30 min	2–3 hr	24–48 hr
Topical 2%	4 mo	1 yr	Unknown
Topical 5%	2 mo	1 yr	Unknown

Mechanism of Action

Reduces blood pressure by inhibiting intracellular phosphodiesterase, an enzyme that facilitates hydrolysis of cAMP and cGMP. This action decreases the intracellular cAMP level, relaxes arterial smooth muscles, and lowers blood pressure. Oral minoxidil produces greater dilation in arteries than in veins. It also reduces peripheral resistance and increases heart rate, cardiac output, and stroke volume.

Topical minoxidil may cause hair regrowth by increasing cutaneous blood flow and stimulating resting hair follicles.

Contraindications

Acute MI; dissecting aortic aneurysm; hypersensitivity to minoxidil or its components, including propylene glycol; pheochromocytoma; skin irritation or abrasions (topical)

Interactions

DRUGS

guanethidine: Possibly severe hypotension, increased risk of orthostatic hypotension (oral)

nitrates, other hypotension-producing drugs, potent parenteral antihypertensives: Possibly severe hypotension

NSAIDs, sympathomimetics: Decreased antihypertensive effects

topical petrolatum, topical steroids: Increased absorption of topical minoxidil if used on same area

topical retinoids: Increased absorption of topical minoxidil and, possibly, formation of granulation tissue

Adverse Reactions

CNS: Fatigue, paresthesia (oral); light-headedness, neuritis (topical); headache (both)

CV: ECG changes, heart failure, pericardial tamponade, pericarditis, rebound hypertension (oral); cardiac tamponade, hypoten-

sion, palpitations, reflex hypertension (topical); angina, edema, fast or irregular heart-beat, pericardial effusion (both)

EENT: Vision changes (topical)

ENDO: Breast tenderness (oral)

GI: Abdominal distention, ascites, nausea, vomiting (oral)

GU: Elevated BUN and serum creatinine levels (oral); sexual dysfunction (topical)

HEME: Leukopenia; thrombocytopenia; transient decrease in hematocrit, hemoglobin, and erythrocyte counts (oral)

RESP: Dyspnea, pulmonary hypertension (oral)

SKIN: Flushing, hyperpigmentation, Stevens-Johnson syndrome (oral); allergic contact dermatitis, alopecia, dry or flaky skin, eczema, erythema, folliculitis, scalp burning (topical); hypertrichosis, rash (both)

Other: Facial edema (topical); sodium and water retention, weight gain (both)

Nursing Considerations

WARNING Be aware that patient who receives guanethidine should be hospitalized before starting oral minoxidil therapy so that his blood pressure can be monitored.

- Be aware that drug isn't usually prescribed for mild hypertension.
- For rapid management of hypertension, expect to adjust dosage up to every 6 hours and to monitor patient as prescribed. Also expect to give a beta blocker and diuretic.
- Monitor progress by measuring blood pressure often and weight daily. Evaluate for signs of fluid and sodium retention and for other systemic adverse reactions.
- Watch for signs of pericardial effusion. Be prepared to stop oral minoxidil, if ordered.
- Expect to discontinue oral minoxidil gradually because abrupt discontinuation may lead to rebound hypertension.
- Apply topical drug only on healthy scalp. Avoid sunburned or abraded scalp.
- Use gloves when applying solution.
- Avoid inhaling mist from spray applicator.
- Expect minoxidil to be least effective in men with mainly frontal hair loss.
- Expect topical form to have little effect on blood pressure in patients who don't have hypertension.

PATIENT TEACHING

- Inform patient that oral minoxidil controls but doesn't cure hypertension.
- Advise him to take tablets at the same time every day.
- Teach patient to take his radial pulse, and advise him to take it daily. Instruct him to notify prescriber if it exceeds normal rate by 20 beats/minute or more.
- Stress the importance of daily blood pressure and weight measurements.
- Instruct patient to notify prescriber immediately about bloating, breathing problems, a fast or irregular heartbeat, flushed or red skin, swelling of feet or lower legs, or weight gain of more than 5 lb (2.3 kg) in 1 day.
- Advise patient to have regular checkups with prescriber to monitor progress.
- Urge patient to consult prescriber before taking other prescription or OTC drugs.
- Reassure patient that body hair thickening and darkening reverses after oral minoxidil is discontinued.
- For patient using topical minoxidil, teach proper application technique and provide manufacturer's written instructions. Advise him to wear gloves when applying drug and to make sure hair and scalp are dry first.
- Instruct patient to start applying drug at center of balding area, to let dry for 2 to 4 hours, and not to use hairdryer to help it dry faster.
- Warn patient to avoid applying drug to abraded, irritated, or sunburned areas of scalp; to avoid inhaling mist when using a spray applicator; and to avoid getting drug in his eyes, nose, or mouth. If accidental contact does occur, advise him to flush the area with large amounts of cool tap water.
- Instruct patient not to shampoo his hair for at least 4 hours after application and to avoid using other skin products on treated skin. Direct him to avoid using minoxidil for 24 hours before and after chemical hair products, such as dyes and relaxers.
- Caution patient not to use more drug or apply it more often than prescribed and not to apply it to other body areas. Explain the risk of adverse systemic reactions with excessive topical use.
- Tell patient to keep topical minoxidil away from heat or flame because it's flammable.
- Inform patient that minoxidil may stain clothing, hats, or bed linens before it's dry.
- Instruct patient to notify prescriber if burning, itching, or redness develops after application. For severe reactions, advise patient to wash drug off and consult prescriber before applying it again.
- Urge patient to consult prescriber if hair loss continues after 2 weeks or if growth fails to increase in 4 months.
- Inform patient that new hair growth may be lost 3 to 4 months after stopping topical minoxidil and that progressive hair loss will resume.

mirtazapine

Remeron, Remeron SolTab

Class and Category*Chemical class:* Piperazinoazepine*Therapeutic class:* Antidepressant*Pregnancy category:* C**Indications and Dosages**➤ *To treat major depression***DISINTEGRATING TABLETS, TABLETS**

Adults. *Initial:* 15 mg daily, preferably at bedtime. Increased as needed and tolerated at 1- to 2-wk intervals. *Maximum:* 45 mg daily.

Route	Onset	Peak	Duration
P.O.	1–2 wk	6 wk or longer	Unknown

Mechanism of Action

May inhibit neuronal reuptake of norepinephrine and serotonin. By doing so, this tetracyclic antidepressant increases the action of these neurotransmitters in nerve cells. Increased neuronal serotonin and norepinephrine levels may elevate mood.

Contraindications

Hypersensitivity to mirtazapine or its components, use within 14 days of an MAO inhibitor

Interactions**DRUGS**

antihypertensives: Increased hypotensive effects of these drugs or enhanced mirtazapine effects

anxiolytics, hypnotics, other CNS depressants (including sedatives): Increased CNS depression

MAO inhibitors: Possibly hyperpyrexia, hypertension, seizures

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Agitation, amnesia, anxiety, apathy, asthenia, ataxia, cerebral ischemia, chills, confusion, delirium, delusions, depersonalization, depression, dizziness, dream disturbances, drowsiness, dyskinesia, dystonia, emotional lability, euphoria, extrapyramidal reactions, fever, hallucinations, hostility, hyperkinesia, hyperreflexia, hypoesthesia, hypokinesia, lack of coordination, malaise, mania, migraine headache, neurosis, paranoia, paresthesia, seizures, somnolence, syncope, tremor, vertigo

CV: Angina, bradycardia, edema, hypercholesterolemia, hypertension, hypertriglyceridemia, hypotension, MI, orthostatic hypotension, peripheral edema, PVCs, vasodilation

EENT: Accommodation disturbances, conjunctivitis, dry mouth, earache, epistaxis, eye pain, glaucoma, gingival bleeding, glossitis, hearing loss, hyperacusis, keratoconjunctivitis, lacrimation, pharyngitis, sinusitis, stomatitis

ENDO: Breast pain

GI: Abdominal distention and pain, anorexia, cholecystitis, colitis, constipation, elevated ALT level, eructation, increased appetite, nausea, thirst, vomiting

GU: Amenorrhea, cystitis, dysmenorrhea, dysuria, hematuria, impotence, increased libido, leukorrhea, renal calculi, urinary frequency and incontinence, urine retention, UTI, vaginitis

HEME: Agranulocytosis, neutropenia

MS: Arthralgia, back pain, dysarthria, muscle twitching, myalgia, myasthenia, neck pain and rigidity

RESP: Asthma, bronchitis, cough, dyspnea, pneumonia

SKIN: Acne, alopecia, dry skin, exfoliative dermatitis, photosensitivity, pruritus, rash

Other: Dehydration, facial edema, flulike symptoms, herpes simplex, weight change

Nursing Considerations

- Administer mirtazapine before bedtime.

- Expect disintegrating tablet to dissolve on patient's tongue within 30 seconds.

WARNING Don't give drug within 14 days of an MAO inhibitor to avoid serious, possibly fatal, reaction.

- If patient takes drug for depression, watch closely for suicidal tendencies, especially when therapy starts or dosage changes, because depression may briefly worsen.
- Monitor patient closely for infection (fever, pharyngitis, stomatitis), which may be linked to a low WBC count. If these signs occur, notify prescriber and expect to stop drug.
- Expect mirtazapine therapy to last 6 months or longer for acute depression.

PATIENT TEACHING

- Instruct patient not to swallow disintegrating tablet. Tell him to hold tablet on tongue and let it dissolve. Inform him that tablet will dissolve within 30 seconds.
- Inform phenylketonuric patient that mirtazapine disintegrating tablets contain phenylalanine 2.6 mg per 15-mg tablet, 5.2 mg per 30-mg tablet, and 7.8 mg per 45-mg tablet.
- Instruct patient to avoid alcohol and other CNS depressants during therapy and for up to 7 days after drug is discontinued.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Direct patient to change position slowly to minimize the effects of orthostatic hypotension.
- Instruct patient to notify prescriber at once about chills, fever, mouth irritation, sore throat, and other signs of infection.
- Encourage patient to visit prescriber regularly during therapy to monitor progress.

misoprostol

Cytotec

Class and Category

Chemical class: Prostaglandin E₁ analogue

Therapeutic class: Antiulcer, gastric anti-secretory

Pregnancy category: X

Indications and Dosages

↗ To prevent NSAID-induced gastric ulcers

TABLETS

Adults. 200 mcg q.i.d. or 400 mcg b.i.d.

with food, with last dose at bedtime every day.

DOSE ADJUSTMENT Dosage reduced to 100 mcg q.i.d. if patient can't tolerate 200-mcg dose.

Route	Onset	Peak	Duration
P.O.	30 min	60–90 min	3–6 hr

Mechanism of Action

May protect the stomach from NSAID-induced mucosal damage by increasing gastric mucus production and mucosal bicarbonate secretion. Misoprostol also inhibits gastric acid secretion caused by such stimuli as food, coffee, and histamine.

Contraindications

Hypersensitivity to prostaglandins or their analogues, pregnancy

Interactions

DRUGS

magnesium-containing antacids: Increased misoprostol-induced diarrhea

Adverse Reactions

CNS: Anxiety, asthenia, chills, confusion, depression, drowsiness, dizziness, fatigue, fever, headache, neuropathy, neurosis, rigors, stroke, syncope, thirst

CV: Arrhythmias, chest pain, edema, hypertension, hypotension, increased cardiac enzyme levels, MI, phlebitis, thromboembolism

EENT: Abnormal taste or vision, conjunctivitis, deafness, earache, epistaxis, gingivitis, tinnitus

ENDO: Hyperglycemia

GI: Abdominal pain, constipation, diarrhea, dysphagia, flatulence, GI bleeding or inflammation, hepatobiliary dysfunction, indigestion, nausea, reflux, vomiting

GU: Dysmenorrhea, dysuria, hematuria, hypermenorrhea, impotence, loss of libido, menstrual irregularities, polyuria, urinary tract infection, vaginal bleeding

HEME: Anemia, abnormal differential thrombocytopenia purpura, increased erythrocyte sedimentation rate

MS: Arthralgia, back pain, myalgia, muscle cramps or stiffness

RESP: Bronchitis, bronchospasm, dyspnea, pneumonia, pulmonary embolism, upper respiratory tract infection

SKIN: Alopecia, diaphoresis, dermatitis, pallor, rash

Other: Anaphylaxis, gout, weight changes

Nursing Considerations

WARNING Ask female patient if she is or may be pregnant. If so, notify prescriber because misoprostol may cause uterine bleeding, contractions, spontaneous abortion, and teratogenic effects in the fetus.

- Use drug cautiously in patients with cerebrovascular disease, coronary artery disease, or uncontrolled epilepsy because of the risk of severe complications.
- Also use misoprostol cautiously in patients with inflammatory bowel disease because drug may worsen intestinal inflammation and cause diarrhea. If diarrhea causes severe dehydration, misoprostol may be discontinued.

PATIENT TEACHING

- Caution female patient about risk of taking misoprostol during pregnancy, and urge her to use reliable contraception during therapy. Urge her to notify prescriber at once if she is or might be pregnant.
- Instruct patient to take misoprostol with meals and at bedtime.
- Advise patient that he may take NSAIDs, if prescribed, during misoprostol therapy.
- Explain that diarrhea is dose related and usually resolves after 8 days. Tell patient to avoid magnesium-containing antacids because they may worsen diarrhea and to call prescriber if diarrhea lasts more than 8 days.
- Urge female patient to notify prescriber immediately about postmenopausal bleeding; she may need diagnostic tests.

mitoxantrone hydrochloride

Novantrone

Class and Category

Chemical class: Anthracenedione

Therapeutic class: Antineoplastic

Pregnancy category: D

Indications and Dosages

↗ To reduce neurologic disability and frequency of relapses in patients with sec-

ondary (chronic) progressive, progressive relapsing, or worsening relapsing-remitting multiple sclerosis (patients whose neurologic status is significantly abnormal between relapses)

I.V. INFUSION

Adults. 12 mg/m² over 5 to 15 min every 3 mo. *Maximum:* Cumulative dose of 140 mg/m².

↗ *As adjunct to treat pain related to advanced hormone-refractory prostate cancer*

I.V. INFUSION

Adults. 12 to 14 mg/m² over 5 to 15 min every 21 days.

↗ *As adjunct to treat acute nonlymphocytic leukemia (ANLL)*

I.V. INFUSION

Adults, Initial: 12 mg/m² over at least 3 min on days 1 to 3 with 100 mg/m² of cytarabine as a continuous 24-hr infusion on days 1 to 7. If patient's antileukemic response is inadequate or incomplete, second induction course is given at same dosage. *Maintenance:* 6 wk after induction, 12 mg/m² over at least 3 min on days 1 and 2 with 100 mg/m² of cytarabine as a continuous 24-hr infusion on days 1 to 5. A second maintenance course is given 4 wk after the first if needed and tolerated.

Mechanism of Action

Binds to DNA, causing cross-linkage and strand breakage, interfering with RNA synthesis, and inhibiting topoisomerase II, an enzyme that uncoils and repairs damaged DNA. Mitoxantrone produces a cytotoxic effect on proliferating and nonproliferating cells and doesn't appear to be cell-cycle specific. It's known to inhibit B-cell, T-cell, and macrophage proliferation and impair antigen function.

Incompatibilities

Don't mix mitoxantrone in the same infusion as heparin (because a precipitate may form); don't mix with any other drugs.

Contraindications

Hypersensitivity to mitoxantrone or its components

Interactions

DRUGS

allopurinol, colchicine, probenecid, sulfipyrazone: Possibly interference with antihy-

peruricemic action of these drugs
blood-dyscrasia-causing drugs (such as cephalosporins and sulfasalazine): Increased risk of leukopenia and thrombocytopenia
bone marrow depressants, such as carboplatin and lomustine: Possibly additive bone marrow depression
daunorubicin, doxorubicin: Increased risk of cardiotoxicity
methotrexate and other antineoplastics: Risk of developing leukemia
vaccines, killed virus: Decreased antibody response to vaccine
vaccines, live virus: Increased risk of replication of and adverse effects of vaccine virus, decreased antibody response to vaccine

Adverse Reactions

CNS: Headache, seizures

CV: Arrhythmias, cardiotoxicity, chest pain, congestive heart failure, decreased left ventricular ejection fraction, ECG changes

EENT: Blue-colored cornea, conjunctivitis, mucositis, stomatitis

GI: Abdominal pain, diarrhea, GI bleeding, nausea, vomiting

GU: Blue-green urine, renal failure

HEME: Acute myelogenous leukemia, leukopenia, other leukemias, thrombocytopenia

MS: Myelodysplasia

RESP: Cough, dyspnea

SKIN: Alopecia, extravasation, jaundice

Other: Allergic reaction, anaphylaxis, hyperuricemia, infection, infusion site pain or redness

Nursing Considerations

- Before mitoxantrone therapy and before each dose, expect patient to have an ECG and evaluation of left ventricular ejection fraction. Expect to obtain hematocrit, hemoglobin level, and CBC with platelet count. If patient's left ventricular ejection fraction drops below normal, expect drug to be discontinued.
- Be aware that drug shouldn't be given to patient with multiple sclerosis whose neutrophil count is less than 1,500/mm³ or who has a below-normal left ventricular ejection fraction.
- Check liver function test results, as ordered, before each course of therapy. Expect that drug won't be given to multiple sclerosis patient with abnormal liver function.

- Assess patient for cardiac dysfunction throughout therapy. Watch for evidence of cardiotoxicity, such as arrhythmias and chest pain, in patient with heart disease. Risk increases when cumulative dose reaches 140 mg/m² in cancer or 100 mg/m² in multiple sclerosis. Notify prescriber of any significant changes, and expect drug to be discontinued. Be aware that congestive heart failure may occur months or years after drug has been discontinued.
- Anticipate obtaining pregnancy test before each course of therapy for women of childbearing age with multiple sclerosis.
- Follow facility policy for handling anti-neoplastics. Be aware that manufacturer recommends goggles, gloves, and a gown during drug preparation and delivery.
- Before infusing drug, dilute it in at least 50 ml of normal saline solution or D₅W.

WARNING Drug shouldn't be given intrathecally because paralysis may occur.

- If mitoxantrone solution contacts your skin or mucosa, wash thoroughly with warm water. If it contacts your eyes, irrigate them thoroughly with water or normal saline solution.
- Discard unused diluted solution because it contains no preservatives. After penetration of stopper, store undiluted drug for up to 7 days at room temperature or 14 days refrigerated. Avoid freezing drug.
- If extravasation occurs, stop infusion immediately and notify prescriber. Reinsert I.V. line in another vein and resume infusion. Although mitoxantrone is a nonvesicant, observe the extravasation site for signs of necrosis or phlebitis.
- Monitor patients with chickenpox or recent exposure and patients with herpes zoster for severe, generalized disease.
- Monitor blood uric acid level for hyperuricemia in patients with a history of gout or renal calculi. Expect to give allopurinol, as prescribed, to patients with leukemia or lymphoma and elevated blood uric acid level to prevent uric acid nephropathy.

WARNING If severe or life-threatening non-hematologic or hematologic toxicity occurs during first induction course, expect to withhold the second course until it resolves.

- If patient develops thrombocytopenia, take precautions per facility policy.

- Assess patient for evidence of infection, such as fever, if leukopenia occurs. Expect to obtain appropriate specimens for culture and sensitivity testing.
- Be aware that patients receiving mitoxantrone in combination with other anti-neoplastics or radiation therapy are at risk for developing secondary leukemia, including acute myelogenous leukemia.

PATIENT TEACHING

- Advise patient to complete dental work, if possible, before treatment begins or defer it until blood counts return to normal; drug may delay healing and cause gingival bleeding. Teach patient proper oral hygiene, and advise use of a toothbrush with soft bristles.
- Urge patient to drink plenty of fluid to increase urine output and uric acid excretion.
- Advise patient to contact prescriber immediately if GI upset occurs, but to continue taking drug unless otherwise directed.
- Stress the importance of complying with the dosage regimen and keeping follow-up medical and laboratory appointments.
- Explain that urine may appear blue-green for 24 hours after treatment and that the whites of the eyes may appear blue. Stress that these effects are temporary and harmless. Explain that hair loss is possible, but that hair should return after therapy ends.
- Caution patient not to receive immunizations unless approved by prescriber. Also, advise persons who live in same household as patient to avoid receiving immunization with oral polio vaccine. Tell patient to avoid persons who recently received the oral polio vaccine or to wear a mask over his nose and mouth.
- Instruct patient to avoid persons with infections if bone marrow depression occurs. Advise patient to contact prescriber if fever, chills, cough, hoarseness, lower back or side pain, or painful or difficult urination occurs; these changes may signal an infection.
- Tell patient to contact prescriber immediately if he has unusual bleeding or bruising, black or tarry stools, blood in urine or stool, or pinpoint red spots on his skin.
- Urge patient not to touch his eyes or the inside of his nose unless he has just washed his hands.

- Stress the need to avoid accidental cuts, as from a razor or fingernail clippers, because of possible excessive bleeding or infection.
- Caution patient to avoid contact sports or activities that may cause bruising or injury.
- Urge patient to comply with yearly examinations after therapy ends to check for late-occurring drug-induced heart problems. Tell patient to report trouble breathing, swelling in legs or ankles, or an uneven or fast heartbeat even after drug has been discontinued.

modafinil

Provigil

Class, Category, and Schedule

Chemical class: Benzhydryl sulfinylacetamide derivative

Therapeutic class: CNS stimulant

Pregnancy category: C

Controlled substance schedule: IV

Indications and Dosages

↗ *To improve daytime wakefulness in patients with narcolepsy, obstructive sleep apnea hypopnea syndrome, and shift work sleep disorder*

TABLETS

Adults and adolescents age 16 and over.

200 mg daily in the morning or 1 hr before starting work shift *Maximum:* 400 mg daily.

DOSAGE ADJUSTMENT For patients with severe hepatic impairment, dosage should be reduced by 50%.

Mechanism of Action

May inhibit the release of gamma-aminobutyric acid (GABA), the most common inhibitory neurotransmitter, or CNS depressant, in the brain. Modafinil also increases the release of glutamate, an excitatory neurotransmitter, or CNS stimulant, in the thalamus and hippocampus. These two actions may improve wakefulness.

Contraindications

Hypersensitivity to modafinil or its components

Interactions

DRUGS

amitriptyline, citalopram, clomipramine, diazepam, imipramine, propranolol, tolbuta-

mide, topiramate: Possibly prolonged elimination time and increased blood levels of these drugs

carbamazepine: Possibly decreased modafinil effectiveness and decreased blood carbamazepine level

cimetidine, clarithromycin, erythromycin, fluconazole, fluoxetine, fluvoxamine, itraconazole, ketoconazole, nefazodone, sertraline: Possibly inhibited metabolism, decreased clearance, and increased blood level of modafinil

contraceptive-containing implants or devices, oral contraceptives: Possibly contraceptive failure

cyclosporine: Possibly decreased blood cyclosporine level and increased risk of organ transplant rejection

dexamethasone, phenobarbital and other barbiturates, primidone, rifabutin, rifampin: Possibly decreased blood level and effectiveness of modafinil

dextroamphetamine, methylphenidate: Possibly 1-hour delay in modafinil absorption when these drugs are given together

fosphenytoin, mephenytoin, phenytoin: Possibly decreased effectiveness of modafinil, increased blood phenytoin level, and increased risk of phenytoin toxicity

theophylline: Possibly decreased blood level and effectiveness of theophylline

triazolam: Possibly decreased effectiveness of triazolam

warfarin: Possibly decreased warfarin metabolism and increased risk of bleeding

FOODS

all foods: 1-hour delay in modafinil absorption and possibly delayed onset of action

caffeine: Increased CNS stimulation

grapefruit juice: Possibly decreased modafinil metabolism

Adverse Reactions

CNS: Aggressiveness, agitation, anxiety, confusion, delusions, depression, hallucinations, headache, insomnia, mania, nervousness, psychosis, suicidal ideation

GI: Nausea

HEME: Agranulocytosis

SKIN: Drug rash with eosinophilia and systemic symptoms (DRESS), rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, angioedema, infection, multi-organ hypersensitivity

Nursing Considerations

- Modafinil shouldn't be given to patients with mitral valve prolapse syndrome or a history of left ventricular hypertrophy because drug may cause ischemic changes.
- Use cautiously in patients with recent MI or unstable angina because effect of drug is unknown in these disorders.
- Use cautiously in patients with a history of psychosis, depression, or mania because these conditions may worsen during therapy and may require modafinil to be stopped.

WARNING Monitor patient with a history of alcoholism, stimulant abuse, or other substance abuse for compliance with modafinil therapy. Observe for signs of misuse or abuse, including frequent prescription refill requests, increased frequency of dosing, or drug-seeking behavior. Also watch for evidence of excessive modafinil dosage, including aggressiveness, anxiety, confusion, decreased prothrombin time, diarrhea, irritability, nausea, nervousness, palpitations, sleep disturbances, and tremor.

- Be aware that modafinil, like other CNS stimulants, may alter mood, perception, thinking, judgment, feelings, motor skills, and signs that patient needs sleep.
- If giving drug to patient with a history of psychosis, emotional instability, or psychological illness with psychotic features, be prepared to perform baseline behavioral assessments or frequent clinical observation.
- Stop drug at first sign of rash, and notify prescriber. Although rare, rash may indicate a potentially life-threatening event.
- Monitor patient for signs and symptoms of multisystem organ hypersensitivity, such as fever, rash, myocarditis, hepatitis, hematologic abnormalities, pruritus, asthenia, or any other serious abnormality because multi-organ hypersensitivity may vary in its presentation. Notify prescriber if suspected, and expect to discontinue drug and provide supportive care, as ordered.
- Watch closely for suicidal tendencies, especially in patients with a psychiatric history.

PATIENT TEACHING

- Inform patient that modafinil can help, but not cure, narcolepsy and that drug's

full effects may not be seen right away.

- Advise patient to avoid taking modafinil within 1 hour of eating because food may delay drug's absorption and onset of action. If he drinks grapefruit juice, encourage him to drink a consistent amount daily.
- Instruct patient to stop taking modafinil and to notify prescriber if he develops a rash, fever, or other serious effect.
- Urge patient to report chest pain, depression, anxiety, or evidence of psychosis or mania to prescriber.
- Inform patient that drug can affect concentration and function and can hide signs of fatigue. Urge him not to drive or perform activities that require mental alertness until full CNS effects are known.
- Because alcohol may decrease alertness, advise patient to avoid it while taking modafinil.
- Encourage a regular sleeping pattern.
- Caution patient to avoid excessive intake of foods, beverages, and OTC drugs that contain caffeine because caffeine may lead to increased CNS stimulation.
- Inform female patient that modafinil can decrease the effectiveness of certain contraceptives, including birth control pills and implantable hormonal contraceptives. If she uses such contraceptives, urge her to use an alternate birth control method during modafinil therapy and for up to 1 month after she stops taking the drug.
- Advise patient to keep follow-up appointments with prescriber so that her progress can be monitored.
- Urge family or caregiver to watch patient closely for abnormal behaviors, including suicidal tendencies, especially if patient has a psychiatric history.

moexipril hydrochloride

Univasc

Class and Category

Chemical class: Prodrug of moexiprilat

Therapeutic class: Antihypertensive

Pregnancy category: C (first trimester), D (later trimesters)

Indications and Dosages

↗ *To manage hypertension without diuretic therapy*

TABLETS

Adults. *Initial:* 7.5 mg daily 1 hr before a meal. *Maintenance:* 7.5 to 30 mg as a single dose or in divided doses b.i.d. 1 hr before meals. *Maximum:* 30 mg/day.

DOSAGE ADJUSTMENT For patients with creatinine clearance of less than 40 ml/min/1.73 m², initial dosage reduced to 3.75 mg daily and increased, as ordered, to maximum of 15 mg daily.

↗ *To manage hypertension with diuretic therapy*

TABLETS

Adults. *Initial:* 3.75 mg daily 1 hr before a meal. Increased gradually, as ordered, until blood pressure is controlled.

Route	Onset	Peak	Duration
P.O.	1 hr	3–6 hr	24 hr

Mechanism of Action

Is converted to the active metabolite moexiprilat, which reduces blood pressure by inhibiting ACE activity. ACE normally catalyzes conversion of angiotensin I to angiotensin II—a vasoconstrictor that stimulates aldosterone secretion by adrenal cortex and directly suppresses renin release. Inhibited ACE activity results in decreased peripheral arterial resistance, increased plasma renin activity, and decreased aldosterone secretion. Decreased aldosterone secretion causes water and sodium excretion.

Contraindications

History of angioedema with previous ACE inhibitor use, hypersensitivity to moexipril or its components

Interactions

DRUGS

allopurinol, bone marrow depressants, corticosteroids (systemic), cytostatic drugs, procainamide: Increased risk of possibly fatal neutropenia or agranulocytosis
antacids: Possibly decreased moexipril bioavailability
cyclosporine, heparin, potassium-containing drugs, potassium-sparing diuretics, potassium supplements: Increased risk of hyperkalemia
digoxin: Possibly increased digoxin level
diuretics, other hypotension-producing drugs:

Hypotension, risk of renal failure (from sodium or volume depletion), possibly decreased secondary aldosteronism and hypokalemia caused by diuretics
lithium: Increased blood lithium level and risk of lithium toxicity
NSAIDs (especially indomethacin), sympathomimetics: Decreased antihypertensive effect of moexipril
phenothiazines: Increased pharmacologic effects of moexipril

FOODS

all foods: Decreased moexipril absorption
low-salt milk, salt substitutes: Possibly hyperkalemia

ACTIVITIES

alcohol use: Possibly hypotension

Adverse Reactions

CNS: Anxiety, chills, confusion, dizziness, drowsiness, fatigue, fever, headache, malaise, mood changes, nervousness, sleep disturbance, stroke, syncope

CV: Angina, arrhythmias, chest pain, hypotension, MI, orthostatic hypotension, palpitations, peripheral edema

EENT: Dry mouth, hoarseness, laryngeal edema, mouth or tongue swelling, pharyngitis, rhinitis, sinusitis, taste perversion, tinnitus

GI: Abdominal distention or pain, anorexia, constipation, diarrhea, dysphagia, elevated liver function test results, hepatitis, increased appetite, nausea, pancreatitis, vomiting

GU: Azotemia, elevated BUN and serum creatinine and uric acid levels, interstitial nephritis, oliguria, proteinuria, renal insufficiency, urinary frequency

HEME: Agranulocytosis, bone marrow depression, elevated erythrocyte sedimentation rate, hemolytic anemia, leukocytosis, leukopenia, neutropenia, thrombocytopenia

MS: Arthralgia, leg heaviness or weakness, myalgia, myositis

RESP: Bronchospasm, cough, dyspnea, upper respiratory tract infection

SKIN: Alopecia, diaphoresis, flushing, onycholysis, pallor, pemphigus, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, urticaria

Other: Anaphylaxis, angioedema (of arms, face, larynx, legs, lips, mucous membranes, tongue), flulike symptoms, hyperkalemia, hyponatremia, positive ANA titer

Nursing Considerations

WARNING Contact prescriber if patient is or may be pregnant. Moexipril may cause fetal or neonatal harm or death if used during second or third trimester.

- Be aware that patient who already takes a diuretic should be medically supervised for several hours after first moexipril dose.
- Administer drug 1 hour before meals.
- Monitor blood pressure, leukocyte count, and liver and renal function test results during moexipril therapy.
- Be aware that black patients may be less responsive to antihypertensive effect if moexipril is used alone to control blood pressure.

PATIENT TEACHING

- Urge female patient to notify prescriber immediately if she is or may be pregnant.
- Instruct patient to take moexipril at the same time each day, 1 hour before meals.
- Direct patient to take a missed dose as soon as he remembers unless it's nearly time for the next dose. Caution against doubling the dose.

WARNING Instruct patient to stop drug and seek immediate medical attention for hoarseness; swelling of tongue, glottis, larynx, face, hands, or feet; or sudden difficulty swallowing or breathing.

- Caution patient not to stop drug without consulting prescriber, even if he feels better.
- Inform patient about possible dizziness, especially after first dose and if he takes a diuretic.
- Advise patient to change position slowly to minimize orthostatic hypotension.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to notify prescriber if he faints or experiences persistent dizziness.
- Instruct patient to report evidence of infection (such as chills, fever, and sore throat), diarrhea, nausea, or vomiting, which may lead to dehydration-induced hypotension.
- Advise patient to avoid alcohol during moexipril therapy because it may cause hypotension.
- Instruct patient to check with prescriber before taking OTC drugs.
- Urge patient to avoid potassium supplements and potassium-containing salt sub-

- stitutes unless prescriber allows them.
- Advise patient to visit prescriber regularly to monitor progress.
- Discuss importance of weight control and low-salt diet in managing hypertension.

molindone hydrochloride

Moban Concentrate

Class and Category

Chemical class: Dihydroindolone derivative

Therapeutic class: Antipsychotic drug

Pregnancy category: Not rated

Indications and Dosages

↗ *To manage symptoms of psychotic disorders*

ORAL SOLUTION

Adults and children age 12 and over.

Initial: 50 to 75 mg daily in divided doses t.i.d. or q.i.d. Dosage increased to 100 mg daily in 3 to 4 days as needed. *Maintenance:* For mild psychosis, 5 to 15 mg t.i.d. or q.i.d.; for moderate psychosis, 10 to 25 mg t.i.d. or q.i.d.; for severe psychosis, 225 mg daily in divided doses. *Maximum:* 225 mg daily.

DOSAGE ADJUSTMENT Initial dosage reduced for elderly or debilitated patients.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	24–36 hr

Mechanism of Action

Occupies dopamine receptor sites in the reticular activating and limbic systems in the CNS. By blocking dopamine activity in these areas, molindone reduces the symptoms of psychosis, helping the patient to think and behave more coherently.

Contraindications

Hypersensitivity to molindone, its components, or other antipsychotic drugs, including haloperidol, loxapine, phenothiazines, and thioxanthenes

Interactions

DRUGS

amphetamines: Decreased amphetamine effectiveness, decreased antipsychotic effec-

tiveness of molindone

anesthetics, barbiturates, benzodiazepines, CNS depressants, opioid analgesics: Possibly prolonged and intensified CNS depressant effects

antacids, antidiarrheals: Decreased molindone absorption

anticholinergics, antidyskinetics, antihistamines: Possibly increased anticholinergic effects

beta blockers: Possibly increased effect of beta blocker

bromocriptine: Possibly decreased therapeutic effects of bromocriptine and increased serum prolactin level

extrapyramidal reaction-causing drugs, such as amoxapine, haloperidol, loxapine, metoclopramide, olanzapine, phenothiazines, pimozone, rauwolfia alkaloids, risperidone, tacrine, and thioxanthenes: Increased severity of extrapyramidal effects

insulin, oral antidiabetic drugs: Possibly increased serum glucose level

levodopa: Inhibited antidyskinetic effects of levodopa, possibly decreased antipsychotic effects of molindone

lithium: Increased risk of neurotoxicity, increased extrapyramidal effects

MAO inhibitors, maprotiline, trazodone, tricyclic antidepressants: Possibly prolonged and intensified sedative or anticholinergic effects of all drugs

phenytoin, tetracycline: Interference with absorption of phenytoin and tetracycline

ACTIVITIES

alcohol use: Prolonged and intensified CNS depression

Adverse Reactions

CNS: Depression, drowsiness, euphoria, extrapyramidal reactions (such as akathisia, dystonia, motor restlessness, pseudoparkinsonism, and tardive dyskinesia), headache, hyperactivity, lack of coordination, neuroleptic malignant syndrome, tiredness

CV: Orthostatic hypotension, tachycardia, unstable blood pressure

EENT: Blinking or eyelid spasm, blurred vision, dry mouth, inability to move eyes, nasal congestion

ENDO: Breast engorgement, lactation

GI: Constipation, nausea

GU: Decreased libido, menstrual irregularities, urine retention

HEME: Agranulocytosis, leukopenia, neu-

troponia

MS: Muscle spasms of back, face, and neck; muscle twitching; twisting movements of the body; weakness or stiffness of limbs

RESP: Dyspnea

SKIN: Diaphoresis, pallor, rash

Other: Heatstroke

Nursing Considerations

- Molindone shouldn't be used to treat dementia-related psychosis in the elderly because of an increased mortality risk.

WARNING Assess patient for signs and symptoms of neuroleptic malignant syndrome, such as diaphoresis, dyspnea, fatigue, fever, incontinence, pallor, severe muscle stiffness, tachycardia, and unstable blood pressure; notify prescriber immediately if they occur. Expect to discontinue drug and begin intensive medical treatment. Monitor patient carefully for recurrence if antipsychotic therapy resumes.

- Molindone shouldn't be given to patients who have severe CNS depression or who are comatose because of drug's CNS depressant effects.

- Monitor elderly patients for orthostatic hypotension and symptoms of tardive dyskinesia, including blinking or eyelid spasms, involuntary movements of the limbs, and unusual facial expressions, because these patients may be sensitive to drug's anticholinergic and extrapyramidal effects. Expect to reduce dosage or discontinue drug.

- Give oral solution undiluted or mixed with water, carbonated beverage, fruit juice, or milk.

- Monitor CBC often during first few months of therapy, especially if patient has low WBC count or history of drug-induced leukopenia or neutropenia. If WBC count drops, and especially if neutrophil count drops below 1000/mm³, expect molindone to be discontinued. If neutropenia is significant, also monitor patient for fever or other evidence of infection and provide appropriate treatment, as prescribed.

PATIENT TEACHING

- Instruct patient to follow treatment regimen and to notify prescriber before discontinuing drug because gradual dosage reduction may be needed.

- Instruct patient not to take drug within

- 2 hours of taking an antacid. Advise him to take drug with food or a full glass of milk or water to reduce gastric irritation.
- Instruct patient to take oral solution undiluted or mixed with water, carbonated beverage, fruit juice, or milk.
 - Urge patient to avoid alcohol consumption because of possible additive effects and hypotension.
 - Advise patient, especially an elderly patient, to rise slowly from a supine or seated position to avoid feeling dizzy, light-headed, or faint.
 - Explain that drug may reduce body's response to heat. Tell patient to avoid temperature extremes, such as hot showers, tubs, or saunas. Urge caution during exercise.
 - Caution patient not to take OTC drugs for colds or allergies during therapy because they can increase the risk of heatstroke and increase anticholinergic effects, such as blurred vision, constipation, dry mouth, and urine retention.
 - Inform patient and family members that maximum clinical improvement in symptoms may take several weeks or months.

mometasone furoate monohydrate

Nasonex

Class and Category

Chemical class: Glucocorticoid

Therapeutic class: Antiasthmatic, anti-inflammatory

Pregnancy category: C

Indications and Dosages

➤ *To manage symptoms of seasonal or perennial allergic rhinitis*

NASAL SPRAY

Adults and children 12 years and over.

100 mcg (2 sprays) in each nostril daily.

Children ages 2 to 12. 50 mcg (1 spray) in each nostril daily.

➤ *To maintain asthma control*

ORAL INHALATION

Adults and children age 12 and over who have been taking bronchodilators alone or

inhaled corticosteroids. *Initial:* 220 mcg (1 inhalation) once daily in evening.

Maximum: 440 mcg (2 inhalations) daily given as 220 mcg (1 inhalation) b.i.d. or 440 mcg (1 inhalation) once daily.

Adults and children age 12 and over who have taken oral corticosteroids. 440 mcg (2 inhalations) b.i.d.

Children ages 4 to 11. 110 mcg (1 inhalation) once daily in evening.

Mechanism of Action

Inhibits the activity of cells and mediators active in the inflammatory response, possibly by decreasing influx of inflammatory cells into nasal passages and thereby decreasing nasal inflammation.

Contraindications

Hypersensitivity to mometasone or its components; recent septal ulcers, nasal surgery, or nasal trauma; status asthmaticus or other asthma episodes that require emergency care

Adverse Reactions

CNS: Headache

CV: Chest pain

EENT: Cataracts, conjunctivitis, dry mouth, earache, epistaxis, glaucoma, nasal irritation, oral and pharyngeal candidiasis, otitis media, pharyngitis, rhinitis, sinusitis, throat tightness, unpleasant taste

ENDO: Adrenal insufficiency, growth suppression

GI: Diarrhea, dyspepsia, nausea, vomiting

GU: Dysmenorrhea

MS: Arthralgia, decreased bone mineral density, myalgia, pain

RESP: Asthma, bronchitis, bronchospasm, increased cough, upper respiratory tract infection, wheezing

SKIN: Urticaria

Other: Angioedema, flulike symptoms, viral infection

Nursing Considerations

- Use mometasone cautiously if patient has tubercular infection; untreated fungal, bacterial, or systemic viral infection; or ocular herpes simplex.
- If patient takes an oral corticosteroid, expect to taper it slowly 1 week after changing to mometasone. If patient takes prednisone, expect to reduce it by no more than 2.5 mg daily at weekly intervals,

beginning at least 1 week after mometasone therapy starts. Monitor patient for symptoms of systemically active corticosteroid withdrawal such as joint and muscle pain, lassitude, and depression despite maintenance or even improvement of respiratory symptoms.

WARNING Assess patient switched from systemic corticosteroid to mometasone for adrenal insufficiency (fatigue, hypotension, lassitude, nausea, vomiting, weakness) during initial treatment and during stress, trauma, surgery, infection or an electrolyte-depleting condition. Notify prescriber immediately if signs or symptoms arise because adrenal insufficiency may be life-threatening. Hypothalamic-pituitary-adrenal axis function may take several months to recover after systemic corticosteroids are discontinued. Abrupt withdrawal of mometasone also may precipitate adrenal insufficiency.

- Notify prescriber immediately if patient has bronchospasm after mometasone oral inhalation, and expect to give a fast-acting inhaled bronchodilator, discontinue mometasone, and use an alternate drug.
- Closely monitor a child's growth pattern; drug may stunt growth.
- Report oropharyngeal candidiasis, and expect patient to receive appropriate antifungal therapy while remaining on mometasone therapy. If candidiasis is severe, however, mometasone therapy may need to be temporarily halted.

PATIENT TEACHING

- For nasal spray, instruct patient to shake container before each use. Instruct her to blow her nose, tilt her head slightly forward, and insert tube into a nostril, pointing toward inner corner of eye, away from nasal septum. Tell her to hold the other nostril closed and spray while inhaling gently. Then have her repeat the procedure in the other nostril.
- For oral inhalation, give patient these instructions for using inhaler: Remove cap only after placing inhaler in an upright position. Twist cap in counterclockwise while holding colored base, making sure indented arrow (on white portion of the inhaler directly above the colored base) is pointing to the dose counter. Removing the cap loads inhaler with drug, and the

dose counter on the base will count down by one. Take a full breath in and out, and then place mouthpiece in your mouth. Firmly close your lips around mouthpiece, taking care not to cover ventilation holes on the inhaler. Then take a fast, deep breath. You may not taste, smell, or feel anything with the inhalation. After taking the breath, remove inhaler from your mouth and hold your breath for about 10 seconds. Don't exhale into the inhaler. Wipe the mouthpiece dry, if needed, and replace the cap right away, turning it clockwise as you press down. You should hear a click when the cap is fully closed. Write down the date inhaler is opened, and discard it 45 days from that date or when dose counter reads 00, whichever comes first.

- Instruct patient to gargle or rinse after each use of oral inhaler to help prevent mouth and throat dryness, relieve throat irritation, and prevent oropharyngeal infection.

WARNING Caution patient not to use mometasone oral inhalation to relieve acute bronchospasm and to notify prescriber if rescue inhaler is required more often or doesn't seem to be as effective.

- If patient switches from an oral corticosteroid to mometasone, advise her to carry or wear medical identification indicating the need for supplemental systemic corticosteroids during stress or severe asthma attack. Tell her to seek emergency care if either occurs.
- Instruct patient to contact prescriber if symptoms persist or worsen after 3 weeks.
- Caution patient to avoid exposure to chickenpox and measles and, if exposed, to contact prescriber immediately.

montelukast sodium

Singulair

Class and Category

Chemical class: Leukotriene receptor antagonist

Therapeutic class: Antiasthmatic

Pregnancy category: B

Indications and Dosages

↗ *To prevent or treat asthma*

ORAL GRANULES

Children ages 12 to 23 mo. 4 mg daily in the evening. *Maximum:* 4 mg daily.

CHEWABLE TABLETS

Children ages 6 to 14. 5 mg daily in the evening. *Maximum:* 5 mg daily.

Children ages 2 to 5. 4 mg daily in the evening. *Maximum:* 4 mg daily.

TABLETS

Adults and adolescents age 15 and over.

10 mg daily in the evening. *Maximum:* 10 mg daily.

↗ *To treat seasonal allergic rhinitis*

ORAL GRANULES

Children ages 2 to 5. 4 mg daily.

CHEWABLE TABLETS

Children ages 6 to 14. 5 mg daily.

Children ages 2 to 5. 4 mg daily.

TABLETS

Adults and adolescents age 15 and over.

10 mg daily.

↗ *To treat perennial allergic rhinitis*

ORAL GRANULES

Children ages 6 months to 5 years. 4 mg daily.

CHEWABLE TABLETS

Children ages 6 to 14. 5 mg daily.

Children ages 2 to 5. 4 mg daily.

TABLETS

Adults and adolescents age 15 and over.

10 mg daily.

↗ *To prevent exercise-induced bronchoconstriction*

TABLETS

Adults and adolescents age 15 and over.

10 mg at least 2 hr before exercise.

Maximum: 10 mg in 24 hr.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	24 hr

Mechanism of Action

Antagonizes receptors for cysteinyl leukotrienes, produced by arachidonic acid metabolism and released from mast cells, eosinophils, and other cells. When cysteinyl leukotrienes bind to receptors in bronchial airways, they increase endothelial membrane permeability, which leads to airway edema, smooth-muscle contraction, and altered activity of cells in asthma's inflammatory process. Montelukast blocks these effects.

Interactions

DRUGS

phenobarbital: Decreased amount of circulating montelukast

Adverse Reactions

CNS: Aggression, agitation, anxiousness, asthenia, depression, dizziness, dream abnormalities, fatigue, fever, hallucinations, headache, hostility, hypoesthesia, insomnia, irritability, paresthesia, restlessness, sleep walking, suicidal ideation, tremor

CV: Palpitations

EENT: Dental pain, epistaxis, laryngitis, nasal congestion, otitis media, pharyngitis, sinusitis

GI: Abdominal pain, cholestatic hepatitis, dyspepsia, elevated liver function test results, hepatotoxicity, indigestion, infectious gastroenteritis (in all patients); diarrhea, nausea (in children)

GU: Pyuria

RESP: Cough, upper respiratory tract infection

SKIN: Erythema nodosum, pruritus, rash, urticaria

Other: Anaphylaxis, angioedema (in all patients); flulike syndrome, viral infection (in children)

Nursing Considerations

WARNING Montelukast isn't for acute asthma attack or status asthmaticus.

- Montelukast shouldn't be abruptly substituted for inhaled or oral corticosteroids; expect to taper corticosteroid dosage gradually, as directed.
- Monitor patient for adverse reactions, such as cardiac and pulmonary symptoms, eosinophilia, and vasculitis, in patient undergoing corticosteroid withdrawal. Notify prescriber if such reactions occur.
- Watch patient closely for suicidal tendencies during montelukast therapy, especially when therapy starts or dosage changes.
- Monitor patient for adverse neuropsychiatric effects and notify prescriber if present. Drug may need to be discontinued.

PATIENT TEACHING

- Advise patient to take montelukast daily as prescribed, even when he feels well. Urge him not to decrease dosage or stop taking other prescribed asthma drugs unless instructed by prescriber.
- Caution patient not to use drug for acute

asthma attack or status asthmaticus; make sure he has appropriate short-acting rescue drug available.

- Tell parents administering oral granules to pour contents directly into the child's mouth or mix with ice cream or cold or room temperature applesauce, carrots, or rice—but not liquids or other foods—just before administration. Liquids may be given after drug has been administered. Once packet is opened, the full dose must be administered within 15 minutes. Drug must not be stored for future use if mixed with food.
- Instruct patient to notify prescriber if he needs a short-acting inhaled bronchodilator more often than usual, or more often than prescribed, to control symptoms.
- Teach patient to use a peak flowmeter to determine his personal best expiratory volume.
- Caution patient with aspirin sensitivity to avoid aspirin and NSAIDs during montelukast therapy. Montelukast may not effectively reduce bronchospasm in such a patient.
- Inform patient (or parents of child) with phenylketonuria that chewable tablet contains phenylalanine.
- Instruct patient to notify prescriber if she is or could be pregnant.
- Urge family or caregiver to watch patient closely for abnormal behaviors, including suicidal tendencies, during therapy, and urge them to notify prescriber if present.

morphine sulfate

Astramorph PF, Avinza, DepoDur, Duramorph, Epimorph (CAN), Kadian, M-Eslon (CAN), Morphine Extra-Forte (CAN), Morphine Forte (CAN), Morphine H.P. (CAN), Morphitec (CAN), MS Contin, MSIR, MS/L, MS/L Concentrate, MS/S, OMS Concentrate, Oramorph SR, Rescudose, RMS Uniserts, Roxanol, Roxanol 100, Roxanol UD, Statex (CAN)

Class, Category, and Schedule

Chemical class: Phenanthrene derivative

Therapeutic class: Analgesic

Pregnancy category: C

Controlled substance schedule: II

Indications and Dosages

↗ *To relieve acute or chronic moderate to severe pain; as adjunct to treat pulmonary edema caused by left-sided heart failure; to supplement general, local, or regional anesthesia*

CAPSULES, ORAL SOLUTION, SYRUP, TABLETS

Adults. *Initial:* 10 to 30 mg every 4 hr, p.r.n.
Children. Individualized dosage based on patient's age, size, and need.

I.V. INFUSION

Adults. *Initial:* 15 mg (or more) followed by 0.8 to 10 mg/hr, increased as needed for effectiveness. *Maintenance:* 0.8 to 80 mg/hr.
Children. 0.01 to 0.04 mg/kg/hr postoperatively, 0.025 to 2.6 mg/kg/hr for severe chronic cancer pain, or 0.03 to 0.15 mg/kg/hr for sickle cell crisis.

Neonates. *Initial:* 0.010 mg/kg/hr (10 mcg/kg/hr) postoperatively. *Maintenance:* 0.015 to 0.02 mg/kg/hr (15 to 20 mcg/kg/hr).

I.V. INJECTION

Adults. 2.5 to 15 mg injected slowly.
Children. 0.5 to 0.1 mg/kg given slowly.

I.M. OR SUBCUTANEOUS INJECTION

Adults. *Initial:* 10 mg (based on 70-kg [154-lb] adult) every 4 hr. *Maintenance:* 5 to 20 mg.

Children. *Initial:* 0.1 to 0.2 mg/kg every 4 hr. *Maximum:* 15 mg/dose.

EPIDURAL INFUSION (PRESERVATIVE-FREE)

Adults. *Initial:* 2 to 4 mg/24 hr, increased by 1 to 2 mg/24 hr, as directed.

EPIDURAL INJECTION (PRESERVATIVE-FREE)

Adults. *Initial:* 5 mg into lumbar region. If pain isn't relieved after 1 hr, 1- to 2-mg doses given at appropriate intervals to relieve pain. *Maximum:* 10 mg/24 hr.

INTRATHECAL INJECTION (PRESERVATIVE-FREE)

Adults. 0.2 to 1 mg as a single dose.

SUPPOSITORIES

Adults. 10 to 30 mg every 4 hr, p.r.n.

Children. Individualized dosage based on patient's age, size, and need.

↗ *To relieve chronic moderate to severe pain that requires opioids for more than a few days*

E.R. CAPSULES

Adults. Individualized dosage given every 12 to 24 hr.

E.R. TABLETS

Adults. 30 mg every 12 hr. Dosage increased based on patient's response.

↗ *To relieve MI pain*

I.V. INJECTION

Adults. 1 to 4 mg by slow I.V. injection. Repeated up to every 5 min, if needed. *Maximum:* 2 to 15 mg.

↗ *To provide preoperative analgesia*

I.M. OR SUBCUTANEOUS INJECTION

Adults. 5 to 20 mg given 45 to 60 min before surgery.

Children. 0.05 to 0.1 mg/kg given 45 to 60 min before surgery. *Maximum:* 10 mg.

↗ *To provide analgesia during labor*

I.M. OR SUBCUTANEOUS INJECTION

Adults. 10 mg, with subsequent doses based on patient's response.

Route	Onset	Peak	Duration
P.O.	Unknown	1–2 hr	4–5 hr
P.O. (E.R.)	Unknown	Unknown	8–12 hr
I.V.	Unknown	20 min	4–5 hr
I.M.	10–30 min	30–60 min	4–5 hr
SubQ	10–30 min	50–90 min	4–5 hr
Epidural	15–60 min	Unknown	Up to 24 hr
Intrathecal	15–60 min	Unknown	Up to 24 hr
P.R.	20–60 min	Unknown	Unknown

Mechanism of Action

Binds with and activates opioid receptors (mainly mu receptors) in brain and spinal cord to produce analgesia and euphoria.

Contraindications

For all drug forms: Asthma, hypersensitivity to morphine or its components, labor (premature delivery), prematurity (in infants), respiratory depression, upper airway obstruction

For oral solution: Acute abdominal disorders, acute alcoholism, alcohol withdrawal syndrome, arrhythmias, brain tumor, head injuries, heart failure caused by chronic lung disease, increased intracranial or cerebrospinal pressure, recent biliary tract surgery, respiratory insufficiency, seizure disorders, severe CNS depression, surgical anastomosis, use within 14 days of an MAO inhibitor

For I.V., I.M., or subcutaneous injection: Acute alcoholism, alcohol withdrawal syndrome, arrhythmias, brain tumor, heart failure caused by chronic lung disease, seizure disorders

For epidural or intrathecal injection: Anticoagulant therapy, bleeding tendency, injec-

tion site infection, parenteral corticosteroid treatment (or other treatment or condition that prohibits drug delivery by intrathecal or epidural route) within 2 weeks

Interactions**DRUGS**

amitriptyline, clomipramine, nortriptyline: Increased CNS and respiratory depression
anticholinergics: Possibly severe constipation leading to ileus, urine retention
antidiarrheals (such as loperamide and paregoric): CNS depression, possibly severe constipation

antihistamines, chloral hydrate, glutethimide, MAO inhibitors, methocarbamol: Increased CNS and respiratory depressant effects
antihypertensives, hypotension-producing drugs: Increased hypotension, risk of orthostatic hypotension

bupivacaine: Increased serum morphine level and possibly significant adverse effects

buprenorphine: Decreased therapeutic effects of morphine, increased respiratory depression, possibly withdrawal symptoms

cimetidine: Increased analgesic and CNS and respiratory depressant effects

CNS depressants (antiemetics, general anesthetics, hypnotics, phenothiazines, sedatives, tranquilizers): Possibly coma, hypotension, respiratory depression, severe sedation

diuretics: Decreased diuretic efficacy

hydroxyzine: Increased analgesic, CNS depressant, and hypotensive effects of morphine

metoclopramide: Possibly antagonized metoclopramide effect on GI motility

mixed agonist-antagonist analgesics: Possibly withdrawal symptoms

naloxone: Antagonized analgesic and CNS and respiratory depressant effects of morphine, possibly withdrawal symptoms

naltrexone: Possibly induction or worsening of withdrawal symptoms if morphine given within 7 to 10 days before naltrexone

neuromuscular blockers: Increased or prolonged respiratory depression

opioid analgesics (such as alfentanil and sufentanil): Increased CNS and respiratory depression, increased hypotension

zidovudine: Decreased zidovudine clearance

ACTIVITIES

alcohol use: Increased CNS and respiratory depression, increased hypotension

Adverse Reactions

CNS: Amnesia, anxiety, coma, confusion, decreased concentration, delirium, delusions, depression, dizziness, drowsiness, euphoria, fever, hallucinations, headache, insomnia, lethargy, light-headedness, malaise, psychosis, restlessness, sedation, seizures, syncope, tremor, unarousable, unresponsiveness

CV: Bradycardia, cardiac arrest, hypotension, orthostatic hypotension, palpitations, shock, tachycardia

EENT: Blurred vision, diplopia, dry mouth, laryngeal edema or laryngospasm (allergic), miosis, nystagmus, rhinitis

GI: Abdominal cramps or pain, anorexia, biliary tract spasm, constipation, diarrhea, dysphagia, elevated liver function test results, gastroesophageal reflux, hiccups, ileus and toxic megacolon (in patients with inflammatory bowel disease), intestinal obstruction, indigestion, nausea, vomiting

GU: Decreased ejaculate potency, decreased libido, difficult ejaculation, impotence, menstrual irregularities, oliguria, prolonged labor, urinary hesitancy, urine retention

HEME: Anemia, leukopenia, thrombocytopenia

MS: Arthralgia

RESP: Apnea, asthma exacerbation, atelectasis, bronchospasm, depressed cough reflex, hypoventilation, pulmonary edema, respiratory arrest and depression, wheezing

SKIN: Diaphoresis, flushing, pallor, pruritus, urticaria

Other: Allergic reaction; anaphylaxis; facial edema; injection site edema, pain, rash, or redness; physical and psychological dependence; withdrawal symptoms

Nursing Considerations

- Use cautiously in patients about to undergo surgery of the biliary tract and patients with acute pancreatitis secondary to biliary tract disease because morphine may cause spasm of the sphincter of Oddi.
- Store morphine at room temperature.
- Before giving morphine, make sure opioid antagonist and equipment for oxygen delivery and respiration are available.
- Before therapy, assess patient's drug use, including all prescription and OTC drugs.
- Expect prescriber to start patient who has never received opioids on immediate-

release form and then switch to E.R. form if therapy must last longer than a few days.

- Keep in mind that when morphine is given by epidural route, dosage must be individualized according to patient's age, body mass, physical status, previous experience with opioids, risk factors for respiratory depression, and drugs to be co-administered before or during surgery.
- Give oral form with food or milk to minimize adverse GI reactions, if needed. Solution can be mixed with fruit juice to improve taste.
- If needed, open E.R. capsules and sprinkle contents on applesauce (at room temperature or cooler) just before giving to patient. Make sure patient doesn't chew or crush capsules or dissolve capsule's pellets in his mouth.
- Be aware that E.R. forms of morphine aren't interchangeable.
- Discard injection solution that is discolored or darker than pale yellow or that contains precipitates that don't dissolve with shaking.

WARNING Don't use highly concentrated solutions (such as 10 to 25 mg/ml) for single-dose I.V., I.M., or subcutaneous administration. These solutions are intended for use in continuous, controlled microinfusion devices.

- For direct I.V. injection, dilute appropriate dose with 4 to 5 ml of sterile water for injection. Inject 2.5 to 15 mg directly into tubing of free-flowing I.V. solution over 4 to 5 minutes. Rapid I.V. injection may increase adverse reactions.
- For continuous I.V. infusion, dilute drug in D₅W and administer with infusion-control device. Adjust dose and rate based on patient response, as prescribed.
- Avoid I.M. route for long-term therapy because of injection site irritation.
- During subcutaneous injection, take care to avoid injecting drug intradermally.
- For intrathecal injection, expect prescriber to give no more than 2 ml of 0.5-mg/ml solution or 1 ml of 1-mg/ml solution. Expect intrathecal dosage to be about one-tenth of epidural dosage.
- If rectal suppository is too soft to insert, refrigerate for 30 minutes or run wrapped suppository under cold tap water.

WARNING Monitor respiratory and cardio-

vascular status carefully and frequently during morphine therapy. Be alert for respiratory depression and hypotension.

- Monitor patient with seizure disorder for increased seizure activity because morphine may worsen the disorder.
- Monitor patient for excessive or persistent sedation; dosage may need to be adjusted.
- If patient is receiving a continuous morphine infusion, watch for and notify prescriber about new neurologic signs or symptoms. Inflammatory masses (such as granulomas) have caused serious neurologic reactions, including paralysis.
- Expect morphine to cause physical and psychological dependence; watch for drug tolerance and withdrawal, such as body aches, diaphoresis, diarrhea, fever, piloerection, rhinorrhea, sneezing, and yawning.
- If tolerance to morphine develops, expect prescriber to increase dosage.
- Morphine may have a prolonged duration and cumulative effect in patients with impaired hepatic or renal function. It also may prolong labor by reducing strength, duration, and frequency of uterine contractions.
- When discontinuing morphine in patients receiving more than 30 mg daily, expect prescriber to reduce daily dose by about one-half for 2 days and then by 25% every 2 days thereafter until total dose reaches initial amount recommended for patients who haven't received opioids (15 to 30 mg daily). This regimen minimizes the risk of withdrawal symptoms.

PATIENT TEACHING

- Instruct patient to take morphine exactly as prescribed and not to change dosage without consulting prescriber.
- Explain that patient may take tablets or capsules with food or milk to relieve GI distress and may mix oral solution with juice to improve taste.
- Urge patient not to break, chew, or crush E.R. capsules and tablets to avoid rapid release and, possibly, toxicity.
- For patient who has difficulty swallowing, suggest that he open E.R. capsules and sprinkle contents on food or liquids. Urge him to take drug immediately and not let capsule contents dissolve in his mouth.
- Instruct patient to moisten rectal suppository before inserting it.

- Urge patient to avoid alcohol and other CNS depressants during therapy.
- Advise patient to avoid potentially hazardous activities during morphine therapy.
- Tell patient to change positions slowly to minimize the orthostatic hypotension.
- Instruct patient to notify prescriber about worsening or breakthrough pain.
- Explain that morphine may be habit-forming. Urge him to notify prescriber if he experiences anxiety, decreased appetite, excessive tearing, irritability, muscle aches or twitching, rapid heart rate, or yawning.
- Advise female patient to notify prescriber if she becomes pregnant. Regular morphine use during pregnancy may cause physical dependence in fetus and withdrawal in neonate.

moxifloxacin hydrochloride

Avelox, Avelox IV

Class and Category

Chemical class: Fluoroquinolone

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

➤ *To treat acute sinusitis caused by Haemophilus influenzae, Moraxella catarrhalis, or Streptococcus pneumoniae; to treat mild to moderate community-acquired pneumonia caused by Chlamydia pneumoniae, H. influenzae, M. catarrhalis, Mycoplasma pneumoniae, or S. pneumoniae (including penicillin- or multi-drug-resistant strains)*

TABLETS, I.V. INFUSION

Adults. 400 mg every 24 hr for 10 days.

➤ *To treat acute exacerbation of chronic bronchitis caused by H. influenzae, H. parainfluenzae, Klebsiella pneumoniae, M. catarrhalis, S. pneumoniae, or Staphylococcus aureus*

TABLETS, I.V. INFUSION

Adults. 400 mg every 24 hr for 5 days.

➤ *To treat uncomplicated skin and soft-tissue infections caused by S. aureus or Streptococcus pyogenes*

TABLETS, I.V. INFUSION

Adults. 400 mg every 24 hr for 7 days.

➤ *To treat complicated skin and skin structure infections caused by S. aureus, E. coli, K. pneumoniae, or Enterobacter cloacae*

TABLETS, I.V. INFUSION

Adults. 400 mg every 24 hr for 7 to 21 days.

➤ *To treat complicated intra-abdominal infections, including polymicrobial infections such as abscesses caused by E.coli, Bacteroides fragilis, Streptococcus anginosus, Streptococcus constellatus, Enterococcus faecalis, Proteus mirabilis, Clostridium perfringens, Bacteroides thetaiotaomicron, or Peptostreptococcus species*

TABLETS, I.V. INFUSION

Adults. 400 mg every 24 hr for 5 to 14 days with initial dosage given as I.V. infusion.

Mechanism of Action

Inhibits synthesis of bacterial enzyme DNA gyrase by counteracting excessive supercoiling of DNA during replication or transcription. Inhibiting DNA gyrase causes rapid- and slow-growing bacterial cells to die.

Incompatibilities

Don't infuse I.V. moxifloxacin simultaneously through the same I.V. line with other I.V. substances, additives, or drugs.

Contraindications

Hypersensitivity to moxifloxacin, other fluoroquinolones, or their components

Interactions

DRUGS

aluminum- or magnesium-containing antacids; drug formulations with divalent or trivalent cations, such as didanosine chewable buffered tablets or powder for oral solution; metal cations, such as iron; multivitamins containing iron or zinc; sucralfate:

Possibly substantial interference with moxifloxacin absorption, causing low blood moxifloxacin level

class IA antiarrhythmics, such as quinidine;

class III antiarrhythmics, such as sotalol;

other drugs known to prolong QTc interval, such as disopyramide and pentamidine:

Possibly prolonged QTc interval

corticosteroids: Increased risk of Achilles and other tendon ruptures

NSAIDs: Increased risk of CNS stimulation and seizures

warfarin: Possibly increased anticoagulation

Adverse Reactions

CNS: Abnormal gait, altered coordination, dizziness, fever, headache, psychosis, psychotic reaction, seizures, syncope

CV: Hypertension, hypotension, palpitations, peripheral edema, prolonged QTc interval, tachycardia, vasculitis, vasodilation, ventricular tachyarrhythmias

EENT: Altered taste, laryngeal edema

GI: Abdominal pain, abnormal liver function test results, acute hepatic necrosis or failure, cholestatic hepatitis, diarrhea, dyspepsia, hepatitis, jaundice, nausea, pseudomembranous colitis, vomiting

GU: Acute renal insufficiency or failure, interstitial nephritis

HEME: Agranulocytosis, aplastic anemia, eosinophilia, hemolytic anemia, leukopenia, pancytopenia, prolonged PT, thrombocytopenia

MS: Arthralgia, myalgia, tendon inflammation, pain, or rupture

RESP: Allergic pneumonitis

SKIN: Photosensitivity, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, anaphylactic shock, angioedema, serum sickness, worsening of myasthenia gravis

Nursing Considerations

- Use cautiously in patients with liver dysfunction, including cirrhosis, because drug may adversely affect liver function.
- Obtain a fluid or tissue specimen for culture and sensitivity, as ordered. Expect to begin therapy before results are available.

WARNING Before starting moxifloxacin therapy, determine if patient takes a class IA antiarrhythmic, such as quinidine; a class III antiarrhythmic, such as sotalol; or other drugs that prolong the QTc interval, such as antipsychotics, cisapride, erythromycin, or tricyclic antidepressants. These drugs should be avoided in patients taking moxifloxacin because they may prolong the QTc interval and lead to life-threatening ventricular tachycardia or torsades de pointes. Monitor patient closely throughout therapy, especially if he has significant bradycardia or acute myocardial ischemia because these conditions increase risk of prolonging the QTc interval.

- Infuse drug over 60 minutes with ready-

to-use flexible bags with 400 mg of moxifloxacin in 250 ml of 0.8% saline. Don't dilute further.

- If giving through Y-type tubing or piggyback, stop other solutions during moxifloxacin infusion, and flush the line before and after infusion with a compatible solution, such as normal saline solution, 1M sodium chloride, 5% dextrose, sterile water for injection, 10% dextrose, or lactated Ringer's. Also flush line before and after giving other drugs in same I.V. line.
- Don't refrigerate I.V. moxifloxacin ready-to-use bags because precipitation will occur. Discard any unused portion; pre-mixed bags are for single-use only.
- Expect to obtain a 12-lead ECG to assess patient for prolonged QTc interval. Ask patient if he or a blood relative has a history of prolonged QTc interval. Monitor elderly patients closely; they may have increased risk of prolonged QT interval.
- If patient has hypokalemia, expect to correct it before beginning moxifloxacin therapy to prevent arrhythmias.
- Determine if patient has a history of CNS disorder, such as cerebral arteriosclerosis or epilepsy, because drug may lower seizure threshold. Notify prescriber before starting drug, and take seizure precautions.
- If profuse, watery diarrhea develops, contact prescriber and expect to obtain a stool specimen to rule out pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold moxifloxacin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- Monitor serum potassium level, as ordered, during therapy to assess for hypokalemia.
- Keep emergency resuscitation equipment readily available, and observe for evidence of hypersensitivity, such as angioedema, dyspnea, and urticaria. If you suspect anaphylaxis, prepare to give epinephrine, corticosteroids, and diphenhydramine, as prescribed.
- Monitor patients who are prone to tendonitis, such as the elderly, athletes, and those taking corticosteroids, for complaints of tendon pain, inflammation, or rupture. If present, notify prescriber and expect to discontinue moxifloxacin, place patient on bedrest with no exercise of

affected limb, and obtain diagnostic tests to confirm rupture.

PATIENT TEACHING

- Urge patient to notify prescriber at once about palpitations or fainting because they may indicate a serious arrhythmia.
- Teach patient to take drug at least 4 hours before and 8 hours after aluminum- or magnesium-containing antacids, didanosine chewable buffered tablets or oral solution prepared from powder, multivitamins containing iron or zinc, or sucralfate.
- Urge patient to drink plenty of fluids while taking moxifloxacin.
- Caution patient to stop drug and notify prescriber if he has trouble breathing, a rash, or other signs of an allergic reaction.
- Urge patient to stop any exercise and contact prescriber immediately if he develops tendon inflammation, pain, or rupture.
- Caution patient to avoid hazardous activities until adverse CNS effects are known.
- Urge patient to tell prescriber if diarrhea develops, even more than 2 months after moxifloxacin therapy ends.
- Caution patient to complete the prescribed course of therapy even if he feels better before it's completed.
- Tell patient to avoid excessive exposure to sunlight or artificial ultraviolet light because severe sunburn may result. Instruct patient to notify prescriber if sunburn develops because moxifloxacin may need to be discontinued.

M

mycophenolate mofetil

CellCept, CellCept Oral Suspension

mycophenolate mofetil hydrochloride

CellCept Intravenous

mycophenolic acid

Myfortic

Class and Category

Chemical class: 2-morpholinoethyl ester of

mycophenolic acid

Therapeutic class: Immunosuppressant

Pregnancy category: D

Indications and Dosages

↗ *To prevent organ rejection in patients receiving allogeneic kidney transplants*

CAPSULES, ORAL SUSPENSION, TABLETS,

I.V. INFUSION

Adults. 1 g (over 2 hr for I.V. infusion) b.i.d.

E.R. TABLETS

Adults. 720 mg b.i.d.

SUSPENSION

Children with body surface area less than 1.25 m². 600 mg/m² b.i.d. *Maximum:* 2 g (10 ml) daily.

CAPSULES

Children with body surface area of 1.25 m² to 1.5 m². 750 mg b.i.d.

CAPSULES, TABLETS

Children with body surface area greater than 1.5 m². 1 g b.i.d.

↗ *To prevent organ rejection in patients receiving allogeneic heart transplants*

CAPSULES, ORAL SUSPENSION, TABLETS,

I.V. INFUSION

Adults. 1.5 g (over 2 hr for I.V. infusion) b.i.d.

↗ *To prevent organ rejection in patients receiving allogeneic liver transplants*

I.V. INFUSION

Adults. 1 g infused over 2 hr b.i.d.

CAPSULES, ORAL SUSPENSION, TABLETS

Adults. 1.5 g b.i.d.

Mechanism of Action

Hydrolyzes to form mycophenolic acid (MPA), which inhibits guanosine nucleotide synthesis and proliferation of T and B lymphocytes. MPA also suppresses antibody formation by B lymphocytes and prevents glycosylation of lymphocyte and monocyte glycoproteins involved in adhesion to endothelial cells. MPA also may inhibit leukocytes from sites of inflammation and graft rejection, which may explain how mycophenolate mofetil prolongs allogeneic transplant survival.

Incompatibilities

Don't mix or give mycophenolate mofetil hydrochloride in same infusion catheter with other I.V. drugs or admixtures.

Contraindications

Hypersensitivity to mycophenolate mofetil,

mycophenolic acid, or any of its components; hypersensitivity to polysorbate 80 (I.V. form)

Interactions

DRUGS

acyclovir, ganciclovir, probenecid: Increased plasma levels of both drugs

amoxicillin plus clavulanic acid, cholestyramine, cyclosporine, metronidazole, norfloxacin, rifampin: Decreased plasma level of mycophenolate mofetil

antacids with magnesium and aluminum hydroxides, sevelamer: Decreased absorption of oral mycophenolate mofetil

azathioprine: Increased bone marrow suppression

live vaccines: Decreased effectiveness of live vaccines

oral contraceptives: Possibly decreased effectiveness of oral contraceptives

Adverse Reactions

CNS: Agitation, anxiety, chills, confusion, delirium, depression, dizziness, emotional lability, fever, hallucinations, headache, hypertonía, hypesthesia, insomnia, malaise, meningitis, nervousness, neuropathy, paresthesia, progressive multifocal leukoencephalopathy, psychosis, seizure, somnolence, syncope, thinking abnormality, tremor, vertigo

CV: Angina pectoris, arrhythmias, arterial thrombosis, atrial fibrillation or flutter, bradycardia, cardiac arrest, CV disorder, congestive heart failure, extrasystole, generalized edema, hemorrhage, hypercholesterolemia, hyperlipemia, hypertension, hypotension, increased lactic dehydrogenase, increased SGOT and SGPT, increased venous pressure, infectious endocarditis, orthostatic hypotension, palpitations, pericardial effusion, peripheral edema, peripheral vascular disorder, pulmonary edema or hypertension, supraventricular tachycardia, thrombosis, vasodilation, vasospasm, ventricular extrasystole, ventricular tachycardia

EENT: Amblyopia, cataract, conjunctivitis, deafness, dry mouth, ear disorder or pain, epistaxis, eye hemorrhage, gingivitis, gum hyperplasia, lacrimation disorder, mouth ulceration, oral candidiasis, pharyngitis, rhinitis, sinusitis, stomatitis, tinnitus, vision abnormality, voice alteration

ENDO: Cushing's syndrome, diabetes mellitus, hypercalcemia, hypocalcemia, hypoglycemia, hypothyroidism, parathyroid disorder

GI: Abdomen enlargement or pain, anorexia, ascites, cholangitis, cholestatic jaundice, colitis, constipation, diarrhea, dyspepsia, dysphagia, esophagitis, flatulence, gastritis, gastroenteritis, GI hemorrhage, GI infection, GI candidiasis, hepatitis, hernia, ileus, jaundice, liver damage, liver function test abnormalities, melena, nausea, pancreatitis, peritonitis, rectal disorder, stomach ulcer, vomiting

GU: Albuminuria; bilirubinemia; BK virus-related nephropathy; dysuria; hematuria; hydronephrosis; impotence; increased BUN or creatinine levels; kidney tubular necrosis; nocturia; oliguria; pain; prostatic disorder; pyelonephritis; renal failure; scrotal edema, urinary tract disorder or infection; urine abnormality, frequency, incontinence, or retention

HEME: Anemia, coagulation disorder, hypochromic anemia, increased prothrombin time or thromboplastin time, leukocytosis, leukopenia, polythemia, pure red cell aplasia, thrombocytopenia

MS: Arthralgia; back, neck or pelvic pain; joint disorder; leg cramps; myalgia; myasthenia; osteoporosis

RESP: Apnea; asthma; atelectasis; bronchitis; cough; dyspnea; hemoptysis; hyperventilation; hypoxia; lung edema; pleural effusion; pneumonia; pneumothorax; pulmonary fibrosis; respiratory acidosis, candidiasis, neoplasm, or pain; sputum increase

SKIN: Abscess; acne; cellulite; ecchymosis; fungal dermatitis; pallor; petechia; pruritus; rash; benign neoplasm, carcinoma, hypertrophy, or ulcer; sweating; vesiculobullous rash

Other: Abnormal healing, accidental injury, acidosis, activation of latent infections (such as tuberculosis), alkalosis, alopecia, cyst, dehydration, facial edema, flulike syndrome, gout, hiccup, hirsutism, hyperkalemia, hyperuricemia, hypervolemia, hypochloremia, hypokalemia, hypomagnesemia, hyponatremia, hypoproteinemia, hypophosphatemia, increased alkaline phosphatase, increased gamma glutamyl transpeptidase, infection, lymphoma,

malignancies, sepsis, thirst, weight gain or loss

Nursing Considerations

- Before starting mycophenolate therapy in a woman of childbearing potential, make sure she has a negative pregnancy test within 1 week of starting therapy, using a test with a sensitivity of at least 25 mIU/ml. Therapy shouldn't start until results are confirmed.
- Expect to give I.V. form within 24 hours of transplantation and for no longer than 14 days. Expect to switch patient to oral form as soon as possible, as ordered.
- Expect to administer oral form of drug as soon as possible following transplantation.
- When preparing oral suspension or I.V. form, avoid inhalation or direct contact with skin or mucous membranes. If contact occurs, wash area thoroughly with soap and water and rinse eyes with water.
- To prepare oral suspension, tap closed bottle several times to loosen powder and then measure 94 ml of water in a graduated cylinder. Add half of the water to the bottle and shake for about 1 minute. Then add remainder of water and shake again for 1 minute. Remove child-resistant cap and push bottle adapter into neck of bottle. Close bottle tightly with child-resistant cap. Be aware that the suspension bottle may become cold immediately after reconstitution.
- Know that oral suspension can be administered by 8F or larger nasogastric tube.
- When giving oral suspension, don't mix with any other drugs. Ask patient about history of phenylketonuria before initial administration because oral suspension contains aspartame.
- Don't open or crush capsules. If necessary, use the oral suspension.
- Handle I.V. form similarly to a chemotherapeutic drug because mycophenolate mofetil is genotoxic and embryotoxic and may have mutagenic properties.
- Know that I.V. form must be reconstituted and diluted to 6 mg/ml using 5% dextrose injection USP. Inject 14 ml 5% dextrose injection USP into each vial (2 vials will be needed for each 1-g dose; 3 vials for each 1.5-g dose), then shake gently. Further dilute a 1-g dose by adding

2 reconstituted vials to 140 ml of 5% dextrose injection USP; dilute a 1.5-g dose by adding 3 reconstituted vials to 210 ml of 5% dextrose injection USP.

- Be aware that I.V. form should be administered within 4 hours of constitution as an infusion and over no less than 2 hours. Never administer by rapid or bolus I.V. injection.
- Know that cyclosporine and corticosteroids should be used with mycophenolate mofetil therapy.
- Obtain CBC weekly during first month of therapy, twice monthly for the second and third months of therapy, and then monthly through the first year, as ordered.
- Monitor patient closely for adverse reactions because drug has many adverse effects, some of which can be serious or severe.
- Expect to stop drug or reduce the dose and provide supportive care, as ordered, if neutropenia develops.

WARNING Mycophenolate mofetil therapy has been associated with progressive multifocal leukoencephalopathy that can be life-threatening. Monitor patient for hemiparesis, apathy, confusion, cognitive deficiencies, and ataxia. Report suspicions of disorder immediately to prescriber.

PATIENT TEACHING

- Advise women of childbearing age that two forms of contraceptives should be used simultaneously before beginning mycophenolate mofetil therapy and for 6 weeks following discontinuation of therapy because of potential for fetal harm. Inform women who use oral contraceptives that drug may decrease effectiveness of oral contraceptives. Urge patient to notify prescriber immediately if pregnancy occurs.
- Before therapy starts, tell patient about increased risk of lymphomas or other malignancies. Tell patient to report any unusual signs or symptoms to prescriber.
- Tell patient to take oral form of drug on an empty stomach.
- Inform patient prescribed oral suspension that it contains aspartame, which is a source of phenylalanine.
- Instruct patient not to crush tablets or capsules or open capsules.
- Inform patient not to receive live vaccines

during therapy. Urge him to avoid people who have received such vaccines or to wear a protective mask when he's around them.

- Tell patient to report any serious or ongoing adverse reactions, especially neurologic abnormalities, to prescriber immediately.
- Caution patient to avoid contact with people who have infections because drug causes immunosuppression.
- Urge patient to report any signs of infection, unexpected bruising or bleeding, or any other sign of bone marrow depression immediately.
- Tell patient that frequent laboratory tests may be needed during therapy. Stress that having these tests done is essential to continuing therapy.
- Advise patient to avoid exposure to direct sunlight and UV light and to wear sunscreen when outdoors because of increased risk for skin cancer.
- Advise patient not to take antacids at the same time as oral mycophenolate mofetil because some antacids can decrease drug's absorption.
- Tell patient to report unusual tiredness, lack of energy, paleness, dizziness, or fainting because dosage may need to be reduced or drug discontinued.
- Stress importance of follow-up care to monitor the drug's effectiveness and possible adverse effects because of the increased risk for cancer and infections as a result of immunosuppression. Inform patient of the need for periodic laboratory tests.

NO

nabumetone

Relafen

Class and Category

Chemical class: Naphthylalkanone derivative

Therapeutic class: Anti-inflammatory, antirheumatic

Pregnancy category: C (first trimester), Not rated (later trimesters)

Indications and Dosages

➤ *To relieve symptoms of acute and chronic osteoarthritis and rheumatoid arthritis*

TABLETS

Adults. *Initial:* 1 g daily as a single dose or in divided doses b.i.d., increased to 1.5 to 2 g daily in divided doses b.i.d.

Maintenance: Adjusted according to clinical response. *Maximum:* 2 g daily.

Mechanism of Action

Blocks activity of cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate the inflammatory response and cause local vasodilation, swelling, and pain. Prostaglandins also promote pain transmission from periphery to spinal cord. By blocking cyclooxygenase and inhibiting prostaglandins, the NSAID nabumetone reduces inflammatory symptoms and relieves pain.

Contraindications

Angioedema, asthma, bronchospasm, nasal polyps, rhinitis, or urticaria induced by aspirin, iodides, or other NSAIDs

Interactions

DRUGS

acetaminophen (long-term use): Increased risk of adverse renal effects

anticoagulants, thrombolytics: Increased risk of GI bleeding

antihypertensives: Decreased antihypertensive effectiveness

beta blockers: Decreased antihypertensive effects of beta blockers

bone marrow depressants, such as aldesleukin and cisplatin: Increased risk of leukopenia and thrombocytopenia

cefamandole, cefoperazone, cefotetan, plicamycin, valproic acid: Increased risk of hypoprothrombinemia and bleeding

colchicine, other NSAIDs, salicylates:

Increased GI irritability and bleeding

cyclosporine, gold compounds, nephrotoxic drugs: Increased risk of nephrotoxicity

digoxin: Increased blood digoxin level and risk of digitalis toxicity

diuretics: Decreased diuretic effectiveness

glucocorticoids, potassium supplements:

Increased GI irritability and bleeding

insulin, oral antidiabetic drugs: Increased effects of these drugs; risk of hypoglycemia

lithium: Increased risk of lithium toxicity

methotrexate: Increased risk of methotrexate toxicity

probenecid: Increased risk of nabumetone toxicity

ACTIVITIES

alcohol use: Increased GI irritability and bleeding

Adverse Reactions

CNS: Drowsiness, fatigue, fever, headache, nervousness, seizures, stroke, vertigo

CV: Edema, hypertension, MI, tachycardia

EENT: Dry mouth, pharyngitis, stomatitis, tinnitus

GI: Abdominal pain, anorexia, constipation, diarrhea, diverticulitis, dyspepsia, dysphagia, esophagitis, flatulence, gastritis, gastroenteritis, gastroesophageal reflux disease, GI bleeding and ulceration, hepatic dysfunction, indigestion, jaundice, melena, nausea, perforation of stomach or intestines, stomatitis, vomiting

GU: Albuminuria, azotemia, interstitial nephritis, nephrotic syndrome

HEME: Agranulocytosis, anemia, eosinophilia, granulocytopenia, hemolytic anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia

MS: Muscle spasms, myalgia

RESP: Asthma, pneumonitis, respiratory depression

SKIN: Alopecia, erythema multiforme, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, angioedema

Nursing Considerations

- Use nabumetone with extreme caution in patients with a history of ulcer disease or

GI bleeding because NSAIDs such as nabumetone increase risk of GI bleeding and ulceration. Expect to use nabumetone for shortest time possible in these patients.

- Be aware that serious GI tract ulceration, bleeding, and perforation may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, withhold drug and notify prescriber immediately.
- Use nabumetone cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

WARNING Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

- Monitor patient—especially if elderly or receiving long-term nabumetone therapy—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver function test results because, rarely, elevations may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure.
- Monitor BUN and serum creatinine levels in elderly patients, patients taking diuretics or ACE inhibitors, and patients with heart failure, impaired renal function, or hepatic dysfunction; nabumetone may cause renal failure.
- Monitor CBC for decreased hemoglobin and hematocrit; drug may worsen anemia.

WARNING If patient has bone marrow suppression or is receiving treatment with an antineoplastic, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of nabumetone may mask signs and symptoms, such as fever and pain.

- Assess patient's skin regularly for signs of rash or other hypersensitivity reaction because nabumetone is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID sensitivity. At first sign of reaction, stop drug and notify prescriber.
- Assess patient for severe hepatic reactions,

including jaundice. Stop drug, as prescribed, if symptoms persist.

PATIENT TEACHING

- Instruct patient to take nabumetone with food to reduce GI distress.
- Advise patient to take drug with a full glass of water and to remain upright for 15 to 30 minutes afterward to prevent drug from lodging in esophagus and causing irritation.
- Tell patient not to increase dose or frequency without consulting prescriber.
- Urge patient to avoid alcohol to reduce risk of GI bleeding.
- Inform patient that regular laboratory tests are needed to check for drug toxicity during long-term therapy.
- Caution pregnant patient not to take NSAIDs such as nabumetone during the last trimester because they may cause premature closure of the ductus arteriosus.
- Explain that nabumetone may increase the risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, weakness, and slurring of speech.
- Explain that nabumetone may increase the risk of serious adverse GI reactions; stress the importance of seeking immediate medical attention for such signs and symptoms as epigastric or abdominal pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions. Urge her to seek immediate medical attention for rash, blisters, itching, fever, or other indications of hypersensitivity.

nadolol

Corgard, Syn-Nadolol (CAN)

Class and Category

Chemical class: Nonselective beta blocker

Therapeutic class: Antianginal, antihypertensive

Pregnancy category: C

Indications and Dosages

↗ *To manage hypertension, alone or with other antihypertensives*

TABLETS

Adults. *Initial:* 40 mg daily, increased by 40 to 80 mg daily every 7 days, as prescribed. *Maintenance:* 40 to 80 mg daily. *Maximum:* 320 mg daily.

↗ **To manage angina pectoris as long-term therapy**

TABLETS

Adults. *Initial:* 40 mg daily, increased by 40 to 80 mg daily every 3 to 7 days, as prescribed. *Maintenance:* 40 to 80 mg daily. *Maximum:* 240 mg daily.

DOSAGE ADJUSTMENT Interval possibly increased to every 24 to 36 hr if creatinine clearance is 31 to 50 ml/min/1.73 m²; to every 24 to 48 hr if it's 10 to 30 ml/min/1.73 m²; or to every 40 to 60 hr if it's less than 10 ml/min/1.73 m².

Route	Onset	Peak	Duration
P.O.	Up to 5 days	4 hr	24 hr

Mechanism of Action

Selectively blocks α_1 and β_2 receptors in vascular smooth muscle and β_1 receptors in the heart, thereby reducing peripheral vascular resistance and blood pressure. Potent beta blockade decreases cardiac excitability, cardiac output, and myocardial oxygen demand, thus reducing angina. It also prevents reflex tachycardia, which typically occurs with most alpha blockers.

Contraindications

Asthma; bronchospasm; cardiogenic shock; heart failure; hypersensitivity to nadolol, other beta blockers, or their components; second- or third-degree AV block; severe COPD; sinus bradycardia

Interactions**DRUGS**

allergen immunotherapy, allergenic extracts for skin testing: Increased risk of serious systemic reactions or anaphylaxis
amiodarone: Increased risk of conduction abnormalities and negative inotropic effects
beta blockers, digoxin: Increased risk of bradycardia
calcium channel blockers: Increased risk of bradycardia
cimetidine: Possibly increased effects of nadolol
clonidine, guanabenz: Impaired blood pressure control

diazoxide, nitroglycerin: Increased risk of hypotension
estrogens, NSAIDs: Possibly reduced antihypertensive effect of nadolol
general anesthetics: Increased risk of hypotension and myocardial depression
insulin, oral antidiabetic drugs: Possibly increased risk of hyperglycemia and impaired recovery from hypoglycemia, masking of signs of hypoglycemia
lidocaine: Increased risk of lidocaine toxicity
neuromuscular blockers: Possibly prolonged action of these drugs
phenothiazines: Possibly increased blood levels of both drugs
reserpine: Increased risk of bradycardia and hypotension
sympathomimetics with alpha- and beta-adrenergic effects, such as pseudoephedrine: Possibly hypertension, excessive bradycardia, and heart block
xanthines, such as theophyllines: Possibly decreased therapeutic effects of both drugs

Adverse Reactions

CNS: Anxiety, depression, dizziness, drowsiness, fatigue, headache, paresthesia, syncope, vertigo, weakness, yawning
CV: Bradycardia, chest pain, edema, heart block, heart failure, hypotension, orthostatic hypotension, ventricular arrhythmias
EENT: Nasal congestion, taste perversion
GI: Dyspepsia, elevated liver function test results, hepatic necrosis, hepatitis, nausea, vomiting
GU: Ejaculation failure, impotence
RESP: Cough, dyspnea, wheezing
SKIN: Jaundice, pruritus, scalp tingling

Nursing Complications

- Use nadolol cautiously in patients with diabetes mellitus because it may prolong or worsen hypoglycemia by interfering with glycogenolysis.
- Anticipate that drug may worsen psoriasis and, in patients with myasthenia gravis, muscle weakness and diplopia.

WARNING Withdraw drug gradually over 2 weeks, or as ordered, to avoid MI caused by unopposed beta stimulation or thyroid storm caused by underlying hyperthyroidism. Expect drug to mask tachycardia caused by hyperthyroidism.

PATIENT TEACHING

- Teach patient how to take her radial pulse,

and direct her to do so before each dose of nadolol.

- Instruct patient to notify prescriber if pulse rate falls below 60 beats/minute.
- Caution patient not to stop taking nadolol abruptly or change dosage. Tell her to take a missed dose as soon as possible unless it's within 8 hours of the next scheduled dose.
- Advise patient with diabetes to check blood glucose level often because nadolol may mask signs of hypoglycemia, such as tachycardia.
- Review signs of impending heart failure, and urge patient to notify prescriber immediately if they occur.

nafarelin acetate

Synarel

Class and Category

Chemical class: Decapeptide, gonadotropin-releasing hormone analogue

Therapeutic class: Antiendometriotic, gonadal hormone inhibitor

Pregnancy category: X

Indications and Dosages

↗ *To treat endometriosis*

NASAL INHALATION

Adults. 1 spray (200 mcg) into a nostril every morning and 1 spray into other nostril every evening for up to 6 mo. If amenorrhea doesn't occur in 2 mo, dosage increased, as prescribed, to 800 mcg daily in divided doses.

↗ *To treat gonadotropin-dependent precocious puberty*

NASAL INHALATION

Children at puberty. 2 sprays (400 mcg) into each nostril every morning and evening. *Maximum:* 1,800 mcg daily in divided doses t.i.d.

Mechanism of Action

Stimulates release of the gonadotropins luteinizing hormone (LH) and follicle-stimulating hormone (FSH), which temporarily increase ovarian steroidogenesis. Within 1 month, however, repeated administration of nafarelin halts pituitary gland stimulation and decreases LH and FSH secretion. This action decreases estrogen

level, which improves symptoms of endometriosis. In children, repeated nafarelin administration returns LH and FSH to prepubescent levels, stopping development of secondary sex characteristics and slowing bone growth.

Route	Onset	Peak	Duration
Nasal	60–120 days*	20 days†	3–6 mo†

Contraindications

Breast-feeding; hypersensitivity to gonadotropin-releasing hormones, gonadotropin-releasing hormone analogues, nafarelin, or their components; pregnancy; undiagnosed vaginal bleeding

Interactions

DRUGS

nasal decongestants: Possibly impaired nafarelin absorption

Adverse Reactions

CNS: Asthenia, depression, fever, headache, mood changes, paresthesia

CV: Chest pain, edema, hot flashes, palpitations

EENT: Eye pain, rhinitis

ENDO: Galactorrhea, gynecomastia, transient increase in pubic hair growth

GU: Hypermenorrhea, hypertrophy of female genitalia, impotence, libido changes, menstrual irregularities, ovarian cysts, uterine bleeding, vaginal dryness, vaginal spotting between menses

MS: Arthralgia, decreased bone density, myalgia

RESP: Dyspnea

SKIN: Acne, hirsutism, rash, seborrhea, skin discoloration (brown)

Other: Body odor

Nursing Considerations

- Be aware that pregnancy must be ruled out before nafarelin therapy starts and that drug isn't recommended for use by breastfeeding women.
- Expect to start treatment for endometriosis between days 2 and 4 of menstrual cycle. Menses should cease after 6 weeks of treatment. Continued menses may indi-

* For gonadal hormone inhibitor effects, 4 wk.

† For antiendometriotic effects.

cate lack of compliance.

- Be aware that bone loss may increase if endometriosis treatment lasts longer than 6 months. Safety of retreatment after 6 months is unknown.
- Avoid giving nasal decongestant within 2 hours after nafarelin because it may impair nafarelin absorption.
- Be aware that prescriber will regularly monitor serum hormone levels in patient with gonadotropin-dependent precocious puberty, especially during first 6 to 8 weeks of therapy, to ensure rapid suppression of pituitary function.

PATIENT TEACHING

- Instruct patient to comply with prescriber's instructions for administering nafarelin to obtain desired drug effects.
- Instruct patient to tilt her head back while administering nafarelin to enhance absorption; urge her to try not to sneeze afterward.
- Caution patient not to change dosage without consulting prescriber.
- Counsel patient to use nonhormonal contraception and to notify prescriber if she is or could be pregnant.
- Direct patient not to use nasal decongestant within 2 hours after using nafarelin. If rhinitis occurs, urge her to contact prescriber for instructions.
- Teach patient how to cope with adverse reactions to help maximize compliance.
- Inform patient with endometriosis that drug should cause menses to stop. Urge her to notify prescriber if periods fail to stop even though she's taking drug exactly as prescribed.
- Advise patient with endometriosis to avoid alcohol and tobacco during therapy because they increase bone loss.
- Inform patient with gonadotropin-dependent precocious puberty that signs of puberty will persist during first month of treatment. If they don't resolve within 2 months, advise patient or parents to notify prescriber.
- Tell patient with gonadotropin-dependent precocious puberty that prescriber will assess bone growth velocity and bone age during first 3 to 6 months of therapy.
- Reassure parents of child with precocious puberty that child will resume growing when treatment stops.

nafcillin sodium

Nafcil, Nallpen, Unipen

Class and Category

Chemical class: Penicillin

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat infections caused by penicillinase-producing Staphylococcus aureus*

CAPSULES, TABLETS

Adults and adolescents. 250 to 1,000 mg every 4 to 6 hr. *Maximum:* 6,000 mg daily. Children over age 1 month. 6.25 to 12.5 mg/kg every 6 hr.

Neonates. 10 mg/kg every 6 to 8 hr.

I.V. INFUSION

Adults and adolescents. 500 to 1,500 mg every 4 hr. *Maximum:* 20,000 mg daily.

Children from birth to age 12. 10 to 20 mg/kg every 4 hr, or 20 to 40 mg/kg every 8 hr.

I.M. INJECTION

Adults and adolescents. 500 mg every 4 to 6 hr. *Maximum:* 12,000 mg daily.

Children over age 1 month. 25 mg/kg every 12 hr.

Neonates. 10 mg/kg every 12 hr.

➤ *To treat streptococcal pharyngitis*

CAPSULES, TABLETS

Children. 250 mg every 8 hr.

➤ *To treat bone and joint infections, endocarditis, meningitis, and pericarditis caused by susceptible organisms*

I.V. INFUSION

Adults and adolescents. 1,500 to 2,000 mg every 4 to 6 hr. *Maximum:* 20,000 mg daily.

I.V. INFUSION, I.M. INJECTION

Children from birth to age 12. 10 to 20 mg/kg every 4 hr or 20 to 40 mg/kg every 8 hr.

For meningitis in neonates weighing up to 2 kg (4.4 lb), 25 to 50 mg/kg every 12 hr for first week after birth and then 50 mg/kg every 8 hr. *For neonates weighing 2 kg or more,* 50 mg/kg every 8 hr during first week after birth and then 50 mg/kg every 6 hr.

Mechanism of Action

Binds to certain penicillin-binding proteins in bacterial cell walls, thereby inhibiting the final stage of bacterial cell wall synthesis. The result is cell lysis. Nafcillin's action is bolstered by its chemical composition; its

unique side chain resists destruction by beta-lactamases.

Incompatibilities

Don't mix nafcillin in same I.V. bag as aminoglycosides; they're chemically incompatible.

Contraindications

Hypersensitivity to nafcillin, other penicillins, or their components

Interactions

DRUGS

aminoglycosides: Substantial mutual inactivation

chloramphenicol, erythromycins, sulfonamides, tetracyclines: Possibly decreased therapeutic effects of nafcillin

hepatotoxic drugs: Increased risk of hepatotoxicity

methotrexate: Increased risk of methotrexate toxicity

probenecid: Increased blood nafcillin level

FOODS

all foods: Decreased nafcillin absorption

Adverse Reactions

CNS: Depression, headache, seizures

EENT: Oral candidiasis

GI: Abdominal pain, diarrhea, nausea, pseudomembranous colitis, vomiting

GU: Vaginitis

HEME: Leukopenia, neutropenia

SKIN: Exfoliative dermatitis, pruritus, rash, urticaria

Other: Anaphylaxis; hypokalemia; injection site pain, redness, and swelling; serum sicknesslike reaction

Nursing Considerations

- Obtain body fluid or tissue samples for culture and sensitivity testing, as prescribed, and obtain test results, if possible, before giving nafcillin, as ordered.
- Give capsules or tablets at least 1 hour before meals or 2 hours afterward.
- For I.M. injection, use only reconstituted solutions from vials. Inject deep into large muscle, preferably upper outer quadrant of gluteus maximus or lateral thigh.
- For intermittent I.V. infusion, infuse over 30 to 60 minutes.
- Give nafcillin at least 1 hour before or after aminoglycosides, especially if patient has renal disease.

- When giving nafcillin to patient at risk for hypertension or fluid overload, be aware that each gram contains 2.5 mEq sodium.

WARNING Avoid giving nafcillin to premature neonate if drug was reconstituted with bacteriostatic water that contains benzyl alcohol. Doing so can cause potentially fatal metabolic acidosis and circulatory, CNS, renal, and respiratory dysfunction.

- Monitor serum nafcillin level closely in children, as ordered, because liver and biliary tract, the main routes of nafcillin elimination, function immaturely in children.
- Watch for evidence of superinfection, such as oral candidiasis and pseudomembranous colitis, especially in elderly, immunocompromised, or debilitated patients who receive large doses of nafcillin. If profuse, watery diarrhea develops, contact prescriber and expect to obtain a stool specimen to rule out pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold nafcillin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

PATIENT TEACHING

- Instruct patient to take nafcillin capsules or tablets on an empty stomach.
- Urge patient to complete entire prescription, even if she feels better.
- Advise patient to notify prescriber if she experiences chills, fever, GI distress, or rash.
- Urge patient to tell prescriber if diarrhea develops, even 2 or more months after nafcillin therapy ends.

nalbuphine hydrochloride

Nubain

Class and Category

Chemical class: Phenanthrene derivative

Therapeutic class: Analgesic, anesthesia adjunct

Pregnancy category: B

Indications and Dosages

↗ *To relieve moderate to severe pain*

I.V., I.M., OR SUBCUTANEOUS INJECTION

Adults weighing 70 kg (154 lb). 10 mg every 3 to 6 hr, p.r.n. Dosage adjusted for patients weighing more or less.

↗ *As adjunct to anesthesia*

I.V. INJECTION

Adults. 0.3 to 3 mg/kg over 10 to 15 min followed by 0.25 to 0.5 mg/kg, as needed.

DOSAGE ADJUSTMENT For patients who have repeatedly received an opioid agonist, initial dose possibly reduced to 25% of usual. For patients in whom tolerance to drug's effects hasn't developed, maximum usually is 20 mg/dose or 160 mg daily.

Route	Onset	Peak	Duration
I.V.	2–3 min	30 min	3–4 hr
I.M.	In 15 min	1 hr	3–6 hr
SubQ	In 15 min	Unknown	3–6 hr

Mechanism of Action

Binds with and stimulates mu and kappa opiate receptors in the spinal cord and higher levels in the CNS. In this way, nalbuphine alters the perception of and emotional response to pain.

Incompatibilities

Don't give nalbuphine with diazepam or pentobarbital. Use separate I.V. line or flush line well before and after administration.

Contraindications

Hypersensitivity to nalbuphine or its components

Interactions**DRUGS**

alfentanil, CNS depressants, fentanyl, sufentanil: Increased risk of hypotension and CNS and respiratory depression

anticholinergics: Increased risk of severe constipation and urine retention
antidiarrheals, such as difenoxin and atropine, loperamide, and paregoric: Increased risk of severe constipation and increased CNS depression

antihypertensives: Increased risk of hypotension

buprenorphine: Possibly decreased therapeutic effects of nalbuphine and increased risk of respiratory depression

hydroxyzine: Increased risk of CNS depression and hypotension

MAO inhibitors: Risk of possibly fatal

increased CNS excitation or depression
metoclopramide: Possibly antagonized effects of metoclopramide
naloxone, naltrexone: Decreased pharmacologic effects of nalbuphine
neuromuscular blockers: Increased risk of prolonged CNS and respiratory depression

ACTIVITIES

alcohol use: Increased risk of coma, hypotension, profound sedation, and respiratory depression

Adverse Reactions

CNS: Confusion, depression, dizziness, euphoria, fatigue, hallucinations, headache, nervousness, restlessness, seizures, syncope, tiredness, weakness

CV: Hypertension, hypotension, tachycardia

EENT: Blurred vision, diplopia, dry mouth

GI: Abdominal cramps, anorexia, constipation, nausea, vomiting

GU: Decreased urine output, ureteral spasm

RESP: Dyspnea, pulmonary edema, respiratory depression, wheezing

SKIN: Diaphoresis, flushing, pruritus, rash, sensation of warmth, urticaria

Other: Injection site burning, pain, redness, swelling, and warmth

Nursing Considerations

- Use nalbuphine cautiously in patients taking other drugs that can cause respiratory depression.
- Keep resuscitation equipment and naloxone readily available to reverse nalbuphine's effects, if needed.
- For direct I.V. injection through an I.V. line with a compatible infusing solution, give drug slowly—no more than 10 mg over 3 to 5 minutes. Inject into free-flowing normal saline solution, D₅-W, or lactated Ringer's solution.
- During prolonged use, expect to give a stool softener to minimize constipation.
- If patient is opioid-dependent, expect drug to cause withdrawal symptoms, such as abdominal cramps, anorexia, anxiety, backache, bone or joint pain, confusion, depression, diaphoresis, dysphoria, erythema, fear, fever, irritability, labile blood pressure and pulse, lacrimation, muscle spasms, myalgia, mydriasis, nasal congestion, nausea, opioid craving, piloerection, restlessness, rhinorrhea, sensation of

crawling skin, sleep disturbances, tremor, uneasiness, vomiting, and yawning.

WARNING Be aware that drug may obscure neurologic assessment findings if patient has a cerebral aneurysm, head injury, or increased intracranial pressure.

PATIENT TEACHING

- Advise patient to avoid hazardous activities until nalbuphine's CNS effects are known.
- Counsel patient against making important decisions while receiving drug because it may cloud her judgment.

nalidixic acid

NegGram

Class and Category

Chemical class: Naphthylidene derivative quinolone

Therapeutic class: Antibiotic

Pregnancy category: Not rated (first trimester), B (later trimesters)

Indications and Dosages

➤ *To treat UTI caused by gram-negative bacteria, such as most Enterobacter species, Escherichia coli, Klebsiella species, Morganella morganii, Proteus mirabilis, Proteus vulgaris, and Providencia rettgeri*

ORAL SUSPENSION, TABLETS

Adults and children age 12 and over.

Initial: 1,000 mg every 6 hr for 1 to 2 wk.

Maintenance: 500 mg every 6 hr. *Maximum:* 4,000 mg daily.

Children ages 3 months to 12 years. *Initial:*

55 mg/kg daily in divided doses q.i.d. for 1 to 2 wk. *Maintenance:* 33 mg/kg daily in divided doses q.i.d.

Mechanism of Action

Inhibits the enzyme DNA gyrase, which is responsible for unwinding and supercoiling of bacterial DNA before it replicates. By inhibiting this enzyme, nalidixic acid causes bacterial cells to die.

Contraindications

Hypersensitivity to nalidixic acid or its components, porphyria, seizure disorder, use with melphalan or other related chemotherapeutic alkylating drugs

Interactions

DRUGS

aluminum-, calcium-, and magnesium-containing antacids; didanosine; multivitamins containing iron or zinc; sucralfate: Possibly interference with nalidixic acid absorption
chloramphenicol, nitrofurantoin, tetracycline: Decreased effects of nalidixic acid
cyclosporine: Possibly increased blood cyclosporine level
melphalan: Possibly increased risk of serious GI toxicity
oral anticoagulants: Increased anticoagulant effects
probencid: Decreased effects of nalidixic acid and increased risk of adverse reactions
theophylline: Possibly increased blood theophylline level

FOODS

caffeine: Decreased clearance and prolonged half-life of caffeine

Adverse Reactions

CNS: Confusion, drowsiness, hallucinations, headache, increased intracranial pressure with bulging fontanels (infants and children), light-headedness, malaise, paresthesia, peripheral neuropathy, psychosis, restlessness, seizures, tremor, weakness

EENT: Altered color perception, blurred vision, diplopia, halo vision, photophobia

GI: Abdominal pain, diarrhea, nausea, pseudomembranous colitis, vomiting

HEME: Eosinophilia, hemolytic anemia, leukopenia, thrombocytopenia

MS: Tendon rupture

SKIN: Jaundice, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, urticaria

Other: Anaphylaxis, metabolic acidosis

Nursing Considerations

- Be aware that nalidixic acid shouldn't be given to patient with creatinine clearance below 10 ml/min/1.73 m² because of the increased risk of drug toxicity and should be used cautiously in patients with liver disease, epilepsy, glucose-6-phosphate dehydrogenase deficiency, or severe cerebral arteriosclerosis or renal failure.
- Avoid giving drug within 2 hours of didanosine; multivitamins that contain iron or zinc; sucralfate; or antacid that contains aluminum, calcium, or magnesium.
- If nalidixic acid therapy exceeds 2 weeks,

monitor patient's blood counts and renal and liver function test results periodically, as ordered.

WARNING Stop nalidixic acid at first sign of hypersensitivity, including rash, because it may indicate anaphylaxis. Reaction may occur with first dose. Expect to give epinephrine and supportive care.

- If patient also takes cyclosporine or theophylline, monitor blood level of these drugs and adjust dosage, as prescribed.
- If patient has a history of seizures or cerebral arteriosclerosis, monitor for seizures during nalidixic acid therapy.
- Notify prescriber if patient has symptoms of peripheral neuropathy (pain, burning, tingling, numbness, weakness, or altered sensations of light touch, pain, temperature, position sense, or vibration sense), which could be permanent; or tendon rupture, which requires immediate rest. In each case, expect to stop nalidixic acid.

PATIENT TEACHING

- Encourage patient to drink plenty of fluids during therapy unless directed otherwise by prescriber.
- Urge patient to complete entire course of therapy, even if she feels better before it's finished.
- Advise patient to protect skin from sunlight.
- Urge patient to notify prescriber immediately about vision changes or such adverse CNS reactions as confusion, drowsiness, hallucinations, psychosis, and seizures.
- Urge patient to stop drug and notify prescriber if rash or other evidence of hypersensitivity develops.
- Tell patient to take drug at least 2 hours before or after aluminum-, calcium-, or magnesium-containing antacids; didanosine chewable buffered tablets or oral solution prepared from powder; multivitamins that contain iron or zinc; or sucralfate.
- Caution patient to avoid hazardous tasks until CNS effects of drug are known.
- Instruct patient to limit caffeine intake while taking nalidixic acid.
- Tell patient to stop drug and notify prescriber if she develops tendon pain or inflammation or abnormal changes in motor or sensory function.
- Urge patient to notify prescriber if diarrhea develops, even up to 2 months after nalidixic acid therapy stops.

naloxone hydrochloride

Narcan

Class and Category

Chemical class: Thebaine derivative

Therapeutic class: Opioid antagonist

Pregnancy category: B

Indications and Dosages

➤ *To treat known or suspected opioid overdose*

I.V. INJECTION

Adults and children age 5 and over weighing more than 20 kg (44 lb). 0.4 to 2 mg repeated every 2 to 3 min, p.r.n. If no response after 10 mg, patient may not have opioid-induced respiratory depression.

Infants and children under age 5.

0.01 mg/kg as a single dose; if no improvement, another 0.1 mg/kg, as prescribed. Or, 0.1 mg/kg repeated every 2 to 3 min, as needed

I.V., I.M., OR SUBCUTANEOUS INJECTION

Neonates. 0.01 mg/kg repeated I.V. every 2 to 3 min, as prescribed, until desired response occurs. Or, initial I.V. dose of 0.1 mg/kg.

➤ *To treat postoperative opioid-induced respiratory depression*

I.V. INJECTION

Adults and adolescents. *Initial:* 0.1 to 0.2 mg every 2 to 3 min until desired response occurs. Additional doses given every 1 to 2 hr, if needed, based on patient response.

Children. *Initial:* 0.005 to 0.01 mg every 2 to 3 min until desired response occurs. Additional doses given every 1 to 2 hr, if needed, based on patient response.

➤ *To reverse opioid-induced asphyxia*

I.V., I.M., OR SUBCUTANEOUS INJECTION

Neonates. *Initial:* 0.01 mg/kg every 2 to 3 min until desired response occurs. Additional doses given every 1 to 2 hr, if needed, based on patient response.

➤ *As adjunct to treat hypotension caused by septic shock*

I.V. INFUSION OR INJECTION

Adults. 0.03 to 0.2 mg/kg over 5 min followed by continuous infusion of 0.03 to 0.3 mg/kg/hr for 1 to 24 hr, as needed,

based on patient response.

Route	Onset	Peak	Duration
I.V.	1–2 min	5–15 min	45 min or longer
I.M., SubQ	2–5 min	5–15 min	45 min or longer

Mechanism of Action

Briefly and competitively antagonizes mu, kappa, and sigma receptors in the CNS, thus reversing analgesia, hypotension, respiratory depression, and sedation caused by most opioids. Mu receptors are responsible for analgesia, euphoria, miosis, and respiratory depression. Kappa receptors are responsible for analgesia and sedation. Sigma receptors control dysphoria and other delusional states.

Incompatibilities

Don't mix naloxone with any other solution unless you verify the drugs are compatible; drug is incompatible with alkaline, bisulfite, and metabisulfite solutions.

Contraindications

Hypersensitivity to naloxone or its components

Interactions

DRUGS

butorphanol, nalbuphine, pentazocine:

Reversal of these drugs' analgesic and adverse effects

opioid analgesics: Reversal of these drugs' analgesic and adverse effects, possibly withdrawal symptoms in opioid-dependent patients

Adverse Reactions

CNS: Excitement, irritability, nervousness, restlessness, seizures, tremor, violent behavior

CV: Hypertension (severe), hypotension, ventricular fibrillation, ventricular tachycardia

GI: Nausea, vomiting

RESP: Pulmonary edema

SKIN: Diaphoresis

Other: Withdrawal symptoms

Nursing Considerations

- Keep resuscitation equipment readily available during naloxone administration.
- Administer drug by I.V. route whenever

possible.

- Give repeat doses as prescribed, depending on patient's response.
- Anticipate that rapid reversal of opioid effects can cause diaphoresis, nausea, and vomiting.

WARNING Watch for withdrawal symptoms, especially when giving naloxone to opioid-dependent patient. Symptoms may include abdominal cramps, anorexia, anxiety, backache, bone or joint pain, confusion, depression, diaphoresis, dysphoria, erythema, fear, fever, irritability, labile blood pressure and pulse, lacrimation, muscle spasms, myalgia, mydriasis, nasal congestion, nausea, opioid craving, piloerection, restlessness, rhinorrhea, sensation of crawling skin, sleep disturbances, tremor, uneasiness, vomiting, and yawning.

- Expect patient with hepatic or renal dysfunction to have increased circulating blood naloxone level.

PATIENT TEACHING

- Inform patient or family that naloxone will reverse opioid-induced adverse reactions.
- Urge opioid-dependent patient to seek drug rehabilitation.

naltrexone hydrochloride

ReVia, Vivitrol

Class and Category

Chemical class: Thebaine derivative

Therapeutic class: Opioid antagonist

Pregnancy category: C

Indications and Dosages

↗ *To treat opioid dependence*

TABLETS

Adults. *Initial:* 25 mg, repeated within 1 hr, if needed and if no withdrawal symptoms occur. *Maintenance:* 50 to 150 mg daily or 350 mg/wk by intermittent dosing regimen.

↗ *As adjunct to treat alcoholism*

TABLETS

Adults. 50 mg daily (up to 100 mg daily for some patients) for 12 wk.

I.M. INJECTION

Adults. 380 mg every 4 wk or once monthly.

Mechanism of Action

Displaces opioid agonists from—or blocks them from binding with— μ , κ , and δ receptors. Opioid receptor blockade reverses the euphoric effect of opioids. Naltrexone also inhibits the effects of endogenous opioids, thus reducing alcohol craving.

Route	Onset	Peak	Duration
P.O.	15–30 min	In 12 hr	24 hr*
I.M.	Unknown	2 hr	Unknown

Contraindications

Acute hepatitis, acute opioid withdrawal, concurrent use of opioid analgesics (including opioid agonists, such as methadone or levo-alpha-acetyl-methadol [LAAM]), failure of naloxone challenge test, hepatic failure, hypersensitivity to naltrexone or its components, opioid dependence, positive urine screen for opioids

Interactions

DRUGS

opioid analgesics: Reversal of analgesic and adverse effects of these drugs, possibly withdrawal symptoms in opioid-dependent patients

thioridazine: Increased somnolence and lethargy

Adverse Reactions

CNS: Anxiety, chills, confusion, depression, dizziness, fatigue, fever, hallucinations, headache, insomnia, irritability, nervousness, restlessness, somnolence, suicidal ideation, syncope

CV: Chest pain, edema, hypertension, tachycardia

EENT: Blurred vision, burning eyes, conjunctivitis, dry mouth, eyelid swelling, hoarseness, pharyngitis, rhinitis, sneezing, tinnitus

GI: Abdominal cramps, anorexia, constipation, diarrhea, GI ulceration, hepatotoxicity with excessive doses, nausea, thirst, vomiting

GU: Difficult ejaculation, urinary frequency

MS: Arthralgia, back pain or stiffness, joint stiffness, muscle cramps, myalgia

RESP: Cough, dyspnea, eosinophilic pneu-

* For 50 mg; 48 hr for 100 mg; 72 hr for 150 mg.

monia, upper respiratory tract infection

SKIN: Pruritus, rash

Other: Injection site reactions, such as pain, tenderness, induration, swelling, erythema, pruritus

Nursing Considerations

- Use naltrexone cautiously in patients with severe renal impairment, thrombocytopenia, hemophilia, or severe hepatic failure.
- To avoid withdrawal symptoms, wait 7 to 10 days after last opioid dose, as prescribed, before starting naltrexone. Because urine testing isn't always conclusive, prepare patient for naloxone challenge test if there are any doubts about patient's abstinence.
- Give oral drug with food or antacids to decrease adverse GI reactions.
- Dilute parenteral form using only diluent supplied in carton. Inject in gluteal muscle using only needle supplied in carton. Don't substitute any components for components in carton. Store entire dose pack in refrigerator; unrefrigerated drug can be stored at room temperature for no more than 7 days.
- Inspect injection site for reactions, such as tenderness, induration, swelling, or redness. Ask if patient feels pain or itching at the site. Report any such findings to prescriber because abscesses and site necrosis may occur and require surgical intervention.

WARNING Never give parenteral form intravenously.

- Patients who receive naltrexone and need pain management are more likely to have longer, deeper respiratory depression and histamine-release reactions (such as facial swelling, itching, generalized erythema, and bronchoconstriction) if given an opioid analgesic. Expect alternative analgesics to be used, such as regional analgesia, conscious sedation with a benzodiazepine, nonopioid analgesics, or general anesthesia. If an opioid analgesic must be used, monitor patient closely.
- Watch patient closely for suicidal tendencies throughout naltrexone therapy.
- Anticipate that some patients may need treatment for up to 1 year.

PATIENT TEACHING

WARNING Caution patient against taking

opioids during naltrexone therapy or in the future because she'll be more sensitive to them. In fact, strongly warn patient that taking large doses of heroin or any other opioid (including methadone or LAAM) while taking naltrexone could lead to coma, serious injury, or death.

- Explain that patient may have nausea after first injection but that it is usually mild and subsides within a few days. Most patients don't have nausea with repeat doses.
- Tell patient to report adverse reactions promptly, especially dyspnea, coughing, wheezing, abdominal pain, and jaundice.
- Urge family or caregiver to watch patient closely for abnormal behaviors, including suicidal tendencies, even after patient stops taking naltrexone.
- Inform patient that naltrexone doesn't eliminate or diminish alcohol withdrawal symptoms.
- Urge patient to have comprehensive rehabilitation in addition to receiving naltrexone.
- Inform patient about nonopioid treatments for cough, diarrhea, and pain.
- Instruct patient to carry medical identification that lists naltrexone therapy.
- Instruct women of childbearing age to notify prescriber if pregnancy is suspected.

naproxen

Apo-Naproxen (CAN), EC-Naprosyn, Naprosyn, Naprosyn-E (CAN), Naxen (CAN), Novo-Naprox (CAN), Nu-Naprox (CAN)

naproxen sodium

Aleve, Anaprox, Anaprox DS, Apo-Napro-Na (CAN), Naprelan, Naprosyn-SR (CAN), Novo-Naprox Sodium (CAN)

Class and Category

Chemical class: Propionic acid derivative

Therapeutic class: Analgesic, anti-inflammatory, antipyretic

Pregnancy category: C

Indications and Dosages

↗ *To relieve mild to moderate musculoskeletal inflammation, including anky-*

losing spondylitis, osteoarthritis, and rheumatoid arthritis

DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS (NAPROXEN)

Adults. 250 to 500 mg b.i.d. *Maximum:* 1,500 mg daily for limited periods, as prescribed.

E.R. TABLETS (NAPROXEN SODIUM)

Adults. 750 to 1,000 mg daily. *Maximum:* 1,500 mg daily.

TABLETS (NAPROXEN SODIUM)

Adults. 275 to 550 mg b.i.d. *Maximum:* 1,650 mg daily for limited periods, as prescribed.

SUPPOSITORIES (NAPROXEN SODIUM)

Adults. 500 mg at bedtime in addition to daytime P.O. administration. *Maximum:* 1,500 mg daily (P.O. and suppository combined).

↗ *To relieve symptoms of juvenile rheumatoid arthritis and other inflammatory conditions in children*

ORAL SUSPENSION, TABLETS (NAPROXEN)

Children. 10 mg/kg daily in divided doses b.i.d.

↗ *To relieve symptoms of acute gouty arthritis*

DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS (NAPROXEN)

Adults. *Initial:* 750 mg, then 250 mg every 8 hr until symptoms subside.

E.R. TABLETS (NAPROXEN SODIUM)

Adults. *Initial:* 1,000 to 1,500 mg on day 1; then 1,000 mg daily until symptoms subside. *Maximum:* 1,500 mg daily.

TABLETS (NAPROXEN SODIUM)

Adults. *Initial:* 825 mg, then 275 mg every 8 hr until symptoms subside.

↗ *To relieve mild to moderate pain, including acute tendinitis and bursitis, arthralgia, dysmenorrhea, and myalgia*

DELAYED-RELEASE TABLETS (NAPROXEN)

Adults. *Initial:* 1,000 mg daily. *Maximum:* 1,500 mg daily.

E.R. TABLETS (NAPROXEN SODIUM)

Adults. *Initial:* 1,100 mg daily, increased as prescribed. *Maximum:* 1,500 mg daily.

ORAL SUSPENSION, TABLETS (NAPROXEN)

Adults. *Initial:* 500 mg, then 250 mg every 6 to 8 hr, p.r.n. *Maximum:* 1,250 mg daily.

TABLETS (NAPROXEN SODIUM)

Adults. *Initial:* 550 mg, then 275 mg every 6 to 8 hr, p.r.n. *Maximum:* 1,375 mg daily.

↗ *To relieve fever and mild to moderate*

*musculoskeletal inflammation or pain***TABLETS (OTC NAPROXEN SODIUM)**

Adults. 220 mg every 8 to 12 hr; or 440 mg and 220 mg 12 hr later. *Maximum:* 660 mg daily for 10 days unless directed otherwise.

DOSE ADJUSTMENT For patients over age 65, 220 mg every 12 hr. *Maximum:* 440 mg for 10 days unless directed otherwise.

Route	Onset	Peak	Duration
P.O. (naproxen)*	1 hr†	2–4 hr†‡	7–12 hr†
P.O. (naproxen sodium)*	30 min†	1 hr†‡	7–12 hr†

Mechanism of Action

Blocks cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate the inflammatory response and cause local vasodilation, swelling, and pain. Thus, naproxen, an NSAID, reduces symptoms of inflammation and relieves pain. Antipyretic action probably stems from effects on the hypothalamus, which increases peripheral blood flow, causing vasodilation and heat dissipation.

Contraindications

Angioedema, asthma, bronchospasm, nasal polyps, rhinitis, or urticaria induced by aspirin, iodides, or other NSAIDs; hypersensitivity to naproxen or its components

Interactions**DRUGS**

ACE inhibitors: Decreased antihypertensive effects; increased risk of renal dysfunction

acetaminophen: Increased risk of adverse renal effects with combined long-term use

aluminum hydroxide or magnesium oxide

antacids, cholestyramine, sucralfate: Possibly delayed absorption of naproxen

anticoagulants, thrombolytics: Prolonged PT, increased risk of bleeding

antihypertensives: Decreased effectiveness of antihypertensive

aspirin: Decreased aspirin effectiveness from lowered plasma and peak aspirin levels

* For antirheumatism, onset is in 14 days, peak is unknown, and duration is 2 to 4 wk.

† For analgesia.

‡ For gout, 1 to 2 days.

beta blockers: Decreased antihypertensive effects of these drugs

bone marrow depressants, such as aldesleukin and cisplatin: Increased risk of leukopenia and thrombocytopenia

cefamandole, cefoperazone, cefotetan, plicamycin, valproic acid: Increased risk of hypoprothrombinemia and bleeding

cimetidine: Altered blood naproxen level
colchicine, glucocorticoids, other NSAIDs, potassium supplements, salicylates: Increased GI irritability and bleeding

cyclosporine, gold compounds, nephrotoxic drugs: Increased risk of nephrotoxicity
digoxin: Increased blood digoxin level and risk of digitalis toxicity

diuretics: Decreased diuretic effectiveness

furosemide: Decreased natriuretic effect

insulin, oral antidiabetic drugs: Increased effectiveness of these drugs; risk of hypoglycemia

lithium: Increased risk of lithium toxicity

methotrexate: Increased risk of methotrexate toxicity

naproxen-containing products: Increased risk of toxicity

phenytoin: Increased blood phenytoin level

probenecid: Increased risk of naproxen toxicity

ACTIVITIES

alcohol use, smoking: Increased risk of naproxen-induced GI ulceration

Adverse Reactions

CNS: Aseptic meningitis, chills, cognitive impairment, decreased concentration, depression, dizziness, dream disturbances, drowsiness, fever, headache, insomnia, light-headedness, malaise, seizures, stroke, vertigo

CV: Edema, heart failure, hypertension, MI, palpitations, tachycardia, vasculitis

EENT: Papilledema, papillitis, retrobulbar optic neuritis, stomatitis, tinnitus, vision or hearing changes

ENDO: Hyperglycemia, hypoglycemia

GI: Abdominal pain, anorexia, colitis, constipation, diarrhea, diverticulitis, dyspepsia, dysphagia, elevated liver function test results, esophagitis, flatulence, gastritis, gastroenteritis, gastroesophageal reflux disease, GI bleeding and ulceration, heartburn, hematemesis, hepatitis, indigestion, melena, nausea, pancreatitis, peptic ulceration, perforation of stomach or intestines, stomatitis, vomiting

GU: Elevated serum creatinine level, glomerulonephritis, hematuria, infertility (in women), interstitial nephritis, menstrual irregularities, nephrotic syndrome, renal failure, renal papillary necrosis

HEME: Agranulocytosis, anemia, aplastic anemia, eosinophilia, granulocytopenia, hemolytic anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia

MS: Muscle weakness, myalgia

RESP: Asthma, dyspnea, eosinophilic pneumonitis, respiratory depression

SKIN: Alopecia, diaphoresis, ecchymosis, erythema multiforme, photosensitivity, pruritus, pseudoporphyria, purpura, rash, Stevens-Johnson syndrome, systemic lupus erythematosus, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, hyperkalemia

Nursing Considerations

- Use naproxen with extreme caution in patients with a history of ulcer disease or GI bleeding because NSAIDs such as naproxen increase risk of GI bleeding and ulceration. Expect to use naproxen for the shortest time possible in these patients.
- Serious GI tract ulceration, bleeding, and perforation may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, withhold drug and notify prescriber immediately.
- Use naproxen cautiously in patients with hypertension, and monitor blood pressure closely. Drug may cause hypertension or worsen it. Because of naproxen's sodium content, watch for fluid retention.
- Rehydrate a dehydrated patient before giving drug. If patient has renal disease, monitor renal function closely during therapy.
- Naproxen isn't recommended for patients with advanced renal disease.

WARNING Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk, especially if used in higher doses than recommended or for extended periods of time.

- Monitor patient—especially if elderly or receiving long-term naproxen therapy—for less common but serious adverse GI reactions, including anorexia, constipa-

tion, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.

- Monitor liver function test results because, in rare cases, elevations may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure.
- Monitor BUN and serum creatinine levels in elderly patients, patients taking diuretics or ACE inhibitors, and patients with heart failure, impaired renal function, or hepatic dysfunction; naproxen may cause renal failure.
- Monitor CBC for decreased hemoglobin and hematocrit because drug may worsen anemia.

WARNING If patient has bone marrow suppression or is receiving treatment with an antineoplastic drug, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of naproxen may mask signs and symptoms, such as fever and pain.

- Assess patient's skin regularly for signs of rash or other hypersensitivity reaction because naproxen is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID sensitivity. At first sign of reaction, stop drug and notify prescriber.
- Assess drug effectiveness in ankylosing spondylitis, as evidenced by decreased night pain, morning stiffness, and pain at rest; in osteoarthritis: decreased joint pain or tenderness and increased mobility, range of motion, and ability to perform daily activities; in rheumatoid arthritis: increased mobility and decreased joint swelling and morning stiffness; in acute gouty arthritis: decreased heat, pain, swelling, and tenderness in affected joints.
- Tell prescriber if patient complains of vision changes; patient may need ophthalmic exam.

PATIENT TEACHING

- Caution patient not to exceed recommended dosage, take for longer than directed, or take for more than 10 days without consulting prescriber because serious adverse reactions may occur.
- Tell patient to swallow delayed-release tab-

lets whole and not to break, crush, or chew them.

- Advise patient to take drug with food to reduce GI distress.
- Tell patient to take drug with a full glass of water and to remain upright for 15 to 30 minutes after taking it to prevent drug from lodging in esophagus and causing irritation.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to keep scheduled appointments with prescriber to monitor progress.
- Tell pregnant patient to avoid taking naproxen-containing products late in pregnancy.
- Explain that naproxen may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, weakness, and slurring of speech.
- Inform patient that naproxen may increase risk of serious adverse GI reactions; stress the importance of seeking immediate medical attention for such signs and symptoms as epigastric or abdominal pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions. Urge her to seek immediate medical attention for rash, blisters, itching, fever, or other indications of hypersensitivity.
- Advise patient to consult prescriber before taking naproxen-containing OTC products if he has asthma, ulcers, bleeding problems, high blood pressure, heart or kidney disease, a need for diuretic therapy, serious adverse effects from previous use of fever reducers or pain relievers, or persistent stomach problems, such as heartburn, upset stomach, or stomach pain.

naratriptan hydrochloride

Amerge

Class and Category

Chemical class: Selective serotonin 5-HT

receptor agonist

Therapeutic class: Antimigraine

Pregnancy category: C

Indications and Dosages

➤ *To relieve acute migraine with or without aura*

TABLETS

Adults. 1 to 2.5 mg as a single dose, repeated in 4 hr p.r.n. if only partial relief obtained. *Maximum:* 5 mg daily.

DOSAGE ADJUSTMENT For patients with mild to moderate renal or hepatic impairment, maximum dosage reduced to 2.5 mg daily.

Mechanism of Action

Binds to receptors on intracranial blood vessels and sensory nerves in trigeminal-vascular system to stimulate negative feedback, which halts serotonin release. Thus, naratriptan selectively constricts inflamed and dilated cranial vessels in the carotid circulation and inhibits production of proinflammatory neuropeptides.

Contraindications

Basilar or hemiplegic migraine; cerebrovascular, peripheral vascular, or coronary artery disease (ischemic or vasospastic); hypersensitivity to naratriptan or its components; hypertension (uncontrolled); severe hepatic or renal dysfunction; use within 24 hours of another 5-HT agonist or an ergotamine-containing or ergot-type drug, such as dihydroergotamine or methysergide

Interactions

DRUGS

ergot-containing drugs: Possibly prolonged or additive vasospastic reactions

fluoxetine, fluvoxamine, paroxetine, sertraline: Possibly weakness, hyperreflexia, and incoordination

oral contraceptives: Possibly reduced clearance and increased blood level of naratriptan

other selective serotonin 5-HT receptor agonists (including rizatriptan, sumatriptan, and zolmitriptan): Possibly additive effects

Adverse Reactions

CNS: Dizziness, drowsiness, fatigue, malaise, paresthesia

CV: Chest pain, pressure, or heaviness

EENT: Decreased salivation, otitis media, pharyngitis, photophobia, rhinitis, throat tightness

GI: Nausea, vomiting

Nursing Considerations

WARNING Because naratriptan therapy can cause coronary artery vasospasm, monitor patient with coronary artery disease for signs or symptoms of angina while taking drug. Because naratriptan may also cause peripheral vasospastic reactions, such as ischemic bowel disease, monitor patient for abdominal pain and bloody diarrhea.

- Monitor patient for hypertension during naratriptan therapy. It may increase systolic blood pressure by up to 32 mm Hg.
- Be prepared to perform complete neurovascular assessment in any patient who reports an unusual headache or who fails to respond to first dose of naratriptan.

PATIENT TEACHING

- Inform patient that naratriptan is used to treat acute migraine attacks and that it won't prevent or reduce the number of migraines.
- Advise patient not to take more than maximum prescribed amount during any 24-hour period.
- If patient has no relief from initial dose of naratriptan, instruct her to notify prescriber rather than taking another dose in 4 hours because she may need a different drug.
- Advise patient to seek reevaluation by prescriber if she has more than four headaches during any 30-day period while taking naratriptan.

natalizumab

Tysabri

Class and Category

Chemical class: Recombinant humanized

IgG4K monoclonal antibody

Therapeutic class: Anti-multiple sclerotic

Pregnancy category: C

Indications and Dosages

➤ *To delay physical disability and reduce frequency of clinical exacerbations in relapsing forms of multiple sclerosis; to induce and maintain remission in mod-*

erately to severely active Crohn's disease with evidence of inflammation in patients who had inadequate response to or are unable to tolerate conventional therapy and inhibitors of tumor necrosis factor alpha

I.V. INFUSION

Adults. 300 mg infused over 1 hr every 4 wk.

Route	Onset	Peak	Duration
I.V.	Unknown	24 wk	Unknown

Mechanism of Action

Inhibits migration of leukocytes from vascular space, increasing the number of circulating leukocytes. It does this by binding to integrins on the surface of leukocytes (except neutrophils) and inhibiting adhesion of leukocytes to their counter receptors. In multiple sclerosis, lesions probably occur when activated inflammatory cells, including T-lymphocytes, cross the blood-brain barrier.

Contraindications

History of or presence of progressive multifocal leukoencephalopathy, hypersensitivity to natalizumab or its components

Interactions

DRUGS

antineoplastics, immunosuppressants, immunomodulating agents: Increased risk of life-threatening infection

Adverse Reactions

CNS: Depression, dizziness, fatigue, headache, progressive multifocal leukoencephalopathy (PML), rigors, somnolence, suicidal ideation, vertigo

CV: Chest discomfort, peripheral edema

EENT: Sinusitis, tonsillitis, tooth infection

GI: Abdominal discomfort, abnormal liver function test results, cholelithiasis, diarrhea, gastroenteritis, hepatotoxicity, jaundice, nausea

GU: Amenorrhea; dysmenorrhea; irregular menstruation; ovarian cysts; UTI; urinary incontinence, frequency, or urgency; vaginitis

MS: Arthralgia, back or limb pain, joint swelling, muscle cramp

RESP: Cough, pneumonia or other respiratory tract infection

SKIN: Dermatitis, night sweats, pruritus, rash, urticaria

Other: Acute hypersensitivity reaction, anaphylaxis, antibody formation, flulike illness, herpes, serious infection, weight gain or loss

Nursing Considerations

- Make sure patient has enrolled in the TOUCH prescribing program before giving natalizumab. Once patient has signed and initialed the TOUCH program enrollment form, place original signed form in the patient's medical record, send a copy to Biogen Idec, and give a copy to patient.
- Be aware that all serious opportunistic and atypical infections must be reported to Biogen Idec at 1-800-456-2255 and the FDA's MedWatch Program at 1-800-FDA-1088.
- Make sure patient with multiple sclerosis has had an MRI of the brain before starting natalizumab therapy. It will help distinguish evidence of multiple sclerosis from PML symptoms if they occur after therapy starts.
- Dilute natalizumab concentrate 300 mg/15 ml in 100 ml of normal saline injection. Gently invert solution to mix completely. Do not shake.
- Following dilution, infuse drug immediately over 1 hour. After infusion, flush line with normal saline injection.
- Do not give natalizumab by I.V. push or bolus injection.
- If not infused right away, refrigerate drug and use within 8 hours.
- Observe patient during and for 1 hour after infusion for hypersensitivity reaction, evidenced by urticaria, dizziness, fever, rash, rigors, pruritus, nausea, flushing, hypotension, dyspnea, and chest pain. Reaction is more likely to occur if natalizumab therapy was interrupted. If hypersensitivity reaction occurs, notify prescriber; expect to withhold drug and provide supportive care.

WARNING Monitor patient closely for evidence of PML, a viral brain infection that may be disabling or fatal, because natalizumab increases the risk. If patient has unexplained neurologic changes, notify prescriber, withhold natalizumab, and prepare patient for a gadolinium-enhanced

brain MRI and possible cerebrospinal fluid analysis, as ordered.

- Expect that patient will be reevaluated 3 months after first infusion, 6 months after first infusion, and every 6 months thereafter.
- Assess patient for evidence of infection because natalizumab may adversely affect immune system, increasing risk of infection. If infection occurs, expect to obtain appropriate specimens for culture and sensitivity and to treat accordingly.
- Be aware that if patient with Crohn's disease has no therapeutic response after 12 weeks, natalizumab should be discontinued. If patient is on chronic oral corticosteroid therapy, expect tapering of oral corticosteroid dose to begin. If patient can't be tapered off oral corticosteroids within 6 months of starting natalizumab therapy, expect natalizumab to be discontinued. Likewise, if patient needs additional steroid use that extends beyond 3 months in a calendar year to control signs and symptoms of Crohn's disease, expect natalizumab to be discontinued.
- Assess patient's liver function regularly, as ordered, because natalizumab may cause significant liver damage. Expect drug to be discontinued if patient becomes jaundiced or liver enzymes become elevated.

PATIENT TEACHING

- Instruct patient on benefits and risks of natalizumab therapy, and provide medication guide for patient to read.
- Encourage patient to ask questions before signing the enrollment form.
- Emphasize need to report any worsening symptoms that persist over several days.
- Tell patient to inform all health care providers that he is receiving natalizumab therapy.
- Stress the need to have follow-up visits 3 months after first infusion, 6 months after first infusion, and at least every 6 months thereafter.
- Instruct patient to report evidence of allergic reaction such as urticaria, dizziness, fever, rash, rigors, pruritus, nausea, flushing, hypotension, dyspnea, and chest pain.
- Instruct patient to avoid people who have infections. Advise him to report fever, cough, lower-back or side pain, or other

unexplained signs and symptoms because they may indicate infection.

nateglinide

Starlix

Class and Category

Chemical class: Amino acid derivative

Therapeutic class: Antidiabetic

Pregnancy category: C

Indications and Dosages

↗ *To control blood glucose level in type 2 diabetes mellitus, either as monotherapy or with metformin or a thiazolidinedione*

TABLETS

Adults. 120 mg t.i.d. 1 to 30 min before meals.

DOSE ADJUSTMENT Dosage reduced to 60 mg t.i.d. in patients with near-goal glycosylated hemoglobin (HbA_{1c}) level.

Contraindications

Diabetic ketoacidosis, hypersensitivity to

nateglinide or its components, type 1 diabetes mellitus

Route	Onset	Peak	Duration
P.O.	20 min	1 hr	4 hr

Interactions

DRUGS

corticosteroids, sympathomimetics, thiazide diuretics, thyroid products: Possibly reduced hypoglycemic effects of nateglinide
MAO inhibitors, nonselective beta-adrenergic blockers, NSAIDs, salicylates: Possibly additive hypoglycemic effects of nateglinide

Adverse Reactions

CNS: Dizziness

ENDO: Hypoglycemia

GI: Cholestatic hepatitis, diarrhea, elevated liver enzyme levels, jaundice

MS: Accidental trauma, arthropathy, back pain

RESP: Bronchitis, cough, upper respiratory tract infection

SKIN: Pruritus, rash, urticaria

Other: Flulike symptoms

Mechanism of Action

Nateglinide stimulates the release of insulin from functioning beta cells of the pancreas. In patients with type 2 diabetes mellitus, a lack of functioning beta cells diminishes blood levels of insulin and causes glucose intolerance. By interacting with the adenosine triphosphatase (ATP)–potassium channel on the beta cell membrane, nateglinide prevents potassium (K⁺) from leaving the cell. This causes

the beta cell to depolarize and the cell membrane's calcium channel to open. Consequently, calcium (Ca⁺⁺) moves into the cell and insulin moves out of it. The extent of insulin release is glucose dependent; the lower the glucose level, the less insulin is secreted from the cell.

By promoting insulin secretion in patients with type 2 diabetes mellitus, nateglinide improves glucose tolerance.

Nursing Considerations

- Give nateglinide 1 to 30 minutes before meals to reduce the risk of hypoglycemia.
- Monitor fasting glucose and HbA_{1c} levels periodically, as ordered, to evaluate treatment effectiveness.
- Monitor patient often in event of fever, infection, trauma, or surgery because transient loss of glucose control may occur, requiring an alteration in therapy.

PATIENT TEACHING

- Instruct patient to take nateglinide 1 to 30 minutes before meals. Advise her to skip scheduled dose if she skips a meal to reduce the risk of hypoglycemia.
- Teach patient to measure blood glucose level and recognize hyperglycemia and hypoglycemia. Advise her to notify prescriber if blood glucose level is abnormal.
- Inform patient that strenuous exercise, insufficient calorie intake, and consumption of alcohol increase risk of hypoglycemia.
- Advise patient to monitor blood glucose level as prescribed and to keep follow-up appointments to monitor HbA_{1c} level because drug may become less effective over time.

neбиволол hydrochloride

Bystolic

Class and Category

Chemical class: Beta-adrenergic blocker

Therapeutic class: Antihypertensive

Pregnancy category: C

Indications and Dosages

➤ *To treat hypertension*

TABLETS

Adults. *Initial:* 5 mg once daily, increased at 2-wk intervals, as needed. *Maximum:* 40 mg once daily.

DOSE ADJUSTMENT For patients with moderate renal impairment (creatinine clearance less than 30 ml/min/1.73 m²) or moderate hepatic impairment (Child-Pugh Class B), initial dose reduced to 2.5 mg.

Mechanism of Action

May prevent arterial dilation and inhibit

renin secretion, although precise mechanism of action isn't known. Negative chronotropic effects may slow resting heart rate, and negative inotropic effects may reduce cardiac output, myocardial contractility, and myocardial oxygen consumption during stress or exercise. All of these actions may work together to lower systolic and diastolic blood pressure.

Route	Onset	Peak	Duration
P.O.	Unknown	1.5–4 hr	Unknown

Contraindications

Advanced AV block, cardiogenic shock, decompensated cardiac failure, hypersensitivity to neбиволол or its components, sick sinus syndrome (unless permanent pacemaker is in place), severe bradycardia, severe hepatic impairment

Interactions

DRUGS

antiarrhythmias such as disopyramide, beta blockers, digoxin, diltiazem: Increased effect on AV conduction and myocardial depression; increased risk of bradycardia
fluoxetine, paroxetine, propafenone, quinidine: Increased hypertensive effect of neбиволол

guanethidine, reserpine: Possibly excessive reduction of sympathetic activity

Adverse Reactions

CNS: Asthenia, dizziness, fatigue, headache, insomnia, paresthesia, somnolence, syncope, vertigo

CV: Allergic vasculitis, AV block, bradycardia, chest pain, hypercholesterolemia, hyperuricemia, MI, peripheral edema, peripheral ischemia, Raynaud's phenomenon

GI: Abdominal pain, diarrhea, elevated liver enzymes, nausea, vomiting

GU: Acute renal failure, elevated BUN level, erectile dysfunction

HEME: Decreased platelet count, thrombocytopenia

RESP: Acute pulmonary edema, bronchospasm, dyspnea

SKIN: Pruritus, psoriasis, rash, urticaria

Other: Angioedema

Nursing Considerations

- Know that patients with bronchospastic

- disease usually shouldn't be treated with beta blocker therapy such as nebivolol.
- Use nebivolol cautiously in patients with impaired hepatic or renal function.
 - Expect to administer an alpha blocker, as ordered, before starting nebivolol therapy in patients with pheochromocytoma.
 - Monitor blood pressure and pulse rate often, especially at start of nebivolol therapy and during dosage adjustments. Also monitor fluid intake and output and daily weight, and watch for evidence of heart failure, such as dyspnea, edema, fatigue, and jugular vein distention. If heart failure occurs or worsens, expect drug to be discontinued.
 - Be aware that drug shouldn't be stopped abruptly because MI, myocardial ischemia, severe hypertension, or ventricular arrhythmias may result.
 - Expect to temporarily withhold nebivolol before surgery. If drug will be continued during perioperative period, monitor patient closely for protracted severe hypotension and difficulty restarting and keeping a heartbeat.
 - Assess distal circulation and peripheral pulses in patient with peripheral vascular disease because drug can worsen it.
 - Be aware that nebivolol may mask tachycardia from hyperthyroidism and that abrupt withdrawal can cause thyroid storm. Drug also can decrease blood glucose level, prolong or mask symptoms of hypoglycemia, and promote hyperglycemia in patient with diabetes mellitus; or worsen psoriasis.
 - Monitor patient closely for hypersensitivity reactions that may occur with beta blockers, especially patients with a history of severe anaphylactic reactions who may not be responsive to usual doses of epinephrine used to treat allergic reactions.

PATIENT TEACHING

- Instruct patient to take nebivolol exactly as prescribed and not to stop abruptly.
- Tell patient to weigh herself daily during nebivolol therapy and to notify prescriber if she gains more than 2 lb (0.9 kg) in 1 day or 5 lb. (2.3 kg) in 1 week.
- Advise patient to rise slowly from a seated or lying position to minimize effects of orthostatic hypotension.
- Advise patient to avoid hazardous activi-

ties until drug's CNS effects are known.

- Instruct patient to contact prescriber about bleeding or bruising, cough at night, dizziness, edema, rash, shortness of breath, or slow pulse rate.
- Advise diabetic patient to monitor her blood glucose level more often during nebivolol therapy because drug may mask symptoms of hypoglycemia.
- Inform patient with psoriasis that drug may aggravate this condition.

nefazodone hydrochloride

Serzone

Class and Category

Chemical class: Phenylpiperazine derivative

Therapeutic class: Antidepressant

Pregnancy category: C

Indications and Dosages

↗ *To treat major depression*

TABLETS

Adults. *Initial:* 100 mg b.i.d., increased by 100 to 200 mg daily every wk, as prescribed.

Maintenance: 150 to 300 mg b.i.d.

Maximum: 600 mg daily.

DOSAGE ADJUSTMENT Initial dosage possibly reduced to 50 mg b.i.d. for elderly or debilitated patients; then dosage adjusted as ordered, based on patient response.

Route	Onset	Peak	Duration
P.O.	Several wk	Unknown	Unknown

Mechanism of Action

May inhibit serotonin reuptake at presynaptic neurons, which may increase neuronal level of serotonin, an inhibitory neurotransmitter thought to regulate mood. Nefazodone also may act as a postsynaptic serotonin receptor antagonist, further increasing the amount of synaptic serotonin that's available.

Contraindications

Concurrent use of astemizole, cisapride, or terfenadine; hypersensitivity to nefazodone, other phenylpiperazine antidepressants, or their components; restarting nefazodone therapy that was discontinued because of

liver injury; use within 14 days of MAO inhibitor therapy

Interactions

DRUGS

alprazolam, buspirone, carbamazepine, cyclosporine, modafinil, triazolam: Increased blood levels of these drugs

antihypertensives: Increased risk of hypotension

astemizole, cisapride, terfenadine: Increased blood levels of these drugs, prolonged QT interval, and, possibly, serious cardiovascular effects, including death from ventricular tachycardia

cilostazol: Decreased cilostazol clearance, increased adverse effects of cilostazol, such as headache

dextromethorphan, sibutramine, tramadol, trazodone: Increased risk of serotonin syndrome

digoxin: Increased blood digoxin level, increased risk of digitalis toxicity

haloperidol: Decreased haloperidol clearance

indinavir: Inhibited indinavir metabolism

levobupivacaine: Increased blood levobupivacaine level, possibly toxicity

lovastatin, simvastatin: Increased risk of rhabdomyolysis and myositis

MAO inhibitors: Possibly fatal reactions, including autonomic instability (with rapidly fluctuating vital signs), hyperthermia, mental status changes (such as severe agitation progressing to delirium and coma), muscle rigidity, and myoclonus

methadone: Increased blood level and adverse effects of methadone, additive CNS effects

nevirapine: Increased nefazodone metabolism, inhibited nevirapine metabolism

ritonavir: Inhibited nefazodone and ritonavir metabolism

sildenafil: Decreased sildenafil clearance

tacrolimus: Decreased tacrolimus clearance and increased adverse effects, including delirium and renal failure

ACTIVITIES

alcohol use: Increased risk of CNS depression

Adverse Reactions

CNS: Abnormal gait, apathy, asthenia, ataxia, chills, confusion, decreased concentration, delusions, depersonalization, dizzi-

ness, dream disturbances, euphoria, fever, hallucinations, headache, hostility, hypotonia, insomnia, light-headedness, malaise, memory loss, myoclonic jerks, neuralgia, paranoia, paresthesia, somnolence, suicidal ideation, syncope, tremor, vertigo

CV: Angina, hypertension, hypotension, peripheral edema, orthostatic hypotension, tachycardia, vasodilation, ventricular arrhythmias

EENT: Abnormal vision, blurred vision, conjunctivitis, diplopia, dry eyes and mouth, earache, epistaxis, eye pain, gingivitis, halitosis, hyperacusis, laryngitis, mydriasis, neck rigidity, periodontal abscess, pharyngitis, photophobia, stomatitis, taste perversion, tinnitus, visual field defects

ENDO: Breast pain, gynecomastia, lymphadenopathy

GI: Abdominal distention, colitis, constipation, diarrhea, elevated liver function test results, eructation, esophagitis, gastritis, gastroenteritis, hernia, hepatotoxicity, hiccups, increased appetite, indigestion, life-threatening hepatic failure, nausea, peptic ulcer, rectal bleeding, thirst, vomiting

GU: Abnormal ejaculation; amenorrhea; cystitis; hematuria; hypermenorrhea; impotence; libido changes; nocturia; pelvic pain; polyuria; renal calculi; urinary frequency, incontinence, or urgency; urine retention; UTI; vaginal bleeding; vaginitis

HEME: Anemia, leukopenia

MS: Arthralgia, arthritis, bursitis, dysarthria, gout, muscle stiffness, tenosynovitis

RESP: Asthma, bronchitis, cough, dyspnea, pneumonia

SKIN: Acne, alopecia, dry skin, ecchymosis, eczema, maculopapular rash, photosensitivity, pruritus, rash, urticaria

Other: Allergic reaction, dehydration, infection, serotonin syndrome, weight loss

Nursing Considerations

WARNING Be aware that nefazodone should not be given with astemizole, cisapride, MAO inhibitors, or terfenadine; serious, even fatal, reactions may occur.

WARNING Be aware that life-threatening hepatic failure has occurred during nefazodone therapy, resulting in need for transplant or even death. Monitor patient for signs of hepatic failure, such as jaun-

dice, malaise, and elevated liver function test results.

- Assess for evidence of serotonin syndrome, such as abdominal cramps, aggression, agitation, chills, diarrhea, headache, insomnia, lack of coordination, nausea, palpitations, paresthesia, poor concentration, and worsening of obsessive thoughts.
- Monitor patient closely for suicidal tendencies, especially when therapy starts or dosage changes, because depression may worsen temporarily. Follow facility policy.

PATIENT TEACHING

- Instruct patient to take nefazodone exactly as prescribed and not to alter dosage.
- Urge patient to immediately report evidence of hepatic failure, such as jaundice, dark urine, lack of appetite, nausea, or abdominal pain.
- Inform patient that antidepressant effects may not occur for several weeks and that treatment may last 6 months or longer.
- Caution patient to avoid alcohol during nefazodone therapy.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Suggest that patient try sugarless gum or hard candy for dry mouth. Urge her to notify prescriber if dry mouth persists.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.

neomycin sulfate

Mycifradin, Neo-Fradin

Class and Category

Chemical class: Aminoglycoside

Therapeutic class: Antibiotic

Pregnancy category: D

Indications and Dosages

↗ *To suppress intestinal bacterial growth in preoperative bowel preparation*

TABLETS (24-HR REGIMEN)

Adults. 1 g every hr for 4 doses and then 1 g every 4 hr for remainder of 24 hr before surgery. Or, for 8 a.m. surgery, 1 g of neomycin with erythromycin at 1 p.m., 2 p.m., and 11 p.m. the day before surgery.

Children. 25 mg/kg at 1 p.m., 2 p.m., and 11 p.m. the day before surgery.

TABLETS (2- TO 3-DAY REGIMEN)

Adults and children. 88 mg/kg every 4 hr in 6 equally divided doses for 2 to 3 days before surgery.

↗ *As adjunct in hepatic encephalopathy*

TABLETS

Adults. 4 to 12 g daily in divided doses every 6 hr for 5 to 6 days.

Children. 50 to 100 mg/kg daily in divided doses every 6 hr for 5 to 6 days.

↗ *To treat infectious diarrhea caused by enteropathic Escherichia coli*

TABLETS

Adults and children. 50 mg/kg daily in divided doses q.i.d. for 2 to 3 days.

Mechanism of Action

Is transported into bacterial cells, where it competes with messenger RNA to bind with a specific receptor protein on the 30S ribosomal subunit of DNA. This action causes abnormal, nonfunctioning proteins to form. A lack of functional proteins causes bacterial cell death.

Contraindications

Hypersensitivity or serious reaction to neomycin, other aminoglycosides, or their components; inflammatory or ulcerative GI disease; intestinal obstruction

Interactions

DRUGS

digoxin, spironolactone: Possibly reduced absorption rate of these drugs

dimenhydrinate: Possibly masked symptoms of neomycin-induced ototoxicity

methotrexate: Possibly decreased absorption and bioavailability of methotrexate

neuromuscular blockers: Potentiated neuromuscular blockade, increased risk of prolonged respiratory depression

oral anticoagulants: Possibly potentiated anticoagulant effects

Adverse Reactions

EENT: Ototoxicity

GI: Diarrhea, malabsorption syndrome (decreased serum carotene level and xylose absorption, increased fecal fat and flatulence), nausea, pseudomembranous colitis, vomiting

GU: Nephrotoxicity

Nursing Considerations

- Monitor patient's BUN and serum creati-

nine levels to assess renal function before and during neomycin therapy. Expect to decrease dosage or stop drug if nephrotoxicity develops.

- Monitor blood neomycin level, as directed, to assess for therapeutic range of 5 to 10 mcg/ml.

WARNING Neomycin is highly ototoxic and may cause hearing loss and tinnitus.

- Watch for evidence of pseudomembranous colitis, such as severe abdominal cramps and severe, watery diarrhea.
- Anticipate that neomycin's curare-like effect may worsen muscle weakness in patients with neuromuscular disorders, such as myasthenia gravis and parkinsonism.

PATIENT TEACHING

- Urge patient to complete full course of neomycin therapy.
- Unless contraindicated, urge patient to drink plenty of fluids to prevent nephrotoxicity.
- Urge patient undergoing bowel preparation to comply with recommended regimen, including low-residue diet, bisacodyl enema administration, and neomycin use.
- Advise patient to notify prescriber about hearing loss or ringing in ears.

neostigmine bromide

Prostigmin

neostigmine methylsulfate

Prostigmin

Class and Category

Chemical class: Quaternary ammonium compound

Therapeutic class: Anticholinesterase, curare antidote

Pregnancy category: C

Indications and Dosages

↗ *To treat symptoms of myasthenia gravis*

TABLETS (NEOSTIGMINE BROMIDE)

Adults. *Initial:* 15 mg every 3 to 4 hr.

Dosage adjusted based on clinical response.

Maintenance: 150 mg daily in divided doses

based on clinical response.

Children. 2 mg/kg daily in 6 to 8 divided doses.

I.M. OR SUBCUTANEOUS INJECTION (NEOSTIGMINE METHYLSULFATE)

Adults. *Initial:* 0.5 mg. Dosage adjusted based on clinical response.

Children. 0.01 to 0.04 mg/kg every 2 to 3 hr.

↗ *To reverse nondepolarizing neuromuscular blockade*

I.V. INJECTION (NEOSTIGMINE METHYLSULFATE)

Adults. 0.5 to 2 mg by slow push, repeated as needed up to 5 mg; 0.6 to 1.2 mg of atropine or 0.2 to 0.6 mg of glycopyrrolate given with or a few minutes before neostigmine, as ordered.

Children. 0.04 mg/kg by slow push; 0.02 mg of atropine/kg is given I.M. or subcutaneously with each dose or alternate doses.

↗ *To prevent postoperative, nonobstructive urine retention and abdominal distention (adynamic ileus)*

I.M. OR SUBCUTANEOUS INJECTION (NEOSTIGMINE METHYLSULFATE)

Adults. 0.25 mg immediately after surgery and repeated every 4 to 6 hr for 2 to 3 days.

↗ *To treat postoperative, nonobstructive urine retention and abdominal distention (adynamic ileus)*

I.M. OR SUBCUTANEOUS INJECTION (NEOSTIGMINE METHYLSULFATE)

Adults. 0.5 mg; injections repeated every 3 hr for at least 5 doses if patient has voided or bladder has emptied within 1 hr.

Route	Onset	Peak	Duration
P.O.	45–75 min*	Unknown	3–6 hr
I.V.	4–8 min†	30 min	2–4 hr
I.M.	20–30 min†	30 min	2–4 hr

Mechanism of Action

Inhibits action of cholinesterase, an enzyme that destroys acetylcholine at myoneuronal junctions, thereby increasing acetylcholine accumulation at myoneuronal junctions and facilitating nerve impulse transmission across the junctions. This action:

- helps prevent or relieve urine retention by increasing detrusor muscle tone in the bladder and causing bladder contractions strong enough to induce urination

* For adynamic ileus, 2 to 4 hr.

† For adynamic ileus, 10 to 30 min.

- prevents or treats postoperative abdominal distention by increasing gastric motility and tone
- improves muscle strength and increases muscle response to repetitive nerve stimulation in myasthenia gravis.

Contraindications

Hypersensitivity to neostigmine, other anticholinesterases, bromides, or their components; mechanical obstruction of intestinal or urinary tract; peritonitis

Interactions

DRUGS

aminoglycosides, anesthetics, capreomycin, colistimethate, colistin, lidocaine, lincomycins, polymyxin B, quinine: Increased risk of neuromuscular blockade

anticholinergics: Possibly masked signs of cholinergic crisis

guanadrel, guanethidine, mecamylamine, trimethaphan: Possibly antagonized effects of neostigmine, possibly decreased antihypertensive effects

neuromuscular blockers: Possibly prolonged action of depolarizing—and antagonized action of nondepolarizing—neuromuscular blockers

procainamide, quinidine: Possibly antagonized effects of neostigmine

quinine: Decreased neostigmine effectiveness

Adverse Reactions

CNS: Dizziness, drowsiness, headache, seizures, syncope, weakness

CV: Arrhythmias (AV block, bradycardia, nodal rhythm, tachycardia), cardiac arrest, ECG changes, hypotension

EENT: Increased salivation, lacrimation, miosis, vision changes

GI: Abdominal cramps, diarrhea, flatulence, increased peristalsis, nausea, vomiting

GU: Urinary frequency

MS: Arthralgia, dysarthria, muscle spasms

RESP: Bronchospasm, dyspnea, increased bronchial secretions, respiratory arrest or depression

SKIN: Flushing, diaphoresis, rash, urticaria

Nursing Considerations

- Be aware that 15 mg oral neostigmine bromide is equivalent to 0.5 mg parenteral neostigmine methylsulfate.
- If also giving atropine, be sure to administer it before neostigmine, as prescribed.

- When giving neostigmine I.V., make sure patient is well ventilated and airway remains patent until normal respiration is assured.
- If patient has myasthenia gravis, give drug night and day, as ordered, with larger portions of daily dose during periods of increased fatigue. If patient's condition becomes refractory to neostigmine, expect to reduce dosage or discontinue drug, as prescribed, for a few days.

WARNING Monitor patient for evidence of neostigmine overdose, which can cause possibly fatal cholinergic crisis (increased muscle weakness, including respiratory muscles). Expect to stop neostigmine and atropine, as ordered.

PATIENT TEACHING

- Instruct patient to take neostigmine exactly as prescribed.
- Advise patient to take drug with food or milk to reduce adverse GI reactions.
- Suggest that patient with myasthenia gravis keep a daily record of doses and adverse reactions during therapy.
- Instruct patient to schedule activities to minimize fatigue.

nesiritide

Natrecor

Class and Category

Chemical class: Human B-type natriuretic peptide

Therapeutic class: Arterial and venous smooth muscle cell relaxant

Pregnancy category: C

Indications and Dosages

↗ To reduce dyspnea at rest or with minimal activity in patients with acute decompensated congestive heart failure

I.V. INFUSION, I.V. INJECTION

Adults. 2-mcg/kg bolus and then continuous infusion of 0.01 mcg/kg/min for up to 48 hr.

Route	Onset	Peak	Duration
I.V.	In 15 min	1 hr	3 hr

Mechanism of Action

Binds to guanylate cyclase receptor of vas-

cular smooth muscle and endothelial cells. This action increases intracellular levels of cyclic guanosine monophosphate, which leads to arterial and venous smooth muscle cell relaxation. Ultimately, nesiritide reduces pulmonary capillary wedge pressure and systemic arterial pressure in patients with congestive heart failure, which decreases the heart's workload and subsequently relieves dyspnea.

Incompatibilities

Don't infuse nesiritide through same I.V. line as bumetanide, enalaprilat, ethacrynate sodium, furosemide, heparin, hydralazine, or insulin because these drugs are chemically and physically incompatible with nesiritide. Don't infuse drugs that contain the preservative sodium metabisulfite through same I.V. line as nesiritide.

Contraindications

Hypersensitivity to nesiritide or its components; primary therapy for cardiogenic shock; systolic blood pressure less than 90 mm Hg

Interactions

DRUGS

ACE inhibitors: Increased risk of symptomatic hypotension

Adverse Reactions

CNS: Anxiety, dizziness, headache, insomnia

CV: Angina, bradycardia, hypotension, PVCs, ventricular tachycardia

GI: Abdominal pain, nausea, vomiting

GU: Elevated serum creatinine level

MS: Back pain

Nursing Considerations

WARNING Be aware that nesiritide isn't recommended for patients suspected to have low cardiac filling pressures or patients for whom vasodilating drugs aren't appropriate, such as those with constrictive pericarditis, pericardial tamponade, restrictive or obstructive cardiomyopathy, significant valvular stenosis, or other conditions in which cardiac output depends on venous return.

- Reconstitute 1.5-mg vial by adding 5 ml diluent removed from a 250-ml plastic I.V. bag containing preservative-free D₅W, normal saline solution, dextrose 5% in

half-normal (0.45) saline solution, or dextrose 5% in quarter-normal (0.2) saline solution.

- Don't shake vial. Rock it gently so all surfaces, including the stopper, are in contact with diluent to ensure complete reconstitution. Inspect drug for particulate matter and discoloration; if present, discard drug.
 - Withdraw entire contents of reconstituted solution and add it to 250-ml plastic I.V. bag used to withdraw diluent to yield a solution of about 6 mcg/ml. Invert I.V. bag several times to ensure complete mixing.
 - After preparing infusion bag, withdraw bolus volume from infusion bag and give it over about 60 seconds. Immediately after bolus, infuse drug at 0.1 ml/kg/hr, which will deliver 0.01 mcg/kg/min.
 - Prime I.V. tubing with 25 ml of solution before connecting to the I.V. line and before administering the bolus dose or starting the infusion.
 - Flush the I.V. line between doses of nesiritide and incompatible drugs.
 - Because nesiritide binds to heparin and therefore could bind to the heparin lining of a heparin-coated catheter, don't give it through a central heparin-coated catheter.
 - Store reconstituted vials at room temperature (20° to 25° C [68° to 77° F]) or refrigerate (2° to 8° C [36° to 46° F]) for up to 24 hours.
 - Because nesiritide contains no antimicrobial preservatives, discard the reconstituted solution after 24 hours.
 - Monitor blood pressure and heart rate and rhythm frequently during therapy.
 - If hypotension occurs, notify prescriber and expect to reduce dosage or discontinued the drug. Implement measures to support blood pressure as prescribed.
 - Assess patient's breath sounds and respiratory rate, rhythm, depth, and quality frequently during drug therapy.
 - Monitor serum creatinine level during drug therapy and notify prescriber of abnormal results.
 - Store unopened drug at controlled room temperature or refrigerate. Keep in carton until time of use.
- #### PATIENT TEACHING
- Instruct patient to notify you or another nurse if she becomes dizzy because this may indicate hypotension.

- Reassure patient that her blood pressure, heart rate, and breathing will be monitored frequently.

netilmicin sulfate

Netromycin

Class and Category

Chemical class: Aminoglycoside

Therapeutic class: Antibiotic

Pregnancy category: D

Indications and Dosages

➤ *To treat serious systemic infections, such as intra-abdominal infections, lower respiratory tract infections, septicemia, and skin and soft-tissue infections, caused by Enterobacter aerogenes, Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis, Pseudomonas aeruginosa, Serratia species, and Staphylococcus aureus*

I.V. INFUSION, I.M. INJECTION

Adults and children age 12 and over. 1.3 to 2.2 mg/kg every 8 hr or 2 to 3.25 mg/kg every 12 hr for 7 to 14 days. *Maximum:* 7.5 mg/kg daily.

Children ages 6 weeks to 12 years. 1.8 to 2.7 mg/kg every 8 hr or 2.7 to 4 mg/kg every 12 hr for 7 to 14 days.

Infants up to age 6 weeks. 2 to 3.25 mg/kg every 12 hr for 7 to 14 days.

➤ *To treat complicated UTI caused by Citrobacter species, Enterobacter species, E. coli, K. pneumoniae, P. mirabilis, P. aeruginosa, Serratia species, and Staphylococcus species*

I.V. INFUSION, I.M. INJECTION

Adults and adolescents. 1.5 to 2 mg/kg every 12 hr for 7 to 14 days. *Maximum:* 7.5 mg/kg daily.

Mechanism of Action

Is transported into bacterial cells, where it competes with messenger RNA to bind with a specific receptor protein on the 30S ribosomal subunit of DNA. This action causes abnormal, nonfunctioning proteins to form. A lack of functional proteins causes bacterial cell death.

Incompatibilities

Don't mix netilmicin with beta-lactam

antibiotics (penicillins and cephalosporins) because substantial mutual inactivation may result. If prescribed concurrently, administer these drugs at separate sites.

Contraindications

Hypersensitivity to netilmicin, other aminoglycosides, or their components

Interactions

DRUGS

capreomycin, other aminoglycosides:

Increased risk of nephrotoxicity, neuromuscular blockade, and ototoxicity

cephalosporins, nephrotoxic drugs: Increased risk of nephrotoxicity

loop diuretics, ototoxic drugs: Increased risk of ototoxicity

methoxyflurane, polymyxins (parenteral):

Increased risk of nephrotoxicity and neuromuscular blockade

neuromuscular blockers: Increased neuromuscular blockade

Adverse Reactions

CNS: Disorientation, dizziness, encephalopathy, headache, myasthenia gravis-like syndrome, neuromuscular blockade (acute muscle paralysis and apnea), paresthesia, peripheral neuropathy, seizures, vertigo, weakness

CV: Hypotension, palpitations

EENT: Blurred vision, hearing loss, nystagmus, tinnitus

GI: Diarrhea, elevated liver function tests results, nausea, vomiting

GU: Elevated BUN and serum creatinine levels, nephrotoxicity, oliguria, proteinuria

HEME: Anemia, eosinophilia, leukopenia, prolonged PT, thrombocytopenia, thrombocytosis

MS: Muscle twitching

RESP: Apnea

SKIN: Allergic dermatitis, erythema, pruritus, rash

Other: Angioedema; hyperkalemia; injection site hematoma, induration, and pain

Nursing Considerations

- To prepare netilmicin for I.V. use, dilute each dose in 50 to 200 ml of suitable diluent, such as normal saline solution, D₅W, or lactated Ringer's solution, and give slowly over 30 to 60 minutes.
- Ensure adequate hydration during therapy to maintain adequate renal function.

- Monitor blood netilmicin level; optimum peak level is 6 to 10 mcg/ml and trough level is 0.5 to 2 mcg/ml.
- Check patient's BUN and serum creatinine levels, urine specific gravity, and creatinine clearance during netilmicin therapy, as ordered.
- Anticipate higher risk of nephrotoxicity in elderly patients, those with impaired renal function, and those who receive high doses or prolonged netilmicin therapy.
- Reduce dosage or discontinue drug, as ordered, if signs of drug-induced auditory or vestibular toxicity develop; the damage may be permanent.

PATIENT TEACHING

- Encourage patient to drink plenty of fluids during netilmicin therapy.
- Instruct patient to notify prescriber immediately about dizziness, hearing loss, muscle twitching, nausea, numbness and tingling, ringing or buzzing in ears, seizures, significant changes in amount of urine or frequency of urination, and vomiting.
- Urge patient to keep follow-up appointments to monitor progress.

nicardipine hydrochloride

Cardene, Cardene IV, Cardene SR

Class and Category

Chemical class: Dihydropyridine derivative
Therapeutic class: Antianginal, antihypertensive

Pregnancy category: C

Indications and Dosages

↗ *To manage angina pectoris and Prinzmetal's angina, to manage hypertension*

CAPSULES

Adults and adolescents. 20 to 40 mg t.i.d., increased every 3 days, as prescribed.

E.R. CAPSULES

Adults. 30 mg b.i.d.

I.V. INFUSION

Adults. 0.5 to 2.2 mg/hr by continuous infusion.

↗ *To control acute hypertension*

I.V. INFUSION

Adults. *Initial:* 5 mg/hr by continuous infusion; increased by 2.5 mg/hr every 5 to

15 min, as prescribed. *Maximum:* 15 mg/hr.

Route	Onset	Peak	Duration
P.O.	20 min	1–2 hr	Unknown
P.O. (E.R.)	20 min	1–2 hr	12 hr
I.V.	Immediate	Unknown	Unknown

Mechanism of Action

May slow extracellular calcium movement into myocardial and vascular smooth-muscle cells by deforming calcium channels in cell membranes, inhibiting ion-controlled gating mechanisms, and interfering with calcium release from the sarcoplasmic reticulum. By decreasing the intracellular calcium level, nicardipine inhibits smooth-muscle cell contraction and dilates coronary and systemic arteries. As with other calcium channel blockers, these actions lead to decreased myocardial oxygen requirements and reduced peripheral resistance, blood pressure, and afterload.

Incompatibilities

Don't mix nicardipine with sodium bicarbonate or LR solution, and don't administer through same I.V. line.

Contraindications

Advanced aortic stenosis, hypersensitivity to any calcium channel blocker, second- or third-degree AV block in patient without artificial pacemaker

Interactions

DRUGS

anesthetics (hydrocarbon inhalation):

Possibly hypotension

beta blockers, other antihypertensives, prazosin: Increased risk of hypotension

calcium supplements: Possibly impaired action of nicardipine

cimetidine: Increased nicardipine bioavailability

digoxin: Transiently increased blood digoxin level, increased risk of digitalis toxicity

disopyramide, flecainide: Increased risk of bradycardia, conduction defects, and heart failure

estrogens: Possibly increased fluid retention and decreased therapeutic effects of nicardipine

lithium: Increased risk of neurotoxicity

NSAIDs, sympathomimetics: Possibly decreased therapeutic effects of nicardipine

procainamide, quinidine: Possibly prolonged QT interval

FOODS

grapefruit, grapefruit juice: Possibly increased bioavailability of nicardipine
high-fat meals: Decreased blood nicardipine level

ACTIVITIES

alcohol use: Increased hypotensive effect

Adverse Reactions

CNS: Anxiety, asthenia, ataxia, confusion, dizziness, drowsiness, headache, nervousness, paresthesia, psychiatric disturbance, syncope, tremor, weakness

CV: Arrhythmias (bradycardia, tachycardia), chest pain, heart failure, hypotension, orthostatic hypotension, palpitations, peripheral edema

EENT: Altered taste, blurred vision, dry mouth, epistaxis, gingival hyperplasia, pharyngitis, rhinitis, tinnitus

ENDO: Gynecomastia, hyperglycemia

GI: Anorexia, constipation, diarrhea, elevated liver function test results, indigestion, nausea, thirst, vomiting

GU: Dysuria, nocturia, polyuria, sexual dysfunction, urinary frequency

HEME: Anemia, leukopenia, thrombocytopenia

MS: Joint stiffness, muscle spasms

RESP: Bronchitis, cough, upper respiratory tract infection

SKIN: Dermatitis, diaphoresis, erythema multiforme, flushing, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, urticaria

Other: Hypokalemia, injection site irritation, weight gain

Nursing Considerations

- Check blood pressure and pulse rate before nicardipine therapy begins, during dosage changes, and periodically throughout therapy. During prolonged therapy, periodically assess ECG tracings for arrhythmias and other changes.
- Dilute each 25-mg ampule of nicardipine with 240 ml of solution to yield 0.1 mg/ml. Mixture is stable at room temperature for 24 hours.
- If using premixed nicardipine for intravenous infusion, check strength carefully because drug comes as single strength (20 mg nicardipine in 200 ml of solution,

providing 0.1 mg/ml) or double strength (40 mg nicardipine in 200 ml of solution, providing 0.2 mg/ml).

- Administer continuous infusion by I.V. pump or controller, and adjust according to patient's blood pressure, as prescribed.
- Change peripheral I.V. site every 12 hours, if feasible, to minimize peripheral venous irritation.
- Give first dose of oral nicardipine 1 hour before stopping I.V. infusion, as ordered.
- Monitor fluid intake and output and daily weight for signs of fluid retention, which may precipitate heart failure. Also assess for signs of heart failure, such as crackles, dyspnea, jugular vein distention, peripheral edema, and weight gain.
- During prolonged therapy, periodically monitor liver and renal function test results. Expect elevated liver function test results to return to normal after drug is discontinued.
- Monitor serum potassium level during prolonged therapy. Hypokalemia increases the risk of arrhythmias.
- Because of drug's negative inotropic effect on some patients, closely monitor patients who take a beta blocker or have heart failure or significant left ventricular dysfunction.

WARNING Expect to taper dosage gradually before discontinuing drug. Otherwise, angina or dangerously high blood pressure could result.

PATIENT TEACHING

- Urge patient to take nicardipine as prescribed, even if she feels well.
- Instruct patient to swallow E.R. capsules whole, not to chew, crush, cut, or open them.
- Advise patient not to take drug within 1 hour of eating a high-fat meal or grapefruit product. Urge her not to alter the amount of grapefruit products in her diet without consulting prescriber.

WARNING Caution patient against stopping nicardipine abruptly because angina or dangerously high blood pressure could result.

- Teach patient how to take her pulse, and urge her to notify prescriber immediately if it falls below 50 beats/minute.
- Teach patient how to measure blood pressure, and urge her to do so weekly if drug

was prescribed for hypertension. Suggest that she keep a log of blood pressure readings and take it to follow-up visits.

- Advise patient to change position slowly to minimize orthostatic hypotension.
- Urge patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Advise patient to notify prescriber immediately about chest pain that's not relieved by rest or nitroglycerin, constipation, irregular heartbeats, nausea, pronounced dizziness, severe or persistent headache, and swelling of hands or feet.
- Encourage patient to comply with suggested lifestyle changes, such as alcohol moderation, low-sodium or low-fat diet, regular exercise, smoking cessation, stress management, and weight reduction.
- Inform patient that saunas, hot tubs, and prolonged hot showers may cause dizziness or fainting.
- Instruct patient to avoid prolonged sun exposure and to use sunscreen when going outdoors.

niclosamide

Niclocide

Class and Category

Chemical class: Salicylanilide derivative
Therapeutic class: Anthelmintic
Pregnancy category: B

Indications and Dosages

➤ *To treat beef (Taenia saginata), fish (Diphyllobothrium latum), or pork (Taenia solium) tapeworm infestations*

CHEWABLE TABLETS

Adults. 2 g as a single dose; repeated in 7 days, if needed. *Maximum:* 2 g daily.

Children weighing more than 34 kg (75 lb). 1.5 g as a single dose; repeated in 7 days, if needed. *Maximum:* 2 g daily.

Children weighing 11 (24 lb) to 34 kg. 1 g as a single dose; repeated in 7 days, if needed. *Maximum:* 2 g daily.

➤ *To treat dwarf tapeworm (Hymenolepis nana) infestations*

CHEWABLE TABLETS

Adults. 2 g daily for 7 days; repeated in 7 to 14 days, if needed.

Children weighing more than 34 kg. 1.5 g on day 1 and then 1 g daily for next 6 days; repeated in 7 to 14 days, if needed.

Maximum: 2 g daily.

Children weighing 11 to 34 kg. 1 g on day 1 and then 500 mg daily for the next 6 days; repeated in 7 to 14 days, if needed.

Maximum: 2 g daily.

Mechanism of Action

May alter anaerobic energy production in tapeworms by inhibiting oxidative phosphorylation in their mitochondria, which decreases synthesis of ATP. Niclosamide causes the scolex (headlike segment) and proximal segment of tapeworm to detach from intestinal wall, which leads to parasite evacuation from intestine through normal peristalsis.

Contraindications

Age under 2 years; hypersensitivity to niclosamide, other anthelmintics, or their components

Interactions

ACTIVITIES

alcohol use: Decreased niclosamide effects

Adverse Reactions

CNS: Dizziness, drowsiness, headache, light-headedness

EENT: Taste perversion

GI: Abdominal distress, anorexia, constipation, diarrhea, nausea, vomiting

SKIN: Anal pruritus, rash

Nursing Considerations

- To identify infestation, collect several stool specimens before starting niclosamide therapy, as ordered, because eggs and parasite segments are released irregularly.
- If patient can't chew tablets thoroughly, crush and give them with small amount of water.
- For young child, crush tablets to fine powder and mix with small amount of water to make paste.
- Be aware that treatment isn't considered successful until stools have shown no eggs or parasites for at least 3 months.

PATIENT TEACHING

- Instruct patient to take niclosamide after a light meal.
- For young child, instruct parent to crush tablets to fine powder and mix with small

amount of water to make paste.

- Urge patient to complete entire course of niclosamide therapy.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to store niclosamide in a cool, dry, dark place. Caution against storing in bathroom, near kitchen sink, or in other damp places because heat and moisture break down drug.
- Inform patient that stool may need to be examined on day 7 of treatment and again 1 and 3 months after treatment.
- Instruct patient to wash hands thoroughly, to wash all bedding, and to use meticulous personal and environmental hygiene to decrease the risk of autoinfection.
- Caution patient against eating undercooked fish, pork, or beef.

nicotine for inhalation

Nicotrol Inhaler

nicotine nasal solution

Nicotrol NS

nicotine polacrilex

Nicorette, Nicorette Plus (CAN), Thrive

nicotine transdermal system

Habitrol, Nicoderm, NicoDerm CQ, Nicotrol, ProStep

Class and Category

Chemical class: Pyridine alkaloid

Therapeutic class: Smoking cessation adjunct

Pregnancy category: C (nicotine polacrilex), D (other forms of nicotine)

Indications and Dosages

↗ *To relieve nicotine withdrawal symptoms, including craving*

CHEWING GUM

Adults. *Initial:* 2 or 4 mg p.r.n. or every 1 to 2 hr, adjusted to complete withdrawal by

4 to 6 mo. *Maximum:* 30 pieces of 2-mg gum daily or 20 pieces of 4-mg gum daily.

NASAL SOLUTION

Adults. 1 to 2 sprays (1 to 2 mg) in each nostril/hr. *Maximum:* 5 mg/hr or 40 mg daily for up to 3 mo.

ORAL INHALATION

Adults and adolescents. 6 to 16 cartridges (24 to 64 mg) daily for up to 12 wk; then dosage gradually reduced over 12 wk or less. *Maximum:* 16 cartridges (64 mg) daily for 6 mo.

TRANSDERMAL SYSTEM

Adults. *Initial:* 14 to 22 mg daily, adjusted to lower-dose systems over 2 to 5 mo.

DOSAGE ADJUSTMENT For adolescents and for adults weighing less than 45 kg (100 lb) and who smoke less than 10 cigarettes daily or have heart disease, initial dosage reduced to 11 to 14 mg daily and adjusted to lower-dose systems over 2 to 5 mo.

Mechanism of Action

Binds selectively to nicotinic-cholinergic receptors at autonomic ganglia, in the adrenal medulla, at neuromuscular junctions, and in the brain. By providing a lower dose of nicotine than cigarettes, this drug reduces nicotine craving and withdrawal symptoms.

Contraindications

Hypersensitivity to nicotine, its components, or components of transdermal system; life-threatening arrhythmias; non-smokers; recovery from acute MI; severe angina pectoris; skin disorders (transdermal); temporomandibular joint disease (chewing gum)

Interactions

DRUGS

acetaminophen, beta blockers, imipramine, insulin, oxazepam, pentazocine, theophylline: Possibly increased therapeutic effects of these drugs (chewing gum, nasal spray, transdermal system)

alpha blockers, bronchodilators: Possibly increased therapeutic effects of these drugs (chewing gum, transdermal system)

bupropion: Potentiated therapeutic effects of nicotine, possibly increased risk of hypertension

sympathomimetics: Possibly decreased therapeutic effects of these drugs (chewing gum, transdermal system)

theophylline, tricyclic antidepressants:

Possibly altered pharmacologic actions of these drugs (oral inhalation)

FOODS

acidic beverages (citrus juices, coffee, soft drinks, tea, wine): Decreased nicotine absorption from gum if beverages consumed within 15 minutes before or while chewing gum

caffeine: Increased effects of caffeine (chewing gum, nasal spray, transdermal system)

Adverse Reactions

CNS: Dizziness, dream disturbances, drowsiness, headache, irritability, lightheadedness, nervousness (chewing gum, transdermal system); amnesia, confusion, difficulty speaking, headache, migraine headache, paresthesia (nasal spray); chills, fever, headache, paresthesia (oral inhalation)

CV: Arrhythmias (all forms); hypertension (chewing gum, transdermal system); peripheral edema (nasal spray)

EENT: Increased salivation, injury to teeth or dental work, mouth injury, pharyngitis, stomatitis (chewing gum); altered taste, dry mouth (chewing gum, transdermal system); altered smell and taste, burning eyes, dry mouth, earache, epistaxis, gum disorders, hoarseness, lacrimation, mouth and tongue swelling, nasal blisters, nasal irritation or ulceration, pharyngitis, rhinitis, sinus problems, sneezing, vision changes (nasal spray); altered taste, lacrimation, pharyngitis, rhinitis, sinusitis, stomatitis (oral inhalation)

GI: Eructation (chewing gum); abdominal pain, constipation, diarrhea, flatulence, increased appetite, indigestion, nausea, vomiting (chewing gum, transdermal system); abdominal pain, constipation, diarrhea, flatulence, hiccups, indigestion, nausea (nasal spray); diarrhea, flatulence, hiccups, indigestion, nausea, vomiting (oral inhalation)

GU: Dysmenorrhea (chewing gum, transdermal system); menstrual irregularities (nasal spray)

MS: Jaw and neck pain (chewing gum); arthralgia, myalgia (chewing gum, transdermal system); arthralgia, back pain, myalgia (nasal spray); back pain (oral inhalation)

RESP: Cough (chewing gum, transdermal

system); bronchitis, bronchospasm, chest tightness, cough, dyspnea, increased sputum production (nasal spray); chest tightness, cough, dyspnea, wheezing (oral inhalation)

SKIN: Diaphoresis, erythema, pruritus, rash, urticaria (chewing gum, transdermal system); acne, flushing of face, pruritus, purpura, rash (nasal spray); pruritus, rash, urticaria (oral inhalation)

Other: Allergic reaction (chewing gum, transdermal system); physical dependence (nasal spray); flulike symptoms, generalized pain, withdrawal symptoms (oral inhalation)

Nursing Considerations

- When administering nicotine by oral inhalation, expect optimal effect to result from continuous puffing for 20 minutes.
- To avoid possible burns, remove patch before patient has an MRI.

PATIENT TEACHING

- Instruct patient to read and follow package instructions to obtain best results with nicotine product.
- Advise patient to notify prescriber about other drugs she takes.
- Stress that patient must stop smoking as soon as nicotine treatment starts to avoid toxicity.
- For chewing gum therapy, instruct patient to wait at least 15 minutes after drinking coffee, juice, soft drink, tea, or wine. Advise her to chew gum until she detects a tingling sensation or peppery taste and then to place gum between her cheek and gum until tingling or peppery taste subsides. Then direct her to move gum to a different site until tingling or taste subsides, repeating until she no longer feels the sensation—usually about 30 minutes. Caution against swallowing the gum.
- For nasal spray, tell patient to tilt her head back and spray into a nostril. Caution against sniffing, swallowing, or inhaling spray because nicotine is absorbed through nasal mucosa.
- Warn patient that prolonged use of nasal form may cause dependence.
- For oral inhalation, tell patient to use 6 to 16 cartridges daily to prevent or relieve withdrawal symptoms and craving. Starting with 1 or 2 cartridges daily yields

poor success. Direct patient to inhale through device like a cigarette, puffing often for 20 minutes.

- For transdermal system, tell patient not to open package until just before use because nicotine is lost in the air. Advise her to apply system to clean, hairless, dry site on upper outer arm or upper body. Instruct her to change systems and rotate sites every 24 hours and not to use the same site for 7 days. To avoid possible burns, advise patient to remove patch before undergoing any MRI procedure.

WARNING Urge patient to keep all unused nicotine forms safely away from children and pets and to discard used forms carefully. (Enough nicotine may remain in used systems to poison children and pets.) Instruct her to contact a poison control center immediately if she suspects that a child has ingested nicotine.

- Explain to patient with asthma or COPD that nicotine may cause bronchospasm.
- Inform patient that it may take several attempts to stop smoking. Urge her to join a smoking cessation program.

nifedipine

Adalat, Adalat CC, Adalat PA (CAN), Adalat XL (CAN), Apo-Nifed (CAN), Novo-Nifedin (CAN), Nu-Nifed (CAN), Procardia, Procardia XL

Class and Category

Chemical class: Dihydropyridine derivative

Therapeutic class: Antianginal, antihypertensive

Pregnancy category: C

Indications and Dosages

↗ *To manage angina*

CAPSULES (ADALAT, APO-NIFED, NOVO-NIFEDIN, NU-NIFED, PROCARDIA)

Adults. *Initial:* 10 mg t.i.d., increased over 1 to 2 wk as needed. *Maintenance:* 10 to 20 mg t.i.d. *Maximum:* 180 mg daily, 30 mg/dose.

E.R. TABLETS (ADALAT XL, PROCARDIA XL)

Adults. *Initial:* 30 to 60 mg daily, increased or decreased over 7 to 14 days based on patient response. *Maximum:* 90 mg daily.

↗ *To manage hypertension*

E.R. TABLETS (ADALAT CC)

Adults. *Initial:* 30 mg daily. *Maintenance:* 30 to 60 mg daily, increased or decreased over 7 to 14 days based on patient response. *Maximum:* 90 mg daily.

E.R. TABLETS (ADALAT PA)

Adults. *Initial:* 10 to 20 mg b.i.d., increased every 3 wk based on patient response. *Maintenance:* 20 mg b.i.d. *Maximum:* 80 mg daily.

E.R. TABLETS (ADALAT XL)

Adults. *Initial:* 30 to 60 mg daily, increased or decreased over 7 to 14 days based on patient response. *Maintenance:* 60 to 90 mg daily. *Maximum:* 120 mg daily.

E.R. TABLETS (PROCARDIA XL)

Adults. 30 to 60 mg daily, increased or decreased over 7 to 14 days based on patient response. *Maximum:* 120 mg daily.

DOSAGE ADJUSTMENT Dosage may be reduced for elderly patients and those with heart failure or impaired hepatic or renal function.

Route	Onset	Peak	Duration
P.O. (caps)	20 min	Unknown	Unknown

Mechanism of Action

May slow movement of calcium into myocardial and vascular smooth-muscle cells by deforming calcium channels in cell membranes, inhibiting ion-controlled gating mechanisms, and disrupting calcium release from sarcoplasmic reticulum. Decreasing intracellular calcium level inhibits smooth-muscle cell contraction and dilates arteries, which decreases myocardial oxygen demand, peripheral resistance, blood pressure, and afterload.

Contraindications

Hypersensitivity to a calcium channel blocker, second- or third-degree AV block without artificial pacemaker, sick sinus syndrome

Interactions

DRUGS

anesthetics (hydrocarbon inhalation):

Possibly hypotension

antiviral drugs, cimetidine, dalfopristin, diltiazem, erythromycin, fluconazole, itraconazole, ketoconazole, nefazodone, other antihypertensives, prazosin, quinupristin, timolol, valproic acid, verapamil: Increased risk of hypotension

benazepril: Possibly increased heart rate and hypotensive effect

beta blockers: Increased risk of profound hypotension, heart failure, and worsening of angina

calcium supplements: Possibly interference with action of nifedipine

carbamazepine, NSAIDs, phenobarbitone, phenytoin, rifampin, rifapentine, St. John's wort, sympathomimetics: Possibly decreased

therapeutic effects of nifedipine

digoxin: Transiently increased blood digoxin level, increased risk of digitalis toxicity

disopyramide, flecainide: Increased risk of bradycardia, conduction defects, and heart failure

doxazocin: Decreased doxazocin effectiveness; increased nifedipine effectiveness

estrogens: Possibly increased fluid retention and decreased nifedipine effects

lithium: Increased risk of neurotoxicity

metformin: Increased metformin absorption and plasma level

tacrolimus: Decreased tacrolimus metabolism

FOODS

grapefruit, grapefruit juice: Possibly increased bioavailability of nifedipine

high-fat meals: Possibly delayed nifedipine absorption

ACTIVITIES

alcohol use: Additive hypotensive effect

Adverse Reactions

CNS: Anxiety, ataxia, confusion, dizziness, drowsiness, headache, nervousness (possibly extreme), nightmares, paresthesia, psychiatric disturbance, syncope, tremor, weakness

CV: Arrhythmias (bradycardia, tachycardia), chest pain, heart failure, hypotension, palpitations, peripheral edema

EENT: Altered taste, blurred vision, dry mouth, epistaxis, gingival hyperplasia, nasal congestion, pharyngitis, sinusitis, tinnitus

ENDO: Gynecomastia, hyperglycemia

GI: Anorexia, constipation, diarrhea, dyspepsia, elevated liver function test results, hepatitis, nausea, vomiting

GU: Dysuria, nocturia, polyuria, sexual dysfunction, urinary frequency

HEME: Anemia, leukopenia, positive Coombs' test, thrombocytopenia

MS: Joint stiffness, muscle cramps

RESP: Chest congestion, cough, dyspnea,

respiratory tract infection, wheezing

SKIN: Dermatitis, diaphoresis, erythema multiforme, flushing, photosensitivity, pruritus, rash, urticaria

Nursing Considerations

- When starting and stopping nifedipine therapy, taper it, as prescribed, over 7 to 14 days.
- For closely monitored hospitalized patient with angina, dosage may be increased 10 mg every 4 to 6 hours to control chest pain.
- Because of drug's negative inotropic effect on some patients, frequently monitor heart rate and rhythm and blood pressure in patients who take a beta blocker or have heart failure or significant left ventricular dysfunction.
- Monitor fluid intake and output and daily weight; fluid retention may lead to heart failure. Also assess for signs of heart failure, such as crackles, dyspnea, jugular vein distention, peripheral edema, and weight gain.

PATIENT TEACHING

- Instruct patient to swallow E.R. tablets whole, not to crush, chew, or break them. Inform her that their empty shells may appear in stool.
- Urge patient to take nifedipine exactly as prescribed, even when she's feeling well. Advise her to notify prescriber if she misses two or more doses.
- Urge patient not to take drug within 1 hour of a high-fat meal or grapefruit. Urge her not to alter the amount of grapefruit in her diet without consulting prescriber.

WARNING Caution patient against stopping nifedipine abruptly because angina or dangerously high blood pressure could result.

- Teach patient to measure pulse rate and blood pressure, and advise her to call prescriber if they drop below accepted levels. Suggest keeping a log of weekly measurements and taking it to follow-up visits.
- Instruct patient to notify prescriber immediately about chest pain, difficulty breathing, ringing in ears, and swollen gums.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcoholic beverages because they may worsen dizziness, drowsiness, and hypotension.
- Teach patient to minimize constipation by

increasing her intake of fluids, if allowed, and dietary fiber.

- Emphasize the need to comply with prescribed lifestyle changes, such as alcohol moderation, low-fat or low-sodium diet, regular exercise, smoking cessation, stress reduction, and weight reduction.
- Stress the need for good oral hygiene and regular dental visits.
- Caution patient that hot tubs, saunas, and prolonged hot showers may cause dizziness and fainting.
- Advise patient to avoid prolonged sun exposure and to wear sunscreen outdoors.

nisoldipine

Sular

Class and Category

Chemical class: Dihydropyridine derivative

Therapeutic class: Antihypertensive

Pregnancy category: C

Indications and Dosages

↗ *To manage hypertension*

E.R. TABLETS

Adults. 20 mg daily, increased by 10 mg every 7 days, as prescribed. *Maintenance:* 20 to 40 mg daily. *Maximum:* 60 mg daily.

DOSE ADJUSTMENT For patients over age 65 and patients with hepatic impairment, initial dosage reduced to 10 mg daily.

Mechanism of Action

May slow extracellular calcium movement into myocardial and vascular smooth-muscle cells by deforming calcium channels in cell membranes, inhibiting ion-controlled gating mechanisms, and interfering with calcium release from the sarcoplasmic reticulum. By decreasing the intracellular calcium level, nisoldipine inhibits smooth-muscle cell contraction and dilates coronary and systemic arteries. As with other calcium channel blockers, these actions lead to decreased myocardial oxygen requirements and reduced peripheral resistance, blood pressure, and afterload.

Contraindications

Hypersensitivity to calcium channel blocker, second- or third-degree AV block with no artificial pacemaker, sick sinus syndrome

Interactions

DRUGS

beta blockers: Possibly increased risk of hypotension

CYP3A4 inducers such as carbamazepine,

phenytoin: Decreased nisoldipine levels and effectiveness

CYP3A4 inhibitors such as azole antifungals, cimetidine, quinidine: Increased blood

nisoldipine level; increased risk of adverse reactions

NSAIDs: Decreased antihypertensive effect of nisoldipine

FOODS

grapefruit, grapefruit juice: Possibly increased bioavailability of nisoldipine

high-fat meals: Possibly delayed nisoldipine absorption

ACTIVITIES

alcohol use: Additive hypotensive effect

Adverse Reactions

CNS: Dizziness, headache

CV: Angina, hypotension, palpitations, peripheral edema, vasodilation

EENT: Pharyngitis, sinusitis

GI: Constipation, nausea

RESP: Bronchospasm, dyspnea

SKIN: Ras

Other: Allergic-type reaction

Nursing Considerations

- Monitor pulse rate and rhythm and blood pressure before starting nisoldipine therapy, during dosage adjustments, and periodically throughout therapy.
- Don't break or crush E.R. tablets.
- For optimal absorption, give drug 1 hour before or 2 hours after meals.
- Monitor fluid intake and output and daily weight to assess for signs of fluid retention, which may lead to heart failure. Also assess for signs of heart failure, such as crackles, dyspnea, jugular vein distention, peripheral edema, and weight gain.
- Monitor patient for allergic-type reaction that may include bronchospasm, especially if patient has aspirin sensitivity, because drug contains FD&C yellow no. 5 dye.

PATIENT TEACHING

- Instruct patient to swallow E.R. nisoldipine tablets whole, not to break, crush, or chew them.
- Advise patient to take drug 1 hour before or 2 hours after meals. Urge her not to

alter amount of grapefruit products in her diet without consulting prescriber.

- Urge patient to continue taking drug as prescribed, even if she feels well.

WARNING Caution patient against stopping drug abruptly because blood pressure could rise dangerously high.

- Instruct patient to notify prescriber about constipation, difficulty breathing, dizziness, irregular heartbeat, nausea, severe headache, and swelling of hands or feet.
- Teach patient and family how to measure blood pressure, and instruct them to notify prescriber if systolic blood pressure falls below 90 mm Hg. Suggest that patient keep a log of weekly measurements and take it to follow-up visits.
- Advise patient to change positions slowly to minimize the effects of orthostatic hypotension. Inform her that hot tubs, saunas, and prolonged hot showers may worsen this adverse reaction.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcohol and OTC alcohol-containing drugs without consulting prescriber. Many OTC preparations can raise blood pressure.
- Emphasize the need to adhere to prescribed lifestyle changes, such as alcohol moderation, low-fat and low-sodium diet, regular exercise, smoking cessation, stress reduction, and weight reduction.

nitazoxanide

Alinia

Class and Category

Chemical class: Benzamide

Therapeutic class: Antiprotozoal

Pregnancy category: B

Indications and Dosages

➤ *To treat diarrhea caused by *Cryptosporidium parvum**

ORAL SUSPENSION, TABLETS

Adults and children age 12 and over.

500 mg every 12 hr with meals for 3 days.

ORAL SUSPENSION

Children ages 4 to 11. 200 mg (10 ml)

every 12 hr with meals for 3 days.

Children ages 12 months to 47 months.

100 mg (5 ml) every 12 hr with meals for 3 days.

➤ *To treat diarrhea caused by *Giardia lamblia**

ORAL SUSPENSION, TABLETS

Children age 12 and over. 500 mg every 12 hr with meals for 3 days

ORAL SUSPENSION

Children ages 4 to 11. 200 mg (10 ml) every 12 hr with meals for 3 days.

Children ages 12 months to 47 months.

100 mg (5 ml) every 12 hr with meals for 3 days.

Route	Onset	Peak	Duration
P.O.	1–4 hr	Unknown	Unknown

Mechanism of Action

May destroy *Cryptosporidium parvum* and *Giardia lamblia* by interfering with enzyme-dependent electron transfer required for their anaerobic energy metabolism. Other unidentified mechanisms may also be involved. With loss of protozoal activity in the intestines, diarrhea ceases.

Contraindications

Hypersensitivity to nitazoxanide or its components

Interactions

DRUGS

other highly plasma protein-bound drugs with narrow therapeutic indices (such as warfarin and phenytoins): Possibly increased risk of toxicity of these drugs

Adverse Reactions

CNS: Headache

GI: Abdominal pain, anorexia, diarrhea, nausea, vomiting

Nursing Considerations

- Use nitazoxanide cautiously in children with impaired hepatic function, biliary disease, or renal insufficiency.
- Prepare suspension by first tapping bottle until powder flows freely. Add 24 ml of tap water to powder and shake vigorously to suspend powder. Add another 24 ml water and shake vigorously again. Keep bottle of reconstituted suspension tightly capped.
- Use oral suspension for children age 11 and under because tablets contain more nitazoxanide than is recommended for children under age 12.

PATIENT TEACHING

- Tell parents of patient to give nitazoxanide with meals.
- Advise parents to keep reconstituted nitazoxanide bottle tightly closed and to shake the bottle well before each use.
- Instruct parents to discard any unused drug after 7 days from first opening bottle.
- Inform parents of diabetic patient that oral nitazoxanide suspension contains 1.48 grams of sucrose/5 ml. Tell them that they should make sure to monitor patient's blood glucose level closely.
- Tell parents that discoloration of eyes or urine, although uncommon, may occur and is harmless.

nitrofurantoin

Apo-Nitrofurantoin (CAN), Furadantin, Macrobid, Macrochantin, Novo-Furantoin (CAN)

Class and Category

Chemical class: Nitrofuran derivative

Therapeutic class: Antibiotic

Pregnancy category: B (except near term)

Indications and Dosages

➤ *To treat acute cystitis*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults. 50 to 100 mg every 6 hr. *Maximum:* 600 mg daily or 10 mg/kg daily.

Children over age 1 month. 0.75 to 1.75 mg/kg every 6 hr.

E.R. CAPSULES

Adults and children age 12 and over.

100 mg every 12 hr for 7 days.

➤ *To suppress chronic cystitis*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults. 50 to 100 mg at bedtime.

Maximum: 600 mg daily or 10 mg/kg daily.

Children over age 1 month. 1 mg/kg daily at bedtime.

Mechanism of Action

Inactivates or alters bacterial ribosomal proteins and other macromolecules. This action of nitrofurantoin inhibits bacterial protein synthesis, aerobic energy metabolism, DNA synthesis, RNA synthesis, and cell wall synthesis. Nitrofurantoin is bacteriostatic at low doses and bactericidal at higher doses.

Contraindications

Age under 1 month, anuria, creatinine clearance less than 60 ml/min/1.73 m², history of cholestatic jaundice or hepatic dysfunction with previous nitrofurantoin therapy, hypersensitivity to nitrofurantoin or parabens, oliguria, pregnancy near term

Interactions**DRUGS**

hepatotoxic drugs: Increased risk of hepatotoxicity

magnesium trisilicate: Decreased nitrofurantoin absorption

methyl dopa, procainamide, hemolytics:

Increased risk of toxic effects from nitrofurantoin

nalidixic acid: Possibly impaired therapeutic effects of this drug

neurotoxic drugs: Increased risk of neurotoxicity

probenecid, sulfapyrazone: Increased blood nitrofurantoin level and increased risk of toxicity

Adverse Reactions

CNS: Chills, confusion, depression, headache, neurotoxicity, peripheral neuropathy

EENT: Optic neuritis, parotitis, tooth discoloration

GI: Abdominal pain, anorexia, cholestatic jaundice, diarrhea, hepatic necrosis, hepatitis, nausea, pancreatitis, pseudomembranous colitis, vomiting

GU: Rust-colored to brown urine

HEME: Aplastic anemia, granulocytopenia, hemolytic anemia, leukopenia, megaloblastic anemia, methemoglobinemia, thrombocytopenia

MS: Arthralgia, myalgia

RESP: Asthma (in asthmatic patients), cyanosis, interstitial pneumonitis (acute), pulmonary fibrosis

SKIN: Alopecia, erythema multiforme, exfoliative dermatitis, jaundice, pruritus, rash, urticaria

Other: Anaphylaxis, angioedema, drug-induced fever

Nursing Considerations

- Obtain a specimen of patient's urine for culture and sensitivity tests, as ordered; review test results if possible before giving nitrofurantoin.

- Give drug with food or milk to avoid staining teeth.
- Don't crush or break capsules.
- Shake oral nitrofurantoin suspension before pouring dose, and mix with food or milk, as needed.
- Monitor patient for evidence of superinfection, such as abdominal pain, diarrhea, and fever. If patient develops diarrhea, it may indicate pseudomembranous colitis caused by *Clostridium difficile*. Notify prescriber and expect to withhold nitrofurantoin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- Monitor patient for pulmonary and hepatic abnormalities because rare but severe reactions have occurred with nitrofurantoin use, especially in the elderly.
- Observe patient for changes in nervous function because peripheral neuropathy, although uncommon, may become severe or irreversible. Patients with renal impairment, anemia, diabetes mellitus, electrolyte imbalance, vitamin B deficiency, or debilitating disease are at higher risk for peripheral neuropathy.

PATIENT TEACHING

- Instruct patient to shake nitrofurantoin oral suspension before measuring dose and to take drug with food or milk.
- Caution patient against taking any preparations that contain magnesium trisilicate during therapy.
- Explain that urine may turn brown, orange, or rust-colored during therapy.
- Instruct patient to complete prescribed course of therapy even if symptoms subside before course is completed.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Explain that watery or bloody stools can occur 2 or more months after nitrofurantoin therapy and can be serious, requiring prompt treatment.

nitroglycerin (glyceryl trinitrate)

Deponit, Minitran, Nitro-Bid, Nitrocot, Nitro-Dur, Nitrogard, Nitroglyin E-R, Nitroject, Nitrol, Nitrolingual,

NitroMist, Nitrong SR, Nitro-par, Nitrostat, Nitro-time, Transderm-Nitro, Tridil

Class and Category

Chemical class: Nitrate

Therapeutic class: Antianginal, antihypertensive, vasodilator

Pregnancy category: C

Indications and Dosages

↗ *To prevent or treat angina*

E.R. BUCCAL TABLETS

Adults. 1 mg every 5 hr while awake.

E.R. CAPSULES

Adults. 2.5, 6.5, or 9 mg every 12 hr.

Frequency of doses increased to every 8 hr based on patient's response.

E.R. TABLETS

Adults. 2.6 or 6.5 mg every 12 hr.

Frequency of doses increased to every 8 hr based on patient's response.

S.L. TABLETS

Adults. 0.3 to 0.6 mg, repeated every 5 min.

Maximum: 3 tabs in 15 min or 10 mg daily.

TRANSDERMAL OINTMENT

Adults. 1" to 2" (15 to 30 mg) every 8 hr.

Frequency of doses increased to every 6 hr if angina occurs between doses. *Maximum:* 5" (75 mg)/application.

TRANSDERMAL PATCH

Adults. 0.1 to 0.8 mg/hr, worn 12 to 14 hr.

TRANSLINGUAL SPRAY

Adults. For treatment, 1 or 2 metered doses (0.4 or 0.8 mg) onto or under tongue, repeated every 5 min as needed. For prevention, 1 or 2 metered doses (0.4 or 0.8 mg) onto or under tongue 5 to 10 minutes before activities that could lead to acute attack.

↗ *To prevent or treat angina, to manage hypertension or heart failure*

I.V. INFUSION

Adults. 5 mcg/min, increased by 5 mcg/min every 3 to 5 min to 20 mcg/min, as prescribed, and then by 10 to 20 mcg/min every 3 to 5 min until desired effect occurs.

Mechanism of Action

May interact with nitrate receptors in vascular smooth-muscle cell membranes. This interaction reduces nitroglycerin to nitric oxide, which activates the enzyme guanylate cyclase, increasing intracellular formation

of cGMP. Increased cGMP level may relax vascular smooth muscle by forcing calcium out of muscle cells, causing vasodilation. Venous dilation decreases venous return to the heart, reducing left ventricular end-diastolic pressure and pulmonary artery wedge pressure. Arterial dilation decreases systemic vascular resistance, systolic arterial pressure, and mean arterial pressure. Thus, nitroglycerin reduces preload and afterload, decreasing myocardial workload and oxygen demand. It also dilates coronary arteries, increasing blood flow to ischemic myocardial tissue.

Route	Onset	Peak	Duration
P.O.*	3 min	Unknown	5 hr
P.O.†	20–45 min	Unknown	8–12 hr
I.V.	1–2 min	Unknown	3–5 min
S.L.	1–3 min	Unknown	30–60 min
Trans-dermal‡	In 30 min	Unknown	4–8 hr
Trans-dermal§	In 30 min	Unknown	8–24 hr
Trans-lingual	2 to 4 min	Unknown	30–60 min

Incompatibilities

Don't administer I.V. nitroglycerin through I.V. bags or tubing made of polyvinyl chloride. Don't mix drug with other solutions.

Contraindications

Acute MI (S.L.), angle-closure glaucoma, cerebral hemorrhage, concurrent use of phosphodiesterase inhibitors, constrictive pericarditis (I.V.), head trauma, hypersensitivity to adhesive in transdermal form, hypersensitivity to nitrates, hypotension (I.V.), hypovolemia (I.V.), inadequate cerebral circulation (I.V.), increased intracranial pressure, orthostatic hypotension, pericardial tamponade, severe anemia

Interactions

DRUGS

acetylcholine, norepinephrine: Possibly decreased therapeutic effects of these drugs
heparin: Possibly decreased anticoagulant

* Buccal.

† E.R.

‡ Ointment.

§ Patch.

effect of heparin (I.V. nitroglycerin)
opioid analgesics, other antihypertensives, vasodilators: Possibly increased orthostatic hypotension
phosphodiesterase inhibitors, such as sildenafil: Possibly severe hypotensive effect of nitroglycerin
sympathomimetics: Possibly decreased anti-anginal effect of nitroglycerin and increased risk of hypotension

ACTIVITIES

alcohol use: Possibly increased orthostatic hypotension

Adverse Reactions

CNS: Agitation, anxiety, dizziness, headache, insomnia, restlessness, syncope, weakness

CV: Arrhythmias (including tachycardia), edema, hypotension, orthostatic hypotension, palpitations

EENT: Blurred vision, burning or tingling in mouth (buccal, S.L. forms), dry mouth

GI: Abdominal pain, diarrhea, indigestion, nausea, vomiting

GU: Dysuria, impotence, urinary frequency

HEME: Methemoglobinemia

MS: Arthralgia

RESP: Bronchitis, pneumonia

SKIN: Contact dermatitis (transdermal forms), flushing of face and neck, rash

Nursing Considerations

- Use nitroglycerin cautiously in elderly patients, especially those who are volume depleted or taking several medications, because of the increased risk of hypotension and falls. Hypotension may be accompanied by angina and paradoxical slowing of the heart rate. Notify prescriber if these occur, and provide appropriate treatment, as ordered.
- Plan a nitroglycerin-free period of about 10 hours each day, as prescribed, to maintain therapeutic effects and avoid tolerance.
- Place E.R. buccal tablets in buccal pouch with patient in sitting or lying position.
- Don't break or crush E.R. tablets or capsules. Have patient swallow them whole with a full glass of water.
- Place S.L. tablet under patient's tongue and make sure it dissolves completely.
- Be sure to remove cotton from S.L. tablet container to allow quick access to drug.

- When applying transdermal ointment, apply correct amount on dose-measuring paper. Then place paper on hairless area of body and spread in a thin, even layer over an area at least 2 inches by 3 inches. Don't place on cuts or irritated areas. Wash your hands after application. Rotate sites. Store at room temperature.
- Open transdermal patch package immediately before use. Apply patch to hairless area, and press edges to seal. Rotate sites. Store at room temperature. If patient needs cardioversion or defibrillation, remove transdermal patch.
- Don't shake translingual spray container before administering. Have patient inhale and hold her breath, and then spray drug under or on her tongue.
- Be aware that I.V. nitroglycerin should be diluted only in D₅W or normal saline solution and shouldn't be mixed with other infusions. The pharmacist should add drug to a glass bottle, not a container made of polyvinyl chloride. Don't use a filter because plastic absorbs drug. Administer with infusion pump.
- Check vital signs before every dosage adjustment and often during therapy.
- Frequently monitor heart and breath sounds, level of consciousness, fluid intake and output, and pulmonary artery wedge pressure, if possible.
- Store premixed containers in the dark; don't freeze them.

WARNING Assess patient for evidence of overdose, such as confusion, diaphoresis, dyspnea, flushing, headache, hypotension, nausea, palpitations, tachycardia, vertigo, vision changes, and vomiting. Treat as prescribed by removing nitroglycerin source, if possible; elevating legs above heart level; and administering an alpha-adrenergic agonist, such as phenylephrine, as prescribed, to treat severe hypotension.

PATIENT TEACHING

- Teach patient to recognize signs and symptoms of angina pectoris, including chest fullness, pain, and pressure, possibly with sweating and nausea. Pain may radiate down left arm or into neck or jaw. Inform women and those with diabetes mellitus or hypertension that they may feel only fatigue and shortness of breath.
- Instruct patient to read and follow package instructions to obtain full benefits of drug.
- To prevent drug tolerance, inform patient that prescriber may order a 10- to 12-hour drug-free period at night (or at another time if she has chest pain at night or in the morning).
- Instruct patient to swallow E.R. tablets or capsules whole—not to break, crush, or chew them—with a full glass of water.
- For sublingual or buccal use, advise patient to place tablet under her tongue or in buccal pouch when angina starts and then to sit or lie down. Instruct her not to swallow drug, but to let it dissolve. Explain that moisture in her mouth helps drug absorption. If angina doesn't subside, instruct patient to place another tablet under her tongue or in buccal pouch after 5 minutes and to repeat, if needed, for three doses total. If pain doesn't subside after 20 minutes, urge patient to call 911 or another emergency service.
- Advise patient to carry S.L. tablets in their original brown bottle in a purse or jacket pocket, but not one that will be affected by body heat. Instruct her to store drug in a dry place at room temperature and to discard cotton from container. Advise her to discard and replace S.L. tablets after 6 months.
- Advise patient using transdermal ointment or patch to rotate sites to avoid skin sensitization.
- Inform patient that swimming or bathing doesn't affect transdermal forms but that hot tubs, saunas, prolonged hot showers, electric blankets, and magnetic therapy over the site may increase drug absorption and cause dizziness and hypotension.
- Caution against inhaling translingual spray. Before first use, tell patient to press actuator button 10 times to prime container and then hold container upright with forefinger on top of actuator button. Tell her to open her mouth, bring container as close as possible, press actuator button firmly to release spray onto or under tongue, and release button and immediately close her mouth. Remind her to replace plastic cover on container and to not spit out the drug or rinse her mouth for 5 to 10 minutes. Tell her to reprime container by pressing actuator button

twice if container hasn't been used for more than 6 weeks. Remind patient to periodically check level of fluid in container. If it reaches the top or middle hole on side of container, more should be obtained. Caution patient not to let level of liquid get to bottom of hole.

- Inform patient that nitroglycerin commonly causes headache, which typically resolves after a few days of continuous therapy. Suggest taking acetaminophen, as needed.
- Advise patient to notify prescriber immediately about blurred vision, dizziness, and severe headache.
- Suggest that patient change positions slowly to minimize orthostatic hypotension.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcohol and erectile dysfunction drugs during therapy.

nitroprusside sodium

Nipride, Nitropress

Class and Category

Chemical class: Cyanonitrosylferrate

Therapeutic class: Antihypertensive, vasodilator

Pregnancy category: C

Indications and Dosages

➤ *To treat hypertensive crisis and manage severe heart failure*

I.V. INFUSION

Adults and children. *Initial:* 0.25 to 0.3 mcg/kg/min, increased gradually every few minutes until blood pressure reaches desired level. *Maintenance:* 3 mcg/kg/min (range, 0.25 to 10 mcg/kg/min). *Maximum:* 10 mcg/kg/min for 10 min.

Route	Onset	Peak	Duration
I.V.	1–2 min	Immediate	1–10 min

Mechanism of Action

May interact with nitrate receptors in vascular smooth-muscle cell membranes. This action reduces nitroprusside to nitric oxide

and then activates intracellular guanylate cyclase, which increases the cGMP level. Increased cGMP level may relax vascular smooth muscle by forcing calcium out of muscle cells. Smooth-muscle relaxation causes arteries and veins to dilate, which reduces peripheral vascular resistance and blood pressure.

Incompatibilities

Don't mix nitroprusside with any other drug.

Contraindications

Acute heart failure with decreased peripheral vascular resistance, congenital optic atrophy, decreased cerebral perfusion, hypersensitivity to nitroprusside or its components, hypertension from aortic coarctation or AV shunting, tobacco-induced amblyopia

Interactions

DRUGS

dobutamine: Increased cardiac output, decreased pulmonary artery wedge pressure
ganglionic blockers, general anesthetics, hypotension-producing drugs: Increased hypotensive effect
sympathomimetics: Decreased antihypertensive effect of nitroprusside

Adverse Reactions

CNS: Anxiety, dizziness, headache, increased intracranial pressure, nervousness, restlessness

CV: Hypotension, tachycardia

ENDO: Hypothyroidism

GI: Abdominal pain, ileus, nausea, vomiting

HEME: Methemoglobinemia

MS: Muscle twitching

SKIN: Diaphoresis, flushing, rash

Other: Infusion site phlebitis

Nursing Considerations

- Obtain baseline vital signs before administering nitroprusside.

WARNING Don't give drug undiluted.

Reconstitute with 2 ml D₅W, and add solution to 250 to 500 ml D₅W to produce 200 mcg/ml or 100 mcg/ml, respectively.

- Be aware that solution is stable at room temperature for 24 hours when protected from light. Don't use reconstituted solution if it contains particles or is blue, green, red, or darker than faint brown.
- Use an infusion pump. Place opaque cover

over infusion container because drug is metabolized by light. I.V. tubing doesn't need to be covered.

- Keep patient supine when starting drug or titrating dose up or down.
- Monitor blood pressure continuously with intra-arterial pressure monitor. Record blood pressure every 5 minutes at start of infusion and every 15 minutes thereafter.
- If patient has severe heart failure, expect to administer an inotropic drug, such as dopamine or dobutamine, as prescribed.

WARNING For patient who receives prolonged nitroprusside therapy or short-term high-dose therapy, watch for evidence of thiocyanate toxicity (ataxia, blurred vision, delirium, dizziness, dyspnea, headache, hyperreflexia, loss of consciousness, nausea, tinnitus, vomiting). Toxicity can cause arrhythmias, metabolic acidosis, severe hypotension, and death.

- Monitor serum thiocyanate level at least every 72 hours; levels above 100 mcg/ml are associated with toxicity.

WARNING Assess patient for evidence of cyanide toxicity (absence of reflexes, coma, distant heart sounds, hypotension, metabolic acidosis, mydriasis, pink skin, shallow respirations, and weak pulse). If you detect such evidence, discontinue nitroprusside, as ordered, and give 4 to 6 mg/kg sodium nitrite over 2 to 4 minutes to convert hemoglobin to methemoglobin. Follow with 150 to 200 mg/kg sodium thiosulfate. Repeat this regimen at half the original doses after 2 hours, as ordered.

PATIENT TEACHING

- Advise patient to change position slowly to minimize dizziness from sudden, severe hypotension.

nizatidine

Apo-Nizatidine (CAN), Axid, Axid AR

Class and Category

Chemical class: Ethenediamine derivative
Therapeutic class: Antilulcer
Pregnancy category: B

Indications and Dosages

↗ *To manage active duodenal ulcer*

CAPSULES

Adults and adolescents. 300 mg at bedtime

or 150 mg b.i.d. for 8 wk.

DOSAGE ADJUSTMENT Dosage reduced to 150 mg daily if creatinine clearance is 20 to 50 ml/min/1.73 m²; to 150 mg every other day if creatinine clearance is less than 20 ml/min/1.73 m².

↗ *To prevent recurrence of duodenal ulcer*

CAPSULES

Adults and adolescents. 150 mg at bedtime.

DOSAGE ADJUSTMENT Dosage reduced to 150 mg every other day for patients with creatinine clearance of 20 to 50 ml/min/1.73 m²; to 150 mg every 3 days for those with creatinine clearance less than 20 ml/min/1.73 m².

↗ *To manage acute benign gastric ulcer*

CAPSULES

Adults and adolescents. 300 mg at bedtime or 150 mg b.i.d.

↗ *To manage gastroesophageal reflux disease*

CAPSULES

Adults and adolescents. 150 mg b.i.d.

↗ *To prevent or relieve acid indigestion or heartburn*

CAPSULES

Adults and adolescents. 75 mg 30 min to 1 hr before meals.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	10–12 hr*

Mechanism of Action

Inhibits basal and nocturnal secretion of gastric acid by reversibly and competitively blocking H₂ receptors, especially those in gastric parietal cells. Nizatidine also inhibits gastric acid secretion in response to stimuli, including food and caffeine.

Contraindications

Hypersensitivity to nizatidine or other H₂-receptor antagonists

Interactions

DRUGS

antacids: Decreased nizatidine bioavailability
itraconazole, ketoconazole: Decreased absorption of these drugs
salicylates: Increased blood level of these

* For nocturnal acid secretion; up to 4 hr for food-stimulated acid secretion.

drugs

sucralfate: Possibly decreased nizatidine absorption

Adverse Reactions

CNS: Agitation, anxiety, confusion, depression, dizziness, fatigue, fever, hallucinations, headache, insomnia, somnolence

CV: Arrhythmias, chest pain, vasculitis

EENT: Amblyopia, dry mouth, laryngeal edema, pharyngitis, rhinitis, sinusitis

ENDO: Gynecomastia

GI: Abdominal pain, constipation, diarrhea, hepatitis, nausea, vomiting

GU: Decreased libido, hyperuricemia not associated with gout or nephrolithiasis, impotence

HEME: Anemia, aplastic anemia, eosinophilia, hemolytic anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia

MS: Back pain, myalgia

RESP: Bronchospasm, cough

SKIN: Alopecia, diaphoresis, erythema multiforme, exfoliative dermatitis, jaundice, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, serum sicknesslike reaction

Nursing Considerations

- Monitor CBC, BUN and serum creatinine levels, and liver function test results before and periodically during nizatidine therapy.
- Don't give within 1 hour of an antacid.

PATIENT TEACHING

- Instruct patient not to take nizatidine within 1 hour of an antacid.
- Urge patient to take nizatidine exactly as prescribed, even if she feels better before prescription is finished. Inform her that ulcer may take up to 8 weeks to heal.
- If patient smokes, urge her to stop because smoking increases gastric acid production.
- Teach patient to minimize constipation by drinking plenty of fluids (if allowed), eating high-fiber foods, and exercising regularly.
- Instruct patient to notify prescriber immediately about abdominal pain, easy bruising, extreme fatigue, yellow skin or sclera, trouble swallowing food, bloody vomitus, or bloody or tarry stools.
- Urge patient not to take nizatidine with other acid reducers.

norepinephrine bitartrate (levarterenol bitartrate)

Levophed

Class and Category

Chemical class: Catecholamine

Therapeutic class: Cardiac stimulant, vasopressor

Pregnancy category: C

Indications and Dosages

↗ *To treat acute hypotension, cardiogenic shock, and septic shock*

I.V. INFUSION

Adults. *Initial:* 0.5 to 1 mcg/min. Increased, as ordered, until systolic blood pressure reaches desired level. *Maintenance:* 2 to 12 mcg/min.

Children. 0.1 mcg/kg/min. *Maximum:* 1 mcg/kg/min.

↗ *To treat refractory shock*

I.V. INFUSION

Adults. Up to 30 mcg/min.

Route	Onset	Peak	Duration
I.V.	Rapid	Unknown	1–2 min

Mechanism of Action

At more than 4 mcg/min, directly stimulates alpha-adrenergic receptors and inhibits adenylyl cyclase, which inhibits cAMP production. Inhibition of cAMP constricts arteries and veins and increases peripheral vascular resistance and systolic blood pressure. At less than 2 mcg/min, norepinephrine directly stimulates beta-adrenergic receptors in the myocardium and increases adenylyl cyclase activity, producing positive inotropic and chronotropic effects.

Contraindications

Concurrent use of hydrocarbon inhalation anesthetics, hypersensitivity to norepinephrine or its components, hypovolemia, mesenteric or peripheral vascular thrombosis

Interactions**DRUGS**

alpha blockers: Decreased vasopressor effects of norepinephrine

beta blockers: Decreased cardiac-stimulating effect of norepinephrine, possibly decreased therapeutic effects of both drugs

digoxin: Increased risk of arrhythmias, possibly potentiated inotropic effect

doxapram: Possibly increased vasopressor effects of both drugs

ergonovine, ergotamine, methylergonovine, methysergide, oxytocin: Possibly increased vasoconstriction

general anesthetics: Risk of arrhythmias

guanadrel, guanethidine: Increased vasopressor response to norepinephrine, possibly severe hypertension

MAO inhibitors: Possibly life-threatening arrhythmias, hyperpyrexia, severe headache, severe hypertension, and vomiting

maprotiline, tricyclic antidepressants: Possibly potentiated cardiovascular and pressor effects of norepinephrine, including arrhythmias, severe hypertension, and hyperpyrexia

methylphenidate: Possibly potentiated vasopressor effect of norepinephrine

nitrates: Possibly decreased therapeutic effects of both drugs

phenoxybenzamine: Possibly arrhythmias or hypotension

sympathomimetics: Increased risk of adverse cardiovascular effects

thyroid hormones: Increased risk of coronary insufficiency

Adverse Reactions

CNS: Anxiety, dizziness, headache, insomnia, nervousness, tremor, weakness

CV: Angina, bradycardia, ECG changes, edema, hypertension, hypotension, palpitations, peripheral vascular insufficiency (including gangrene), PVCs, sinus tachycardia

GI: Nausea, vomiting

GU: Decreased renal perfusion

RESP: Apnea, dyspnea

SKIN: Pallor

Other: Infusion site sloughing and tissue necrosis, metabolic acidosis

Nursing Considerations

- Dilute norepinephrine concentrate for infusion in D₅W, dextrose 5% in normal saline solution, or normal saline solution. Dilutions typically range from 16 to 32 mcg/ml.
- Make sure solution contains no particles

and isn't discolored before administering.

- Give drug with a flow-control device.
- Check blood pressure every 2 to 3 minutes, preferably by direct intra-arterial monitoring, until stabilized and then every 5 minutes.

WARNING Because extravasation can cause severe tissue damage and necrosis, expect prescriber to give multiple subcutaneous injections of phentolamine (5 to 10 mg diluted in 10 to 15 ml normal saline solution) around extravasated infusion site.

- If blanching occurs along vein, change infusion site and notify prescriber at once.
- Monitor continuous ECG during therapy.

PATIENT TEACHING

- Urge patient to immediately report burning, leaking, or tingling around I.V. site.

norfloxacin

Noroxin

Class and Category

Chemical class: Fluoroquinolone

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

↗ *To treat uncomplicated UTI caused by Escherichia coli, Klebsiella pneumoniae, or Proteus mirabilis*

TABLETS

Adults. 400 mg every 12 hr for 3 days.

↗ *To treat uncomplicated UTI caused by Citrobacter freundii, Enterobacter aerogenes, Enterobacter cloacae, Enterococcus faecalis, Proteus species, Pseudomonas aeruginosa, Staphylococcus aureus, Staphylococcus epidermidis, Staphylococcus saprophyticus, or Streptococcus agalactiae*

TABLETS

Adults. 400 mg every 12 hr for 7 to 10 days.

↗ *To treat complicated UTI caused by E. coli, E. faecalis, K. pneumoniae, P. aeruginosa, P. mirabilis, or Serratia marcescens*

TABLETS

Adults. 400 mg every 12 hr for 10 to 21 days. *Maximum*: 800 mg daily.

↗ *To treat uncomplicated gonorrhea*

TABLETS

Adults. 800 mg as a single dose.

➤ *To treat prostatitis caused by E. coli*

TABLETS

Adults. 400 mg every 12 hr for 28 days.

DOSAGE ADJUSTMENT Dosage reduced to 400 mg daily for patients with creatinine clearance of 30 ml/min/1.73 m² or less.

Mechanism of Action

Inhibits the enzyme DNA gyrase, which unwinds and supercoils bacterial DNA before it replicates. By inhibiting this enzyme, norfloxacin interferes with bacterial cell replication and causes cell death.

Contraindications

Hypersensitivity to norfloxacin, other fluoroquinolones, or their components

Interactions**DRUGS**

aluminum-, calcium-, or magnesium-containing antacids; ferrous sulfate; magnesium-containing laxatives; sucralfate;

zinc: Possibly decreased absorption and blood level of norfloxacin

caffeine, clozapine, ropinirole, tacrine, theophylline, tizanidine: Possibly increased blood level of these drugs

class IA antiarrhythmics, such as quinidine; class III antiarrhythmics, such as sotalol;

other drugs known to prolong QTc interval, such as disopyramide and pentamidine:

Possibly prolonged QTc interval

cyclosporine: Possibly increased serum creatinine and blood cyclosporine levels

didanosine: Possibly decreased norfloxacin absorption

glyburide: Risk of severe hypoglycemia

nitrofurantoin: Possibly decreased norfloxacin effectiveness

NSAIDs: Possibly increased risk of CNS stimulation and seizures

probenecid: Decreased norfloxacin excretion and risk of toxicity

warfarin: Possibly increased anticoagulant effect and risk of bleeding

FOODS

caffeine: Reduced clearance of caffeine leading to accumulation of caffeine in blood

Adverse Reactions

CNS: Ataxia, confusion, dizziness, drowsiness, fever, Guillian-Barré syndrome, headache, hypoesthesia, insomnia, paresis, peripheral neuropathy, psychosis, seizures, tremors

CV: Prolonged QT interval, torsades de pointes, vasculitis

EENT: Decreased taste sensation, diplopia, hearing loss, stomatitis, taste perversion, tinnitus, visual changes

GI: Abdominal cramps or pain, acute hepatic necrosis or failure, diarrhea, elevated liver function test results, hepatitis, jaundice, nausea, pancreatitis, pseudomembranous colitis, vomiting

GU: Interstitial nephritis, renal failure, vaginal candidiasis

HEME: Agranulocytosis, aplastic anemia, hemolytic anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia

MS: Arthralgia; myasthenia gravis exacerbation; myalgia; tendinitis; tendon inflammation, pain, or rupture

RESP: Allergic pneumonitis, dyspnea

SKIN: Blisters, diaphoresis, erythema, erythema multiforme, exfoliative dermatitis, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, serum sickness

Nursing Considerations

- Obtain urine specimen for culture and sensitivity tests before starting drug, if possible.
- Determine if patient has a history of CNS disorder because drug may lower seizure threshold. Notify prescriber before starting drug, and institute seizure precautions.

WARNING Before starting therapy, determine if patient takes a class IA antiarrhythmic, such as quinidine; a class III antiarrhythmic, such as sotalol; or other drugs that prolong the QTc interval. Also find out if patient has hypokalemia or an underlying QT-interval prolonging condition. These drugs and conditions, especially in the elderly, may prolong the QTc interval and lead to life-threatening ventricular tachycardia or torsades de pointes in a patient taking norfloxacin.

- Give drug on an empty stomach 2 hours before or after antacids, didanosine, sucralfate, or vitamins that contain iron or zinc.
- Keep emergency resuscitation equipment readily available, and watch for signs of hypersensitivity, such as angioedema, dys-

pnea, jaundice, rash, and urticaria. If you suspect anaphylaxis, prepare to give epinephrine, corticosteroids, and diphenhydramine, as prescribed.

- If patient has myasthenia gravis, assess her often for a change in respiratory status because drug may lead to life-threatening weakness of respiratory muscles.
- Notify prescriber if patient has symptoms of peripheral neuropathy (pain, burning, tingling, numbness, weakness, or altered sensations of light touch, pain, temperature, position sense, or vibration sense), which could be permanent. Expect to stop norfloxacin.
- Monitor patients prone to tendinitis, such as the elderly, athletes, and those taking corticosteroids, for complaints of tendon pain, inflammation, or rupture. If present, notify prescriber and expect to discontinue norfloxacin, place patient on bedrest with no exercise of affected limb, and obtain diagnostic tests to confirm rupture.
- Monitor patient for diarrhea, which may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold norfloxacin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

PATIENT TEACHING

- Instruct patient to take drug on an empty stomach with a large glass of water to prevent crystalluria. Urge her to drink several glasses of water daily during therapy.
- Instruct patient to take norfloxacin at least 2 hours before or after eating, drinking milk, or taking antacids, didanosine, sucralose, or vitamins that contain iron or zinc.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Tell patient to stop drug and report tendon pain or inflammation or abnormal changes in motor or sensory function.
- Urge patient to protect skin from sunlight and to report photosensitivity at once.
- Tell patient to take drug exactly as prescribed, even if symptoms subside.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.

nortriptyline hydrochloride

Aventyl, Pamelor

Class and Category

Chemical class: Dibenzocycloheptene derivative

Therapeutic class: Antidepressant

Pregnancy category: D

Indications and Dosages

➤ *To treat depression*

CAPSULES, ORAL SOLUTION

Adults. *Initial:* 25 mg t.i.d. or q.i.d.

Maximum: 150 mg daily.

Adolescents. 25 to 50 mg daily or 1 to 3 mg/kg daily in divided doses.

Children ages 6 to 12. 10 to 20 mg daily or 1 to 3 mg/kg daily in divided doses.

DOSAGE ADJUSTMENT Dosage possibly reduced to 30 to 50 mg daily (in divided doses or at bedtime) for elderly patients.

Route	Onset	Peak	Duration
P.O.	2–3 wk	Unknown	Unknown

Mechanism of Action

May interfere with reuptake of serotonin (and possibly other neurotransmitters) at presynaptic neurons, thus enhancing serotonin's effects at postsynaptic receptors. By restoring normal neurotransmitter levels at nerve synapses, this tricyclic antidepressant may elevate mood.

Contraindications

Acute recovery phase of stroke or MI; hypersensitivity to nortriptyline, other tricyclic antidepressants, or their components; use within 14 days of MAO inhibitor therapy

Interactions

DRUGS

amantadine, anticholinergics, antidyskinetics, antihistamines: Possibly increased anticholinergic effects, confusion, hallucinations, nightmares; increased CNS depression

anticonvulsants: Possibly increased CNS depression and risk of seizures, possibly decreased anticonvulsant effectiveness

antithyroid drugs: Possibly agranulocytosis

barbiturates, carbamazepine: Possibly decreased level and effects of nortriptyline
bupropion, clozapine, cyclobenzaprine, haloperidol, loxapine, maprotiline, molindone, phenothiazines, thioxanthenes: Possibly increased sedative and anticholinergic effects, possibly increased risk of seizures
cimetidine, fluoxetine: Possibly increased blood nortriptyline level and risk of toxicity
clonidine: Possibly decreased antihypertensive effect and increased CNS depression
disulfiram: Possibly delirium
ethchlorvynol: Possibly delirium, increased CNS depression
guanadrel, guanethidine: Possibly decreased antihypertensive effect of these drugs
MAO inhibitors: Increased risk of hypertensive crisis, severe seizures, and death
oral anticoagulants: Possibly increased anticoagulant activity
pimozide, probucol: Possibly arrhythmias
sympathomimetics, including ophthalmic epinephrine and vasoconstrictive local anesthetics: Increased risk of arrhythmias, hyperpyrexia, hypertension, tachycardia
thyroid hormones: Possibly increased therapeutic and toxic effects of both drugs

ACTIVITIES

alcohol use: Increased CNS and respiratory depression, hypertension, alcohol effects

Adverse Reactions

CNS: Ataxia, confusion, delirium, dizziness, drowsiness, excitation, hallucinations, headache, insomnia, nervousness, nightmares, parkinsonism, stroke, suicidal ideation, tremor

CV: Arrhythmias, orthostatic hypotension

EENT: Blurred vision, dry mouth, increased intraocular pressure, taste perversion

GI: Constipation, diarrhea, heartburn, ileus, increased appetite, nausea, vomiting

GU: Sexual dysfunction, urine retention

HEME: Bone marrow depression

RESP: Wheezing

SKIN: Diaphoresis, urticaria

Other: Weight gain

Nursing Considerations

- Expect to stop MAO inhibitor therapy 10 to 14 days before starting nortriptyline.
- Watch patient closely (especially children, adolescents, and young adults), for suicidal tendencies, particularly when therapy starts and dosage changes because depres-

- sion may worsen temporarily during these times, possibly leading to suicidal ideation.
- Oral solution (10 mg/5 ml) is 4% alcohol.
- Give nortriptyline with food to reduce GI reactions.
- Monitor blood nortriptyline level; therapeutic range is 50 to 150 ng/ml.
- Monitor ECG tracing to detect arrhythmias.

PATIENT TEACHING

- Explain that oral solution contains alcohol.
- Discourage alcohol consumption during therapy.
- Explain that improvement may take weeks.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.
- Instruct patient to change position slowly to minimize orthostatic hypotension.
- Suggest that patient minimize constipation by drinking plenty of fluids (if allowed), eating high-fiber foods, and exercising regularly.

nystatin

Mycostatin, Nadostine (CAN), Nilstat, Nystex, Nystop, Pedi-Dri

Class and Category

Chemical class: Amphoteric polyene macrolide

Therapeutic class: Antifungal

Pregnancy category: Not rated (lozenges, oral suspension, tablets, topical), A (vaginal)

Indications and Dosages

↗ *To treat oropharyngeal candidiasis (thrush)*

LOZENGES (PASTILLES)

Adults and children over age 5. 200,000 to 400,000 units dissolved in mouth 4 or 5 times daily for up to 14 days.

ORAL SUSPENSION

Adults and children. 400,000 to 600,000 units swished and swallowed q.i.d. until at least 48 hr after symptoms subside.

Infants. 200,000 units to each side of mouth q.i.d. until at least 48 hr after symptoms subside.

Neonates. 100,000 units applied to each side of mouth q.i.d. until at least 48 hr after symptoms subside.

TABLETS

Adults and adolescents. 500,000 to 1,000,000 units t.i.d. until at least 48 hr after symptoms subside.

Children age 5 and over. 500,000 units q.i.d. until at least 48 hr after symptoms subside.

➤ *To treat cutaneous and mucocutaneous candidiasis*

CREAM, OINTMENT, POWDER

Adults and children. 100,000 units (1 g) on affected area b.i.d. or t.i.d. for at least 2 wk.

➤ *To treat vulvovaginal candidiasis*

VAGINAL TABLETS

Adults and adolescents. 100,000 units (1 tab) once or twice daily for 14 days.

Mechanism of Action

Binds to sterols in fungal cell membranes, impairing membrane integrity. Cells lose intracellular potassium and other cellular contents and, eventually, die.

Contraindications

Hypersensitivity to nystatin or its components

Adverse Reactions

ENDO: Hyperglycemia (lozenge, oral suspension)

GI: Abdominal pain, diarrhea, nausea, vomiting (oral forms)

GU: Vaginal burning or itching (vaginal form)

SKIN: Irritation (topical forms)

Nursing Considerations

- Prepare nystatin powder for oral suspension for each dose; it has no preservatives.
- Gently rub nystatin cream or ointment into skin at affected area. Keep area dry and avoid occlusive dressings.
- Don't get topical form in patient's eyes.
- When treating candidal infection of feet, dust patient's shoes, socks, and feet.
- For vaginal form, use applicator supplied by manufacturer.

PATIENT TEACHING

- Instruct patient to let nystatin lozenges dissolve slowly in her mouth, not to chew or swallow them.

- Tell patient to swish oral suspension in her mouth as long as possible before swallowing.
- Advise patient to gently rub ointment or cream into skin at affected area, to keep area dry, and to avoid occlusive dressings.
- Caution patient to keep topical form away from her eyes.
- Advise patient with candidal infection of feet to dust her shoes, socks, and feet with nystatin.
- For vaginal form, tell patient to insert with applicator supplied by manufacturer.

octreotide acetate

Sandostatin, Sandostatin LAR Depot

Class and Category

Chemical class: Cyclic octapeptide, somatostatin analogue

Therapeutic class: Antidiarrheal, hormone suppressant

Pregnancy category: B

Indications and Dosages

➤ *To control symptoms associated with vasoactive intestinal peptide tumors (watery diarrhea) and metastatic carcinoid tumors (diarrhea and flushing)*

I.M. INJECTION

Adults currently receiving subcutaneous injections. 20 mg every 4 wk for 2 mo, with subcutaneous doses continued for 2 to 4 wk after I.M. injections start. If patient has positive response to initial 2-mo regimen, dosage reduced to 10 mg every 4 wk. If symptoms persist or increase after initial 2-mo regimen, dosage increased to 30 mg every 4 wk, as prescribed.

SUBCUTANEOUS INJECTION

Adults. *Initial:* 200 to 300 mcg daily in divided doses b.i.d. to q.i.d. for first 2 wk.

Maintenance: Individualized. *Maximum:* 450 mcg daily.

➤ *To treat symptoms of acromegaly, to suppress the release of growth hormone from pituitary tumors*

I.V. OR SUBCUTANEOUS INJECTION

Adults. *Initial:* 50 mcg t.i.d. Usual: 100 mcg t.i.d. *Maximum:* 1,500 mcg daily.

I.M. INJECTION

Adults currently receiving subcutaneous injections. 20 mg every 4 wk for 3 mo; then

adjusted as prescribed in response to serum growth hormone level. *Maximum*: 40 mg every 4 wk.

Route	Onset	Peak	Duration
SubQ	Unknown	Unknown	Up to 12 hr

Mechanism of Action

Controls many types of secretory diarrhea by inhibiting secretion of serotonin and pituitary and GI hormones (including insulin, glucagon, growth hormone, thyrotropin, and, possibly, thyroid-stimulating hormone) as well as vasoactive intestinal peptides and pancreatic polypeptides (including gastrin, secretin, and motilin). Inhibiting serotonin and peptides increases intestinal absorption of water and electrolytes, decreases pancreatic and gastric acid secretions, and increases intestinal transit time by slowing gastric motility.

By inhibiting hormones involved in vasodilation, octreotide increases splanchnic arterial resistance and decreases GI blood flow, hepatic vein wedge pressure, hepatic blood flow, portal vein pressure, and intravascular pressure, thus raising seated and standing blood pressures. By inhibiting serotonin secretion, octreotide eases symptoms of acromegaly, including diarrhea, flushing, wheezing, and urinary excretion of 5-hydroxyindoleacetic acid.

Incompatibilities

Don't mix octreotide in same syringe with fat emulsions or total parenteral nutrition solutions.

Contraindications

Hypersensitivity to octreotide or its components

Interactions

DRUGS

beta blockers, calcium channel blockers:

Additive cardiovascular effects of these drugs

bromocriptine: Increased blood bromocriptine level

cisapride: Decreased effectiveness of both drugs

cyclosporine: Decreased cyclosporine level

diuretics: Increased risk of fluid and electrolyte imbalances

insulin, oral antidiabetic drugs: Increased

risk of hypoglycemia

quinidine, terfenadine: Decreased clearance and increased blood levels of these drugs

vitamin B₁₂: Decreased vitamin B₁₂ level

Adverse Reactions

CNS: Dizziness, drowsiness, fatigue, headache, intracranial hemorrhage, migraine, paranoia, seizures, suicidal ideation

CV: Arrhythmias (including conduction abnormalities), edema, hypertension, hypotension, MI, orthostatic hypotension, Raynaud's syndrome

EENT: Deafness, epistaxis, glaucoma, retinal vein thrombosis, sinusitis, vision changes

ENDO: Hyperglycemia, hypoglycemia, hypothyroidism, pituitary apoplexy

GI: Abdominal pain, acute cholecystitis, ascending cholangitis, biliary obstruction, cholelithiasis, cholestatic hepatitis, constipation, diarrhea, elevated liver enzymes, flatulence, gastric or peptic ulcer, GI hemorrhage, intestinal obstruction, nausea, pancreatitis, vomiting

GU: Decreased libido, hematuria, increased urine output, renal failure

HEME: Anemia, pancytopenia, thrombocytopenia

MS: Arthropathy, back pain, myalgia

RESP: Status asthmaticus, pulmonary hypertension, upper respiratory tract infection

SKIN: Alopecia, petechiae, pruritus, rash, urticaria

Other: Anaphylaxis, angioedema, dehydration, electrolyte imbalances, flulike symptoms, injection site irritation or pain

Nursing Considerations

- Give octreotide by I.V. injection only in an emergency, as prescribed.
- To prepare depot injection (long-acting suspension form), let powder and diluent warm to room temperature and then reconstitute according to manufacturer's instructions. Gently inject 2 ml of supplied diluent down side of vial without disturbing depot powder. Let diluent saturate powder. After 2 to 5 minutes, check sides and bottom of vial without inverting it. Once powder is completely saturated, swirl—don't shake—vial for 30 to 60 seconds to form suspension. Use immediately after reconstituting.

- Don't give depot injection by subcutaneous route; give only by I.M. route and only to patients who respond to and tolerate subcutaneous drug, as prescribed.
 - To minimize pain, use smallest injection volume to deliver dose, and rotate injection sites.
 - Avoid deltoid site for I.M. use because injection site reaction and pain may result. Intragluteal injection is recommended.
- WARNING** To avoid worsening symptoms, expect to continue subcutaneous injections when switching to I.M. injections, as prescribed.
- Be aware that octreotide increases risk of acute cholecystitis, ascending cholangitis, biliary obstruction, cholestatic hepatitis, and pancreatitis.
 - Monitor vital signs, bowels sounds, and stool consistency. Assess for abdominal pain and signs of gallbladder disease.
 - Monitor serum liver enzyme levels, as appropriate.
 - Monitor patient for signs of electrolyte imbalances and dehydration.
 - Carefully monitor diabetic patient for altered glucose control.
 - Monitor patient's thyroid function, as ordered, because octreotide suppresses secretion of thyroid-stimulating hormone, which may cause hypothyroidism.
 - If patient has periodic symptom flare-ups, expect to give additional subcutaneous octreotide temporarily, as prescribed.

PATIENT TEACHING

- Advise patient to change position slowly to minimize orthostatic hypotension.
- Instruct patient to notify prescriber about adverse reactions, especially abdominal pain, which may indicate pancreatitis.
- Urge diabetic patient to check blood glucose level often.
- Caution female patient of childbearing age that drug may restore fertility and, if pregnancy isn't desired, that contraception should be used during octreotide therapy.

ofloxacin

Floxin

Class and Category

Chemical class: Fluoroquinolone

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

↗ *To treat acute, uncomplicated cystitis caused by Escherichia coli or Klebsiella pneumoniae*

TABLETS, I.V. INFUSION

Adults. 200 mg every 12 hr for 3 days.

↗ *To treat uncomplicated cystitis caused by Citrobacter diversus, Enterobacter aerogenes, Proteus mirabilis, or Pseudomonas aeruginosa*

TABLETS, I.V. INFUSION

Adults. 200 mg every 12 hr for 7 days.

↗ *To treat complicated UTI caused by C. diversus, E. coli, K. pneumoniae, P. mirabilis, or P. aeruginosa*

Adults. 200 mg every 12 hr for 10 days.

↗ *To treat uncomplicated gonorrhea*

TABLETS, I.V. INFUSION

Adults and adolescents. 400 mg as single dose.

↗ *To treat urethritis or cervicitis caused by Chlamydia trachomatis or Neisseria gonorrhoeae*

TABLETS, I.V. INFUSION

Adults and adolescents. 300 mg b.i.d. for 7 days as an alternative to doxycycline or azithromycin.

↗ *To treat pelvic inflammatory disease caused by susceptible organisms*

TABLETS

Adults and adolescents. 400 mg b.i.d. with metronidazole P.O. for 10 to 14 days.

I.V. INFUSION

Adults and adolescents. 400 mg every 12 hr with metronidazole I.V.; then switched to oral therapy, as prescribed, after 24 hr. Full course of therapy lasts 14 days.

↗ *To treat prostatitis caused by E. coli*

TABLETS, I.V. INFUSION

Adults. 300 mg every 12 hr for 6 wk.

↗ *To treat lower respiratory tract infections caused by Haemophilus influenzae or Streptococcus pneumoniae and skin and soft-tissue infections caused by Staphylococcus aureus or Streptococcus pyogenes*

TABLETS, I.V. INFUSION

Adults. 400 mg every 12 hr for 10 days.

DOSAGE ADJUSTMENT If creatinine clearance is 20 to 50 ml/min/1.73 m², dosing interval possibly reduced to every 24 hr; if clearance

is less than 10 ml/min/1.73 m², dosage possibly reduced by 50% and given every 24 hr.

Mechanism of Action

Inhibits synthesis of the bacterial enzyme DNA gyrase by counteracting excessive supercoiling of DNA during replication or transcription. Inhibition of DNA gyrase causes rapid- and slow-growing bacterial cells to die.

Incompatibilities

Don't mix ofloxacin with other I.V. drugs or additives.

Contraindications

Hypersensitivity to ofloxacin, other fluoroquinolones, or their components

Interactions

DRUGS

aluminum-, calcium-, or magnesium-containing antacids; didanosine; ferrous sulfate; magnesium-containing laxatives; multivitamins; sevelamer; sucralfate; zinc:

Decreased absorption of oral ofloxacin
probenecid: Decreased ofloxacin excretion, increased risk of toxicity

procainamide: Decreased renal clearance of procainamide

warfarin: Possibly increased anticoagulant activity and risk of bleeding

Adverse Reactions

CNS: Aggressiveness, agitation, ataxia, dizziness, drowsiness, emotional lability, exacerbation of extrapyramidal disorders and myasthenia gravis, fever, headache, incoordination, insomnia, light-headedness, mania, peripheral neuropathy, psychotic reactions, restlessness, stroke, suicidal ideation, syncope

CV: Arrhythmias, prolonged QT interval, severe hypotension, torsades de pointes, vasculitis

EENT: Blurred vision; diplopia; disturbances in taste, smell, hearing, and equilibrium

ENDO: Hyperglycemia, hypoglycemia

GI: Abdominal cramps or pain, acute hepatic necrosis or failure, diarrhea, hepatitis, jaundice, nausea, pseudomembranous colitis, vomiting

GU: Acute renal insufficiency or failure, interstitial nephritis, renal calculi, vaginal candidiasis

HEME: Agranulocytosis, aplastic or hemolytic anemia, leukopenia, pancytopenia, thrombocytopenia

MS: Arthralgia; myalgia; rhabdomyolysis; tendinitis; tendon inflammation, pain, or rupture

RESP: Allergic pneumonitis, pulmonary edema

SKIN: Blisters, diaphoresis, erythema, erythema multiforme, exfoliative dermatitis, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Acidosis, anaphylaxis, infusion site phlebitis, serum sickness

Nursing Considerations

- Because of increased risk of prolonged QT interval, ofloxacin shouldn't be used if patient has had a prolonged QT interval, has an uncorrected electrolyte disorder, or takes a Class IA or III antiarrhythmic. Monitor elderly patients closely because risk of prolonged QT interval may be increased in this group.
- For I.V. infusion, dilute drug in normal saline solution or D₅W to at least 4 mg/ml, and infuse over 60 minutes to minimize the risk of hypotension. Discard unused portion.
- Monitor patient closely for hypersensitivity, which may occur as early as first dose. Reaction may include angioedema, bronchospasm, dyspnea, itching, rash, jaundice, shortness of breath, and urticaria. If these signs or symptoms appear, notify prescriber immediately and expect to discontinue drug.
- Notify prescriber if patient has symptoms of peripheral neuropathy (pain, burning, tingling, numbness, weakness, or altered sensations of light touch, pain, temperature, position sense, or vibration sense), which could be permanent; tendon rupture (pain and inflammation), which may occur more often in patients (especially elderly ones) taking corticosteroids and requires immediate rest; or a severe photosensitivity reaction. In each case, expect to stop ofloxacin.
- Maintain adequate hydration to prevent development of highly concentrated urine and crystalluria.
- Expect an increased risk of toxicity in

- severe hepatic disease, including cirrhosis.
- Be aware that ofloxacin may stimulate the CNS and aggravate seizure disorders.
 - If diarrhea develops, notify prescriber because it may indicate pseudomembranous colitis. Ofloxacin may need to be discontinued and additional therapy started.
 - Be alert for secondary fungal infection.

PATIENT TEACHING

- Encourage patient to take each oral dose with a full glass of water.
- Tell patient to complete full course of ofloxacin therapy exactly as prescribed, even if he feels better before it's complete.
- Urge patient not to take antacids, iron or zinc preparations, or other drugs (such as sucralfate and didanosine), within 2 hours of ofloxacin to prevent decreased or delayed drug absorption.
- Advise patient to avoid hazardous activities until CNS effects of drug are known.
- Tell patient to limit exposure to sun and ultraviolet light to prevent phototoxicity.
- Advise patient to notify prescriber immediately about burning skin, hives, itching, rash, rapid heart rate, abnormal motor or sensory function, and tendon pain.
- Urge patient to seek medical care immediately for trouble breathing or swallowing, which may signal an allergic reaction.
- Instruct diabetic patient who takes insulin or an antidiabetic to notify prescriber immediately if he develops a hypoglycemic reaction; ofloxacin will have to be stopped.
- Advise patient to notify prescriber if diarrhea develops, even up to 2 months after ofloxacin therapy ends. Additional therapy may be needed.

olanzapine

Zydis, Zyprexa

Class and Category

Chemical class: Thienobenzodiazepine derivative

Therapeutic class: Antipsychotic

Pregnancy category: C

Indications and Dosages

➤ *To treat psychosis*

ORALLY DISINTEGRATING TABLETS, TABLETS

Adults. *Initial:* 5 to 10 mg daily. *Usual:* 10 mg daily. *Maximum:* 20 mg daily.

➤ *To treat manic phase of acute bipolar disorder*

ORALLY DISINTEGRATING TABLETS, TABLETS

Adults. *Initial:* 10 to 15 mg daily; may be increased or decreased by 5 mg every 24 hr as needed and prescribed. *Usual:* 5 to 20 mg daily for 3 to 4 wk. *Maximum:* 20 mg daily.

➤ *As adjunct to treat acute bipolar disorder*

ORALLY DISINTEGRATING TABLETS, TABLETS

Adults. *Initial:* 10 mg daily with lithium or valproate sodium; may be increased or decreased by 5 mg every 24 hr, as needed and prescribed. *Usual:* 5 to 20 mg/day for 6 wk. *Maximum:* 20 mg daily.

DOSAGE ADJUSTMENT Initial dosage possibly reduced to 5 mg for debilitated patients, those prone to hypotension, and female nonsmokers over age 65.

➤ *To treat agitation associated with schizophrenia and bipolar I mania*

I.M. INJECTION

Adults. 5 to 10 mg p.r.n. Repeat as needed every 2 to 4 hr.

DOSAGE ADJUSTMENT Dosage decreased to 5 mg for elderly patients and 2.5 mg for debilitated patients, those prone to hypotension, and female nonsmokers over age 65.

Route	Onset	Peak	Duration
P.O.	1 wk	Unknown	Unknown
I.M.	Unknown	Unknown	Unknown

Mechanism of Action

May achieve antipsychotic effects by antagonizing dopamine and serotonin receptors. Anticholinergic effects may result from competitive binding to and antagonism of the muscarinic receptors M₁ through M₅.

Contraindications

Blood dyscrasias, bone marrow depression, cerebral arteriosclerosis, coma, coronary artery disease, hepatic dysfunction, high-dose CNS depressants, hypersensitivity to olanzapine or its components, hypertension, hypotension, myeloproliferative disorders, severe CNS depression, subcortical brain damage

Interactions

DRUGS

anticholinergics: Increased anticholinergic effects, altered thermoregulation

antihypertensives: Increased effects of both drugs, increased risk of hypotension
benzodiazepines (parenteral): Increased risk of excessive sedation and cardiorespiratory depression

carbamazepine, omeprazole, rifampin:

Increased olanzapine clearance

CNS depressants: Additive CNS depression, potentiated orthostatic hypotension

diazepam: Increased CNS depressant effects

flvoxamine: Decreased olanzapine clearance

levodopa: Decreased levodopa efficacy

lorazepam (parenteral): Possibly increased somnolence with I.M. olanzapine injection

ACTIVITIES

alcohol use: Additive CNS depression, potentiated orthostatic hypotension

smoking: Decreased blood olanzapine level

Adverse Reactions

CNS: Abnormal gait, agitation, akathisia, altered thermoregulation, amnesia, anxiety, asthenia, dizziness, euphoria, fatigue, fever, headache, hypertonia, insomnia, nervousness, neuroleptic malignant syndrome, restlessness, somnolence, stuttering, suicidal ideation, tardive dyskinesia, tremor

CV: Chest pain, hyperlipidemia, hypertension, hypotension, orthostatic hypotension, peripheral edema, tachycardia

EENT: Amblyopia, dry mouth, increased salivation, pharyngitis, rhinitis

ENDO: Hyperglycemia, prolactin elevation

GI: Abdominal pain, constipation, dysphagia, hepatitis, increased appetite, nausea, thirst, vomiting

GU: Urinary incontinence, UTI

HEME: Agranulocytosis, leukopenia, neutropenia

MS: Arthralgia; back, joint, or limb pain; muscle spasms and twitching

RESP: Cough

SKIN: Ecchymosis, photosensitivity, pruritus, urticaria

Other: Anaphylaxis, angioedema, flulike symptoms, weight gain

Nursing Considerations

WARNING Olanzapine shouldn't be used for elderly patients with dementia-related psychosis because drug increases risk of death in these patients.

- Reconstitute parenteral olanzapine by dissolving contents of vial in 2.1 ml sterile

water to yield 5 mg/ml. Solution should be clear yellow. Use within 1 hour.

- Inject I.M. olanzapine slowly, deep into muscle mass.
- Keep patient recumbent after I.M. injection of olanzapine if drowsiness, dizziness, bradycardia, or hypoventilation occurs. Don't let patient sit or stand up until blood pressure and heart rate have returned to baseline.
- Monitor patient's blood pressure routinely during therapy because olanzapine may cause orthostatic hypotension.
- Olanzapine may worsen such conditions as angle-closure glaucoma, benign prostatic hyperplasia, and seizures.
- Assess daily weight to detect fluid retention.
- Notify prescriber if patient develops tardive dyskinesia or urinary incontinence.
- Be alert for and immediately report signs of neuroleptic malignant syndrome.
- Watch patient closely (especially children, adolescents, and young adults), for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.
- Monitor patient's lipid levels throughout therapy, as ordered, because olanzapine may cause significant elevations.
- Monitor patient's blood glucose level routinely because olanzapine may increase risk of hyperglycemia.
- Monitor CBC often during first few months of therapy, especially if patient has low WBC count or history of drug-induced leukopenia or neutropenia. If WBC count declines, and especially if neutrophil count drops below 1,000/mm³, expect olanzapine to be discontinued. If neutropenia is significant, also monitor patient for fever or other evidence of infection and provide appropriate treatment, as prescribed.

PATIENT TEACHING

- Advise patient to avoid alcohol and smoking during olanzapine therapy.
- Teach patient to open orally disintegrating tablet sachet by peeling back foil on the blister and not by pushing tablet through the foil. Immediately after opening blister, tell him to use dry hands to remove tablet and place it in his mouth. Explain that

tablet will disintegrate rapidly in saliva so he can easily swallow it without liquid.

- Caution patient with phenylketonuria that disintegrating olanzapine tablets contain phenylalanine.
- Urge patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to change position slowly to minimize effects of orthostatic hypotension.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.

olmesartan medoxomil

Benicar

Class and Category

Chemical class: Angiotensin II receptor antagonist

Therapeutic class: Antihypertensive

Pregnancy category: C (first trimester), D (later trimesters)

Indications and Dosages

➤ *To manage or as adjunct to manage hypertension*

TABLETS

Adults. *Initial:* 20 mg daily, increased in 2 wk to 40 mg daily, if needed.

DOSAGE ADJUSTMENT Lower starting dosage is recommended for patients with possible depletion of intravascular volume, such as

those treated with diuretics, especially if impaired renal function is present.

Contraindications

Hypersensitivity to olmesartan medoxomil or its components

Adverse Reactions

CNS: Astenia, dizziness, fatigue, headache, insomnia, vertigo

CV: Chest pain, hypercholesterolemia, hyperlipidemia, hypertriglyceridemia, peripheral edema, tachycardia

EENT: Pharyngitis, rhinitis, sinusitis

ENDO: Hyperglycemia, hyperuricemia

GI: Abdominal pain, diarrhea, gastroenteritis, indigestion, nausea, vomiting

GU: Acute renal failure, elevated BUN and serum creatinine levels, hematuria, UTI

MS: Arthralgia, arthritis, back pain, myalgia, rhabdomyolysis, skeletal pain

RESP: Bronchitis, cough, upper respiratory tract infection

SKIN: Alopecia, pruritus, rash, urticaria

Other: Angioedema, hyperkalemia, increased CK level, flulike symptoms, pain

Nursing Considerations

- Expect to provide treatment such as normal saline solution I.V., as prescribed, to correct known or suspected hypovolemia before beginning olmesartan therapy.
- Monitor patient for increased BUN and serum creatinine levels, especially in a patient with impaired renal function, because drug may cause acute renal failure. If increased levels are significant or persist, notify prescriber immediately.
- Monitor blood pressure frequently to assess effectiveness of therapy. If blood

Mechanism of Action

Olmesartan medoxomil blocks angiotensin II from binding to receptor sites in many tissues, including vascular smooth muscle and adrenal glands. Angiotensin II, a potent vasoconstrictor, is then free to stimulate the adrenal cortex to secrete aldosterone, and the inhibiting effects of angiotensin II reduce blood pressure.

pressure isn't controlled with olmesartan alone, expect to administer a diuretic, such as hydrochlorothiazide, as prescribed.

WARNING Monitor patient's blood pressure frequently if he receives a diuretic or other antihypertensive during olmesartan therapy because of an increased risk of hypotension.

- Expect to discontinue drug temporarily if patient experiences hypotension. Place patient in supine position immediately and prepare to administer normal saline solution I.V., as prescribed. Expect to resume drug therapy after blood pressure stabilizes.
- If patient also receives a diuretic, provide adequate hydration, as appropriate, to help prevent hypovolemia. Watch for evidence of hypovolemia, such as hypotension with dizziness and fainting.

PATIENT TEACHING

- Advise patient to avoid exercise in hot weather and excessive alcohol use to reduce the risk of dehydration and hypotension. Also instruct him to notify prescriber if he has prolonged diarrhea, nausea, or vomiting.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Explain the importance of regular exercise, proper diet, and other lifestyle changes in controlling hypertension.
- Advise female patient to notify prescriber immediately about known or suspected pregnancy. Explain that if she becomes pregnant, prescriber may replace olmesartan with another antihypertensive that's safe to use during pregnancy.

olsalazine sodium

Dipentum

Class and Category

Chemical class: Salicylate derivative

Therapeutic class: Bowel disease suppressant

Pregnancy category: C

Indications and Dosages

↗ *To maintain remission of ulcerative colitis*

CAPSULES, TABLETS

Adults and adolescents. 500 mg b.i.d.

Mechanism of Action

Exerts anti-inflammatory action in GI tract after being converted by colonic bacteria to mesalamine (5-aminosalicylic acid), which inhibits cyclooxygenase. Inhibition of cyclooxygenase reduces prostaglandin production in intestinal mucosa. This in turn reduces production of arachidonic acid metabolites, which may be increased in patients with inflammatory bowel disease. Olsalazine also exerts an anti-inflammatory effect by indirectly inhibiting leukotriene synthesis, which normally catalyzes production of arachidonic acid.

Contraindications

Hypersensitivity to olsalazine, salicylates, or their components

Interactions

DRUGS

6-mercaptopurine, thioguanine: Increased risk of myelosuppression

low-molecular-weight heparins or heparinoids: Increased risk of bleeding after neuraxial anesthesia

oral anticoagulants: Possibly prolonged PT

varicella vaccine: Increased risk of Reye's syndrome

Adverse Reactions

CNS: Anxiety, depression, dizziness, drowsiness, fatigue, fever, headache, insomnia, lethargy, paresthesia, peripheral neuropathy, vertigo

CV: Myocarditis, pericarditis, second-degree AV block

ENDO: Hot flashes

EENT: Dry eyes and mouth, lacrimation, stomatitis, tinnitus

GI: Abdominal pain, anorexia, cholestatic jaundice, cirrhosis, diarrhea, dyspepsia, elevated liver enzymes, hepatic failure or necrosis, hepatitis, hepatotoxicity, nausea, vomiting

GU: Dysuria, hematuria, interstitial nephritis, nephrotic syndrome, urinary frequency

HEME: Aplastic or hemolytic anemia, lymphopenia, neutropenia, pancytopenia

MS: Arthralgia, joint pain, muscle spasms, myalgia

RESP: Dyspnea, interstitial lung disease

SKIN: Acne, alopecia, erythema nodosum, photosensitivity, pruritus, rash

Other: Angioedema, dehydration

Nursing Considerations

- Assess patient for aspirin allergy before giving olsalazine.
- If patient has severe allergies or asthma, watch closely for worsening symptoms during olsalazine therapy, and notify prescriber immediately if they occur.
- Assess quantity and consistency of stools and frequency of bowel movements before, during, and after therapy.
- Give drug with food to decrease adverse GI reactions.
- Monitor skin for adequate hydration.
- Assess patient for abdominal pain and hyperactive bowel sounds.
- Monitor renal and hepatic status in patient with underlying renal or hepatic dysfunction because drug may further impair these functions.

PATIENT TEACHING

- Instruct patient to take olsalazine with food.
- Urge patient to continue taking drug as prescribed, even if symptoms improve.
- Advise patient to watch for signs of dehydration.
- Tell patient to report unusual, persistent, or severe adverse effects to prescriber.

omalizumab

Xolair

Class and Category

Chemical class: Recombinant IgG1K anti-IgE monoclonal antibody

Therapeutic class: Antiallergenic

Pregnancy category: B

Indications and Dosages

➤ *To treat moderate to severe persistent asthma in patients with positive skin test or in vitro reactivity to a perennial aeroallergen whose symptoms have been inadequately controlled with inhaled corticosteroids*

SUBCUTANEOUS INJECTION

Adults and adolescents age 12 and over.

150 to 375 mg every 2 or 4 wk. Dose and frequency determined by body weight and blood IgE levels.

DOSAGE ADJUSTMENT Dosage adjusted for significant changes in body weight.

Mechanism of Action

Helps reduce inflammation by binding to circulating IgE and keeping it from binding to mast cells. This action inhibits degranulation and blocks release of histamine and other chemical mediators. In asthma, inflammation results when antigen reexposure causes mast cells to degranulate and release histamine and chemical mediators.

Contraindications

Hypersensitivity to omalizumab or its components

Adverse Reactions

CNS: Dizziness, fatigue, headache, vertigo

EENT: Earache, pharyngitis, sinusitis

MS: Arm or leg pain, arthralgia, fractures

RESP: Upper respiratory tract infection

SKIN: Dermatitis, pruritus, urticaria

Other: Anaphylaxis; generalized pain; injection site bruising, burning, hive or mass formation, induration, inflammation, itching, pain, redness, stinging, and warmth; malignancies; viral infection

Nursing Considerations

- Record patient's weight, and obtain blood IgE levels, as ordered, before starting omalizumab; dosage and dosing frequency are based on these factors.
- Reconstitute using sterile water for injection, and allow 15 to 20 minutes (on average) for lyophilized product to dissolve. Draw 1.4 ml sterile water for injection into a 3-ml syringe with a 1" 18G needle. Place omalizumab vial upright, and inject sterile water into vial using aseptic technique. Gently swirl upright vial for about 1 minute to evenly wet powder. Don't shake. Every 5 minutes, gently swirl for 5 to 10 seconds until solution contains no gel-like particles. Discard if powder takes longer than 40 minutes to dissolve, and start with a new vial. Once reconstituted, solution should be clear or slightly opalescent and may have a few small bubbles or foam around edge of vial. Use omalizumab within 8 hours if refrigerated or 4 hours if stored at room temperature.
- To remove reconstituted omalizumab from vial, invert vial for 15 seconds to let solution drain toward stopper. Using a new 3-ml syringe with a 1" 18G needle, insert needle into inverted vial and posi-

tion needle tip at the very bottom of solution in the vial stopper. Then pull plunger all the way back to end of syringe barrel to remove all solution from inverted vial. To obtain full 150-mg dose (1 vial containing 1.2 ml of reconstituted omalizumab), you must withdraw all product from vial before expelling any air or excess solution from syringe.

- Don't give more than 150 mg of omalizumab per injection site.
- Be prepared to inject omalizumab over 5 to 10 seconds because solution is slightly viscous.

WARNING Monitor patient closely for hypersensitivity reactions, particularly for first 2 hours after delivery. Although rare, anaphylaxis has occurred as early as first dose and more than 1 year after starting regular treatment. Keep emergency medication and equipment readily available.

WARNING Monitor patient closely for signs of cancer. Report any abnormal findings to prescriber.

PATIENT TEACHING

- Instruct patient to notify prescriber immediately about possible hypersensitivity, such as rash, hives, or difficulty breathing.
- Caution patient that any improvement in his asthma may take time.
- Encourage patient to comply with regularly scheduled prescriber visits.
- Inform patient of risk of malignancy and suggest routine cancer screening.
- Explain that omalizumab isn't used to treat acute bronchospasm or status asthmaticus.
- Tell patient not to abruptly stop any prescribed systemic or inhaled corticosteroid when starting omalizumab therapy because steroid dosage must be tapered gradually under prescriber's supervision.
- If female patient becomes pregnant within 8 weeks before or during omalizumab therapy, urge her to enroll in the Xolair Pregnancy Exposure Registry at 1-866-496-5247. Also, tell her to notify prescriber because drug may need to be changed.

omega-3-acid ethyl esters

Lovaza

Class and Category

Chemical class: Ethyl esters of omega-3 fatty acids

Therapeutic class: Lipid regulator

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to diet to reduce triglyceride level that exceeds 500 mg/dl*

CAPSULES

Adults. 4 g once daily or 2 g b.i.d.

Mechanism of Action

Omega-3-acid ethyl esters are essential fatty acids that may inhibit very-low-density lipoprotein and triglyceride synthesis in the liver. With less triglyceride synthesis, plasma triglyceride levels decrease.

Contraindications

Hypersensitivity to omega-3-acid ethyl esters or their components

Interactions

DRUGS

anticoagulants: Possibly increased bleeding time

Adverse Reactions

CV: Angina pectoris

EENT: Halitosis, nosebleeds, taste perversion

GI: Diarrhea, dyspepsia, eructation, nausea, vomiting

HEME: Prolonged bleeding time

MS: Back pain

SKIN: Bruising, rash

Other: Anaphylaxis, flulike symptoms

Nursing Considerations

- Be aware that drugs known to increase triglyceride levels—such as beta blockers, thiazide diuretics, and estrogens—should be discontinued or changed, if possible, before omega-3 ethyl ester therapy starts.
- Expect to check patient's triglyceride level before starting and periodically throughout omega-3-acid ethyl ester therapy to determine effectiveness.
- Administer drug with meals.
- Expect to stop omega-3-acid ethyl ester therapy after 2 months if patient's triglyceride level doesn't decrease as expected.

PATIENT TEACHING

- Explain to patient the importance of dietary measures, an exercise program, and controlling other factors—such as

blood glucose level—that may contribute to elevated tricycleride levels.

- Advise patient to take drug with meals.
- Explain that patient will need periodic laboratory tests to evaluate therapy.
- Instruct patient to seek immediate medical attention if chest pain occurs.

omeprazole

Losec (CAN), Prilosec, Zegerid

Class and Category

Chemical class: Substituted benzimidazole

Therapeutic class: Antiulcer

Pregnancy category: C

Indications and Dosages

↗ *To treat gastroesophageal reflux disease (GERD) without esophageal lesions, to prevent erosive esophagitis*

DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION

Adults. 20 mg daily for 4 wk.

↗ *To treat GERD with erosive esophagitis*

DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION

Adults. 20 mg daily for 4 to 8 wk.

↗ *To treat pediatric GERD and other acid-related disorders*

DELAYED-RELEASE CAPSULES

Children age 2 and over weighing more than 20 kg. 20 mg daily.

Children age 2 and over weighing 20 kg (44 lb) or less. 10 mg daily.

↗ *To provide short-term treatment of active benign gastric ulcer*

DELAYED-RELEASE CAPSULES

Adults. 40 mg daily for 4 to 8 wk.

DELAYED-RELEASE TABLETS

Adults. 20 mg daily for 4 to 8 wk, increased to 40 mg daily, p.r.n.

↗ *To treat duodenal or gastric ulcer associated with Helicobacter pylori*

DELAYED-RELEASE CAPSULES, ORAL SUSPENSION

Adults. 40 mg daily with clarithromycin for 14 days, followed by 20 mg daily alone for another 14 days. Or, 20 mg b.i.d. with amoxicillin for 14 days. Or, 20 mg b.i.d. with amoxicillin and clarithromycin for 10 days.

DELAYED-RELEASE TABLETS

Adults. 20 mg b.i.d. with clarithromycin and amoxicillin or metronidazole for

7 days, followed by 20 mg daily for up to 3 wk (for duodenal ulcer) or 20 to 40 mg daily for up to 12 wk (for gastric ulcer).

↗ *To provide long-term treatment of gastric hypersecretory conditions, such as multiple endocrine adenoma syndrome, systemic mastocytosis, and Zollinger-Ellison syndrome*

DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS

Adults. 60 mg daily or in divided doses, as prescribed. *Maximum:* 120 mg t.i.d.

Route	Onset	Peak	Duration
P.O.	1 hr	In 2 hr	72–96 hr

Contraindications

Hypersensitivity to omeprazole, other proton pump inhibitors, or their components

Interactions

DRUGS

alprazolam, astemizole, carbamazepine, cisapride, cyclosporine, diazepam, diltiazem, erythromycin, felodipine, lidocaine, lovastatin, midazolam, quinidine, simvastatin, terfenadine, triazolam, verapamil, voriconazole: Decreased clearance and increased blood levels of these drugs

ampicillin, iron salts, itraconazole, ketoconazole, vitamin B₁₂: Impaired absorption of these drugs

atazanavir, nelfinavir: Decreased plasma atazanavir or nelfinavir level

cilostazol: Increased blood cilostazol level

clarithromycin: Increased blood levels of omeprazole and clarithromycin

digoxin: Increased digoxin bioavailability, possibly digitalis toxicity

levobupivacaine: Increased risk of levobupivacaine toxicity

methotrexate: Possibly delayed methotrexate elimination

nifedipine: Decreased nifedipine clearance, increased risk of hypotension

phenytoin: Decreased phenytoin clearance, increased risk of phenytoin toxicity

saquinavir: Increased plasma saquinavir level

sucralfate: Decreased omeprazole absorption

tacrolimus: Possibly increased tacrolimus level

warfarin: Possibly increased risk of abnormal bleeding

Mechanism of Action

Omeprazole interferes with gastric acid secretion by inhibiting the hydrogen-potassium-adenosine triphosphatase (H^+K^+ -ATPase) enzyme system, or proton pump, in gastric parietal cells. Normally, the proton pump uses energy from hydrolysis of adenosine triphosphate to drive hydrogen (H^+) and chloride (Cl^-) out of parietal cells and into the stomach lumen in exchange for potassium (K^+),

which leaves the stomach lumen and enters parietal cells. After this exchange, H^+ and Cl^- combine in the stomach to form hydrochloric acid (HCl), as shown below left. Omeprazole irreversibly blocks the exchange of intracellular H^+ and extracellular K^+ , as shown below right. By preventing H^+ from entering the stomach lumen, omeprazole keeps additional HCl from forming.

Adverse Reactions

CNS: Agitation, asthenia, dizziness, drowsiness, fatigue, headache, psychic disturbance, somnolence

CV: Chest pain, hypertension, peripheral edema

EENT: Anterior ischemic optic neuropathy, optic atrophy or neuritis, stomatitis

ENDO: Hypoglycemia

GI: Abdominal pain, constipation, diarrhea, dyspepsia, elevated liver function tests, flatulence, hepatic dysfunction or failure, indigestion, nausea, pancreatitis, vomiting

GU: Interstitial nephritis

HEME: Agranulocytosis, anemia, hemolytic anemia, leukopenia, leukocytosis, neutropenia, pancytopenia, thrombocytopenia

MS: Back pain

RESP: Cough

SKIN: Erythema multiforme, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, hyponatremia

Nursing Considerations

• Give omeprazole before meals, preferably

in the morning for once-daily dosing. If needed, also give an antacid, as prescribed.

- If needed, open capsule and sprinkle enteric-coated granules on applesauce or yogurt or mix with water or acidic fruit juice, such as apple or cranberry juice. Give immediately.
- To give drug via NG tube, mix granules in acidic juice because enteric coating dissolves in alkaline pH.
- Because drug can interfere with absorption of vitamin B_{12} , monitor patient for macrocytic anemia.
- Be aware that long-term use of omeprazole may increase the risk of gastric carcinoma.

PATIENT TEACHING

- Tell patient to take drug before eating—usually before breakfast—and to swallow delayed-release capsules or tablets whole. If needed, patient may sprinkle contents of capsule onto 1 tablespoon of applesauce and swallow immediately without chewing pellets. Tell him to follow with a glass of cool water and not to keep any leftover mixture.
- If patient takes the oral suspension, tell

him to empty package into a small cup containing 2 tablespoons of water (no other beverage should be used), stir the mixture well, drink it immediately, refill the cup with water, and drink again.

- Encourage patient to avoid alcohol, aspirin products, ibuprofen, and foods that may increase gastric secretions during therapy. Tell him to notify all prescribers about prescription drug use.
- Advise patient to notify prescriber immediately about abdominal pain or diarrhea.
- Urge female patient of childbearing age to use effective contraception during therapy and to inform prescriber immediately if she is or suspects she may be pregnant.

ondansetron hydrochloride

Zofran, Zofran ODT

Class and Category

Chemical class: Carbazole

Therapeutic class: Antiemetic

Pregnancy category: B

Indications and Dosages

➤ *To prevent chemotherapy-induced nausea and vomiting*

DISINTEGRATING TABLETS, ORAL SOLUTION, TABLETS

Adults and children age 12 and over.

Initial: 8 mg given 30 min before chemotherapy. *After chemotherapy:* 8 mg given 8 hr after initial dose; then 8 mg every 12 hr for 1 to 2 days.

Children ages 4 to 12. *Initial:* 4 mg given 30 min before chemotherapy. *After chemotherapy:* 4 mg given 4 and 8 hr after initial dose; then 4 mg every 8 hr for 1 to 2 days.

I.V. INFUSION

Adults. 32 mg infused over 15 min starting 30 min before chemotherapy; or three 0.15-mg/kg doses, each infused over 15 min, starting with first dose given 30 min before chemotherapy and second and third doses given 4 and 8 hours after first dose.

Children ages 6 months to 18 years. Three 0.15-mg/kg doses, each infused over 15 min, starting with first dose given 30 min before chemotherapy and second and third doses

given 4 and 8 hours after first dose.

➤ *To prevent postoperative nausea and vomiting*

DISINTEGRATING TABLETS, ORAL SOLUTION, TABLETS

Adults. 16 mg as a single dose 1 hr before anesthesia induction.

I.V. INJECTION

Adults and children age 12 and over. 4 mg as a single dose over 2 to 5 min just before anesthesia induction or if nausea or vomiting develops shortly after surgery.

Children ages 2 to 12 weighing more than 40 kg (88 lb). 4 mg as a single dose over 2 to 5 min just before anesthesia induction or if nausea or vomiting develops shortly after surgery.

Children ages 1 month to 12 years weighing less than 40 kg. 0.1 mg/kg as a single dose over 2 to 5 min just before or immediately after anesthesia induction or if nausea or vomiting develops shortly after surgery.

I.M. INJECTION

Adults and children age 12 and over. 4 mg as a single dose just before anesthesia induction or if nausea or vomiting develops shortly after surgery.

➤ *To prevent nausea and vomiting after radiation therapy*

DISINTEGRATING TABLETS, ORAL SOLUTION, TABLETS

Adults and children age 12 and over.

Initial: 8 mg as a single dose given 1 to 2 hr before radiation therapy. *Posttherapy:* 8 mg every 8 hr, as needed and tolerated.

DOSAGE ADJUSTMENT For patients with hepatic impairment, maximum dosage limited to 8 mg daily I.V. or P.O.

Mechanism of Action

Blocks serotonin receptors centrally in the chemoreceptor trigger zone and peripherally at vagal nerve terminals in the intestine. This action reduces nausea and vomiting by preventing serotonin release in the small intestine (probable cause of chemotherapy- and radiation-induced nausea and vomiting) and by blocking signals to the CNS. Ondansetron may also bind to other serotonin receptors and to mu-opioid receptors.

Incompatibilities

Don't give ondansetron in same I.V. line as acyclovir, allopurinol, aminophylline, amphotericin B, ampicillin, ampicillin and

sulbactam, amsacrine, cefepime, cefoperazone, furosemide, ganciclovir, lorazepam, methylprednisolone, mezlocillin, piperacillin, or sargramostim. Alkaline solutions and highly concentrated fluorouracil solutions are physically incompatible.

Contraindications

Hypersensitivity to ondansetron or its components

Interactions

DRUGS

cisplatin, cyclophosphamide: Possibly altered blood levels of these drugs

ACTIVITIES

alcohol use: Increased stimulant and sedative effects, including mood and physical sensations

Adverse Reactions

CNS: Agitation, akathisia, anxiety, ataxia, dizziness, drowsiness, fever, headache, hypotension, restlessness, seizures, syncope, somnolence, weakness

CV: Arrhythmias, chest pain, hypotension, pulmonary embolism, shock, tachycardia, transient prolonged QT interval

EENT: Accommodation disturbances, altered taste, blurred vision, dry mouth, laryngeal edema, laryngospasm, transient blindness

GI: Abdominal pain, anorexia, constipation, diarrhea, elevated liver function test results, flatulence, indigestion, intestinal obstruction, thirst

RESP: Bronchospasm, shortness of breath

SKIN: Flushing, hyperpigmentation, maculopapular rash, pruritus

Other: Anaphylaxis, angioedema, injection site burning, pain, and redness

Nursing Considerations

WARNING Be aware that oral disintegrating tablets may contain aspartame, which is metabolized to phenylalanine and must be used cautiously in patients with phenylketonuria.

- Place disintegrating tablet on patient's tongue immediately after opening package. It dissolves in seconds.
- Use calibrated container or oral syringe to measure dose of oral solution.
- Give up to 4 mg I.V. diluted in 50 ml of D₅W or normal saline solution.

WARNING Be aware that ondansetron may

mask symptoms of adynamic ileus or gastric distention after abdominal surgery.

PATIENT TEACHING

- Advise patient to use calibrated container or oral syringe to measure oral solution.
- Instruct patient to place ondansetron disintegrating tablet on his tongue immediately after opening package and to let it dissolve on his tongue before swallowing.
- Advise patient to immediately report signs of hypersensitivity, such as rash.
- Reassure patient with transient blindness that it will resolve within a few minutes to 48 hours.

orlistat

Alli, Xenical

Class and Category

Chemical class: Lipase inhibitor

Therapeutic class: Antiobesity

Pregnancy category: B

Indications and Dosages

➤ *To promote weight loss in patients with body mass index above 30 kg (66 lb)/m² (27 kg [59.4 lb]/m² in those with diabetes mellitus, hyperlipidemia, or hypertension) and to reduce the risk of weight regain*

GELCAPS

Adults. 120 mg t.i.d. with fat-containing meals.

Contraindications

Cholestasis, chronic malabsorption syndrome, hypersensitivity to orlistat or its components

Interactions

DRUGS

cyclosporine: Altered cyclosporine absorption

fat-soluble vitamins: Decreased vitamin absorption, especially vitamin E and beta-carotene

levothyroxine: Possibly decreased levothyroxine effectiveness, resulting in hypothyroidism

pravastatin: Potentiated lipid-lowering effect

Adverse Reactions

CNS: Anxiety, depression, dizziness, fatigue,

Mechanism of Action

In the GI tract, orlistat binds with and inactivates gastric and pancreatic enzymes known as lipases, as shown. Normally, lipase enzymes convert ingested triglycerides into absorbable free fatty acids and monoglycerides. By inactivat-

ing lipase, orlistat allows undigested triglycerides to pass through the GI tract and exit the body in feces. Blocking the absorption of some of these fats lowers the number of calories received from food, which promotes weight loss.

headache, sleep disturbance

CV: Pedal edema

EENT: Gingival or tooth disorder, otitis

GI: Abdominal discomfort or pain, cholelithiasis, diarrhea (infectious), elevated liver enzyme levels, fatty or oily stool, fecal incontinence or urgency, flatulence with discharge, hepatitis, increased frequency of bowel movements, nausea, pancreatitis, rectal pain, vomiting

GU: Menstrual irregularities, UTI, vaginitis

MS: Arthralgia, arthritis, back pain, leg pain, myalgia, tendinitis

RESP: Respiratory tract infection

SKIN: Dry skin, pruritus, rash, urticaria

Other: Anaphylaxis, angioedema, flulike symptoms

Nursing Considerations

- Give orlistat with or up to 1 hour after meals that contain fat.
- Give levothyroxine and orlistat at least 4 hours apart because orlistat may decrease levothyroxine effectiveness, resulting in hypothyroidism.
- Consult prescriber if you think patient has an eating disorder, such as anorexia nervosa or bulimia.

PATIENT TEACHING

- Instruct patient to take orlistat with or shortly after meals that contain fat.

- Advise patient to take a multivitamin that contains fat-soluble vitamins and beta-carotene at least 2 hours before or after orlistat, if indicated.
- If patient takes levothyroxine, tell him to separate it from orlistat by at least 4 hours.
- Explain orlistat's adverse GI effects and that reducing dietary fat may decrease them. Instruct him to notify prescriber if they become too unpleasant.
- Help patient plan a reduced-fat diet (less than 30% of daily calories) and an exercise program to promote weight loss.
- Advise patient to weigh himself daily, at the same time and wearing similar clothes, to check his progress in losing weight.

orphenadrine citrate

Aniflex, Banflex, Flexoject, Miolin, Mio-Rel, Myotrol, Norflex, Orfro, Orphenate

orphenadrine hydrochloride

Disipal (CAN)

Class and Category

Chemical class: Tertiary amine

Therapeutic class: Skeletal muscle relaxant

Pregnancy category: C

Indications and Dosages

↗ *To relieve muscle spasms in painful musculoskeletal conditions*

E.R. TABLETS (ORPHENADRINE CITRATE)

Adults and adolescents. 100 mg b.i.d. in the morning and evening.

TABLETS (ORPHENADRINE HYDROCHLORIDE)

Adults and adolescents. 50 mg t.i.d.

Maximum: 250 mg daily.

I.V. OR I.M. INJECTION (ORPHENADRINE CITRATE)

Adults and adolescents. 60 mg every 12 hr, p.r.n.

DOSAGE ADJUSTMENT Dosage reduced to 25 to 50 mg t.i.d. or q.i.d. if patient also receives aspirin and caffeine.

Route	Onset	Peak	Duration
P.O.	In 1 hr	Unknown	4–6 hr*
I.V.	Immediate	Unknown	4–6 hr
I.M.	30 min	Unknown	4–6 hr

Mechanism of Action

May reduce muscle spasms by acting on cerebral motor centers or medulla. Post-ganglionic anticholinergic effects and some antihistaminic and local anesthetic action contribute to skeletal muscle relaxation.

Contraindications

Angle-closure glaucoma; hypersensitivity to orphenadrine or its components; myasthenia gravis; obstruction of bladder neck, duodenum, or pylorus; prostatic hypertrophy; stenosing peptic ulcers

Interactions

DRUGS

amantadine, amitriptyline, amoxapine, anti-muscarinics, atropine, bupropion, carbinoxamine, chlorpromazine, clemastine, clomipramine, clozapine, cyclobenzaprine, diphenhydramine, disopyramide, doxepin, imipramine, maprotiline, mesoridazine, methdilazine, nortriptyline, phenothiazines, procainamide, promazine, promethazine, propriptyline, thioridazine, trifluorpromazine, trimепrazine, trimipramine: Possibly additive anticholinergic effects

* 12 hr for extended-release.

CNS depressants: Increased CNS depression
haloperidol: Increased schizophrenic symptoms, possibly tardive dyskinesia
propoxyphene: Increased risk of anxiety, confusion, and tremor

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Agitation, confusion, dizziness, drowsiness, light-headedness, syncope, tremor

CV: Palpitations, tachycardia

EENT: Blurred vision, dry eyes and mouth, increased contact lens awareness

GI: Abdominal distention, constipation, nausea, vomiting

GU: Urine retention

Nursing Considerations

- Be aware that orphenadrine shouldn't be given to patients with tachycardia or cardiac insufficiency.
- Give I.V. form over 5 minutes with patient in supine position. Have patient stay in this position for 5 to 10 minutes to minimize adverse reactions. Then help him to sitting position.
- Be aware that drug can aggravate myasthenia gravis and cause tachycardia.
- Anticipate that drug's anticholinergic effects may cause blurred vision, dry eyes, and increased contact lens awareness.

PATIENT TEACHING

- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Explain that dry mouth may occur, and suggest increased fluid intake, ice chips, and sugarless candy or gum.
- Suggest that patient (especially one who wears contact lenses) use artificial tears to avoid discomfort from dry eyes.

oxacillin sodium

Bactocill, Prostaphlin

Class and Category

Chemical class: Penicillin

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ *To treat bacteremia, bone and joint*

infections (such as osteomyelitis and infectious arthritis), CNS infections (such as ventriculitis and meningitis), endocarditis, septicemia, skin and soft-tissue infections, upper and lower respiratory tract infections, and UTI caused by penicillinase-producing strains of Staphylococcus or other susceptible organisms

CAPSULES, ORAL SOLUTION

Adults and children weighing 40 kg (88 lb) or more. 500 to 1,000 mg every 4 to 6 hr.

Maximum: 6 g daily.

Children weighing less than 40 kg. 50 to 100 mg/kg daily in divided doses every 4 to 6 hr.

➤ *To treat mild to moderate infections caused by penicillinase-producing strains of Staphylococcus or other susceptible organisms*

I.V. INFUSION, I.M. INJECTION

Adults and children weighing 40 kg or more. 250 to 500 mg every 4 to 6 hr.

Infants and children weighing less than 40 kg. 50 mg/kg daily in divided doses every 4 to 6 hr.

Neonates over age 7 days weighing more than 2,000 g. 25 to 50 mg/kg every 6 hr.

Neonates over age 7 days weighing less than 2,000 g. 25 to 50 mg/kg every 8 hr.

Neonates age 7 days and under weighing more than 2,000 g. 25 to 50 mg/kg every 8 hr.

Neonates age 7 days and under weighing 2,000 g or less. 25 to 50 mg/kg every 12 hr.

➤ *To treat severe infections caused by penicillinase-producing strains of Staphylococcus or other susceptible organisms*

I.V. INFUSION, I.M. INJECTION

Adults and children weighing 40 kg or more. 1,000 mg every 4 to 6 hr.

Infants and children weighing less than 40 kg. 100 to 200 mg/kg daily in divided doses every 4 to 6 hr.

Neonates over age 7 days weighing more than 2,000 g. 25 to 50 mg/kg every 6 hr.

Neonates over age 7 days weighing less than 2,000 g. 25 to 50 mg/kg every 8 hr.

Neonates age 7 days and under weighing more than 2,000 g. 25 to 50 mg/kg every 8 hr.

Neonates age 7 days and under weighing 2,000 g or less. 25 to 50 mg/kg every 12 hr.

➤ *To treat endocarditis caused by methi-*

illin-susceptible Staphylococcus aureus in patients without a prosthetic valve

I.V. INFUSION

Adults. 2 g every 4 hr for 4 to 6 wk.

➤ *To treat endocarditis caused by methicillin-susceptible S. aureus in patients with a prosthetic valve*

I.V. INFUSION

Adults. 2 g every 4 hr for at least 6 wk.

Mechanism of Action

Inhibits bacterial cell wall synthesis. In susceptible bacteria, the rigid, cross-linked cell wall is assembled in several steps. Oxacillin affects final stage of cross-linking process by binding with and inactivating penicillin-binding proteins (enzymes responsible for linking the cell wall strands). This action causes bacterial cell lysis and death.

Incompatibilities

Don't give oxacillin at same time or in same admixture as aminoglycosides because they are chemically and physically incompatible and will inactivate each other.

Contraindications

Hypersensitivity to oxacillin, penicillins, or their components

Interactions

DRUGS

aminoglycosides: Inactivation of both drugs
chloramphenicol, erythromycins, sulfonamides, tetracyclines: Decreased therapeutic effects of oxacillin

oral contraceptives: Decreased contraceptive efficacy

probenecid: Increased blood oxacillin level

FOODS

all foods: Altered absorption of oxacillin

Adverse Reactions

CNS: Anxiety, depression, fatigue, hallucinations, headache, seizures

EENT: Oral candidiasis

GI: Diarrhea, nausea, pseudomembranous colitis, vomiting

GU: Interstitial nephritis, vaginal candidiasis

HEME: Agranulocytosis, anemia, granulocytopenia, neutropenia

SKIN: Exfoliative dermatitis, pruritus, rash, urticaria

Other: Anaphylaxis

Nursing Considerations

- Administer oxacillin at least 1 hour before

other antibiotics.

- Give oral forms on an empty stomach, preferably 1 hour before or 2 hours after a meal, to prevent impaired absorption.
- Before reconstitution, tap bottle several times to loosen powder. For I.M. injection, reconstitute with sterile water for injection, half-normal (0.45) saline solution, or normal saline solution. Shake until solution is clear.
- For I.V. infusion, reconstitute only with normal saline solution or D₅W.
- When giving drug to patient at risk for hypertension or fluid overload, be aware that each gram of oxacillin contains 4.02 mEq of sodium.
- Monitor patient closely for diarrhea, which may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold oxacillin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

PATIENT TEACHING

- Advise patient to take oxacillin on an empty stomach.
- Instruct patient to notify prescriber immediately should a rash develop.
- Advise female patient who uses an oral contraceptive to use an additional contraceptive method during oxacillin therapy.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.

oxandrolone

Oxandrin

Class, Category, and Schedule

Chemical class: Testosterone derivative

Therapeutic class: Appetite stimulant

Pregnancy category: X

Controlled substance schedule: III

Indications and Dosages

➤ *To promote weight gain after chronic infection, extensive surgery, failure to maintain weight despite no evidence of pathology, or severe trauma; to offset*

protein catabolism from prolonged use of corticosteroids

TABLETS

Adults. 2.5 to 20 mg in divided doses given b.i.d. to q.i.d. for 2 to 4 wk; intermittent therapy repeated as prescribed. *Maximum:* 20 mg daily.

Children. 0.1 mg/kg daily; intermittent therapy repeated as prescribed.

DOSAGE ADJUSTMENT Dosage shouldn't exceed 5 mg b.i.d. for elderly patients.

Mechanism of Action

Promotes tissue-building processes and reverses catabolic or tissue-depleting processes by promoting protein anabolism.

Contraindications

Breast cancer (males); breast cancer with hypercalcemia (females); hypersensitivity to oxandrolone, anabolic steroids, or their components; nephrosis; pregnancy; prostate cancer

Interactions

DRUGS

corticosteroids: Increased risk of edema and severe acne

hepatotoxic drugs: Increased risk of hepatotoxicity

insulin, oral antidiabetic drugs: Possibly hypoglycemia

NSAIDs, oral anticoagulants, salicylates:

Increased anticoagulant effects

sodium-containing drugs: Increased risk of edema

somatrem, somatropin: Possibly accelerated epiphyseal closure

warfarin: Increased warfarin half-life and risk of bleeding

FOODS

high-sodium foods: Increased risk of edema

Adverse Reactions

CNS: Depression, excitement, insomnia

CV: Decreased serum HDL level, edema, hyperlipidemia, hypertension

ENDO: Feminization in postpubertal males (epididymitis, gynecomastia, impotence, oligospermia, priapism, testicular atrophy); glucose intolerance; virilism in females

(acne, clitoral enlargement, decreased breast size, deepened voice, diaphoresis, emotional lability, flushing, hirsutism, hoarseness, libido changes, male-pattern baldness, menstrual irregularities, nervousness, oily skin

or hair, vaginal bleeding, vaginitis, weight gain), virilism in prepubertal males (acne, decreased ejaculatory volume, penis enlargement, prepubertal closure of epiphyseal plates, unnatural growth of body and facial hair)

GI: Diarrhea, elevated liver function test results, hepatocellular carcinoma, nausea, vomiting

GU: Benign prostatic hyperplasia, prostate cancer, urinary frequency, urine retention (elderly men)

HEME: Iron deficiency anemia, leukemia, prolonged bleeding time

SKIN: Jaundice

Other: Fluid retention, hypercalcemia (females), physical and psychological dependence, sodium retention

Nursing Considerations

- Use oxandrolone cautiously in patients with heart disease because drug has hypercholesterolemic effects.
- Provide adequate calories and protein, as ordered, to maintain a positive nitrogen balance during oxandrolone therapy.
- Anticipate an increased risk of fluid and sodium retention in patients with cardiac, hepatic, or renal dysfunction.
- Weigh patient daily to detect fluid retention. If patient has fluid retention, expect a sodium-restricted diet or diuretics.

WARNING Be aware that oxandrolone may suppress spermatogenesis in males and cause permanent virilization in females.

- Monitor blood glucose level frequently in patient with diabetes mellitus.
- If patient takes an oral anticoagulant, check INR or PT as ordered.

PATIENT TEACHING

- Advise patient to consume a diet high in protein and calories to achieve maximum therapeutic effect of oxandrolone.
- Urge patient to weigh himself daily during therapy and to report swelling or unexplained weight gain at once.
- Explain that drug may alter libido.
- Inform woman that drug may cause permanent physical changes, such as clitoral enlargement, deepened voice, and hair growth.
- Advise female patient of childbearing age that she must use contraception during oxandrolone therapy and should notify

prescriber immediately about suspected or known pregnancy.

- Instruct diabetic patient to monitor blood glucose level frequently.
- If patient takes warfarin, advise bleeding precautions (such as an electric shaver and soft toothbrush). Tell patient to notify prescriber immediately if bleeding occurs.

oxaprozin

Daypro

Class and Category

Chemical class: Propionic acid derivative

Therapeutic class: Anti-inflammatory, anti-rheumatic

Pregnancy category: C (first trimester), Not rated (later trimesters)

Indications and Dosages

➤ To treat rheumatoid arthritis

TABLETS

Adults. 1,200 mg daily. Dosage adjusted based on response. *Maximum:* 1,800 mg daily or 26 mg/kg daily (whichever is less) in divided doses b.i.d. or t.i.d.

➤ To treat osteoarthritis

TABLETS

Adults. 600 to 1,200 mg daily. *Maximum:* 1,800 mg daily or 26 mg/kg (whichever is less) in divided doses b.i.d. or t.i.d.

DOSAGE ADJUSTMENT Initial loading dose of 1,200 to 1,800 mg possibly given to speed onset of action. Initial dose limited to 600 mg daily for patients with renal impairment.

Route	Onset	Peak	Duration
P.O.	In 7 days	Unknown	Unknown

Mechanism of Action

Blocks cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate the inflammatory response and cause local vasodilation, swelling, and pain. By blocking cyclooxygenase and prostaglandins, the NSAID oxaprozin relieves pain.

Contraindications

Angioedema, asthma, bronchospasm, nasal polyps, rhinitis, or urticaria induced by aspirin, iodides, or other NSAIDs

Interactions

DRUGS

ACE inhibitors, antihypertensives: Decreased antihypertensive response, possibly impaired renal function

acetaminophen: Increased risk of adverse renal effects with long-term use of both drugs

anticoagulants, thrombolytics: Prolonged PT, increased risk of bleeding

beta blockers: Decreased antihypertensive effect

bone marrow depressants: Increased risk of leukopenia and thrombocytopenia

cefamandole, cefoperazone, cefotetan, plicamycin, valproic acid: Increased risk of hypoprothrombinemia and bleeding

cimetidine: Decreased oxaprozin clearance

corticosteroids, potassium supplements: Increased risk of adverse GI effects

digoxin: Increased blood digoxin level and risk of digitalis toxicity

diuretics: Possibly decreased diuretic effect

insulin, oral antidiabetic drugs: Increased effects of these drugs; risk of hypoglycemia

lithium: Increased blood lithium level

methotrexate: Increased blood methotrexate level and risk of methotrexate toxicity

other NSAIDs, salicylates: Increased GI irritability and bleeding

probenecid: Increased risk of oxaprozin toxicity

ACTIVITIES

alcohol use, smoking: Increased risk of adverse GI effects

Adverse Reactions

CNS: Aseptic meningitis, cerebral hemorrhage, confusion, dizziness, drowsiness, fatigue, headache, insomnia, ischemic stroke, nervousness, sedation, transient ischemic attacks, vertigo, weakness

CV: Deep vein thrombosis, hypertension, hypotension, MI, peripheral edema

EENT: Tinnitus

ENDO: Hypoglycemia

GI: Abdominal pain, constipation, diarrhea, dyspepsia, elevated liver function test results, GI bleeding or ulceration, hepatitis, jaundice, liver failure, nausea, perforation of stomach or intestine, vomiting

GU: Acute renal failure, dysuria, interstitial nephritis, urinary frequency

HEME: Agranulocytosis, anemia, aplastic anemia, leukopenia, pancytopenia, throm-

bocytopenia

SKIN: Alopecia, erythema multiforme, exfoliative dermatitis, maculopapular rash, photosensitivity, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, angioedema

Nursing Considerations

- Use oxaprozin with extreme caution in patients with a history of ulcer disease or GI bleeding because NSAIDs such as oxaprozin increase risk of GI bleeding and ulceration. Expect to use oxaprozin for the shortest time possible in these patients.
- Be aware that serious GI tract ulceration, bleeding, and perforation may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, withhold drug and notify prescriber at once.
- Use oxaprozin cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

WARNING Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

WARNING If patient has bone marrow suppression or is receiving antineoplastic drug therapy, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of oxaprozin may mask signs and symptoms, such as fever and pain.

- Especially if patient is elderly or taking oxaprozin long-term, watch for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver function test results because, in rare cases, elevated levels may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure.
- Monitor BUN and serum creatinine levels in patients with heart failure, impaired renal function, or hepatic dysfunction; those taking diuretics or ACE inhibitors; and elderly patients because drug may cause renal failure.
- Monitor CBC for decreased hemoglobin level and hematocrit because drug may

worsen anemia.

- Assess patient's skin routinely for rash or other signs of hypersensitivity reaction because oxaprozin and other NSAIDs may cause serious skin reactions without warning, even in patients with no history of NSAID hypersensitivity. Stop drug at first sign of reaction, and notify prescriber.

PATIENT TEACHING

- Instruct patient to take oxaprozin exactly as prescribed.
- Advise patient to take drug with a full glass of water and to stay upright for 15 to 30 minutes afterward to keep drug from lodging in esophagus and causing irritation.
- Urge patient to avoid alcohol as well as aspirin and other NSAIDs during oxaprozin therapy to avoid bleeding complications.
- Advise patient to avoid excessive sun exposure to reduce the risk of photosensitivity.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Inform patient that risk of bleeding may continue up to 2 weeks after stopping drug.
- Explain that oxaprozin may increase the risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, weakness, and slurring of speech.
- Inform patient that oxaprozin also may increase the risk of serious adverse GI reactions; stress need to seek immediate medical attention for such signs and symptoms as epigastric or abdominal pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions. Urge him to seek immediate medical attention for rash, blisters, itching, fever, or other indications of hypersensitivity.

oxazepam

Apo-Oxazepam (CAN), Novoxapam (CAN), Serax

Class, Category, and Schedule

Chemical class: Benzodiazepine

Therapeutic class: Antianxiety, sedative hypnotic

Pregnancy category: Not rated

Controlled substance schedule: IV

Indications and Dosages

↗ *To treat anxiety*

CAPSULES, TABLETS

Adults. 10 to 15 mg t.i.d. or q.i.d. for mild to moderate anxiety; up to 30 mg t.i.d. or q.i.d. for severe anxiety.

↗ *To help manage acute alcohol withdrawal symptoms*

CAPSULES, TABLETS

Adults. 15 to 30 mg t.i.d. or q.i.d.

DOSAGE ADJUSTMENT For elderly or debilitated patients, initial dose of 10 mg t.i.d. increased cautiously to 15 mg t.i.d. or q.i.d.

Mechanism of Action

May potentiate the effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptors in limbic and cortical areas of the CNS. GABA inhibits excitatory stimulation, which helps control emotional behavior. The limbic system contains highly dense areas of benzodiazepine receptors, which may explain oxazepam's antianxiety effects.

Contraindications

Acute angle-closure glaucoma; concurrent use of itraconazole or ketoconazole; hypersensitivity to oxazepam, benzodiazepines, or their components; psychoses

Interactions

DRUGS

cimetidine, oral contraceptives: Impaired metabolism and elimination of oxazepam

clozapine: Increased risk of respiratory depression and arrest

CNS depressants: Increased risk of apnea and CNS depression

levodopa: Decreased therapeutic effects of levodopa

probenecid: Increased therapeutic effects of oxazepam and risk of oversedation

ACTIVITIES

alcohol use: Increased risk of apnea and CNS depression

Adverse Reactions

CNS: Anxiety (in daytime), ataxia, confusion, depression, dizziness, drowsiness,

fatigue, headache, insomnia, nightmares, sleep disturbance, slurred speech, syncope, talkativeness, tremor, vertigo

GI: Nausea

Other: Drug tolerance, physical and psychological dependence, withdrawal symptoms

Nursing Considerations

WARNING Oxazepam may cause physical and psychological dependence.

- Be aware that drug shouldn't be stopped abruptly after prolonged use; doing so may cause seizures or withdrawal symptoms, such as insomnia, irritability, and nervousness.
- Be aware that withdrawal symptoms can occur when therapy lasts only 1 or 2 weeks.

WARNING Monitor respiratory status in patients with pulmonary disease (such as severe COPD), respiratory depression, or sleep apnea; drug may worsen ventilatory failure.

- Expect an increased risk of falls among elderly patients from impaired cognition and motor function. Take safety precautions.
- Be aware that drug may worsen acute intermittent porphyria, myasthenia gravis, and severe renal impairment.
- Expect patient with late-stage Parkinson's disease to experience decreased cognition or coordination and, possibly, increased psychosis.

PATIENT TEACHING

- Instruct patient to take oxazepam exactly as prescribed and not to stop taking it without consulting prescriber.
- Caution patient about possible drowsiness and reduced coordination.
- Urge patient to avoid alcohol, which increases oxazepam's sedative effects.

oxcarbazepine

Trileptal

Class and Category

Chemical class: Tricyclic iminostilbene derivative

Therapeutic class: Anticonvulsant

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat partial seizures*

ORAL SUSPENSION, TABLETS

Adults and adolescents over age 16. *Initial:* 300 mg b.i.d. Dosage increased by 600 mg/day every wk. *Usual:* 1,200 mg daily. *Maximum:* 2,400 mg daily.

Children ages 4 to 16. *Initial:* 4 to 5 mg/kg b.i.d. to maximum initial dose of 600 mg daily. *Usual:* 900 mg daily for children weighing 20 to 29 kg (44 to 64 lb); 1,200 mg daily for those weighing 29.1 to 39 kg (65 to 86 lb); 1,800 mg daily for those weighing more than 39 kg. *Maximum:* 1,800 mg daily.

DOSAGE ADJUSTMENT For patients with creatinine clearance less than 30 ml/min/1.73 m², usual initial dosage reduced by 50%.

↗ *As monotherapy to treat partial seizures*

ORAL SUSPENSION, TABLETS

Adults and adolescents over age 16. *Initial:* 300 mg b.i.d. Dosage increased by 300 mg/day every 3 days as needed. *Usual:* 1,200 mg daily. *Maximum:* 2,400 mg daily.

Children ages 4 to 16. *Initial:* 4 to 5 mg/kg b.i.d., increased by 5 mg/kg daily every third day to maximum maintenance dosage, as needed. *Maximum:* 900 mg daily for children weighing 20 to 24.9 kg (44 to 55 lb); 1,200 mg daily for those weighing 25 to 34.9 kg (55 to 77 lb); 1,500 mg daily for those weighing 35 to 49.9 kg (77 to 110 lb); 1,800 mg daily for those weighing 50 to 59.9 kg (110 to 132 lb); 2,100 mg daily for those weighing 60 to 70 kg (132 to 154 lb).

↗ *To convert to monotherapy in treating partial seizures*

ORAL SUSPENSION, TABLETS

Adults and adolescents over age 16. *Initial:* 300 mg b.i.d. Dosage increased by 600 mg daily every wk over 2 to 4 wk, as needed, while dosage of other anticonvulsant is reduced. *Usual:* 1,200 mg daily. *Maximum:* 2,400 mg daily.

Children ages 4 to 16. *Initial:* 4 to 5 mg/kg b.i.d., increased by 10 mg/kg daily weekly as needed to maximum maintenance dosage while dosage of other anticonvulsant is reduced over 3 to 6 wk. *Maximum:* 900 mg daily for children weighing 20 to 24.9 kg (44 to 55 lb); 1,200 mg daily for those weighing 25 to 34.9 kg (55 to 77 lb);

1,500 mg daily for those weighing 35 to 49.9 kg (77 to 110 lb); 1,800 mg daily for those weighing 50 to 59.9 kg (110 to 132 lb); 2,100 mg daily for those weighing 60 to 70 kg (132 to 154 lb).

Mechanism of Action

May prevent or halt seizures by closing or blocking sodium channels in neuronal cell membrane. By preventing sodium from entering the cell, oxcarbazepine may slow nerve impulse transmission, thus decreasing the rate at which neurons fire.

Contraindications

Hypersensitivity to carbamazepine, oxcarbazepine, or their components

Interactions

DRUGS

carbamazepine, phenobarbital, phenytoin, valproic acid: Decreased blood oxcarbazepine level, possibly increased blood levels of phenobarbital and phenytoin
felodipine, verapamil: Decreased blood levels of these drugs

oral contraceptives: Decreased effectiveness

ACTIVITIES

alcohol use: Possibly additive CNS depressant effects

Adverse Reactions

CNS: Abnormal gait, ataxia, dizziness, fatigue, fever, headache, somnolence, suicidal ideation, tremor

EENT: Abnormal vision, diplopia, nystagmus, rhinitis

GI: Abdominal pain, indigestion, nausea, vomiting

SKIN: Rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, hyponatremia

Nursing Considerations

- Patient with allergic reaction to carbamazepine may have hypersensitivity to oxcarbazepine.
- Monitor serum sodium level for signs of hyponatremia, especially during first 3 months.
- Monitor therapeutic oxcarbazepine levels during initiation and titration, and expect to adjust dosage accordingly.
- Implement seizure precautions as needed.
- Monitor patient's skin closely. If a reaction develops, notify prescriber at once because

skin reactions caused by oxcarbazepine may be serious or life-threatening.

WARNING Watch closely for evidence of multi-organ hypersensitivity, such as fever, rash, organ dysfunction, lymphadenopathy, hepatitis, liver function abnormalities, hematologic abnormalities, pruritus, nephritis, oliguria, hepato-renal syndrome, arthralgia, and asthenia. If suspected, notify prescriber and expect to stop drug. Provide supportive care, as prescribed.

- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

PATIENT TEACHING

- Teach patient to shake suspension well and prepare dose immediately afterward. Tell him to then withdraw prescribed amount using supplied oral dosing syringe. Instruct him to mix dose in a small glass of water just before taking it, or tell him that he can swallow drug directly from syringe. Instruct him to close bottle and rinse syringe with warm water and let it dry thoroughly.
- Inform patient that he may experience dizziness, double vision, and unsteady gait.
- Instruct patient not to drink alcohol during oxcarbazepine therapy.
- Alert patient to possibility of hypersensitivity or serious skin reactions and need to report them to prescriber.
- Warn patient to notify prescriber immediately if he develops a fever; rash; swelling of face, eyes, lips, tongue; difficulty swallowing or breathing; or other evidence of hypersensitivity because drug may need to be stopped and emergency medical care given.
- Alert woman of childbearing age that oxcarbazepine may render hormonal contraceptives ineffective. Urge patient to use an additional or a different contraceptive during oxcarbazepine therapy.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report concerns to prescriber at once.
- Urge female patient who becomes pregnant while taking oxcarbazepine to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting

information about the safety of antiepileptic drugs during pregnancy.

oxtriphylline

Apo-Oxtriphylline (CAN), Choledyl, Choledyl SA

Class and Category

Chemical class: Xanthine derivative

Therapeutic class: Bronchodilator

Pregnancy category: C

Indications and Dosages

➤ *To treat acute asthma, bronchospasm due to chronic bronchitis or COPD*

DELAYED-RELEASE TABLETS

Adults and children age 6 and over. 300 mg daily for 3 days; then increased to 400 mg daily for 3 days. *Maintenance:* 600 mg daily in divided doses every 6 to 8 hr.

E.R. TABLETS

Adults and children age 6 and over. 300 mg daily for 3 days; then increased to 400 mg daily for 3 days. *Maintenance:* 600 mg daily in divided doses every 12 hr.

Mechanism of Action

Inhibits phosphodiesterase enzymes, causing bronchodilation. Normally, these enzymes inactivate cAMP and cGMP, which are responsible for bronchial smooth-muscle relaxation. Other mechanisms of action may include calcium translocation, prostaglandin antagonism, catecholamine stimulation, inhibition of cGMP metabolism, and adenosine receptor antagonism.

Contraindications

Hypersensitivity to oxtriphylline, xanthines, or their components; peptic ulcer; seizure disorder unless controlled by an anticonvulsant

Interactions

DRUGS

activated charcoal, aminoglutethimide, barbiturates, ketoconazole, rifampin, sulfipyrazone, sympathomimetics: Decreased blood theophylline level
allopurinol, beta blockers (nonselective), calcium channel blockers, cimetidine, corticosteroids, disulfiram, ephedrine, influenza virus vaccine, interferon, macrolides, mexiletine, oral contraceptives, quinolones, thiaben-

dazole: Increased blood theophylline level
benzodiazepines, propofol: Possibly antagonized sedative effects of these drugs
carbamazepine, isoniazid, loop diuretics: Possibly altered blood theophylline level
halothane anesthetics: Increased risk of cardiotoxicity
hydantoins: Possibly decreased blood hydantoin level
ketamine: Increased risk of seizures
lithium: Decreased blood lithium level
neuromuscular blockers: Possibly reversal of neuromuscular blockade
tetracyclines: Possibly increased adverse effects of theophylline

FOODS

all foods: Altered bioavailability and absorption of E.R. oxtriphylline
charcoal broiled beef; low-carbohydrate, high-protein diet: Increased theophylline elimination
high-carbohydrate, low-protein diet: Decreased elimination and prolonged half-life of theophylline

ACTIVITIES

alcohol use: Increased CNS effects, especially with elixir
smoking (1 or more packs daily): Decreased effects of oxtriphylline

Adverse Reactions

CNS: Anxiety, dizziness, headache, insomnia, restlessness, seizures

CV: Hypotension, palpitations, sinus tachycardia

EENT: Unpleasant taste

GI: Anorexia, diarrhea, nausea, vomiting

RESP: Tachypnea

SKIN: Alopecia, flushing, rash

Nursing Considerations

- Be aware that oxtriphylline contains 64% anhydrous theophylline, so dosage is based on equivalent of 5 to 6 mg of anhydrous theophylline/kg.
- Be aware that food delays absorption of delayed-release and E.R. forms and that large volumes of fluid may increase absorption.
- Know that delayed-release and E.R. preparations vary in their absorption rate.
- Monitor blood theophylline level because toxicity may develop at a level only slightly above therapeutic.

PATIENT TEACHING

- If patient complains of GI discomfort, suggest taking drug with or just after meals.
- Urge patient to stop smoking and to notify prescriber about changes in smoking habits. Also instruct him to avoid alcohol during oxtriphylline therapy.
- Encourage patient to keep follow-up appointments for laboratory studies.

oxybutynin chloride

Ditropan, Ditropan XL, Gelnique 10%

Class and Category

Chemical class: Tertiary amine

Therapeutic class: Antispasmodic

Pregnancy category: B

Indications and Dosages

↗ *To treat overactive bladder, including neurogenic bladder, with urinary frequency, urgency, or incontinence from involuntary contraction of detrusor muscle*

E.R. TABLETS

Adults. *Initial:* 5 mg daily, adjusted by 5 mg/wk, as prescribed. *Maximum:* 30 mg daily.

SYRUP, TABLETS

Adults. 5 mg b.i.d. or t.i.d. *Maximum:* 5 mg q.i.d. or 20 mg daily.

Children age 5 and over. 5 mg b.i.d.

Maximum: 15 mg t.i.d.

TRANSDERMAL SYSTEM

Adults. System supplying 3.9 mg daily, applied twice weekly.

TOPICAL GEL

Adults. 1 sachet (containing 100 mg/g oxybutynin chloride gel) applied once daily to dry, intact skin on the abdomen, upper arms, shoulders, or thighs.

DOSAGE ADJUSTMENT For elderly patients, possibly 2.5 mg b.i.d. initially, increased to maximum of 5 mg t.i.d., as prescribed.

Route	Onset	Peak	Duration
P.O.	30–60 min	3–6 hr	6–10 hr
Trans-dermal	Unknown	24–48 hr	96 hr

Mechanism of Action

Exerts antimuscarinic (atropine-like) and potent direct antispasmodic (papaverine-

like) actions on smooth muscle in the bladder and decreases detrusor muscle contractions. The result is increased bladder capacity and a decreased urge to void.

Contraindications

Acute hemorrhage, angle-closure glaucoma, gastric retention (gel form), GI obstruction, hypersensitivity to oxybutynin or its components, ileus, intestinal atony in elderly or debilitated patients, myasthenia gravis, obstructive uropathy, toxic megacolon with ulcerative colitis, urine retention (gel form)

Interactions

DRUGS

amantadine, amitriptyline, amoxapine, antimuscarinics, brompheniramine, bupropion, carbinoxamine, chlorpheniramine, chlorpromazine, clemastine, clomipramine, clozapine, cyclobenzaprine, dimenhydrinate, diphenhydramine, disopyramide, doxepin, doxylamine, imipramine, maprotiline, mesoridazine, methdilazine, nortriptyline, procainamide, promazine, promethazine, protriptyline, thioridazine, triflupromazine, trimeprazine, trimipramine: Increased anticholinergic effects

CNS depressants: Increased sedation

ketoconazole: Possibly altered total absorption rate and blood level of ketoconazole

opioid agonists: Increased depressive effects on GI motility and bladder function

parasympathomimetics: Decreased antimuscarinic action of oxybutynin

ACTIVITIES

alcohol use: Increased sedation

Adverse Reactions

CNS: Agitation, asthenia, confusion, dizziness, drowsiness, fatigue, hallucinations, headache, insomnia, memory impairment, nervousness, psychosis, restlessness, seizures, somnolence

CV: Arrhythmias, hypertension, hypotension, palpitations, peripheral edema, QT-interval prolongation, tachycardia, vasodilation

EENT: Blurred vision; cycloplegia; dry eyes, mouth, nose, and throat; keratoconjunctivitis sicca; eye irritation; mydriasis; nasopharyngitis; rhinitis; sinusitis

ENDO: Hyperglycemia, suppression of lactation

GI: Abdominal pain, constipation,

decreased GI motility, diarrhea, dysphagia, esophagitis, flatulence, gastroesophageal reflux, indigestion, nausea, vomiting

GU: Cystitis, dysuria, impotence, urinary hesitancy, urine retention, UTI

MS: Arthralgia, arthritis, back pain

RESP: Asthma, bronchitis, cough, upper respiratory tract infection

SKIN: Decreased sweating, dry skin, flushing, pruritus, rash, urticaria

Other: Application site reactions (anesthesia, dermatitis, erythema, irritation, papules, pruritus), flulike symptoms, fungal infections, heatstroke

Nursing Considerations

- Use oxybutynin cautiously in patients with diarrhea because it may signal incomplete GI obstruction, especially in patients with colostomy or ileostomy. Also use cautiously in patients with dementia because drug may aggravate symptoms.
- Use cautiously in patients with myasthenia gravis or GI disorders because drug may adversely affect these conditions.
- Assess urinary symptoms before and after treatment.
- Make sure patient swallows E.R. tablets whole and doesn't crush, chew, or divide them. Expect to see portions of drug in stool.
- Apply transdermal system to dry, intact skin of abdomen, hip, or buttock; avoid using same site for at least 7 days by rotating sites.
- Apply gel form to dry, intact skin on patient's abdomen, upper arms, shoulders, or thighs. Rotate application sites.

WARNING Watch for adverse cardiovascular reactions in patients with arrhythmias, coronary artery disease, heart failure, or hypertension because drug's antimuscarinic effects may increase their risk.

- Decreased GI motility can cause adynamic ileus; assess for abdominal pain and ileus.
- Be aware that drug may aggravate benign prostatic hyperplasia, gastroesophageal reflux disease, and hyperthyroidism.
- Monitor patient for anticholinergic CNS effects, such as hallucinations, agitation, confusion and somnolence, especially in the first few months of therapy or when dosage is increased. If such effects occur, notify prescriber and expect dosage to be reduced or drug discontinued.

PATIENT TEACHING

- Instruct patient to take oxybutynin on an empty stomach. If adverse GI reactions develop, suggest taking drug with food or milk.
- Advise patient to swallow tablets whole and not to chew, crush, or break them.
- Instruct patient how to apply transdermal system or gel. Tell her to apply to clean, dry skin, avoiding areas that have been recently shaved or have open sores or rashes. Remind patient to wash hands after handling product.
- Warn patient that gel is flammable and that she should avoid open fire or smoking until gel has dried. Also tell patient to avoid bathing, swimming, showering, exercising, or immersing application site in water for 1 hour after application and to cover site with clothing once gel has dried.
- Warn of possible decreased alertness, and advise patient against performing hazardous activities until drug's CNS effects are known.
- Caution patient to avoid strenuous exercise and excessive sun exposure because of increased risk of heatstroke.
- Urge patient to avoid alcohol during therapy.

oxycodone hydrochloride

OxyContin, Roxicodone, Supeudol (CAN)

Class, Category, and Schedule

Chemical class: Phenanthrene derivative

Therapeutic class: Analgesic

Pregnancy category: Not rated

Controlled substance schedule: II

Indications and Dosages

↗ *To relieve moderate to severe pain*

ORAL SOLUTION

Adults. 5 mg every 3 to 6 hr, p.r.n., and increased as needed.

TABLETS

Adults. 5 mg every 3 to 6 hr or 10 mg every 6 to 8 hr, p.r.n.

↗ *To manage pain for more than a few days*

CONTROLLED-RELEASE TABLETS, E.R. TABLETS

Adults who haven't received opioids before. *Initial:* 10 to 20 mg every 12 hr, adjusted every 1 to 2 days, as prescribed, based on total amount of oxycodone needed daily to control pain.

Adults who currently receive an opioid agonist or fixed-ratio combination drugs (opioid agonist plus acetaminophen, aspirin, or NSAID). Half the 24-hr oxycodone dose every 12 hr, as prescribed. Be prepared to manage breakthrough pain with immediate-release tablets, p.r.n., and adjust every 1 to 2 days, as prescribed.

Adults who use fentanyl transdermal patch. 10 mg oxycodone for each 25 mcg/hr of fentanyl patch dosage every 12 hr, beginning 12 to 18 hr after removing patch.

DOSAGE ADJUSTMENT To provide supplemental analgesia for adults receiving controlled-release oxycodone, one-fourth to one-third the 12-hr controlled-release dose given as tablet every 3 to 6 hr, p.r.n.

Route	Onset	Peak	Duration
P.O.	10–15 min	1 hr	3–4 hr

Mechanism of Action

Alters perception of and emotional response to pain at spinal cord and higher levels of CNS by blocking release of inhibitory neurotransmitters, such as gamma-aminobutyric acid and acetylcholine.

Contraindications

Hypercapnia, hypersensitivity to oxycodone or its components, ileus, use within 14 days of MAO inhibitor therapy

Interactions**DRUGS**

anticholinergics: Possibly severe constipation and ileus

antidiarrheals: Possibly severe constipation and additive CNS depression

antihypertensives: Possibly exaggerated antihypertensive effects and risk of orthostatic hypotension

butorphanol, pentazocine: Possibly acute withdrawal symptoms in opioid-dependent patients, decreased analgesic effects
carbamazepine, phenytoin, primidone, rifampin: Possibly need for increased oxycodone dosage to achieve analgesia and prevent

withdrawal symptoms in opioid-dependent patients

cimetidine: Possibly apnea, confusion, disorientation, and seizures from respiratory depression and impaired CNS function

CNS depressants: Possibly increased CNS and respiratory depression and orthostatic hypotension

MAO inhibitors: Possibly fatal reactions, including cardiac arrest, coma, respiratory depression, seizures, and severe hypertension

nalbuphine, nalmefene, naloxone, naltrexone: Blocked oxycodone effects, withdrawal symptoms in opioid-dependent patients

ACTIVITIES

alcohol use: Additive CNS effects

Adverse Reactions

CNS: Abnormal dreams, anxiety, asthenia, chills, dizziness, drowsiness, euphoria, excitation, headache, insomnia, nervousness, sedation, seizures, somnolence, syncope, twitching

CV: Bradycardia, chest pain, hypotension, orthostatic hypotension, palpitations

EENT: Blurred vision, dry eyes or mouth, lens opacities, miosis

ENDO: Syndrome of inappropriate antidiuretic hormone secretion

GI: Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, elevated liver function test results, gastritis, hiccups, nausea, vomiting

GU: Amenorrhea, decreased libido, erectile dysfunction, oliguria, urinary hesitancy, urine retention

RESP: Dyspnea, respiratory depression

SKIN: Diaphoresis, pruritus, rash

Other: Anaphylaxis, drug tolerance, hyponatremia, physical and psychological dependence, withdrawal symptoms

Nursing Considerations

WARNING Be aware that oxycodone has a high potential for abuse.

WARNING Be aware that abuse of crushed controlled-release tablets poses a hazard of overdose and death. If you suspect abuse and determine that patient also is abusing alcohol or illicit substances, notify prescriber immediately because risk of overdose and death is increased. If you suspect parenteral abuse, be aware that tablet excipients, especially talc, may result in

local tissue necrosis, infection, pulmonary granulomas, endocarditis, and valvular heart injury.

- Assess baseline neurologic status before each dose in patient with head injury because oxycodone may obscure progression of his condition.
- Assess patient's pain level regularly, and give drug as prescribed before pain becomes severe.
- Be prepared to adjust dosage for patient who hasn't previously received opioids until he can tolerate drug's effects.
- Expect to give controlled-release tablets only to opioid-tolerant patients who need at least 160 mg daily.
- Assess patient for possible respiratory depression or paradoxical excitation during dosage titration.
- Assess patient for abdominal pain because oxycodone may mask underlying GI disorders.

PATIENT TEACHING

WARNING Strongly warn patient to swallow oxycodone tablets whole and not to break, chew, or crush them because taking broken, chewed, or crushed tablets leads to rapid release and absorption of a potentially fatal dose.

- Instruct patient not to take oxycodone more often than prescribed and not to stop abruptly after long-term use.
- Instruct patient to avoid alcohol and hazardous activities during therapy.
- Tell patient to notify prescriber about signs of possible toxicity or hypersensitivity, such as excessive light-headedness, extreme dizziness, itching, swelling, and trouble breathing.

oxymetholone

Anadrol-50, Anapolon-50 (CAN)

Class, Category, and Schedule

Chemical class: Testosterone derivative

Therapeutic class: Antianemic, antian-gioedema (hereditary)

Pregnancy category: X

Controlled substance schedule: III

Indications and Dosages

↗ To treat acquired and congenital aplastic

anemias, anemias caused by deficient RBC production, bone marrow failure anemias, hypoplastic anemias caused by myelotoxic drugs, and myelofibrosis; to prevent or treat hereditary angioedema

TABLETS

Adults and children. 1 to 2 mg/kg daily for 3 to 6 mo. *Maximum:* 5 mg/kg daily.

Mechanism of Action

Combats anemia by increasing production of erythropoietin, a precursor of RBCs. Oxymetholone also increases hemoglobin level and RBC volume.

Contraindications

Breast or prostate cancer in men, hypercalcemia in women with breast cancer, hypersensitivity to oxymetholone or anabolic steroids, nephrosis, nephrotic phase of nephritis, pregnancy, severe hepatic dysfunction

Interactions

DRUGS

corticosteroids: Increased risk of edema and severe acne

hepatotoxic drugs: Increased risk of hepatotoxicity

insulin, oral antidiabetic drugs: Possibly hypoglycemia

NSAIDs, oral anticoagulants, salicylates: Increased anticoagulant effects

sodium-containing drugs: Increased risk of edema

somatrem, somatropin: Possibly accelerated epiphyseal maturation

FOODS

high-sodium foods: Increased risk of edema

Adverse Reactions

CNS: Depression, excitement, insomnia

CV: Decreased serum HDL level, edema, hyperlipidemia, hypertension

ENDO: Feminization in postpubertal males (epididymitis, gynecomastia, impotence, oligospermia, priapism, testicular atrophy), glucose intolerance, virilism in females (acne, clitoral enlargement, decreased breast size, deepened voice, diaphoresis, emotional lability, flushing, hirsutism, hoarseness, libido changes, male-pattern baldness, menstrual irregularities, nervousness, oily hair or skin, vaginal bleeding, vaginitis, weight gain), virilism in prepubertal males (acne, decreased ejaculatory volume, penis

enlargement, prepubertal closure of epiphyseal plates, unnatural growth of body and facial hair)

GI: Diarrhea, elevated liver function test results, hepatocellular carcinoma, nausea, vomiting

GU: Benign prostatic hyperplasia, prostate cancer, urinary frequency, urine retention (elderly men)

HEME: Iron deficiency anemia, leukemia, prolonged bleeding time

SKIN: Jaundice

Other: Fluid retention, hypercalcemia (females), physical and psychological dependence, sodium retention

Nursing Considerations

- Be aware that oxymetholone shouldn't be used in patients with a history of hypercalcemia because drug may exacerbate this condition or in patients with prostate problems because drug may promote benign or cancerous tumor growth.
- Anticipate increased risk of fluid and sodium retention in patients with cardiac, hepatic, or renal dysfunction. Monitor for signs and symptoms of fluid retention.
- Monitor daily weight. Expect to place patient with fluid retention on sodium-restricted diet or diuretics, as prescribed.

WARNING Be aware that oxymetholone may suppress spermatogenesis in males and cause permanent virilization in females.

PATIENT TEACHING

- Advise patient to consume a diet high in protein and calories to achieve maximum therapeutic effect of oxymetholone.
- Instruct patient to check his weight daily during oxymetholone therapy and to notify prescriber immediately about swelling or unexplained weight gain.
- Inform patient that drug may alter libido.
- Advise diabetic patient to monitor blood glucose levels frequently because drug may increase hypoglycemic effect of antidiabetic drugs.
- Inform female patient that drug may cause permanent physical changes, such as clitoral enlargement, deepened voice, and unnatural hair growth.
- Advise female patient of childbearing age to use contraception during therapy and to notify prescriber immediately about suspected or known pregnancy.

oxymorphone hydrochloride

Numorphan, Opana, Opana ER

Class, Category, and Schedule

Chemical class: Phenanthrene derivative

Therapeutic class: Analgesic

Pregnancy category: Not rated

Controlled substance schedule: II

Indications and Dosages

➤ *To relieve moderate to severe pain*

TABLETS

Adults. *Initial:* 5 to 20 mg every 4 to 6 hr, p.r.n.

➤ *To relieve moderate to severe pain in patients requiring continuous, around-the-clock opioid treatment for an extended time*

E.R. TABLETS

Adults. *Initial:* 5 mg every 12 hr, increased as needed in 5- to 10-mg increments every 3 to 7 days.

DOSAGE ADJUSTMENT For patients with creatinine clearance less than 50 ml/min/1.73 m² or elderly patients, dosage started at lowest level and titrated slowly. For patients receiving other CNS depressants, dosage started at one-third to one-half the usual starting dose.

➤ *To relieve moderate to severe pain, to relieve anxiety in patients with dyspnea from pulmonary edema caused by acute left ventricular dysfunction*

I.V. INJECTION

Adults. *Initial:* 0.5 mg, repeated every 3 to 6 hr, p.r.n.

I.M. OR SUBCUTANEOUS INJECTION

Adults. *Initial:* 1 to 1.5 mg, repeated every 3 to 6 hr, p.r.n.

SUPPOSITORIES

Adults. 5 mg every 4 to 6 hr, p.r.n.

➤ *To relieve obstetric pain during labor*

I.M. INJECTION

Adults. 0.5 to 1 mg as a single dose.

Mechanism of Action

Alters perception of and emotional response to pain at spinal cord and higher levels of CNS by blocking release of inhibitory neurotransmitters, such as gamma-aminobutyric acid and acetylcholine.

Contraindications

Acute or severe asthma; hypercarbia; hypersensitivity to oxymorphone, other morphine analogues, or their components; ileus; moderate to severe hepatic impairment; pulmonary edema from a chemical respiratory irritant; severe respiratory depression; upper airway obstruction

Route	Onset	Peak	Duration
I.V.	5–10 min	15–30 min	3–4 hr
I.M.	10–15 min	30–90 min	3–6 hr
SubQ	10–20 min	30–90 min	3–6 hr
P.R.	15–30 min	2 hr	3–6 hr

Interactions

DRUGS

anticholinergics: Increased risk of urine retention, severe constipation

antidiarrheals, antiperistaltics: Increased risk of severe constipation, CNS depression

antihypertensives, diuretics, hypotension-producing drugs: Increased hypotensive effects

buprenorphine: Reduced oxymorphone effectiveness if buprenorphine is given first, possibly withdrawal symptoms in oxymorphone-dependent patients

CNS depressants: Additive CNS depressant effects, increased risk of habituation

hydroxyzine, other opioid analgesics: Increased analgesia, CNS depression, and hypotensive effects

MAO inhibitors: Increased risk of unpredictable, severe, sometimes fatal adverse reactions

metoclopramide: Antagonized effects of metoclopramide on GI motility

naloxone: Antagonized analgesic, CNS, and respiratory depressant effects of oxymorphone

naltrexone: Withdrawal symptoms in oxymorphone-dependent patients

neuromuscular blockers: Additive respiratory depression

ACTIVITIES

alcohol use: Additive CNS depressant effects, increased risk of habituation

Adverse Reactions

CNS: Agitation, asthenia, CNS depression, confusion, delusions, depersonalization, dizziness, drowsiness, euphoria, fatigue, hallucinations, headache, insomnia, light-

headedness, nervousness, nightmares, restlessness, seizures, somnolence, tiredness, tremor, weakness

CV: Bradycardia, hypertension, hypotension, palpitations, tachycardia

EENT: Blurred vision, diplopia, dry mouth, laryngeal edema, laryngospasm, miosis, tinnitus

GI: Abdominal cramps or pain, anorexia, biliary colic, constipation, hepatotoxicity, ileus, nausea, vomiting

GU: Decreased urine output, dysuria, urinary frequency and hesitancy, urine retention

MS: Muscle rigidity (with large doses), uncontrolled muscle movements

RESP: Apnea, atelectasis, bradypnea, bronchospasm, dyspnea, irregular breathing, respiratory depression, wheezing

SKIN: Dermatitis, diaphoresis, erythema, flushing of face, pruritus, urticaria

Other: Angioedema, injection site burning, pain, redness, and swelling

Nursing Considerations

- Use with extreme caution in patients with increased intracranial pressure or head injury because oxymorphone may obscure neurologic signs of increasing severity.
- Use cautiously in patients with mild hepatic impairment because drug is metabolized in liver; impaired renal function because drug is excreted by kidneys; and biliary tract disease because drug may cause spasm of sphincter of Oddi.
- Use cautiously in patients receiving mixed agonist-antagonist opioid analgesics because these drugs may reduce analgesic effect of oxymorphone or may cause withdrawal symptoms.
- Use cautiously in elderly patients because plasma oxymorphone levels are higher in elderly than in younger patients.
- Oral hydromorphone shouldn't be used "as needed" or for first 24 hours after surgery in patients not already taking opioids because of the risk of oversedation and respiratory depression.
- If patient is being converted from one form of drug to another, watch closely for analgesic effectiveness and adverse reactions. For conversion from immediate-release oral form to extended-release oral form, expect to give half the total daily

dose every 12 hours. For conversion from parenteral to oral oxymorphone, expect that you may give 10 times the total daily parenteral dose as tablets, divided into equal doses and given over 24 hours.

- Taper dosage, as ordered, before stopping therapy to prevent withdrawal in physically dependent patients.
- Monitor vital signs during oxymorphone therapy to detect respiratory depression and hypotension, especially in elderly patients, debilitated patients, and those with conditions accompanied by hypoxia, when even moderate doses may severely decrease pulmonary ventilation.
- Monitor urinary and bowel status; constipation may be so severe it causes ileus.
- Offer fluids to relieve dry mouth.

PATIENT TEACHING

- Instruct patient to take oxymorphone exactly as prescribed and not to stop abruptly; warn that drug can cause physical dependence.
- Stress importance of taking drug before pain becomes severe.
- Instruct patient prescribed tablet form to take it on an empty stomach.
- Tell patient prescribed extended-release tablet form not to break, chew, dissolve, or crush tablets before taking them because going so will lead to a rapid drug release and increased risk of a potentially fatal dose.
- Instruct patient to store suppositories in refrigerator.
- Encourage patient to increase fluid and fiber intake during therapy to prevent constipation.
- Stress need to avoid alcohol and CNS depressants during therapy because of risk of severe life-threatening adverse reactions.
- Caution patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Advise female patient to stop drug and notify prescriber about known or suspected pregnancy.

oxytetracycline

Terramycin I.M.

oxytetracycline hydrochloride

Terramycin

Class and Category

Chemical class: Tetracycline derived from *Streptomyces rimosus*

Therapeutic class: Antibiotic, antiprotozoal

Pregnancy category: D

Indications and Dosages

➤ *To treat systemic bacterial and protozoal infections, such as bronchitis, chlamydial infection, Lyme disease, nongonococcal urethritis, rickettsial infection, traveler's diarrhea, and UTI*

CAPSULES (OXYTETRACYCLINE HYDROCHLORIDE)

Adults and adolescents. 250 to 500 mg every 6 hr. *Maximum:* 4,000 mg daily.

Children ages 8 to 12. 6.25 to 12.5 mg/kg every 6 hr.

I.M. INJECTION (OXYTETRACYCLINE)

Adults and adolescents. 100 mg every 8 hr, 150 mg every 12 hr, or 250 mg daily.

Maximum: 500 mg daily.

Children ages 8 to 12. 5 to 8.3 mg/kg every 8 hr or 7.5 to 12.5 mg/kg every 12 hr.

Maximum: 250 mg daily.

DOSAGE ADJUSTMENT Dosage possibly reduced for patients with renal impairment.

➤ *To treat brucellosis*

CAPSULES (OXYTETRACYCLINE HYDROCHLORIDE)

Adults and adolescents. 500 mg every 6 hr for 3 wk with 1,000 mg of streptomycin

I.M. every 12 hr in wk 1 and daily in wk 2.

Maximum: 4,000 mg daily.

➤ *To treat uncomplicated gonorrhea*

CAPSULES (OXYTETRACYCLINE HYDROCHLORIDE)

Adults and adolescents. *Initial:* 1,500 mg, then 500 mg every 6 hr to total of 9,000 mg for full course of treatment.

➤ *To treat syphilis*

CAPSULES (OXYTETRACYCLINE HYDROCHLORIDE)

Adults and adolescents. 500 to 1,000 mg every 6 hr for 10 to 15 days to total of 30 to 40 g for full course of treatment.

Mechanism of Action

Binds with ribosomal subunits of susceptible bacteria and alters cytoplasmic membrane, inhibiting bacterial protein synthesis and rendering the organism ineffective.

Contraindications

Hypersensitivity to tetracyclines or their components

Interactions

DRUGS

antacids, calcium supplements, cholestyramine, choline salicylates, colestipol, iron supplements, magnesium salicylates: Possibly decreased absorption of oxytetracycline

digoxin: Increased blood digoxin level

lithium: Altered blood lithium level

methoxyflurane: Increased risk of nephrotoxicity

oral anticoagulants: Increased anticoagulant effects

oral contraceptives: Decreased contraceptive effectiveness, increased risk of breakthrough bleeding and pregnancy

penicillins: Decreased bactericidal effects of penicillins

sodium bicarbonate: Possibly decreased absorption of oral oxytetracycline

vitamin A: Increased risk of benign intracranial hypertension

FOODS

all foods, especially dairy products: Possibly interference with oxytetracycline absorption

Adverse Reactions

CNS: Dizziness, light-headedness, tiredness, unsteadiness, weakness

EENT: Darkened, discolored, or sore tongue; stomatitis, tooth discoloration (in infants and children under age 8)

GI: Abdominal cramps, diarrhea, indigestion, nausea, thirst, vomiting

GU: Urinary frequency

SKIN: Photosensitivity

Other: Superinfection

Nursing Considerations

WARNING Be aware that oxytetracycline shouldn't be given to premature infants because it may impair skeletal growth or to children under age 8 because it may permanently discolor teeth and cause enamel hypoplasia.

- For an adult, give I.M. injection in upper outer quadrant of buttocks or mid-lateral thigh; deltoid muscle may be used but only if well developed. In children, give injection only in mid-lateral thigh.
- Be aware that patient should be switched

from parenteral to oral form as soon as possible.

PATIENT TEACHING

- Instruct patient to take oxytetracycline capsules 1 hour before meals and 3 hours before or after other drugs and dairy products.
- Advise patient to take drug with a full glass of water and in an upright position to minimize adverse GI reactions.
- Urge patient to complete entire course of oxytetracycline therapy, even if he feels better beforehand.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to avoid excessive sun exposure and to protect skin when outdoors.
- Urge female patient who uses oral contraceptives to use an additional form of birth control during oxytetracycline therapy.
- Advise patient to discard outdated capsules because drug may become toxic.

P

paliperidone

Invega

Class and Category

Chemical class: Benzisoxazole derivative
Therapeutic class: Antipsychotic (Atypical)
Pregnancy category: C

Indications and Dosages

➤ *To treat schizophrenia*

E.R. TABLETS

Adults. *Initial:* 6 mg once daily in the morning; then increased or decreased in increments of 3 mg daily every 6 or more days, as needed. *Maximum:* 12 mg daily.

DOSE ADJUSTMENT For patients with mild renal impairment (creatinine clearance 50 to 79 ml/min/1.73 m²), maximum dosage is 6 mg daily. For patients with moderate to severe renal impairment (creatinine clearance less than 50 ml/min/1.73 m²), maximum dosage is 3 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	24 hr	Unknown

Mechanism of Action

The main active metabolite of risperidone, paliperidone selectively blocks serotonin and dopamine receptors in mesocortical tract of CNS to suppress psychotic symptoms.

Contraindications

AV block, cardiac arrhythmias, congenital heart disease, history of congenital long-QT syndrome; hypersensitivity to paliperidone, risperidone, or its components

Interactions

DRUGS

antiarrhythmics of class IA (such as quinidine, procainamide) and class III (such as amiodarone, sotalol), antibiotics (such as gatifloxacin, moxifloxacin), antipsychotics (such as chlorpromazine, thioridazine): Increased risk of QT-interval prolongation
antihypertensives: Increased antihypertensive effects
bromocriptine, levodopa, pergolide: Possibly

antagonized effects of these drugs
carbamazepine: Decreased paliperidone level
CNS depressants: Additive CNS depression
paroxetine: Possible increased blood paliperidone level

ACTIVITIES

alcohol use: CNS depression

Adverse Reactions

CNS: Agitation, akathisia, anxiety, asthenia, dizziness, dyskinesia, dystonia, extrapyramidal disorder, fatigue, fever, headache, hyperkinesia, hypertension, neuroleptic malignant syndrome, parkinsonism, somnolence, syncope, tardive dyskinesia, tremor

CV: Bundle branch block, first-degree heart block, hypertension, orthostatic hypotension, palpitations, prolonged QT interval, tachycardia, venous thrombosis

EENT: Blurred vision, dry mouth, salivary hypersecretion, swollen tongue

ENDO: Hyperglycemia

GI: Dyspepsia, nausea, upper abdominal pain

GU: Priapism

HEME: Agranulocytosis, leukopenia, neutropenia, thrombocytopenia

MS: Back or limb pain

RESP: Cough, dyspnea

Other: Anaphylaxis, weight gain

Nursing Considerations

- Paliperidone shouldn't be used to treat dementia-related psychosis in the elderly because of an increased mortality risk.
- Drug shouldn't be given if patient has a condition that severely narrows GI tract because tablet doesn't change shape as it passes and could cause blockage.

WARNING Immediately notify prescriber and expect to stop drug if patient shows signs of neuroleptic malignant syndrome (altered mental status, autonomic instability, hyperpyrexia, muscle rigidity).

- Monitor patient for involuntary, dyskinesic movements. Notify prescriber if present, and expect to stop therapy. In some cases, therapy may need to continue despite tardive dyskinesia.
- Monitor blood glucose level because drug increases risk of hyperglycemia and possible ketoacidosis or hyperosmolar coma.
- Dosage adjustments of paliperidone may be needed when carbamazepine therapy is started or discontinued because of carbamazepine's interaction with paliperidone.

- Check CBC often during first few months of therapy, especially if patient has low WBC count or history of drug-induced leukopenia or neutropenia. If WBC count declines, and especially if neutrophil count goes $1,000/\text{mm}^3$, expect to stop drug. If neutropenia is significant, also watch for evidence of infection and provide appropriate treatment, as prescribed.

PATIENT TEACHING

- Instruct patient to take tablet whole with liquid. Caution against chewing, splitting, or crushing it because it's designed to release drug at a controlled rate.
- Explain that shell of tablet will be eliminated in stool and that patient need not worry if he sees tablet in stool.
- Urge patient to rise slowly from sitting or lying to minimize orthostatic hypotension.
- Caution patient to avoid hazardous activities until CNS effects of drug are known.
- Advise patient to avoid activities that may cause overheating, such as exercising strenuously, being exposed to extreme heat, or becoming dehydrated.

palonosetron hydrochloride

Aloxi

Class and Category

Chemical class: Selective serotonin subtype 3 (5-HT₃) receptor antagonist

Therapeutic class: Antiemetic

Pregnancy category: B

Indications and Dosages

➤ *To prevent acute and delayed nausea and vomiting from chemotherapy*

CAPSULES

Adults. 0.5 mg 1 hr before chemotherapy.

I.V. INJECTION

Adults. 0.25 mg over 30 sec about 30 min before start of chemotherapy.

➤ *To prevent postoperative nausea and vomiting for up to 24 hr after surgery*

I.V. INJECTION

Adults. 0.75 mg over 10 sec immediately before induction of anesthesia.

Incompatibilities

Palonosetron shouldn't be mixed with any other drug.

Contraindications

Hypersensitivity to palonosetron or its components

Adverse Reactions

CNS: Anxiety, dizziness, drowsiness, fatigue, headache, insomnia, weakness

CV: Bradycardia, hypotension, prolonged QT interval, tachycardia

GI: Abdominal pain, constipation, diarrhea

SKIN: Dermatitis, pruritus, rash

Other: Hyperkalemia, hypersensitivity reaction, injection site reaction (burning, induration, discomfort, pain)

Nursing Considerations

- Use palonosetron cautiously in patients

Mechanism of Action

Chemotherapy may induce nausea and vomiting by irritating the small intestine's mucosa, causing mucosal enterochromaffin cells to release serotonin (5-HT₃). The 5-HT₃ stimulates sympathetic receptors on afferent vagal nerve endings, and the vagus nerve causes the vomiting reflex.

Palonosetron selectively blocks these 5-HT₃ receptors. By keeping the vagus nerve from inducing the vomiting reflex, drug reduces or prevents nausea and vomiting. It also may block 5-HT₃ receptors centrally, in the brain's chemoreceptor trigger zone.

who have or may develop prolonged cardiac conduction intervals—especially QT interval—such as those with congenital QT syndrome, hypokalemia, or hypomagnesemia; those taking a diuretic known to induce electrolyte abnormalities, an antiarrhythmic, or another drug that may prolong QT interval; and those who have received cumulative high-dose anthracycline therapy. With these patients, obtain a baseline ECG before giving palonosetron; repeat the ECG 15 minutes or 24 hours after giving drug, as ordered. Notify prescriber of any delayed conduction.

- Flush I.V. line with normal saline solution before and after giving I.V. palonosetron.
- Closely monitor any patient hypersensitive to other selective serotonin receptor antagonists for a similar reaction. If a reaction occurs, notify prescriber immediately.

PATIENT TEACHING

- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to notify prescriber of any hypersensitivity reaction, such as rash or allergic dermatitis.

pamidronate disodium

Aredia

Class and Category

Chemical class: Bisphosphonate

Therapeutic class: Antihypercalcemic, bone resorption inhibitor

Pregnancy category: D

Indications and Dosages

↗ *To treat cancer-induced hypercalcemia that's inadequately managed by oral hydration alone*

I.V. INFUSION

Adults. 60 to 90 mg over 2 to 24 hr as a single dose when corrected serum calcium level is 12 to 13.5 mg/dl; 90 mg over 2 to 24 hr when corrected serum calcium level is greater than 13.5 mg/dl. May be repeated as prescribed after 7 days if hypercalcemia recurs.

DOSAGE ADJUSTMENT For patients with renal failure, dosage is limited to 30 mg over 4 to 24 hr, as prescribed. For patients

with cardiac or renal failure, drug is given in a smaller volume of fluid or at a slower rate, as prescribed.

↗ *To treat moderate to severe Paget's disease of bone*

I.V. INFUSION

Adults. 30 mg daily over 4 hr on 3 consecutive days for a total dose of 90 mg. Repeated as needed and tolerated.

↗ *To treat osteolytic bone metastases of breast cancer*

I.V. INFUSION

Adults. 90 mg over 2 hr every 3 to 4 wk.

↗ *To treat osteolytic bone metastases of multiple myeloma*

I.V. INFUSION

Adults. 90 mg over 4 hr every mo.

Mechanism of Action

Inhibits bone resorption, possibly by impairing attachment of osteoclast precursors to mineralized bone matrix, thus reducing the rate of bone turnover in Paget's disease and osteolytic metastases. Pamidronate also reduces the flow of calcium from resorbing bone into bloodstream.

Incompatibilities

Don't mix pamidronate with calcium-containing infusion solutions, such as Ringer's solution.

Contraindications

Hypersensitivity to pamidronate, other bisphosphonates, or their components

Interactions

DRUGS

calcium-containing preparations; vitamin D preparations, such as calcifediol and calcitriol:

Antagonized pamidronate effects when used to treat hypercalcemia

thalidomide: Increased risk of renal dysfunction in patients with multiple myeloma

Adverse Reactions

CNS: Confusion, fever, psychosis, visual hallucinations

CV: Hypotension

EENT: Conjunctivitis

GI: Abdominal cramps, anorexia, GI bleeding, indigestion, nausea, vomiting

GU: Azotemia, focal segmental glomerulosclerosis, nephrotic syndrome, hematuria, renal toxicity leading to failure

HEME: Leukopenia, lymphopenia

MS: Bone pain, muscle spasms or stiffness,

osteonecrosis (mainly of jaw)

RESP: Dyspnea

SKIN: Pruritus, rash

Other: Anaphylaxis, angioedema, flulike symptoms, hyperkalemia, hypernatremia, hypocalcemia, hypokalemia, hypomagnesemia, hypophosphatemia, injection site pain and swelling, reactivation of herpes simplex and zoster infections

Nursing Considerations

- Make sure patient has had a dental check-up before invasive dental procedures during pamidronate therapy, especially if he has cancer; is receiving chemotherapy, head or neck radiation, or a corticosteroid; or has poor oral hygiene. Risk of osteonecrosis is increased in these patients.

WARNING Don't give more than 90 mg at any one time because of increased risk of serious adverse effect on kidneys.

- Monitor patient for hypocalcemia, especially if patient has had thyroid surgery.
- Stay alert for fever during first 3 days of therapy, especially in patients receiving high doses. If fever develops, obtain patient's CBC with differential, as ordered.
- Obtain serum creatinine level before each treatment. Notify prescriber of abnormal results because drug may need to be withheld or dosage adjusted until creatinine level returns to normal.
- Assess patient with anemia, leukopenia, or thrombocytopenia for worsening of the condition during first 2 weeks of therapy.

PATIENT TEACHING

- Stress need to comply with prescribed administration schedule for pamidronate.
- Advise patient to avoid calcium and vitamin D supplements during therapy.
- Instruct patient on proper oral hygiene and on need to notify prescriber about invasive dental procedures.

pancreatin

Donnazyme: 500 mg pancreatin, 1,000 units lipase, 12,500 units protease, 12,500 units amylase

Hi-Vegi-Lip: 2,400 mg pancreatin, 4,800 units lipase, 60,000 units protease, 60,000 units amylase

4X Pancreatin: 2,400 mg pancreatin, 12,000 units lipase, 60,000 units pro-

tease, 60,000 units amylase

8X Pancreatin: 7,200 mg pancreatin, 22,500 units lipase, 180,000 units protease, 180,000 units amylase

Pancrezyme 4X: 2,400 mg pancreatin, 12,000 units lipase, 60,000 units protease, 60,000 units amylase

Class and Category

Chemical class: Pancreatic enzyme

Therapeutic class: Digestant, pancreatic enzyme replacement

Pregnancy category: C

Indications and Dosages

↗ *To treat pancreatic insufficiency, including steatorrhea*

CAPSULES, TABLETS

Adults. 8,000 to 24,000 units of lipase with meals or snacks, adjusted as prescribed, according to need for steatorrhea control. For severe insufficiency, up to 36,000 units of lipase with meals or snacks.

Mechanism of Action

Releases the enzymes pancreatin, lipase, amylase, and protease, mainly in the duodenum and upper jejunum. These enzymes facilitate the hydrolysis of fats into glycerol and fatty acids, starches into dextrins and sugars, and proteins into peptides. Pancreatin acts locally in the GI tract but is quickly inactivated by gastric acid.

Contraindications

Acute exacerbation of chronic pancreatic disease; acute pancreatitis; hypersensitivity to pancreatin, pancrelipase, or pork

Interactions

DRUGS

acarbose, miglitol: Decreased effectiveness of these drugs

aluminum hydroxide, H₂-receptor antagonists, omeprazole, sodium bicarbonate:

Increased gastric pH, prolonged enzymatic action of pancreatin

calcium carbonate- and magnesium hydroxide-containing antacids: Decreased pancreatin effectiveness

iron supplements: Decreased iron absorption

Adverse Reactions

EENT: Stomatitis

GI: Abdominal cramps or pain, diarrhea, intestinal obstruction, nausea

SKIN: Rash, urticaria
Other: Hyperuricemia

Nursing Considerations

WARNING Don't administer pancreatin to patient who is allergic to pork.

- Assess patient for GI disturbances and hyperuricemia when giving high doses of pancreatin.
- If patient opens capsules and sprinkles contents on food, watch for signs or symptoms of sensitization (chest tightness, dyspnea, nasal congestion, wheezing), which may result from repeated inadvertent inhalation of powder.
- Be aware that brands of pancreatin aren't interchangeable because the same doses don't contain equivalent amounts of drug.

PATIENT TEACHING

- Instruct patient to take pancreatin before or with meals or snacks to maximize effectiveness.
- To prevent capsule or tablet from lodging in esophagus, advise patient to take drug with a beverage while sitting upright, to swallow it quickly, and to follow with 1 or 2 mouthfuls of solid food.
- Caution patient not to chew tablets; doing so may irritate mouth, lips, and tongue.
- If patient has trouble swallowing capsules, advise her to open capsule and sprinkle its contents on food without inhaling them.
- Caution patient not to take antacids that contain calcium carbonate or magnesium hydroxide during therapy.

pancrelipase

Cotazym: 8,000 units lipase, 30,000 units protease, 30,000 units amylase

Cotazym-S: 5,000 units lipase, 20,000 units protease, 20,000 units amylase

Creon: 6,000 units lipase, 19,000 units protease, 30,000 units amylase

Creon: 12,000 units lipase, 38,000 units protease, 60,000 units amylase

Creon: 24,000 units lipase, 76,000 units protease, 120,000 units amylase

Ilozyme: 11,000 units lipase, 30,000 units protease, 30,000 units amylase

Ku-Zyme HP: 8,000 units lipase, 30,000 units protease, 30,000 units amylase

Pancrease: 4,500 units lipase, 25,000 units protease, 20,000 units amylase

Pancrease MT 4: 4,000 units lipase, 12,000 units protease, 12,000 units amylase

Pancrease MT 10: 10,000 units lipase, 30,000 units protease, 30,000 units amylase

Pancrease MT 16: 16,000 units lipase, 48,000 units protease, 48,000 units amylase

Pancrease MT 20: 20,000 units lipase, 44,000 units protease, 56,000 units amylase

Protilase: 4,000 units lipase, 25,000 units protease, 20,000 units amylase

Ultrase MT 12: 12,000 units lipase, 39,000 units protease, 39,000 units amylase

Ultrase MT 20: 20,000 units lipase, 65,000 units protease, 65,000 units amylase

Viokase Tablets: 8,000 units lipase, 30,000 units protease, 30,000 units amylase

Viokase Powder: 16,800 units lipase, 70,000 units protease, 70,000 units amylase

Zenpep: 5,000 units lipase, 17,000 units protease, 27,000 units amylase

Zenpep: 10,000 units lipase, 34,000 units protease, 55,000 units amylase

Zenpep: 15,000 units lipase, 51,000 units protease, 82,000 units amylase

Zenpep: 20,000 units lipase, 68,000 units protease, 109,000 units amylase

Zymase: 12,000 units lipase, 24,000 units protease, 24,000 units amylase

Class and Category

Chemical class: Porcine pancreatic enzyme

Therapeutic class: Pancreatic enzyme replacement

Pregnancy category: C

Indications and Dosages

➤ To treat pancreatic insufficiency, including steatorrhea

CAPSULES, DELAYED-RELEASE CAPSULES, POWDER, TABLETS

Adults and adolescents. 33,000 to 44,000 units of lipase before or with meals or snacks; adjusted as prescribed. For

patients with severe deficiency, possibly up to 88,000 units of lipase with meals or snacks or dosing frequency increased to every hr.

Children ages 7 to 12. 4,000 to 12,000 units of lipase with meals and snacks; adjusted as needed and tolerated.

Children ages 1 to 6. 4,000 to 8,000 units of lipase with meals and 4,000 units of lipase with each snack; adjusted as needed and tolerated.

Infants ages 6 to 11 months. 2,000 units of lipase with meals; adjusted as needed and tolerated.

Mechanism of Action

Releases high levels of the enzymes lipase, amylase, and protease, mainly in duodenum and upper jejunum. These enzymes facilitate hydrolysis of fats into glycerol and fatty acids, starches into dextrins and sugars, and proteins into peptides.

Contraindications

Acute exacerbation of chronic pancreatic disease; acute pancreatitis; hypersensitivity to pancreatin, pancrelipase, or pork

Interactions

DRUGS

acarbose, miglitol: Decreased effectiveness of these drugs

aluminum hydroxide, H₂-receptor antagonists, omeprazole, sodium bicarbonate:

Increased gastric pH, prolonged enzymatic action of pancrelipase

calcium carbonate- and magnesium hydroxide-containing antacids: Decreased pancrelipase effectiveness

iron supplements: Decreased iron absorption

Adverse Reactions

EENT: Stomatitis

GI: Abdominal cramps or pain, diarrhea, intestinal obstruction, nausea

HEME: Anemia

SKIN: Rash, urticaria

Other: Hyperuricemia

Nursing Considerations

WARNING Don't administer pancrelipase to patient who is allergic to pork.

- Be aware that brands of pancrelipase aren't interchangeable because the same doses don't contain equivalent amounts of drug.
- Mix powder with fluid or soft, nondairy food.

- If needed, open delayed-release capsules and mix contents (enteric-coated spheres, microspheres, or microtablets) with liquid or soft food that requires no chewing. Give immediately because enteric coating will dissolve after prolonged contact with foods at a pH greater than 6.
- If patient opens capsules and sprinkles contents on food, assess for signs of sensitization (chest tightness, dyspnea, nasal congestion, wheezing), which may result from repeated inadvertent inhalation of powder.
- Give drug before or with meals and snacks, and follow with a glass of water or juice.
- Expect drug to cause stomatitis if held in mouth.
- Check stool for fecal fat content, as ordered.
- Monitor patient for iron deficiency anemia because serum iron level may decline during pancrelipase therapy.

PATIENT TEACHING

- Instruct patient to take pancrelipase before or with meals and snacks and to follow with a glass of water or juice.
- Instruct patient not to chew capsules (or capsule contents) or crush tablets and to swallow immediately because drug may cause irritation if held in mouth.
- Urge patient not to inhale powder from delayed-release capsules; doing so may cause chest tightness, shortness of breath, stuffy nose, trouble breathing, and wheezing.
- Inform patient that sneezing and tearing also may result from contact with powder.
- Caution patient not to use antacids; they may decrease drug effectiveness.
- Inform patient that her stool may have foul smell.

pantoprazole sodium

Pantoloc (CAN), Protonix

Class and Category

Chemical class: Substituted benzimidazole

Therapeutic class: Antiulcer, gastric acid proton pump inhibitor

Pregnancy category: B

Indications and Dosages

➤ *To treat gastroesophageal reflux disease (GERD)*

DELAYED-RELEASE TABLETS

Adults. 40 mg daily for up to 8 wk. Repeated for another 4 to 8 wk if healing doesn't occur.

I.V. INFUSION

Adults. 40 mg daily infused over 2 min or 15 min for 7 to 10 days, followed by oral doses.

➤ *To maintain healing of erosive esophagitis and reduce relapse of daytime and nighttime symptoms in patients with GERD*

DELAYED-RELEASE TABLETS

Adults. 40 mg daily for up to 12 mo.

➤ *To treat pathological hypersecretion associated with Zollinger-Ellison syndrome or other neoplastic conditions*

I.V. INFUSION

Adults. 80 mg every 12 hr infused over 2 min or 15 min; adjusted based on patient's acid output measurements up to 80 mg every 8 hr.

Route	Onset	Peak	Duration
P.O.	1 day	1 wk	1 wk
I.V.	1 day	Unknown	1 wk

Mechanism of Action

Interferes with gastric acid secretion by inhibiting the hydrogen-potassium-adenosine triphosphatase ($H^+-K^+-ATPase$) enzyme system, or proton pump, in gastric parietal cells. Normally, the proton pump uses energy from hydrolysis of ATPase to drive H^+ and chloride (Cl^-) out of parietal cells and into the stomach lumen in exchange for potassium (K^+), which leaves the stomach lumen and enters parietal cells. After this exchange, H^+ and Cl^- combine in the stomach to form hydrochloric acid (HCl). Pantoprazole irreversibly inhibits the final step in gastric acid production by blocking the exchange of intracellular H^+ and extracellular K^+ , thus preventing H^+ from entering the stomach and additional HCl from forming.

Incompatibilities

Midazolam and products containing zinc may cause precipitation or discoloration.

Contraindications

Hypersensitivity to pantoprazole, substituted benzimidazoles (omeprazole, lansoprazole, rabeprazole sodium), or their components

Interactions

DRUGS

ampicillin, cyanocobalamin, digoxin, iron salts, ketoconazole: Possibly impaired absorption of these drugs
atazanavir: Significantly decreased atazanavir level
warfarin: Increased INR, PT, and bleeding risk

Adverse Reactions

CNS: Anxiety, asthenia, confusion, dizziness, headache, hypertonia, hypokinesia, insomnia, malaise, migraine, speech disorder
CV: Chest pain, hypercholesterolemia, hyperlipidemia
EENT: Anterior ischemic optic neuropathy, blurred vision, increased salivation, pharyngitis, rhinitis, sinusitis, tinnitus
ENDO: Hyperglycemia
GI: Abdominal pain, atrophic gastritis, constipation, diarrhea, elevated liver function tests results, flatulence, gastroenteritis, hepatotoxicity, indigestion, nausea, pancreatitis, vomiting
GU: Elevated serum creatinine level, interstitial nephritis
HEME: Pancytopenia
MS: Arthralgia, back or neck pain, rhabdomyolysis
RESP: Bronchitis, dyspnea, increased cough, upper respiratory tract infection
SKIN: Erythema multiforme, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis
Other: Anaphylaxis, angioedema, elevated creatine kinase and phosphokinase levels, flulike symptoms, generalized pain, hyperuricemia, infection, injection site reaction

Nursing Considerations

- Ensure the continuity of gastric acid suppression during transition from oral to I.V. pantoprazole (or vice versa) because even a brief interruption of effective suppression can lead to serious complications.
- Don't give pantoprazole within 4 weeks of testing for *Helicobacter pylori* because

antibiotics, proton pump inhibitors, and bismuth preparations suppress *H. pylori* and may lead to false-negative results. Drug also may cause false-positive results in urine screening tests for tetrahydrocannabinol. Consult guidelines for pantoprazole use before testing.

- Flush I.V. line with D₅W, normal saline solution, or lactated Ringer's injection before and after giving drug.
- When giving I.V. over 2 minutes, reconstitute with 10 ml of normal saline injection. Solution may be stored up to 2 hours at room temperature.
- When giving I.V. over 15 minutes, reconstitute with 10 ml normal saline injection. Then, further reconstitute with 100 ml (for GERD) or 80 ml (for pathological hypersecretion in Zollinger-Ellison syndrome) of D₅W, normal saline injection, or lactated Ringer's injection. Solution may be stored up to 2 hours before further dilution and up to 22 hours before use.
- Expect to monitor PT or INR during therapy if patient takes an oral anticoagulant.
- If therapy lasts more than 3 years, patient may not be able to absorb vitamin B₁₂ because of hypochlorhydria or achlorhydria. Treatment for cyanocobalamin deficiency may be needed.

PATIENT TEACHING

- Instruct patient to swallow pantoprazole tablets whole and not to chew or crush them.
- Advise patient to expect relief of symptoms within 2 weeks of starting therapy.
- Advise patient who takes warfarin to follow bleeding precautions and to notify prescriber immediately if bleeding occurs.

paricalcitol

Zemplar

Class and Category

Chemical class: Sterol derivative, vitamin D analogue

Therapeutic class: Antihyperparathyroid

Pregnancy category: Not rated

Indications and Dosages

- *To prevent and treat secondary hyperparathyroidism in patients with chronic renal failure stage 3 or 4*

I.V. INJECTION

Adults. *Initial:* 0.04 to 0.1 mcg/kg (2.8 to 7 mcg) no more than every other day at any time during dialysis. *Maintenance:* If initial dosage doesn't produce a satisfactory response, 2 to 4 mcg given every 2 to 4 wk. *Maximum:* 0.24 mcg/kg/dose or up to 16.8 mcg/dose.

Children age 5 and over. *Initial:* 0.04 mcg/kg three times weekly if baseline intact parathyroid hormone (iPTH) level is less than 500 pg/ml, or 0.08 mcg/kg three times weekly if baseline iPTH level equals or exceeds 500 pg/ml. *Maintenance:* If initial dosage isn't adequate, adjust in 0.04-mcg/kg increments as needed.

DOSAGE ADJUSTMENT If serum PTH level remains the same or increases, dosage is increased. If PTH level decreases by less than 30%, dosage is increased. If PTH level decreases by 30% to 60%, dosage is maintained. If PTH level decreases by more than 60%, dosage is decreased. If PTH level is 1.5 to 3 times the upper limit of normal, dosage is maintained.

DOSAGE ADJUSTMENT Dosage is immediately reduced or drug stopped if serum calcium level is elevated or serum calcium-phosphorus product exceeds 75. Dosage restarted at a lower dose when these levels return to normal.

CAPSULES

Adults. *Initial:* If baseline iPTH level is less than 500 pg/ml, 1 mcg daily or 2 mcg three times weekly, doses separated by at least 1 day. If iPTH level exceeds 500 pg/ml, 2 mcg daily or 4 mcg three times weekly, doses separated by at least 1 day.

Maintenance: Dosage adjusted in 1-mcg increments based on iPTH level relative to baseline.

Route	Onset	Peak	Duration
I.V.	Unknown	Unknown	15 hr

Mechanism of Action

Reduces serum PTH level by an unknown mechanism. In chronic renal failure, decreased renal synthesis of vitamin D leads to chronic hypocalcemia. In response, parathyroid glands secrete PTH to stimulate vitamin D synthesis, but serum calcium levels can't normalize because of renal failure.

Contraindications

Evidence of vitamin D toxicity, hypercalcemia, hypersensitivity to paricalcitol or components

Interactions

DRUGS

atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, voriconazole: Increased effects of oral paricalcitol

drugs, such as cholestyramine, that impair absorption of fat-soluble vitamins: Possibly impaired absorption of oral paricalcitol

Adverse Reactions

CNS: Arthritis, asthenia, chills, depression, dizziness, fever, headache, insomnia, lightheadedness, malaise, neuropathy, syncope, vertigo

CV: Cardiomyopathy, chest pain, congestive heart failure, edema, hypertension, hypotension, MI, orthostatic hypotension, palpitations

EENT: Amblyopia, bronchitis, dry mouth, epistaxis, laryngeal edema, pharyngitis, retinal abnormality, rhinitis, sinusitis, taste perversion

ENDO: Hypoglycemia

GI: Abdominal pain, constipation, diarrhea, dyspepsia, gastritis, gastroenteritis, GI bleeding, nausea, vomiting

GU: Abnormal kidney function, uremia, UTI

MS: Back pain, leg cramps, myalgia

RESP: Increased cough, pneumonia

SKIN: Ecchymosis, hypertrophy, pruritus, rash (including vesiculobullous), ulceration, urticaria

Other: Acidosis, allergic reaction, angioedema, dehydration, generalized edema, gout, hyperkalemia, hyperphosphatemia, hypervolemia, hypokalemia, infections, influenza, sepsis

Nursing Considerations

- Before giving drug, look for particles and discoloration; if present, discard drug.
- Give as I.V. bolus; discard unused portion.
- Monitor serum calcium and phosphorus levels, as ordered, twice weekly to guide dosage adjustments and then monthly.

WARNING Paricalcitol may lead to vitamin D toxicity and hypercalcemia. Early evidence includes arthralgia, constipation, dry mouth, headache, metallic taste, myal-

gia, nausea, somnolence, vomiting, and weakness. Late evidence includes albuminuria, anorexia, arrhythmias, azotemia, conjunctivitis (calcific), decreased libido, elevated BUN and serum ALT and AST levels, vascular calcification, hypercholesterolemia, hypertension, hyperthermia, irritability, mild acidosis, nephrocalcinosis, nocturia, pancreatitis, photophobia, polydipsia, polyuria, pruritus, rhinorrhea, and weight loss.

- If toxicity occurs, notify prescriber immediately and expect to decrease or stop drug. Place patient on bed rest and give fluids, low-calcium diet, and a laxative, as prescribed. If patient has a hypercalcemic crisis and dehydration, expect to infuse normal saline solution and a loop diuretic to prompt renal calcium excretion.
- Expect to check patient's serum PTH level every 3 months.
- If patient also takes digoxin, monitor her for evidence of digitalis glycoside toxicity, which is potentiated by hypercalcemia.
- Store drug at 25° C (77° F).

PATIENT TEACHING

- Advise patient to follow a diet high in calcium and low in phosphorus.
- Explain that phosphate binders may be needed to control serum phosphorus level.
- Review early evidence of hypercalcemia and vitamin D toxicity. Tell patient to contact prescriber immediately if it develops.
- Urge patient to avoid hazardous activities until drug's CNS effects are known.
- If patient takes digoxin, explain evidence of toxicity and the need to contact prescriber immediately if it develops.

paroxetine hydrochloride

Paxil, Paxil CR

paroxetine mesylate

Pexeva

Class and Category

Chemical class: Phenylpiperidine derivative
Therapeutic class: Antidepressant, anti-obsessional, antipanic
Pregnancy category: D

Indications and Dosages**↗ To treat major depression****C.R. TABLETS**

Adults. *Initial:* 25 mg daily, increased as prescribed and tolerated by 12.5 mg daily every wk. *Maximum:* 62.5 mg daily.

ORAL SUSPENSION, TABLETS

Adults. *Initial:* 20 mg daily, increased as prescribed and tolerated by 10 mg daily every wk. *Maximum:* 50 mg daily.

↗ To treat obsessive-compulsive disorder**ORAL SUSPENSION, TABLETS**

Adults. *Initial:* 20 mg daily, increased as prescribed and tolerated by 10 mg daily every wk. *Usual:* 20 to 60 mg daily.

Maximum: 60 mg daily.

↗ To treat panic disorder**C.R. TABLETS**

Adults. *Initial:* 12.5 mg daily, increased by 12.5 mg daily every wk as needed.

Maximum: 75 mg daily.

ORAL SUSPENSION, TABLETS

Adults. *Initial:* 10 mg daily, increased as prescribed and tolerated by 10 mg daily every wk. *Usual:* 10 to 60 mg daily.

Maximum: 60 mg daily.

↗ To treat social anxiety disorder**C.R. TABLETS**

Adults. *Initial:* 12.5 mg daily, increased by 12.5 mg daily every wk as needed.

Maximum: 37.5 mg daily.

ORAL SUSPENSION, TABLETS (HYDROCHLORIDE)

Adults. *Initial:* 20 mg daily, increased as prescribed and tolerated by 10 mg daily every wk. *Usual:* 20 to 60 mg daily.

Maximum: 60 mg daily.

↗ To treat generalized anxiety disorder**ORAL SUSPENSION, TABLETS (HYDROCHLORIDE)**

Adults. *Initial:* 20 mg daily, increased as prescribed and tolerated by 10 mg daily every wk. *Usual:* 20 to 50 mg daily.

Maximum: 60 mg daily.

↗ To treat posttraumatic stress disorder**ORAL SUSPENSION, TABLETS (HYDROCHLORIDE)**

Adults. *Initial:* 20 mg daily, increased as prescribed and tolerated by 10 mg daily every wk. *Usual:* 20 to 50 mg daily.

Maximum: 50 mg daily.

↗ To treat premenstrual dysphoric disorder**C.R. TABLETS**

Adults. *Initial:* 12.5 mg daily in the morning, increased as needed after 1 wk to 25 mg daily. Or, 12.5 mg daily in the morning only during luteal phase of menstrual cycle (2-wk

period before onset of monthly cycle), increased as needed after 1 wk to 25 mg daily in the morning during luteal phase of menstrual cycle.

DOSAGE ADJUSTMENT For patients who are elderly, debilitated, or have creatinine clearance less than 30 ml/min/1.73 m², initially 10 mg daily; maximum, 40 mg daily. Avoid C.R. form. For patients taking C.R. tablets with creatinine clearance less than 30 ml/min/1.73 m², initially 12.5 mg daily; maximum, 50 mg daily.

Route	Onset	Peak	Duration
P.O.	1–4 wk	Unknown	Unknown

Mechanism of Action

Exerts antidepressant, antiobsessional, and antipanic effects by potentiating serotonin activity in CNS and inhibiting serotonin reuptake at presynaptic neuronal membrane. Blocked serotonin reuptake increases levels and prolongs activity of serotonin at synaptic receptor sites.

Contraindications

Hypersensitivity to paroxetine or its components, pimozide therapy, use within 14 days of an MAO inhibitor, thioridazine therapy

Interactions**DRUGS**

antacids: Hastened release of C.R. paroxetine

aspirin, NSAIDs, warfarin: Increased anticoagulant activity and risk of bleeding

astemizole: Increased risk of arrhythmias

atomoxetine; risperidone; other drugs metabolized by CYP2D6, such as amitriptyline,

desipramine, fluoxetine, imipramine, phenothiazines, tamoxifen, type IC antiarrhythmics: Increased plasma levels of these drugs

barbiturates, primidone: Decreased blood paroxetine level

cimetidine: Possibly increased blood paroxetine level

cisapride, isoniazid, MAO inhibitors, procarbazine: Possibly serotonin syndrome

codeine, haloperidol, metoprolol, perphenazine, propranolol, risperidone, thioridazine: Decreased metabolism and increased effects of these drugs

cyproheptadine: Decreased paroxetine effects

dextromethorphan: Decreased dextromethorphan metabolism and increased risk

of toxicity

digoxin: Possibly decreased digoxin effects
encainide, flecainide, propafenone, quinidine: Potentiated toxicity of these drugs
fosamprenavir, ritonavir: Decreased plasma paroxetine level
lithium: Possibly increased blood paroxetine level, increased risk of serotonin syndrome
methadone: Decreased methadone metabolism, increased risk of adverse effects
phenytoin: Possibly phenytoin toxicity
pimozide: Increased risk of prolonged QT interval
procyclidine: Increased blood procyclidine level and anticholinergic effects
serotonergic drugs such as linezolid, St. John's wort, tramadol, triptans, and tryptophan: Increased risk of serotonin syndrome
tamoxifen: Decreased tamoxifen effectiveness
theophylline: Possibly increased blood theophylline level and risk of toxicity
thioridazine: Increased thioridazine level, possibly leading to prolonged QT interval and life-threatening ventricular arrhythmias
tramadol: Increased risk of serotonin syndrome and seizures
tricyclic antidepressants: Increased metabolism and blood antidepressant levels; increased risk of toxicity, including seizures

Adverse Reactions

CNS: Agitation, akathisia, asthenia, confusion, decreased concentration, dizziness, drowsiness, emotional lability, hallucinations, headache, insomnia, mania, neuroleptic malignant syndrome, psychomotor agitation, restlessness, serotonin syndrome, somnolence, suicidal ideation, tremor

CV: Palpitations, tachycardia

EENT: Blurred vision, dry mouth, rhinitis, taste perversion

GI: Abdominal cramps or pain, anorexia, constipation, diarrhea, flatulence, nausea, vomiting

GU: Decreased libido, difficult ejaculation, impotence, sexual dysfunction, urine retention

MS: Back pain, myalgia, myasthenia, myopathy

SKIN: Diaphoresis, rash

Other: Weight gain or loss

Nursing Considerations

- Shake oral suspension well. Measure with an oral syringe or calibrated device.

- Don't give enteric-coated form with antacids.
- Watch for akathisia (inner sense of restlessness) and psychomotor agitation, especially during the first few weeks of therapy.
- Watch patient closely (especially children, adolescents, and young adults), for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.
- Watch for mania, which may result from any antidepressant in a susceptible patient.
- Monitor patient closely for evidence of GI bleeding, especially if patient also takes a drug known to cause GI bleeding, such as aspirin, an NSAID, or warfarin.

WARNING Monitor patient closely for serotonin syndrome exhibited by agitation, hallucinations, coma, tachycardia, labile blood pressure, hyperthermia, hyperreflexia, incoordination, nausea, vomiting, or diarrhea. Notify prescriber immediately because serotonin syndrome may be life-threatening, and provide supportive care.

WARNING Be aware that serotonin syndrome in its most severe form may resemble neuroleptic malignant syndrome, which includes hyperthermia, muscle rigidity, and autonomic instability with possibly rapid changes in vital signs and mental status. Stop drug immediately, and provide supportive care.

- To minimize adverse reactions, expect to taper drug rather than stopping abruptly.

PATIENT TEACHING

- Advise patient to take paroxetine in the morning to minimize insomnia and to take it with food if adverse GI reactions develop.
- Instruct patient to avoid taking C.R. paroxetine within 2 hours of an antacid.
- Tell patient to swallow C.R. tablets whole and not to cut, crush, or chew them.
- Suggest that patient avoid hazardous activities until drug's CNS effects are known.
- Tell family or caregiver to observe patient closely for suicidal tendencies, especially when therapy starts or dosage changes and especially if patient is a child, teenager, or young adult.
- Explain that full effect may take 4 weeks.
- Urge patient to avoid alcohol during therapy; effects with paroxetine are unknown.

- Tell patient not to take aspirin or NSAIDs during therapy because they increase the risk of bleeding. If patient takes warfarin, tell her to use bleeding precautions and to notify prescriber at once if bleeding occurs.
- Inform patient that episodes of acute depression may persist for months or longer and that they require continued follow-up.
- Instruct patient not to stop drug abruptly but to taper dosage as instructed.
- Alert female patients of childbearing age that paroxetine may cause birth defects and persistent pulmonary hypertension in the newborn if taken during the first trimester of pregnancy. Stress the need for effective contraception and to notify prescriber if pregnancy occurs or is suspected.
- Caution patient to alert all prescribers about paroxetine therapy because of potentially serious drug interactions.

pegfilgrastim

Neulasta

Class and Category

Chemical class: Recombinant granulocyte colony-stimulating factor conjugate

Therapeutic class: Antineutropenic, hematopoietic stimulator

Pregnancy category: C

Indications and Dosages

➤ *To reduce the risk of infection, as manifested by febrile neutropenia, after myelosuppressive chemotherapy*

SUBCUTANEOUS INJECTION

Adults. 6 mg with each chemotherapy cycle.

Mechanism of Action

Induces formation of neutrophil progenitor cells by binding to receptors on granulocytes, which then divide. Pegfilgrastim also potentiates the effects of mature neutrophils, thus reducing fever and the risk of infection from severe neutropenia. It is pharmacologically identical to human granulocyte colony-stimulating factor.

Contraindications

Hypersensitivity to filgrastim, pegfilgrastim, or their components or to proteins derived from *Escherichia coli*

Interactions

DRUGS

lithium: Increased neutrophil production

Adverse Reactions

CNS: Fever

GI: Elevated liver function test results, splenic rupture, splenomegaly

GU: Elevated uric acid level

HEME: Leukocytosis, sickle cell crisis

MS: Bone pain

RESP: Acute respiratory distress syndrome, dyspnea, hypoxia, pulmonary infiltrates

SKIN: Acute febrile neutrophilic dermatosis (Sweet's syndrome), erythema, flushing, rash, urticaria

Other: Anaphylaxis, angioedema, antibody formation to pegfilgrastim, injection site reactions (pain, induration, erythema)

Nursing Considerations

- Avoid giving pegfilgrastim for 14 days before and 24 hours after cytotoxic chemotherapy.
- Check CBC, hematocrit, and platelet count before and periodically during therapy.
- Let drug warm to room temperature before injection. Use prefilled syringe and needles.
- Don't shake the solution.
- Discard drug that contains particles, is discolored, or was stored more than 48 hours at room temperature.

WARNING If signs of allergy occur, stop pegfilgrastim infusion and notify prescriber at once. If anaphylaxis occurs, give antihistamine, epinephrine, corticosteroid, and bronchodilator, as ordered.

WARNING Patients receiving filgrastim (parent drug) have had splenic rupture and acute respiratory distress syndrome. Assess patient for fever, respiratory distress, and upper abdominal or shoulder tip pain.

- Assess patients with sickle cell disease for signs of sickle cell crisis; urge hydration.
- Give nonopioid and opioid analgesics, as ordered, if patient experiences bone pain.
- Store drug at 2° to 8° C (36° to 46° F), and protect from freezing and light.
- Be aware that needle cover contains dry natural rubber and should not be handled by persons with a latex allergy.

PATIENT TEACHING

- Urge patient to promptly report possibly

serious reactions (trouble breathing, rash, chest tightness, left upper abdominal pain, shoulder tip pain) and evidence of infection (fever, chills).

- If patient will self-administer, teach her how to prepare, give, and store drug.
- Alert her that needle cover contains dry natural rubber and should not be handled if she has a latex allergy.
- Tell patient to rotate injection sites among thigh, abdomen (except for 2 inches around navel), buttocks, and outer, upper arms. Caution her to avoid tender, hard, red, or bruised areas.
- Urge patient to discard used needles and syringes in a puncture-resistant container and not to reuse them.
- Stress the importance of follow-up tests.
- Advise patient to store pegfilgrastim in refrigerator and not to freeze it. Tell her to discard drug if left unrefrigerated for more than 48 hours.

pegvisomant

Somavert

Class and Category

Chemical class: Human growth hormone (GH) receptor antagonist

Therapeutic class: Growth suppressant

Pregnancy category: B

Indications and Dosages

➤ *To treat acromegaly in patients with an inadequate response to surgery, radiation, or other medical treatment or for whom such treatment is inappropriate*

SUBCUTANEOUS INJECTION

Adults. *Initial:* 40 mg as loading dose on day 1; then 10 mg daily. *Maintenance:* Adjusted every 4 to 6 wk in 5-mg increments if insulin-like growth factor-I (IGF-I) levels are abnormal. *Maximum:* 30 mg daily.

Contraindications

Hypersensitivity to pegvisomant, its components, or latex

Interactions

DRUGS

insulin, oral antidiabetics: Enhanced action of insulin and oral antidiabetics, possibly

resulting in hypoglycemia
opioids: Decreased pegvisomant level

Adverse Reactions

CNS: Dizziness, paresthesia

CV: Chest pain, hypertension, peripheral edema

EENT: Ear infection, sinusitis

GI: Diarrhea, elevated liver function test results, nausea

MS: Back pain

RESP: Upper respiratory tract infection

SKIN: Blisters

Other: Cold, flulike symptoms, injection site lipohypertrophy and pain, weight gain

Nursing Considerations

- Obtain liver enzyme levels before starting pegvisomant, as ordered. If they're elevated but 3 times or less normal, expect to monitor them monthly for 6 months, quarterly for 6 months, and then twice yearly for the next year. If they're more than 3 times normal, expect to withhold drug until the cause of elevation has been determined.
- Reconstitute drug by injecting 1 ml of diluent provided (sterile water for injection) into vial, aiming the stream against vial wall. Hold vial between the palms of both hands and roll gently to dissolve powder. Don't shake. Give within 6 hours of reconstitution, and discard any remaining amount.
- Watch for evidence of liver dysfunction during therapy. If liver enzyme levels rise to 3 to 5 times normal but patient has no evidence of liver dysfunction (jaundice, bilirubinuria, fatigue, nausea, right-upper-quadrant pain, ascites, unexplained edema, easy bruising) or increases in serum total bilirubin level, expect therapy to continue but liver enzymes to be monitored weekly and a complete hepatic workup to be done. If enzyme levels are at least 5 times above normal or transaminase level is at least 3 times above normal with increased total bilirubin (with or without evidence of hepatic dysfunction), notify prescriber immediately and expect to stop drug. If patient develops evidence of hepatic dysfunction, regardless of liver enzyme levels, notify prescriber immediately, and expect a complete liver workup to be performed. If liver damage is con-

Mechanism of Action

In acromegaly, elevated blood levels of growth hormone (GH) overstimulate the liver to produce excessive amounts of insulin-like growth factors (IGFs), such as IGF-1. Excessive IGFs before puberty stimulate the linear growth of bones, causing the patient's unusual height and extremely long arms and legs. After puberty, the excessive hormone secretion

causes periosteal bone proliferation, resulting in widening of the hands and feet, and coarsening of the facial features, as well as other complications.

Pegvisomant selectively blocks GH cell surface receptors. As a result, the liver delivers less IGF-1 and other proteins to the blood, preventing the overgrowth of bone and other tissues.

firmed, expect drug to be stopped.

- Monitor patient's IGF-1 levels every 4 to 6 weeks, as ordered, until they've normalized and then every 6 months. Notify prescriber if levels are decreased or elevated. Be aware that GH levels should not be used to make dosage adjustments because pegvisomant interferes with laboratory measurement of GH.

PATIENT TEACHING

- Teach patient how to reconstitute and administer pegvisomant.
- Tell patient about the need for frequent laboratory studies and their importance to properly adjust drug dosage and detect drug-related abnormalities.
- Advise patient to stop drug immediately and notify prescriber if her skin or whites of her eyes become yellow or she has other evidence of liver dysfunction, such as dark urine, light-colored stools, little or no appetite for several days, nausea, tiredness, or abdominal pain.
- Instruct woman of childbearing age to report known or suspected pregnancy.
- Caution patient to tell prescriber about all other drugs she's taking.

penbutolol sulfate

Levatol

Class and Category

Chemical class: Nonselective beta-adrenergic blocker

Therapeutic class: Antihypertensive

Pregnancy category: Not rated

Indications and Dosages

↗ *To manage hypertension*

TABLETS

Adults. 20 mg daily.

DOSAGE ADJUSTMENT For elderly patients, dosage individualized according to sensitivity to drug.

Route	Onset	Peak	Duration
P.O.	Unknown	1.5–3 hr	Unknown

Mechanism of Action

May reduce blood pressure by competing with beta-adrenergic receptor agonists, which helps reduce cardiac output, decrease sympathetic outflow to peripheral blood

vessels, and inhibit renin release by kidneys.

Contraindications

Asthma, bradycardia (fewer than 45 beats/min), cardiogenic shock, heart failure, hypersensitivity to penbutolol or its components, second- or third-degree AV block

Interactions

DRUGS

allergen immunotherapy, allergenic extracts for skin testing: Increased risk of serious systemic reaction or anaphylaxis

amiodarone: Additive depressant effect on cardiac conduction, negative inotropic effects

anesthetics (hydrocarbon inhalation): Increased risk of myocardial depression and hypotension

calcium channel blockers, clonidine, diazoxide, guanabenz, other hypotension-producing drugs, reserpine: Additive hypotension and possibly other beta blocker effects

cimetidine: Possibly increased blood penbutolol level

estrogens: Decreased antihypertensive effect of penbutolol

fentanyl and its derivatives: Possibly increased risk of initial bradycardia after induction doses of fentanyl derivative (with long-term penbutolol use)

insulin, oral antidiabetic drugs: Possibly impaired glucose control and masking of hypoglycemia symptoms such as tachycardia

lidocaine: Decreased lidocaine clearance, increased risk of lidocaine toxicity

MAO inhibitors: Increased risk of significant hypertension

neuromuscular blockers: Possibly potentiated and prolonged action of these drugs

NSAIDs: Possibly decreased hypotensive effect of penbutolol

other beta blockers: Additive beta blocker effects

phenothiazines: Increased blood levels of both drugs

phenytoin (parenteral): Additive cardiac depressant effects

sympathomimetics, xanthines: Possibly inhibited effects of penbutolol and these drugs

Adverse Reactions

CNS: Anxiety, depression, dizziness, drowsi-

ness, fatigue, insomnia, light-headedness, nervousness, syncope, weakness

CV: Bradycardia, chest pain, edema, peripheral vascular insufficiency

EENT: Nasal congestion

GI: Constipation, diarrhea, epigastric pain, nausea, vomiting

GU: Impotence

RESP: Bronchospasm, dyspnea

Nursing Considerations

- Expect varied drug effectiveness in elderly patients, who may be more sensitive to antihypertensive effects because of reduced drug clearance by kidneys.

WARNING Avoid stopping penbutolol abruptly because doing so may precipitate MI, myocardial ischemia, severe hypertension, or ventricular arrhythmias, particularly in patients with cardiovascular disease. Watch for tachycardia because drug also may mask some signs of hyperthyroidism. Abrupt withdrawal of drug in patients with hyperthyroidism or thyrotoxicosis can precipitate thyroid storm.

- Monitor blood pressure and cardiac output, as appropriate, in patients who have a history of systolic heart failure or left ventricular dysfunction. Drug's negative inotropic effect can depress cardiac output.
- Monitor patients with diabetes mellitus who take antidiabetics because penbutolol can prolong hypoglycemia or promote hyperglycemia. It also can mask evidence of hypoglycemia, especially tachycardia, palpitations, and tremor.
- Watch for impaired circulation in elderly patients with age-related peripheral vascular disease or patients with Raynaud's phenomenon. Elderly patients are also at increased risk for beta blocker-induced hypothermia.
- Monitor drug refill frequency to help determine patient compliance.

PATIENT TEACHING

- Instruct patient to take penbutolol at the same time every day and not to change dosage without consulting prescriber.
- Advise patient not to stop taking drug abruptly, but to taper dosage gradually under prescriber's supervision.
- Instruct patient with diabetes mellitus to regularly monitor blood glucose level and test urine for ketones.

- Advise patient to consult prescriber before taking OTC drugs, especially cold products.
- Urge patient to avoid hazardous activities until CNS effects of drug are known.
- Instruct patient to inform prescriber of chest pain, fainting, light-headedness, or shortness of breath, any of which may indicate the need for a dosage change.
- Inform patient that penbutolol doesn't cure hypertension. Encourage her to follow recommended diet and lifestyle changes.

penicillamine

Cuprimine, Depen

Class and Category

Chemical class: Degradation product of penicillin

Therapeutic class: Antirheumatic, anti-uro lithic, chelating agent

Pregnancy category: D

Indications and Dosages

↗ *To treat cystinuria*

CAPSULES, TABLETS

Adults and adolescents. 500 mg q.i.d.

Children. 7.5 mg/kg q.i.d.

↗ *To treat rheumatoid arthritis*

CAPSULES, TABLETS

Adults and adolescents. *Initial:* 125 or 250 mg daily. Dosage increased by 125 or 250 mg daily every 2 to 3 mo. *Maximum:* 1,500 mg daily.

↗ *To treat Wilson's disease*

CAPSULES, TABLETS

Adults and adolescents. Dosage individualized up to 2 g daily in divided doses q.i.d. by measuring urinary copper excretion.

DOSAGE ADJUSTMENT For elderly patients, 125 mg daily initially, then increased by 125 mg daily every 2 to 3 mo, up to maximum of 750 mg daily. For pregnant women, maximum dose of 1 g daily. For women having planned cesarean section, dosage limited to 250 mg daily during last 6 wk of pregnancy and until wound healing completed.

Mechanism of Action

Combines with copper to form a ring-shaped complex that's excreted in urine, thereby reducing copper levels in the body.

Penicillamine also lowers urine cystine levels by binding with cystine to form penicillamine-cystine disulfide, which is more soluble than cystine and more easily excreted in urine. The decrease in urine cystine level also helps prevent formation of cystine calculi and may help existing cystine calculi dissolve over time. In addition, penicillamine improves lymphocyte function by reducing IgM rheumatoid factor and immune complexes in serum and synovial fluid, which may play a role in treatment of rheumatoid arthritis.

Route	Onset	Peak	Duration
P.O.	2–3 mo*	Unknown	Unknown

Contraindications

Hypersensitivity to penicillin, penicillamine, or their components; penicillamine-related aplastic anemia or agranulocytosis; renal insufficiency (for patients with rheumatoid arthritis)

Interactions

DRUGS

4-aminoquinolines, bone marrow depressants, gold compounds, immunosuppressants (excluding glucocorticoids), phenylbutazone: Possibly increased risk of serious hematologic or renal adverse reactions

iron supplements: Possibly decreased effectiveness of penicillamine

pyridoxine: Decreased effectiveness of pyridoxine, possibly increased risk of anemia or peripheral neuritis reaction

Adverse Reactions

CNS: Agitation, anxiety, fever, mental changes, myasthenic syndrome, neuropathy

EENT: Altered or loss of taste, optic neuritis, stomatitis, tinnitus

GI: Anorexia, diarrhea, hepatic dysfunction, intrahepatic cholestasis, mild epigastric pain, pancreatitis, nausea, toxic hepatitis, vomiting

GU: Glomerulonephropathy, hematuria, proteinuria, renal failure

HEME: Agranulocytosis, aplastic anemia, hemolytic anemia, leukopenia, thrombocytopenia

MS: Arthralgia, dystonia, muscle weakness

* For rheumatoid arthritis; 1 to 3 mo for Wilson's disease.

SKIN: Pemphigus, pruritus, rash, urticaria

Other: Lupuslike symptoms, lymphadenopathy

Nursing Considerations

- Use penicillamine cautiously in elderly patients because they're at greater risk for rash, altered taste, and renal impairment.
- Give penicillamine 1 hour before or 2 hours after meals and at least 1 hour before or after any other drug, food, or milk. Give last dose of day at least 3 hours after evening meal to maximize absorption.
- For patient who has difficulty swallowing capsules or tablets, open capsule and mix contents in 15 to 30 ml of pureed fruit or fruit juice to mask drug's sulfur odor. Alternatively, ask pharmacist to prepare elixir for oral administration.
- Expect to give 25 mg pyridoxine, as prescribed, to patients receiving penicillamine because penicillamine increases intake requirements for this vitamin.
- Watch for febrile reactions in patients who developed a fever during previous penicillamine therapy. Expect to stop drug if patient develops drug-induced fever.
- Assess skin and mucous membranes for possible sensitivity reactions, such as skin lesions and mouth ulcers. Be prepared to discontinue drug as prescribed.
- Expect to monitor urine laboratory test results twice weekly during first month of therapy, then every 2 weeks for next 5 months, and monthly thereafter. Watch for proteinuria or hematuria, which may precipitate nephrotic syndrome, especially in patients with renal disease or history of renal insufficiency. Also, weigh patient daily, watch for edema, and monitor intake and output because penicillamine may worsen underlying renal disease.

WARNING Monitor patient's WBC and differential cell count, hemoglobin, and platelet count, as ordered, and assess skin, lymph nodes, and body temperature for abnormalities twice weekly during first month of therapy, then every 2 weeks for next 5 months, and monthly thereafter because drug may cause potentially serious hematologic reactions.

- Because of the potential for cross-sensitivity between penicillamine and penicillin, monitor for allergic reaction in patients

with a history of penicillin allergy.

- Notify prescriber if patient reports decreased sense of taste, especially for salty and sweet foods. Expect normal taste sensation to be restored (except in patients with Wilson's disease) by giving of 5 to 10 mg of copper a day, as prescribed.
- Monitor patients with diabetes mellitus for reduced insulin requirements to prevent risk of nighttime hypoglycemia because penicillamine may promote formation of anti-insulin antibodies.
- Check liver function tests, as ordered, every 6 months (every 3 months for first year if patient has Wilson's disease) during penicillamine therapy because drug may cause serious hepatic dysfunction.

PATIENT TEACHING

- Advise patient to take penicillamine on an empty stomach.
- Instruct men and nonpregnant women with cystinuria to increase fluid intake and follow prescribed low-methionine diet to minimize cystine production and enhance drug's effectiveness. Urge patient to drink about 1 pint of fluid at bedtime and again during the night because this is when urine is more concentrated.
- Tell patient to notify prescriber immediately if he develops a fever, sore throat, chills, bruising, or bleeding because drug may need to be stopped.
- Instruct patient being treated for Wilson's disease to follow a diet low in copper, avoiding such foods as broccoli, chocolate, copper-enriched cereals, liver, molasses, mushrooms, nuts, and shellfish. Inform her that it may take 1 to 3 months of therapy for her condition to improve.
- Advise patient to consult prescriber before having dental work done during penicillamine therapy because drug can promote mouth ulcers.
- Instruct patient to avoid consuming iron during penicillamine therapy because iron can decrease drug's effectiveness.
- Explain that sense of taste may decrease during penicillamine therapy. Advise patient to notify prescriber if it becomes intolerable.
- Inform patient with rheumatoid arthritis that improvement may take 2 to 3 months of therapy.
- Caution female patient to notify prescriber

immediately if she becomes or may be pregnant because dosage may need to be reduced to prevent serious birth defects.

penicillin G benzathine

Bicillin C-R, Bicillin C-R 900/300, Bicillin L-A, Megacillin (CAN), Permapen

penicillin G potassium

Megacillin (CAN), Pentids, Pfizerpen

penicillin G procaine

Ayercillin (CAN), Crysticillin 300 AS, Pfizerpen-AS, Wycillin

penicillin G sodium

penicillin V potassium

Apo-Pen-VK (CAN), Beepen-VK, Betapen-VK, Ledercillin VK, Nadopen-V 200 (CAN), Nadopen-V 400 (CAN), Novo-Pen-VK (CAN), Nu-Pen VK (CAN), Pen Vee (CAN), Pen Vee K, V-Cillin K (CAN), Veetids

Class and Category

Chemical class: Penicillin
Therapeutic class: Antibiotic
Pregnancy category: B

Indications and Dosages

➤ *To treat systemic infections caused by gram-positive organisms (including Bacillus anthracis, Corynebacterium diphtheriae, enterococci, Listeria monocytogenes, Staphylococcus aureus, and S. epidermidis), gram-negative organisms (including Neisseria gonorrhoeae, N. meningitidis, Pasteurella multocida, and Streptobacillus moniliformis [rat-bite fever]), and gram-positive anaerobes (including Actinomyces israelii*

[actinomycosis], Clostridium perfringens, C. tetani, Peptococcus species, Peptostreptococcus species, and spirochetes, especially Treponema carateum [pinta], T. pallidum, and T. pertenu [yaws])

ORAL SOLUTION, TABLETS (PENICILLIN G POTASSIUM)

Adults and adolescents. 200,000 to 500,000 units (125 to 312 mg) every 4 to 6 hr. *Maximum:* 2 million units daily.

Children. 4,167 to 15,000 units/kg every 4 hr, 6,250 to 22,500 units/kg every 6 hr, or 8,333 to 30,000 units/kg every 8 hr.

TABLETS (PENICILLIN V POTASSIUM)

Adults and adolescents. 200,000 to 800,000 units (125 to 500 mg) every 6 to 8 hr. *Maximum:* 11,520,000 units (7,200 mg) daily

Children. 4,167 to 13,280 units (2.5 to 8.3 mg)/kg every 4 hr, 6,250 to 20,000 units (3.75 to 12.5 mg)/kg every 6 hr, or 8,333 to 26,720 units (5 to 16.7 mg)/kg every 8 hr.

I.V. INFUSION, I.M. INJECTION (PENICILLIN G POTASSIUM, PENICILLIN G SODIUM)

Adults and adolescents. 1 to 5 million units every 4 to 6 hr. *Maximum:* 80 million units daily.

Children. 8,333 to 16,667 units/kg every 4 hr or 12,500 to 25,000 units/kg every 6 hr.

Premature and full-term neonates.

30,000 units/kg every 12 hr.

I.M. INJECTION (PENICILLIN G PROCAINE)

Adults and adolescents. 600,000 to 1,200,000 units daily in divided doses every 12 to 24 hr.

➤ *To treat moderately severe to severe streptococcal infections*

I.M. INJECTION (PENICILLIN G BENZATHINE)

Adults and children weighing more than 45 kg (100 lb). 1.2 million units as a single injection.

Children weighing 27 to 45 kg (59 to 100 lb). 900,000 units as a single injection.

Children weighing less than 27 kg. 300,000 to 600,000 units as single injection.

➤ *To treat congenital syphilis*

I.M. INJECTION (PENICILLIN G BENZATHINE:

BICILLIN L-A ONLY)

Children under age 2. 50,000 units/kg as a single injection.

➤ *To treat syphilis of less than 1 year's duration*

I.M. INJECTION (PENICILLIN G BENZATHINE:

BICILLIN L-A ONLY

Adults and adolescents. 2.4 million units as a single injection.

Children. 50,000 units/kg up to adult dosage as a single injection. *Maximum:* 2.4 million units/dose.

↗ *To treat syphilis of more than 1 year's duration*

I.M. INJECTION (PENICILLIN G BENZATHINE: BICILLIN L-A ONLY)

Adults and adolescents. 2.4 million units every wk for 3 wk.

Children. 50,000 units/kg every wk for 3 wk.

↗ *To treat bacterial meningitis*

I.V. INFUSION, I.M. INJECTION (PENICILLIN G POTASSIUM)

Adults. 50,000 units/kg every 4 hr or 24 million units daily in divided doses every 2 to 4 hr.

Mechanism of Action

Inhibits final stage of bacterial cell wall synthesis by competitively binding to penicillin-binding proteins inside the cell wall. Penicillin-binding proteins are responsible for various steps in bacterial cell wall synthesis. By binding to these proteins, penicillin leads to cell wall lysis.

Incompatibilities

Don't mix any penicillin in the same syringe or container with aminoglycosides because aminoglycosides will be inactivated. Don't mix penicillin G with drugs that may result in a pH below 5.5 or above 8.

Contraindications

Hypersensitivity to penicillin or its components

Interactions**DRUGS**

ACE inhibitors, potassium-containing drugs, potassium-sparing diuretics: Increased risk of hyperkalemia (penicillin G potassium) *chloramphenicol, erythromycin, sulfonamides, tetracycline, thrombolytics:* Possibly interference with penicillin's bactericidal effect

cholestyramine, colestipol: Possibly impaired absorption of oral penicillin G

methotrexate: Decreased methotrexate clearance, increased risk of toxicity

oral contraceptives: Decreased contraceptive effectiveness (with penicillin V)

probenecid: Increased blood penicillin level

FOODS

acidic beverages, such as fruit juices: Possibly altered effects of oral penicillin G

Adverse Reactions

CNS: Confusion, dizziness, dysphasia, hallucinations, headache, lethargy, sciatic nerve irritation, seizures

CV: Labile blood pressure, palpitations

EENT: Black "hairy" tongue, oral candidiasis, stomatitis, taste perversion

GI: Abdominal pain, diarrhea, elevated liver function test results (transient), indigestion, nausea, pseudomembranous colitis

GU: Interstitial nephritis (acute), vaginal candidiasis

MS: Muscle twitching

SKIN: Rash

Other: Electrolyte imbalances; injection site necrosis, pain, or redness

Nursing Considerations

- Obtain body tissue and fluid samples for culture and sensitivity tests as ordered before giving first dose. Expect to begin drug therapy before test results are known.
 - Reconstitute vials of penicillin for injection with sterile water for injection, D₅W, or sodium chloride for injection.
 - Administer penicillin at least 1 hour before other antibiotics.
 - Inject I.M. form deep into large muscle mass. Apply ice to relieve pain.
- WARNING** Give penicillin G benzathine and penicillin G procaine only by deep I.M. injection; I.V. injection may be fatal, and intra-arterial injection may cause extensive tissue and organ necrosis.

- Be aware that I.M. drug is absorbed slowly, which may make allergic reactions difficult to treat.

- Assess patient for signs of secondary infection, such as profuse, watery diarrhea. If such diarrhea develops, contact prescriber and expect to obtain a stool specimen to rule out pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold penicillin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

- Monitor serum sodium level and assess for early signs of heart failure in patients receiving high doses of penicillin G sodium.

- When giving penicillin G potassium to patient at risk for hypertension or fluid overload, be aware that each gram of penicillin G potassium also contains 1.02 mEq of sodium.

PATIENT TEACHING

- Instruct patient to report previous allergies to penicillins and to notify prescriber immediately about adverse reactions, including fever.
- Advise patient who uses oral contraceptives to use an additional form of contraception during penicillin V therapy.
- Urge patient to tell prescriber if diarrhea develops, even 2 months or more after penicillin therapy ends.

pentamidine isethionate

NebuPent, Pentacarinat (CAN), Pentam 300, Pneumopent (CAN)

Class and Category

Chemical class: Diamidine derivative

Therapeutic class: Antiprotozoal

Pregnancy category: C

Indications and Dosages

↗ *To prevent *Pneumocystis jiroveci* (carinii) pneumonia*

ORAL INHALATION (NEBUPENT, PENTACARINAT)
Adults and adolescents. 300 mg every 4 wk or 150 mg every 2 wk, using nebulizer and continuing until chamber is empty (30 to 45 min).

ORAL INHALATION (PNEUMOPENT)
Adults and adolescents. *Initial:* 60 mg every 24 to 72 hr for 5 doses over 2 wk, using ultrasonic nebulizer and continuing until nebulizer chamber is empty (about 15 min). *Maintenance:* 60 mg every 2 wk, using ultrasonic nebulizer and continuing until nebulizer chamber is empty.

↗ *To treat *P. jiroveci* (carinii) pneumonia*

I.V. INFUSION, I.M. INJECTION
Adults and children. 4 mg/kg daily for 14 to 21 days, given deep I.M. or by I.V. infusion over 1 to 2 hr.

DOSE ADJUSTMENT Dosage possibly reduced or I.V. infusion time or dosing interval extended for patients with renal failure.

Mechanism of Action

May bind to DNA and inhibit DNA replication in *Pneumocystis jiroveci* (carinii). Pentamidine also may inhibit dihydrofolate reductase, an enzyme needed to convert dihydrofolic acid to tetrahydrofolic acid in this organism. This action inhibits formation of coenzymes essential to growth and replication of *P. jiroveci*.

Incompatibilities

Don't mix pentamidine with other drugs or with saline solutions because precipitation may occur.

Contraindications

History of anaphylactic reaction to pentamidine or its components (inhalation form)

Interactions

DRUGS

bone marrow depressants, drugs that cause blood dyscrasias: Increased risk of adverse hematologic effects

didanosine: Increased risk of pancreatitis
erythromycin (I.V.): Increased risk of torsades de pointes

foscarnet: Increased risk of severe but reversible hypocalcemia, hypomagnesemia, and nephrotoxicity

nephrotoxic drugs: Increased risk of nephrotoxicity

Adverse Reactions

CNS: Chills, confusion, dizziness, fatigue, fever, hallucinations, headache (I.V., I.M. forms)

CV: Arrhythmias, edema, hypotension, prolonged QT interval, torsades de pointes, ventricular tachycardia (I.V., I.M. forms)

EENT: Bitter or metallic taste (all forms), pharyngitis (inhalation form)

ENDO: Diabetes mellitus, hyperglycemia (I.V., I.M. forms); hypoglycemia (all forms)

GI: Abdominal pain, anorexia, diarrhea, elevated liver function test results, nausea, vomiting (I.V., I.M. forms); pancreatitis (all forms)

GU: Elevated serum creatinine level (I.V., I.M. forms); renal insufficiency (inhalation form)

HEME: Anemia, leukopenia, thrombocytopenia, unusual bleeding or bruising (I.V., I.M. forms)

MS: Myalgia (I.V., I.M. forms)

RESP: Bronchospasm, chest pain or congestion, cough, dyspnea, extrapulmonary pneumocystosis, pneumothorax (inhalation form)

SKIN: Night sweats (I.V., I.M. forms); rash (all forms)

Other: Hyperchloremic acidosis; hyperkalemia; hypocalcemia; hypomagnesemia; infusion site sterile abscess (I.V. form); injection site induration, pain, and phlebitis (I.M. form)

Nursing Considerations

- Store pentamidine at room temperature, protected from light. Use within 24 hours after reconstitution.
- For I.V. use, dissolve contents of 300-mg vial with 3 to 5 ml sterile water for injection or D₅W. Further dilute in 50 to 250 ml D₅W and infuse over 1 to 2 hours.
- For I.M. use, dissolve contents of vial in 3 ml sterile water for injection and inject deep into large muscle mass. Be aware that I.M. administration increases risk of sterile abscess formation at injection site.
- When giving drug I.V. or I.M., keep patient supine and monitor blood pressure frequently during and after administration. Keep emergency resuscitation equipment readily available.
- Assess for hypoglycemia and arrhythmias in patient receiving I.V. or I.M. pentamidine. Although uncommon, these adverse reactions can be severe.
- For inhalation, reconstitute contents of vial with 6 ml sterile water for injection (NebuPent or Pentacarinat) or 3 to 5 ml sterile water for injection or inhalation (Pneumopent). Reconstitute immediately before use. Don't use normal saline solution because it causes precipitation. Place reconstituted drug in Respigard II nebulizer, and set flow rate at 5 to 7 L/min for NebuPent or Pentacarinat. Don't mix with other drugs. For Pneumopent, place reconstituted drug in Fisoneb ultrasonic nebulizer and set flow rate at mid-flow mark.
- Administer aerosolized pentamidine with patient in supine or recumbent position for best distribution of drug.
- If patient who uses inhalation form has a history of asthma or smoking, notify prescriber if bronchospasm or a cough develops. She may need an aerosolized bron-

chodilator before each dose of pentamidine.

- Monitor CBC; platelet count; liver function test results; BUN, serum creatinine and calcium, and blood glucose levels; and ECG tracing throughout therapy, as ordered.
- Monitor blood glucose level because pentamidine use can induce insulin release from pancreas and severe hypoglycemia that can last from 1 day to several weeks.
- Be aware that hyperglycemia and diabetes mellitus can occur up to several months after parenteral therapy stops.

PATIENT TEACHING

- Stress importance of complying with prescribed administration schedule when pentamidine is used to prevent *P. jirovecii* (*carinii*) pneumonia.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to notify prescriber about unusual bleeding or bruising and to take precautions to avoid bleeding, as by using a soft-bristled toothbrush and an electric shaver.
- Caution patient about possible hypoglycemic effects of pentamidine therapy.
- Advise patient to have follow-up laboratory studies to test for diabetes mellitus, which can occur up to several months after stopping pentamidine therapy.

pentazocine lactate

Talwin

Class, Category, and Schedule

Chemical class: Synthetic opioid

Therapeutic class: Analgesic

Pregnancy category: C

Controlled substance schedule: IV

Indications and Dosages

↗ *To relieve moderate to severe pain*

I.V., I.M., OR SUBCUTANEOUS INJECTION

Adults. *Initial:* 30 mg every 3 to 4 hr, p.r.n. *Maximum:* 30 mg/single dose I.V., 60 mg/single dose I.M. or subcutaneously, or 360 mg/24 hr for all parenteral forms.

↗ *To relieve obstetric pain*

I.V. INJECTION

Adults. 20 mg when contractions become regular; repeated 2 or 3 times every 2 to

3 hr, as prescribed.

I.M. INJECTION

Adults. 30 mg as a single dose.

Route	Onset	Peak	Duration
I.V.	2–3 min	15–30 min	2–3 hr
I.M., SubQ	15–20 min	30–60 min	2–3 hr

Mechanism of Action

Binds with opioid receptors, mainly kappa and sigma receptors, at many CNS sites to alter perception of and emotional response to pain.

Incompatibilities

Don't mix pentazocine in same syringe with a soluble barbiturate because precipitation will occur.

Contraindications

Hypersensitivity to pentazocine or its components

Interactions

DRUGS

anticholinergics: Increased risk of urine retention and severe constipation
antidiarrheals, antiperistaltics: Increased risk of severe constipation and CNS depression
antihypertensives, diuretics, other hypotension-producing drugs: Additive hypotensive effects
buprenorphine: Decreased pentazocine effectiveness, increased respiratory depression
CNS depressants: Increased CNS depression, increased risk of habituation
hydroxyzine, other opioid analgesics: Increased analgesia, CNS depression, and hypotensive effects
MAO inhibitors: Increased risk of unpredictable, severe, even fatal adverse reactions
metoclopramide: Antagonized metoclopramide effects on GI motility
naloxone: Antagonized analgesic, CNS, and respiratory depressant effects of pentazocine
naltrexone: Withdrawal symptoms in patients physically dependent on pentazocine
neuromuscular blockers: Increased respiratory depression

ACTIVITIES

alcohol use: Additive CNS depression and increased risk of habituation

Adverse Reactions

CNS: Chills, dizziness, drowsiness, euphoria, fatigue, headache, insomnia, light-headedness, nervousness, nightmares, paresthesia, restlessness, weakness

CV: Hypotension, tachycardia

EENT: Blurred vision, diplopia, dry mouth, laryngeal edema, laryngospasm

GI: Constipation, hepatotoxicity, nausea, vomiting

GU: Decreased urine output, dysuria, urinary frequency, urine retention

MS: Muscle rigidity (with large doses)

RESP: Atelectasis, bronchospasm, dyspnea, hypoventilation, wheezing

SKIN: Diaphoresis, erythema multiforme, facial flushing, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Facial edema; injection site burning, pain, redness, or swelling; physical and psychological dependence

Nursing Considerations

- Use pentazocine with extreme caution in patients with head injury, intracranial lesion, or increased intracranial pressure. Drug may mask neurologic evidence.
- Use pentazocine cautiously in patients physically dependent on opioid agonists because drug may prompt withdrawal symptoms; in patients with acute MI because drug's cardiovascular effects can increase cardiac workload; in patients with renal or hepatic dysfunction because drug is metabolized in liver and excreted in urine; and in patients with respiratory conditions because drug depresses respiratory system.
- When giving repeated parenteral doses, use I.M. or I.V. route when possible and as prescribed because subcutaneous route may cause severe tissue damage at injection site. Rotate I.M. sites to avoid tissue damage.
- After giving parenteral form, expect to taper dosage gradually, as prescribed, to reduce the risk of withdrawal symptoms.

PATIENT TEACHING

- Caution patient that prolonged use of pentazocine may result in dependence.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Caution patient not to use alcohol or OTC drugs without consulting prescriber.

- Advise patient to report possible allergic reaction, such as a rash or itching.

pentobarbital sodium

Nembutal, Nova Rectal (CAN),
Novopentobarb (CAN)

Class, Category, and Schedule

Chemical class: Barbiturate

Therapeutic class: Anticonvulsant, sedative-hypnotic

Pregnancy category: D

Controlled substance schedule: II (oral, parenteral), III (rectal)

Indications and Dosages

↗ *To provide daytime sedation*

ELIXIR

Adults. 20 mg t.i.d. or q.i.d.

Children. 2 to 6 mg/kg daily.

SUPPOSITORIES

Adults. 30 mg b.i.d. to q.i.d.

Children. 2 mg/kg t.i.d.

↗ *To provide short-term treatment of insomnia*

CAPSULES, ELIXIR

Adults. 100 mg at bedtime.

I.V. INJECTION

Adults. *Initial:* 100 mg, with additional small doses at 1-min intervals, as prescribed. *Maximum:* 500 mg.

I.M. INJECTION

Adults. 150 to 200 mg at bedtime.

SUPPOSITORIES

Adults and adolescents over age 14. 120 to 200 mg at bedtime.

Children ages 12 to 14. 60 to 120 mg at bedtime.

Children ages 5 to 12. 60 mg at bedtime.

Children ages 1 to 4. 30 to 60 mg at bedtime.

Infants ages 2 months to 1 year. 30 mg at bedtime.

↗ *To provide preoperative sedation*

CAPSULES, ELIXIR

Adults. 100 mg before surgery.

Children. 2 to 6 mg/kg before surgery.

Maximum: 100 mg/dose.

I.M. INJECTION

Adults. 150 to 200 mg before surgery.

Children. 2 to 6 mg/kg before surgery.

Maximum: 100 mg/dose.

SUPPOSITORIES

Children ages 12 to 14. 60 to 120 mg before surgery.

Children ages 5 to 12. 60 mg before surgery.

Children ages 1 to 4. 30 to 60 mg before surgery.

Infants ages 2 months to 1 year. 30 mg before surgery.

↗ *To provide emergency treatment of seizures associated with eclampsia, meningitis, status epilepticus, tetanus, or toxic reactions to local anesthetics or strychnine*

I.V. INJECTION

Adults. 100 mg, with additional small doses at 1-min intervals, as prescribed. *Maximum:* 500 mg.

Children. 50 mg, with additional small doses at 1-min intervals, as prescribed, until desired effect occurs.

I.M. INJECTION

Children. 50 mg, with additional small doses at 1-min intervals, as prescribed, until desired effect occurs.

DOSE ADJUSTMENT Dosage possibly reduced for elderly or debilitated patients and those with hepatic dysfunction.

Route	Onset	Peak	Duration
P.O., P.R.	15–60 min	1–4 hr	3–4 hr
I.V.	In 1 min	Unknown	15 min
I.M.	10–25 min	Unknown	3–4 hr

Mechanism of Action

Inhibits ascending conduction in reticular formation, which controls CNS arousal to produce drowsiness, hypnosis, and sedation. Pentobarbital also decreases spread of seizure activity in cortex, thalamus, and limbic system. It promotes an increased threshold for electrical stimulation in the motor cortex, which may contribute to anticonvulsant effects.

Contraindications

Hepatic disease; history of addiction to hypnotics or sedatives; hypersensitivity to pentobarbital, barbiturates, or their components; nephritis; porphyria; severe respiratory disease with airway obstruction or dyspnea

Interactions

DRUGS

acetaminophen: Possibly decreased effects of

acetaminophen (long-term pentobarbital use)

carbamazepine, chloramphenicol, corticosteroids, cyclosporine, dacarbazine, digoxin, disopyramide, doxycycline, griseofulvin, metronidazole, oral contraceptives, phenylbutazone, quinidine, theophyllines, vitamin D: Decreased effectiveness of these drugs

CNS depressants: Increased CNS depression and risk of habituation

divalproex sodium, valproic acid: Increased risk of CNS toxicity and neurotoxicity

guanadrel, guanethidine: Possibly increased risk of orthostatic hypotension

halogenated hydrocarbon anesthetic: Increased risk of hepatotoxicity (with long-term pentobarbital use)

haloperidol: Possibly decreased blood haloperidol level, possibly altered seizure pattern or frequency

hydantoins: Possibly interference with hydantoin metabolism

leucovorin: Possibly decreased anticonvulsant effect of pentobarbital

maprotiline: Possibly enhanced CNS depression and decreased therapeutic effects of pentobarbital

mexiletine: Possibly decreased blood mexiletine level

oral anticoagulants: Possibly decreased effects of these drugs, possibly increased risk of bleeding when pentobarbital stops

tricyclic antidepressants: Possibly decreased therapeutic effects of these drugs

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Agitation, anxiety, ataxia, confusion, delusions, depression, dizziness, drowsiness, fever, hallucinations, headache, insomnia, irritability, nervousness, nightmares, paradoxical stimulation, seizures, syncope, tremor

CV: Orthostatic hypotension

EENT: Vision changes

GI: Anorexia, constipation, hepatic dysfunction, nausea, vomiting

HEME: Agranulocytosis

MS: Arthralgia, bone pain, muscle twitching or weakness

RESP: Respiratory depression

SKIN: Exfoliative dermatitis, rash, Stevens-Johnson syndrome

Other: Physical and psychological dependence, weight loss

Nursing Considerations

- Use pentobarbital with extreme caution in patients with depression, a history of drug abuse, or suicidal tendencies.
- Use drug cautiously in elderly or debilitated patients and those with acute or chronic pain because it may induce paradoxical stimulation.
- When using I.V. route, inject drug at 50 mg/min or less to avoid adverse respiratory and circulatory reactions.
- If patient shows premonitory signs of hepatic coma, withhold drug and notify prescriber immediately.
- Monitor I.V. site closely and avoid extravasation. Drug is highly alkaline and may cause local tissue damage and necrosis.

PATIENT TEACHING

- Inform patient that pentobarbital is habit-forming, and stress the importance of taking it exactly as prescribed.
- Instruct patient who takes elixir form to use a calibrated measuring device and to close container tightly after use.
- Instruct patient who uses suppositories to refrigerate them.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcohol and other CNS depressants because they may increase drug's adverse CNS effects.

pentosan polysulfate sodium

Elmiron

Class and Category

Chemical class: Low-molecular-weight heparin-like compound

Therapeutic class: Local anti-inflammatory (bladder-specific)

Pregnancy category: B

Indications and Dosages

↗ *To relieve bladder discomfort or pain caused by interstitial cystitis*

CAPSULES

Adults. 100 mg t.i.d. for up to 3 mo, possibly followed by another 3 mo if no

improvement and no adverse reactions.

Mechanism of Action

Adheres to mucosal membrane of bladder wall and may block irritating solutes from reaching cells, thereby decreasing local pain and discomfort.

Contraindications

Hypersensitivity to pentosan, other structurally related compounds, or their components

Interactions

DRUGS

alteplase (recombinant), aspirin (high doses), heparin, oral anticoagulants, streptokinase: Increased risk of hemorrhage

Adverse Reactions

CNS: Depression, dizziness, emotional lability, headache

GI: Abdominal pain, diarrhea, elevated liver enzyme levels, hepatic dysfunction, indigestion, nausea, rectal hemorrhage

HEME: Unusual bleeding or bruising

SKIN: Alopecia, rash

Nursing Considerations

- Use pentosan with extreme caution in patients with conditions that increase bleeding risk, such as aneurysm, diverticula, GI ulceration, hemophilia, polyps, and thrombocytopenia (especially heparin-induced).
- Use drug cautiously in patients with hepatic dysfunction because drug is desulfated in liver and spleen.
- Monitor patient for abnormal bleeding, such as unexplained bruises and epistaxis, because drug is a weak anticoagulant.

PATIENT TEACHING

- Instruct patient to take pentosan with a full glass of water at least 1 hour before or 2 hours after meals.
- Explain the pattern of exacerbations and remissions with interstitial cystitis. Reassure patient that symptoms should improve within 3 months after starting pentosan therapy.
- Advise patient to take bleeding precautions during therapy, such as using an electric shaver and a soft-bristled toothbrush.
- If alopecia develops, explain that it's usually confined to a single area.

pentoxifylline

Trental

Class and Category

Chemical class: Xanthine derivative

Therapeutic class: Blood viscosity reducer

Pregnancy category: C

Indications and Dosages

↗ *To treat peripheral vascular disease*

E.R. TABLETS

Adults. 400 mg t.i.d. with meals.

DOSAGE ADJUSTMENT Dosage possibly reduced to 400 mg b.i.d. for patients who experience adverse GI or CNS reactions.

Route	Onset	Peak	Duration
P.O.	2–4 wk	Unknown	Unknown

Mechanism of Action

Relieves symptoms of peripheral vascular disease by:

- reducing blood viscosity by decreasing plasma fibrinogen level and inhibiting RBC and platelet aggregation
- improving erythrocyte flexibility by inhibiting phosphodiesterase and increasing the amount of cAMP in RBCs
- decreasing peripheral vascular resistance and improving microcirculatory blood flow and tissue oxygenation.

Contraindications

Hypersensitivity to pentoxifylline, methylxanthines (such as caffeine, theophylline, and theobromine), or their components; recent cerebral or retinal hemorrhage

Interactions

DRUGS

antihypertensives: Potentiated antihypertensive effects

cefamandole, cefoperazone, cefotetan, heparin, oral anticoagulants, other platelet aggregation inhibitors, plicamycin, thrombolytics, valproic acid: Increased risk of bleeding

cimetidine: Increased blood pentoxifylline level, increased risk of adverse effects
sympathomimetics, xanthines: Enhanced CNS stimulation

ACTIVITIES

smoking: Possibly decreased therapeutic

effects of pentoxifylline

Adverse Reactions

CNS: Aseptic meningitis, dizziness, headache

GI: Indigestion, nausea, vomiting

Nursing Considerations

- Use pentoxifylline cautiously in elderly patients and those with hepatic or renal dysfunction.
- Give drug with meals and an antacid, if needed, to reduce adverse GI reactions.

PATIENT TEACHING

- Instruct patient to swallow pentoxifylline E.R. tablets whole and not to crush, break, or chew them.
- Advise patient to take drug with meals to reduce GI irritation. If adverse GI reactions occur anyway, advise her to also take an antacid with meals.
- Although symptoms may not improve for several weeks, urge patient to continue taking drug as prescribed to achieve maximum therapeutic effect.
- Instruct patient not to smoke during therapy because smoking constricts blood vessels and may reduce drug effectiveness.
- Urge patient to report adverse reactions; dosage may need reduction.

perindopril erbumine

Aceon

Class and Category

Chemical class: Perindoprilat prodrug

Therapeutic class: Antihypertensive

Pregnancy category: D

Indications and Dosages

↗ *To manage hypertension*

TABLETS

Adults. *Initial:* 4 mg daily as a single dose or in divided doses b.i.d., increased as prescribed until blood pressure is controlled or maximum dosage is reached. *Maintenance:* 4 to 8 mg daily. *Maximum:* 8 mg daily.

DOSAGE ADJUSTMENT If patient takes a diuretic, initial dosage possibly reduced to 2 to 4 mg daily; if patient has renal failure, initial dosage possibly reduced to 2 mg daily.

↗ *To reduce risk of cardiovascular death or nonfatal MI in patients with stable coronary artery disease*

TABLETS

Adults. *Initial:* 4 mg daily for 2 wk; then increased to 8 mg daily. *Maintenance:* 8 mg daily.

DOSAGE ADJUSTMENT If patient is elderly, 2 mg daily for 1 wk, increased to 4 mg daily for 1 wk and then to 8 mg daily if tolerated.

Mechanism of Action

Is converted to the active metabolite perindoprilat, which competes with angiotensin I binding sites, blocking conversion of angiotensin I to angiotensin II, a potent vasoconstrictor. As a result, this ACE inhibitor reduces vasoconstriction and blood pressure. Decreased angiotensin II also reduces aldosterone secretion, increasing renal excretion of water and sodium.

Contraindications

History of angioedema with ACE inhibitor treatment; hypersensitivity to perindopril, other ACE inhibitors, or their components

Interactions

DRUGS

diuretics: Increased risk of hypotension

lithium: Increased blood lithium level and risk of toxicity

potassium-sparing diuretics, potassium supplements: Increased risk of hyperkalemia

sodium aurothiomalate: Increased risk of nitritoid reaction with facial flushing, nausea, vomiting, and hypotension

Adverse Reactions

CNS: Amnesia, anxiety, dizziness, fatigue, fever, headache, hypertonia, migraine, syncope, vertigo

CV: Chest pain, ECG changes, heart murmur, hypotension, orthostatic hypotension, palpitations, PVCs

EENT: Conjunctivitis, earache, epistaxis, hoarseness, pharyngitis, rhinitis, sinusitis, sneezing, tinnitus

GI: Abdominal pain, diarrhea, elevated liver function test results, flatulence, increased appetite, indigestion

GU: Flank pain, renal calculi, urinary frequency and urgency, vaginitis

HEME: Hematoma, leukopenia, neutropenia

MS: Arthritis, back pain, gout, limb pain, myalgia, neck pain

RESP: Cough

SKIN: Canker sores, diaphoresis, dry skin, ecchymosis, erythema, pruritus, rash

Other: Angioedema, facial edema

Nursing Considerations

- Use cautiously with heart failure, renal artery stenosis, or renal dysfunction.
- Also use cautiously in elderly patients, and watch closely for adverse effects such as dizziness or vertigo, because these patients have an increased risk of falling.
- Monitor patients with hepatic dysfunction for enhanced therapeutic drug effects because drug's bioavailability is increased.
- Monitor serum potassium level to detect hyperkalemia, especially in patients with renal insufficiency or diabetes mellitus and those who use a potassium-containing salt substitute or take a potassium-sparing diuretic or potassium supplement.

PATIENT TEACHING

- Instruct patient to take perindopril exactly as prescribed, even if she feels well.

WARNING Urge patient to stop taking drug and notify prescriber immediately if she experiences signs of angioedema.

- Advise patient to notify prescriber at once about fever, sore throat, or other signs that may indicate neutropenia.
- Urge patient to avoid potassium supplements and potassium-containing salt substitutes unless prescriber approves.
- Instruct patient to avoid hazardous activities until drug's CNS effects are known.
- Advise woman to promptly report suspected, known, or intended pregnancy. Drug will need to be discontinued.

perphenazine

Apo-Perphenazine (CAN), PMS Perphenazine (CAN), Trilafon, Trilafon Concentrate

Class and Category

Chemical class: Piperazine phenothiazine

Therapeutic class: Antiemetic, antipsychotic

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat psychotic disorders*

ORAL SOLUTION

Hospitalized adults and adolescents. 8 to

16 mg b.i.d. to q.i.d., adjusted as prescribed and tolerated. *Maximum:* 64 mg daily.

TABLETS

Adults and adolescents. 4 to 16 mg b.i.d. to q.i.d., adjusted as prescribed and tolerated.

Maximum: 64 mg daily.

I.M. INJECTION

Adults and adolescents. 5 to 10 mg every 6 hr, adjusted as prescribed and tolerated.

Maximum: 15 mg daily for outpatients,

30 mg daily for hospitalized patients.

↗ *To treat severe nausea and vomiting*

TABLETS

Adults and adolescents. 8 to 16 mg daily in divided doses, decreased as appropriate.

Maximum: 24 mg daily.

I.V. INFUSION OR INJECTION

Adults and adolescents. 1 mg every 1 to 2 min, up to 5 mg total.

I.M. INJECTION

Adults and adolescents. 5 mg, increased to 10 mg as ordered for rapid control of severe vomiting.

Maximum: 15 mg daily for outpatients, 30 mg daily for hospitalized patients.

DOSAGE ADJUSTMENT Initial dose possibly reduced and gradually increased for elderly, emaciated, or debilitated patients.

Adolescents may need low adult dosage.

Route	Onset	Peak	Duration
P.O.	Several wk	4–7 days	Unknown
I.M.	Unknown	1–2 hr	6 hr

Mechanism of Action

Depresses areas of the brain that control activity and aggression, including cerebral cortex, hypothalamus, and limbic system, by an unknown mechanism. Perphenazine also prevents nausea and vomiting by inhibiting or blocking dopamine receptors in medullary chemoreceptor trigger zone and peripherally by blocking vagus nerve in the GI tract.

Incompatibilities

Don't mix perphenazine oral solution with beverages that contain caffeine or tannins (such as coffee, colas, and teas) or pectinates (such as apple juice) because they're physically incompatible.

Contraindications

Blood dyscrasias; bone marrow depression; cerebral arteriosclerosis; coma; concurrent

use of CNS depressants (large doses); coronary artery disease; hepatic impairment; hypersensitivity to perphenazine, other phenothiazines, or their components; myeloproliferative disorders; severe CNS depression; severe hypertension or hypotension; subcortical brain damage

Interactions

DRUGS

aluminum- and magnesium-containing antacids, antidiarrheals (adsorbent): Decreased absorption of oral perphenazine
amantadine, anticholinergics, antidyskinetics, antihistamines: Increased adverse anticholinergic effects
amphetamines: Decreased therapeutic effects of both drugs
 anticonvulsants: Decreased seizure threshold, inhibited metabolism and toxicity of anticonvulsant
antithyroid drugs: Increased risk of agranulocytosis
apomorphine: Additive CNS depression, decreased emetic response to apomorphine if perphenazine is given first
appetite suppressants (except phenmetrazine): Antagonized anorectic effect of appetite suppressants
beta blockers: Increased blood levels of both drugs and risk of arrhythmias, hypotension, irreversible retinopathy, and tardive dyskinesia
bromocriptine: Possibly interference with bromocriptine's effects
CNS depressants: Increased CNS and respiratory depression and hypotensive effects
dopamine: Antagonized peripheral vasoconstriction with high doses of dopamine
ephedrine: Decreased vasopressor response to ephedrine
epinephrine: Blocked alpha-adrenergic effects of epinephrine, possibly causing severe hypotension and tachycardia
hepatotoxic drugs: Increased risk of hepatotoxicity
hypotension-causing drugs: Increased risk of severe orthostatic hypotension
levodopa: Inhibited antidyskinetic effects of levodopa
lithium: Possibly neurotoxicity (disorientation, extrapyramidal symptoms, unconsciousness)
maprotiline, selective serotonin reuptake

inhibitors, tricyclic antidepressants:

Prolonged and intensified sedative and anticholinergic effects of these drugs or perphenazine

metrizamide: Decreased seizure threshold
opioid analgesics: Increased CNS and respiratory depression, increased risk of orthostatic hypotension and severe constipation
ototoxic drugs, especially antibiotics: Possibly masking of some symptoms of ototoxicity, such as dizziness, tinnitus, and vertigo
 probucol, other drugs that prolong QT interval: Prolonged QT interval, which may increase risk of ventricular tachycardia
thiazide diuretics: Possibly hyponatremia and water intoxication

ACTIVITIES

alcohol use: Increased CNS and respiratory depression, hypotensive effects, and risk of heatstroke

Adverse Reactions

CNS: Behavioral changes, cerebral edema, dizziness, drowsiness, extrapyramidal reactions (such as akathisia, dystonia, pseudoparkinsonism), fever, headache, neuroleptic malignant syndrome, seizures, suicidal ideation, syncope, tardive dyskinesia (persistent)

CV: Bradycardia, cardiac arrest, hypertension, hypotension, orthostatic hypotension, tachycardia

EENT: Blurred vision, dry mouth, glaucoma, laryngeal edema, miosis, mydriasis, nasal congestion, ocular changes (corneal opacification, retinopathy)

ENDO: Decreased libido, galactorrhea, gynecomastia, syndrome of inappropriate ADH secretion

GI: Anorexia, constipation, diarrhea, fecal impaction, nausea, vomiting

GU: Bladder paralysis, ejaculation failure, menstrual irregularities, polyuria, urinary frequency, urinary incontinence, urine retention

HEME: Agranulocytosis, eosinophilia, hemolytic anemia, leukopenia, pancytopenia, thrombocytopenic purpura

RESP: Asthma

SKIN: Diaphoresis, eczema, erythema, exfoliative dermatitis, hyperpigmentation, jaundice, pallor, photosensitivity, pruritus, urticaria

Other: Anaphylaxis, angioedema

Nursing Considerations

- Perphenazine shouldn't be used to treat dementia-related psychosis in the elderly because of an increased mortality risk.
- Use perphenazine cautiously in patients with depression or hepatic, pulmonary, or renal dysfunction and in elderly patients, who are at increased risk for increased plasma concentrations and tardive dyskinesia.
- For I.V. use, dilute drug to 0.5 mg/ml with sodium chloride for injection. Protect solution from light. Slight yellowing is acceptable, but discard solution if it's markedly discolored or contains precipitate.
- Obtain blood samples for CBC and liver and renal function tests, as ordered, to detect adverse reactions.
- Monitor temperature frequently, and notify prescriber if it rises; a significant increase suggests drug intolerance.
- Monitor blood pressure of patient who takes large doses of perphenazine, especially if surgery is indicated, because of the increased risk of hypotension.
- Watch patient closely (especially children, adolescents, and young adults), for suicidal tendencies, particularly when perphenazine therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.

PATIENT TEACHING

- Instruct patient to take drug exactly as prescribed to ensure optimal effectiveness and minimize adverse reactions.
- Remind patient who takes oral solution to use a calibrated measuring device.
- Instruct patient taking oral solution to dilute every 5 ml (teaspoon) of drug in 2 fluid oz of water, milk, tomato juice, fruit juice (except apple), soup, or carbonated beverage. Caution against using beverages that contain caffeine or tannins (cola, coffee, tea).
- Caution patient not to spill oral solution on skin or clothing because it can cause contact dermatitis and damage clothing.
- Urge patient to avoid alcohol and other CNS depressants during perphenazine therapy and to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to avoid excessive sun exposure and to protect skin when outdoors.

- Instruct patient to notify prescriber about persistent or severe adverse reactions.
- Urge patient to comply with long-term follow-up to detect adverse reactions and determine possible need for perphenazine dosage adjustments.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.

phenazopyridine hydrochloride

Azo-Standard, Baridium, Eridium, Geridium, Phenazo (CAN), Phenazodine, Pyridiate, Pyridium, Urodine, Urogesic, Viridium

Class and Category

Chemical class: Azo dye

Therapeutic class: Urinary analgesic

Pregnancy category: B

Indications and Dosages

➤ *To relieve burning and pain on urination, and urinary frequency and urgency*

TABLETS

Adults and adolescents. 200 mg t.i.d. with or without food for no longer than 2 days.

Children. 4 mg/kg t.i.d. with food for no longer than 2 days.

Mechanism of Action

Exerts a topical or local anesthetic effect on urinary tract mucosa as drug is excreted in urine. Phenazopyridine's exact mechanism is unknown.

Contraindications

Hypersensitivity to phenazopyridine or its components, renal insufficiency

Adverse Reactions

CNS: Headache

GI: Indigestion, nausea, vomiting

GU: Reddish orange urine

SKIN: Pruritus, rash

Other: Discoloration of body fluids

Nursing Considerations

- Notify prescriber if yellowish skin or sclerae develop in patient taking phenazopyridine because this may indicate drug accu-

mulation from impaired renal excretion. Expect prescriber to discontinue drug.

- Be aware that phenazopyridine treatment should be limited to 2 days in patients with UTI.

PATIENT TEACHING

- Instruct patient not to take drug for longer than 2 days and to notify prescriber if symptoms persist beyond that time.
- If GI distress develops, advise patient to take drug with meals.
- Inform patient that drug turns urine orange to red and may discolor other body fluids, such as tears.
- Advise patient not to wear contact lenses during therapy because they may become stained.

phenelzine sulfate

Nardil

Class and Category

Chemical class: Hydrazine derivative

Therapeutic class: Antidepressant

Pregnancy category: C

Indications and Dosages

➤ *To treat depression*

TABLETS

Adults. *Initial:* 1 mg/kg daily, increased gradually as prescribed and tolerated.

Maintenance: 45 mg daily. *Maximum:* 90 mg daily.

DOSAGE ADJUSTMENT For elderly patients, initially may be reduced to 0.8 to 1 mg/kg daily in divided doses, increased as ordered and tolerated to maximum of 60 mg daily.

Route	Onset	Peak	Duration
P.O.	7–10 days	4–8 wk	10 days

Contraindications

Cardiovascular disease; cerebrovascular disease; heart failure; hepatic disease; history of headaches; hypersensitivity to phenelzine or its components; hypertension; pheochromocytoma; severe renal impairment; use of anesthetics, antihypertensives, bupropion, buspirone, carbamazepine, CNS depressants, cyclobenzaprine, dextromethorphan, meperidine, selective serotonin-reuptake inhibitors, sympathomimetics, or tricyclic

antidepressants; use within 14 days of other MAO inhibitor

Interactions

DRUGS

anticholinergics, antidyskinetics, antihistamines: Increased anticholinergic effect, prolonged CNS depression (antihistamines)

anticonvulsants: Increased CNS depression, possibly altered pattern of seizures

beta blockers: Increased risk of bradycardia
bromocriptine: Possibly interference with bromocriptine effects

bupropion: Increased risk of bupropion toxicity

buspirone: Increased risk of hypertension
caffeine-containing drugs: Increased risk of dangerous arrhythmias and severe hypertension

carbamazepine, cyclobenzaprine, maprotiline, other MAO inhibitors: Increased risk of hyperpyretic crisis, hypertensive crisis, severe seizures, and death; altered pattern of seizures (with carbamazepine)

CNS depressants: Increased CNS depression
dextromethorphan: Increased risk of excitation, hypertension, and hyperpyrexia

diuretics: Increased hypotensive effect
doxapram: Increased vasopressor effects of either drug

fluoxetine: Increased risk of agitation, confusion, GI symptoms, hyperpyretic episodes, hypertensive crisis, potentially fatal serotonin syndrome, restlessness, and severe seizures.

guanadrel, guanethidine: Increased risk of hypertension

haloperidol, loxapine, molindone, phenothiazines, pimozone, thioxanthenes: Prolonged and intensified anticholinergic, hypotensive, and sedative effects of these drugs or phenelzine

insulin, oral antidiabetic drugs: Increased hypoglycemic effects

levodopa: Increased risk of sudden, moderate to severe hypertension

local anesthetics (with epinephrine or levonordefrin): Possibly severe hypertension
meperidine, other opioid analgesics:

Increased risk of coma, hyperpyrexia, hypotension, immediate excitation, rigidity, seizures, severe hypertension, severe respiratory depression, sweating, vascular collapse, and death

methylodopa: Increased risk of hallucina-

Mechanism of Action

Phenelzine relieves symptoms of unipolar depressive disorders by inhibiting the enzyme monoamine oxidase (MAO). Normally, MAO breaks down monoamine neurotransmitters, such as serotonin, as shown below left. By inhibiting this enzyme, phenelzine increases the

concentration of serotonin in the vesicles of monoamine nerve endings, allowing more serotonin to be released and engage with receptors on postsynaptic cells, as shown below right. A serotonin deficiency may be responsible in part for endogenous depression.

tions, headache, hyperexcitability, and severe hypertension

methylphenidate: Increased CNS stimulant effect of methylphenidate

metrizamide: Decreased seizure threshold, increased risk of seizures

oral anticoagulants: Increased anticoagulant activity

paroxetine, sertraline, trazodone, tricyclic antidepressants: Increased risk of potentially fatal serotonin syndrome

phenylephrine (nasal or ophthalmic): Potentiated vasopressor effect of phenylephrine

rauwolfia alkaloids: Increased risk of moderate to severe hypertension, CNS depression (when phenelzine is added to rauwolfia alkaloid therapy), CNS excitation and hypertension (when rauwolfia alkaloid is added to phenelzine therapy)

spinal anesthetics: Increased risk of hypotension

succinylcholine: Possibly increased neuromuscular blockade of succinylcholine

sympathomimetics: Prolonged and intensified cardiac stimulant and vasopressor effects

tryptophan: Increased risk of confusion, dis-

orientation, hyperreflexia, hyperthermia, hyperventilation, mania or hypomania, and shivering

FOODS

foods and beverages high in tyramine or other pressor amines, such as aged cheese; beer; fava beans or other broad beans; cured meat or sausage; liqueurs; overripe fruit; red and white wine; reduced-alcohol and alcohol-free beer and wine; sauerkraut; sherry; smoked or pickled fish, meats, and poultry; yeast or protein extracts: Increased risk of sudden, severe hypertension

ACTIVITIES

alcohol use: Increased CNS depressant effects and hypertensive crisis

Adverse Reactions

CNS: Agitation, dizziness, drowsiness, headache, overstimulation, restlessness, sedation, sleep disturbance, suicidal ideation, weakness

CV: Bradycardia, edema, hypertensive crisis, orthostatic hypotension, palpitations, tachycardia

EENT: Blurred vision, dry mouth, photophobia

ENDO: Hypoglycemia in diabetic patients

GI: Abdominal pain, constipation, diarrhea,

elevated liver function test results, increased appetite, nausea

GU: Impotence, priapism, sexual dysfunction, urinary frequency, urine retention

MS: Muscle twitching

SKIN: Diaphoresis, rash

Other: Hyponatremia, weight gain

Nursing Considerations

- Use phenelzine cautiously in patients with epilepsy because drug may alter seizure threshold.
- Use phenelzine cautiously in patients with diabetes mellitus because insulin sensitivity may increase, predisposing patient to hypoglycemia.
- Expect to observe some therapeutic effect within 7 to 10 days, but keep in mind that full effect may not occur for 4 to 8 weeks.
- Monitor cardiovascular status closely for changes in heart rate (especially if patient receives more than 30 mg daily) and signs of life-threatening hypertensive crisis. Question patient often about headaches and palpitations. If either occurs, notify prescriber and expect to discontinue drug.
- Keep phentolamine readily available to treat hypertensive crisis. Give 5 mg by slow I.V., as prescribed, to reduce blood pressure without causing excessive hypotension. Use external cooling measures, as prescribed, to manage fever.
- To avoid hypertensive crisis, expect to wait 10 to 14 days, as prescribed, when switching patient from one MAO inhibitor to another or when switching from a dibenzazepine-related drug, such as amitriptyline or perphenazine.
- Watch closely for suicidal tendencies, especially in children, adolescents, and young adults and especially when therapy starts or dosage changes.

PATIENT TEACHING

- Inform patient and family members that therapeutic effects of phenelzine may take several weeks to appear and that she should continue taking drug as prescribed.
- Caution patient to rise slowly from a lying or sitting position to minimize effects of orthostatic hypotension.

WARNING Instruct patient to avoid the following foods, beverages, and drugs during phenelzine therapy and for 2 weeks afterward: alcohol-free and reduced-alcohol

beer and wine; appetite suppressants; beer; broad beans; cheese (except cottage and cream cheese); chocolate and caffeine in large quantities; dry sausage (including Genoa salami, hard salami, pepperoni, and Lebanon bologna); hay fever drugs; inhaled asthma drugs; liver; meat extract; OTC cold and cough preparations (including those containing dextromethorphan), nasal decongestants (tablets, drops, or spray); pickled herring; products that contain tryptophan; protein-rich foods that may have undergone protein changes by aging, pickling, fermenting, or smoking; sauerkraut; sinus drugs; weight-loss preparations; yeast extracts (including brewer's yeast in large quantities); yogurt; and wine.

- Advise patient to inform all health care providers (including dentists) that she takes an MAO inhibitor because certain drugs are contraindicated within 2 weeks.
- Urge patient to avoid hazardous activities until drug's CNS effects are known.
- Stress the importance of reporting headaches and other unusual, persistent, or severe symptoms.
- Tell family or caregiver to watch closely for suicidal tendencies, especially in children, adolescents, and young adults and especially when therapy starts or dosage changes.
- Urge patient with diabetes who's taking insulin or an oral antidiabetic to check blood glucose level often during therapy because phenelzine may affect glucose control.

phenobarbital

Ancalixir (CAN), Barbital, Solfoton

phenobarbital sodium

Luminal

Class, Category, and Schedule

Chemical class: Barbiturate

Therapeutic class: Anticonvulsant, sedative-hypnotic

Pregnancy category: D

Controlled substance schedule: IV

Indications and Dosages

↗ *To treat seizures*

CAPSULES, ELIXIR, TABLETS

Adults. 60 to 250 mg daily as a single dose or in divided doses.

Children. 1 to 6 mg/kg daily as a single dose or in divided doses.

I.V. INJECTION

Adults. 100 to 320 mg, repeated as needed and as prescribed. *Maximum:* 600 mg daily.

Children. *Initial:* 10 to 20 mg/kg as a single dose. *Maintenance:* 1 to 6 mg/kg daily.

↗ *To treat status epilepticus*

I.V. INFUSION OR INJECTION

Adults. 10 to 20 mg/kg given slowly and repeated as needed and as prescribed.

Children. 15 to 20 mg/kg over 10 to 15 min.

↗ *To provide short-term treatment of insomnia*

CAPSULES, ELIXIR, TABLETS

Adults. 100 to 320 mg at bedtime.

I.V., I.M., OR SUBCUTANEOUS INJECTION

Adults. 100 to 325 mg at bedtime.

↗ *To provide daytime sedation*

CAPSULES, ELIXIR, TABLETS

Adults. 30 to 120 mg daily in divided doses b.i.d. or t.i.d.

Children. 2 mg/kg t.i.d.

I.V., I.M., OR SUBCUTANEOUS INJECTION

Adults. 30 to 120 mg daily in divided doses b.i.d. or t.i.d.

↗ *To provide preoperative sedation*

CAPSULES, ELIXIR, TABLETS

Children. 1 to 3 mg/kg before surgery.

I.M. INJECTION

Adults. 130 to 200 mg 60 to 90 min before surgery.

I.V. OR I.M. INJECTION

Children. 1 to 3 mg/kg 60 to 90 min before surgery.

DOSAGE ADJUSTMENT Dosage possibly reduced for elderly or debilitated patients to minimize confusion, depression, and excitement.

Route	Onset	Peak	Duration
P.O.	20–60 min	Unknown	Unknown
I.V.	5 min	30 min	4–6 hr
I.M.,	5–20 min	Unknown	4–6 hr
SubQ			

Mechanism of Action

Inhibits ascending conduction of impulses

in the reticular formation, which controls CNS arousal to produce drowsiness, hypnosis, and sedation. Phenobarbital also decreases the spread of seizure activity in cortex, thalamus, and limbic system. It promotes an increased threshold for electrical stimulation in the motor cortex, which may contribute to its anticonvulsant properties.

Contraindications

Hepatic disease; history of addiction to hypnotics or sedatives; hypersensitivity to phenobarbital, other barbiturates, or their components; nephritis; porphyria; severe respiratory disease with airway obstruction or dyspnea

Interactions

DRUGS

acetaminophen: Decreased acetaminophen effectiveness with long-term phenobarbital therapy

amphetamines: Delayed intestinal absorption of phenobarbital

anesthetics (halogenated hydrocarbon):

Possibly hepatotoxicity

anticonvulsants (hydantoin): Unpredictable effects on metabolism of anticonvulsant

anticonvulsants (succinimide), including carbamazepine: Decreased blood levels and elimination half-lives of these drugs

calcium channel blockers: Possibly excessive hypotension

carbonic anhydrase inhibitors: Enhanced osteopenia induced by phenobarbital

chloramphenicol, corticosteroids, cyclosporine, dacarbazine, digoxin, metronidazole, quinidine: Decreased effectiveness of these drugs from enhanced metabolism

CNS depressants: Additive CNS depression

cyclophosphamide: Possibly reduced half-life and increased leukopenic activity of cyclophosphamide

disopyramide: Possibly ineffectiveness of disopyramide

doxycycline, fenoprofen: Shortened half-life of these drugs

griseofulvin: Possibly decreased absorption and effectiveness of griseofulvin

guanadrel, guanethidine: Possibly increased orthostatic hypotension

haloperidol: Decreased seizure threshold, decreased blood haloperidol level

ketamine (high doses): Increased risk of hypotension and respiratory depression

leucovorin: Interference with phenobarbital's anticonvulsant effect
levothyroxine, oral contraceptives, phenylbutazone, tricyclic antidepressants: Decreased effectiveness of these drugs
loxapine, phenothiazines, thioxanthenes: Decreased seizure threshold
MAO inhibitors: Prolonged phenobarbital effects, possibly altered pattern of seizure activity
maprotiline: Increased CNS depression, decreased seizure threshold at high doses, decreased phenobarbital effectiveness
methoxyflurane: Possibly hepatotoxicity and nephrotoxicity
methylphenidate: Increased risk of phenobarbital toxicity
mexiletine: Decreased blood mexiletine level
oral anticoagulants: Decreased anticoagulant activity, increased risk of bleeding when phenobarbital is discontinued
pituitary hormones (posterior): Increased risk of arrhythmias and coronary insufficiency
primidone: Altered pattern of seizures, increased CNS effects of both drugs
valproate, valproic acid: Decreased phenobarbital metabolism, increased risk of barbiturate toxicity
vitamin D: Decreased phenobarbital effectiveness
xanthines: Increased xanthine metabolism, antagonized hypnotic effect of phenobarbital

ACTIVITIES
alcohol use: Additive CNS depression

Adverse Reactions

CNS: Anxiety, depression, dizziness, drowsiness, headache, irritability, lethargy, mood changes, paradoxical stimulation, sedation, vertigo
CV: Hypotension, sinus bradycardia
EENT: Miosis, ptosis
GI: Constipation, diarrhea, nausea, vomiting
GU: Decreased libido, impotence, sexual dysfunction
MS: Arthralgia, bone tenderness
RESP: Bronchospasm, respiratory depression
SKIN: Dermatitis, photosensitivity, rash, urticaria
Other: Injection site phlebitis (I.V.), physical and psychological dependence

Nursing Considerations

- Be aware that phenobarbital shouldn't be given during third trimester of pregnancy because repeated use can cause dependence in neonate. It also shouldn't be given to breast-feeding women because it may cause CNS depression in infants.
- Use I.V. route cautiously in patients with CV disease, hypotension, pulmonary disease, or shock because drug may cause adverse hemodynamic or respiratory effects.
- Because drug can cause respiratory depression, assess respiratory rate and depth before use, especially in patient with bronchopneumonia, pulmonary disease, respiratory tract infection, or status asthmaticus.
- Give elixir undiluted or mix with water, milk, or fruit juice. Use a calibrated device to measure doses.
- If necessary, crush tablets and mix with food or fluids.
- Reconstitute sterile powder with at least 10 ml sterile water for injection. Don't use reconstituted solution if it fails to clear within 5 minutes. Further dilute prescribed dose with normal saline solution or D₅W and infuse over 30 to 60 minutes.
- Don't give more rapidly than 60 mg/min by I.V. injection.
- During I.V. use, monitor blood pressure, respiratory rate, and heart rate and rhythm. Anticipate increased risk of hypotension, even at recommended rate. Keep resuscitation equipment readily available.
- During I.M. use, don't inject more than 5 ml into any one I.M. site to prevent sterile abscess formation.
- Be aware that drug may cause physical and psychological dependence.
- Expect that phenobarbital's CNS effects may exacerbate major depression, suicidal tendencies, or other mental disorders.
- Take safety precautions for elderly patients, as appropriate, because they're more likely to experience confusion, depression, and excitement as adverse CNS reactions.
- Anticipate that phenobarbital may cause paradoxical stimulation in children.
- Be aware that drug may trigger signs and symptoms in patients with acute intermittent porphyria.

PATIENT TEACHING

- Instruct patient to take phenobarbital elixir undiluted or to mix it with water, milk, or fruit juice. Advise her to use a calibrated device to measure doses.
- If patient has trouble swallowing tablets, suggest crushing and adding to food or fluid.
- Caution patient about possible drowsiness and reduced alertness. Advise her to avoid potentially hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcohol during therapy.
- Inform parents that a child may react with paradoxical excitement. Tell them to notify prescriber if this occurs.
- Instruct woman to report suspected, known, or intended pregnancy. Advise against breast-feeding during therapy.

phentolamine mesylate

Regitine

Class and Category

Chemical class: Imidazoline

Therapeutic class: Antihypertensive, diagnostic aid, vasodilator

Pregnancy category: Not rated

Indications and Dosages

↗ *To diagnose pheochromocytoma*

I.V. INJECTION

Adults. 2.5 mg as a single dose. After negative result, repeat test with 5-mg dose, as prescribed.

Children. 1 mg as a single dose. After negative result, repeat test with 0.1-mg/kg dose, as prescribed.

↗ *To manage hypertension before or during pheochromocytectomy*

I.V. OR I.M. INJECTION

Adults. 5 mg 1 to 2 hr before surgery, repeated as needed and as prescribed. During surgery, 5 mg I.V., as ordered.

Children. 1 mg 1 to 2 hr before surgery, repeated as needed and as prescribed. During surgery, 1 mg I.V., as ordered.

↗ *To prevent dermal necrosis or sloughing after extravasation of I.V. norepinephrine*

I.V. INJECTION

Adults, children, and infants. 10 mg/L of I.V. fluid that contains norepinephrine at rate determined by patient response.

↗ *To treat dermal necrosis or sloughing after extravasation of I.V. norepinephrine*

INTRADERMAL INJECTION

Adults. 5 to 10 mg in 10 ml of normal saline solution infiltrated in affected area within 12 hr of extravasation.

Children. 0.1 to 0.2 mg/kg. *Maximum:* 10 mg.

Mechanism of Action

Blocks the actions of circulating epinephrine and norepinephrine by antagonizing α_1 and α_2 receptors. Phentolamine causes peripheral vasodilation through direct relaxation of vascular smooth muscle and α blockade. Positive inotropic and chronotropic effects increase cardiac output. A positive inotropic effect primarily raises blood pressure, but in larger doses, phentolamine causes peripheral vasodilation and can reduce blood pressure.

In patients with pheochromocytoma, phentolamine causes systolic and diastolic blood pressures to fall dramatically. In those without pheochromocytoma, it causes blood pressure to fall or rise slightly or remain the same.

Contraindications

Angina, hypersensitivity to phentolamine or its components, MI

Interactions**DRUGS**

antihypertensives: Additive hypotensive effect

dopamine: Antagonized vasopressor activity of dopamine

epinephrine, methoxamine, norepinephrine,

phenylephrine: Inhibited α adrenergic effects of these drugs

metaraminol: Possibly decreased vasopressor effect of metaraminol

ACTIVITIES

alcohol use: Additive vasodilation, increased risk of hypotension and tachycardia

Adverse Reactions

CNS: Dizziness

CV: Angina; arrhythmias, including tachycardia; hypotension

EENT: Nasal congestion

GI: Diarrhea, nausea, vomiting

GU: Ejaculation disorders, priapism

MS: Muscle weakness

SKIN: Flushing

Nursing Considerations

- Reconstitute each 5-mg vial phenolamine with 1 ml sterile water for injection.
- Use reconstituted solution immediately; don't store unused portion.
- Dilute 5 to 10 mg of reconstituted solution in 500 ml D₅W. Inspect drug for particles and discoloration before administering.
- When diagnosing pheochromocytoma, hold nonessential drugs, as ordered, for at least 24 hours (preferably 48 to 72) before test.
- Before giving I.V. test dose for pheochromocytoma, place patient in supine position and assess baseline blood pressure with readings every 10 minutes for at least 30 minutes.
- In pheochromocytoma, expect excessive hypotension after patient receives drug.
- Take safety precautions according to facility policy if patient experiences dizziness.

PATIENT TEACHING

- Instruct patient to move slowly after phenolamine administration to minimize dizziness and avoid falls.

phenylephrine hydrochloride

Alconefrin Nasal Drops 12, Alconefrin Nasal Drops 25, Alconefrin Nasal Drops 50, Alconefrin Nasal Spray 25, Doktors, Duration, Neo-Synephrine, Neo-Synephrine Nasal Drops, Neo-Synephrine Nasal Jelly, Neo-Synephrine Nasal Spray, Neo-Synephrine Pediatric Nasal Drops, Nostril Spray Pump, Nostril Spray Pump Mild, Rhinall, Rhinall-10 Children's Flavored Nose Drops, Vicks Sinex

Class and Category

Chemical class: Sympathomimetic amine
Therapeutic class: Antiarrhythmic, decongestant, vasoconstrictor, vasopressor
Pregnancy category: C (parenteral), Not rated (nasal)

Indications and Dosages

↗ *To manage mild to moderate hypotension*

I.V. INJECTION

Adults. *Initial:* 0.1 to 0.5 mg. *Usual:* 0.2 mg, repeated no more than every 10 to 15 min.

I.M. OR SUBCUTANEOUS INJECTION

Adults. *Initial:* 1 to 5 mg. *Usual:* 2 to 5 mg (range, 1 to 10 mg), repeated no more than every 10 to 15 min, as prescribed.

↗ *To treat severe hypotension or shock*

I.V. INFUSION

Adults. *Initial:* 100 to 180 mcg/min (0.1 to 0.18 mg/min) until blood pressure is stable. *Maintenance:* 40 to 60 mcg/min (0.04 to 0.06 mg/min). Infusion concentration and flow rate adjusted as prescribed, based on patient response.

↗ *To prevent hypotension during spinal anesthesia*

I.M. OR SUBCUTANEOUS INJECTION

Adults. 2 to 3 mg 3 or 4 min before injection of spinal anesthetic.

Children. 0.5 to 1 mg for each 11.3 kg (25 lb).

↗ *To treat hypotension during spinal anesthesia*

I.V. INJECTION

Adults. *Initial:* 0.2 mg, increased by no more than 0.2 mg, as prescribed.

Maximum: 0.5 mg/dose.

Children. 0.5 to 1 mg for each 11.3 kg (25 lb).

↗ *To treat paroxysmal supraventricular tachycardia*

I.V. INJECTION

Adults. *Initial:* Up to 0.5 mg by rapid injection; later doses increased 0.1 to 0.2 mg higher than preceding dose, as prescribed. *Maximum:* 1 mg/dose.

↗ *To treat sinus, nasal, and eustachian tube congestion*

NASAL JELLY OR SOLUTION

Adults and children age 12 and over. 2 or 3 drops or sprays of 0.25% or 0.5% solution every 4 hr, p.r.n., or small quantity of 0.5% nasal jelly in each nostril every 3 to 4 hr, p.r.n. A 1% solution may be used for severe congestion.

Children ages 6 to 12. 2 or 3 drops or sprays of 0.25% solution in each nostril every 4 hr, p.r.n.

Children ages 2 to 6. 2 or 3 drops or sprays of 0.125% or 0.16% solution in each nostril every 4 hr, p.r.n.

Mechanism of Action

Directly stimulates alpha-adrenergic receptors and inhibits the intracellular enzyme adenylyl cyclase, which then inhibits production of cAMP. Inhibition of cAMP causes arterial and venous constriction and increases peripheral vascular resistance and systolic blood pressure. With greater-than-therapeutic doses, phenylephrine directly stimulates beta-adrenergic receptors in the myocardium, which increases activity of adenylyl cyclase and produces positive inotropic and chronotropic effect. Intranasal use directly stimulates alpha-adrenergic receptors on the nasal mucosa, constricting local vessels and decreasing blood flow and mucosal edema.

Route	Onset	Peak	Duration
I.V.	Immediate	Unknown	15–20 min
I.M.	10–15 min	Unknown	30 min–2 hr
SubQ	10–15 min	Unknown	50 min–1 hr
Nasal	Unknown	Unknown	30 min–4 hr

Incompatibilities

Don't combine nasal form with alkalis, butacaine, ferrous salts, metals, or oxidizing agents.

Contraindications

Hypersensitivity to bisulfites, phenylephrine, or their components; severe coronary artery disease or hypertension; use within 14 days of MAO inhibitor; ventricular tachycardia

Interactions

DRUGS

alpha blockers, haloperidol, loxapine, phenothiazines, thioxanthenes: Possibly decreased vasoconstrictor effect of phenylephrine; decreased decongestant effect of nasal phenylephrine (with phenothiazines)
antihypertensives, diuretics: Possibly decreased antihypertensive effects
atropine: Possibly enhanced vasopressor effect of phenylephrine
beta blockers: Decreased therapeutic effects of both drugs
bretylum: Possibly potentiated vasopressor effect and arrhythmias

doxapram: Increased vasopressor effect of both drugs

ergot alkaloids: Possibly cerebral blood vessel rupture, increased vasopressor effect, peripheral vascular ischemia, and gangrene (with ergotamine)

guanadrel, guanethidine: Increased vasopressor effect of phenylephrine, increased risk of severe hypertension and arrhythmias
hydrocarbon inhalation anesthetics:

Increased risk of serious arrhythmias

MAO inhibitors: Increased and prolonged cardiac stimulation, increased vasopressor effect, increased risk of severe cardiovascular and cerebrovascular effects, hyperpyrexia, vomiting

maprotiline, tricyclic antidepressants:

Increased risk of severe cardiovascular effects (including arrhythmias, hyperpyrexia, severe hypertension); possibly increased or decreased sensitivity to I.V. phenylephrine

mecamylamine, methyl dopa: Decreased hypotensive effects of these drugs, increased vasopressor effect of phenylephrine

nitrates: Possibly decreased vasopressor effect of phenylephrine and decreased antianginal effect of nitrates

oxytocin: Possibly severe, persistent hypertension

phenoxybenzamine: Decreased vasoconstrictor effect of phenylephrine, possibly hypotension and tachycardia

theophylline: Possibly enhanced toxicity (including cardiotoxicity); decreased theophylline level (with nasal phenylephrine)

thyroid hormones: Increased cardiovascular effects of both drugs

urinary acidifiers: Possibly increased elimination and decreased therapeutic effects (with nasal phenylephrine)

urinary alkalizers: Possibly decreased elimination and toxic effects (with nasal phenylephrine)

Adverse Reactions

CNS: Dizziness, headache, insomnia, nervousness, paresthesia, restlessness, sleep disturbance (nasal), tremor, weakness

CV: Angina, bradycardia, hypertension, hypotension, palpitations, peripheral vasoconstriction that may lead to necrosis or gangrene, tachycardia, ventricular arrhythmias

EENT: Burning, dry, or stinging nasal

mucosa; rebound congestion; and rhinitis (nasal forms)

GI: Nausea, vomiting

RESP: Dyspnea

SKIN: Extravasation with tissue necrosis and sloughing, pallor

Other: Allergic reaction

Nursing Considerations

- Don't dilute phenylephrine for I.M. or subcutaneous use.
- To reduce the risk of tissue extravasation, don't inject subcutaneous drug intradermally.
- For I.V. use, dilute with D₅W or sodium chloride for injection and prepare as prescribed—usually 10 mg/500 ml.
- After nasal application, rinse spray bottle tip or nasal dropper with hot water and dry with clean tissue. Wipe tip of nasal jelly tube with clean tissue.
- To prevent transmission of infection, don't use nasal form on more than one patient.
- Assess for signs and symptoms of angina, arrhythmias, and hypertension because phenylephrine may increase myocardial oxygen demand and the risk of proarrhythmias and blood pressure changes.

WARNING If patient has thyroid disease, watch for increased sensitivity to catecholamines and possible thyrotoxicity or cardiotoxicity.

WARNING Be aware that extravasation may cause tissue necrosis, gangrene, and other reactions around injection site. Expect to use phentolamine if extravasation occurs.

PATIENT TEACHING

- If patient uses nasal form, explain that excessive use may cause rebound congestion. Urge her not to exceed recommended dosage and to use for only 3 to 5 days.
- Teach patient who uses nasal form how to care for spray bottle, dropper, or tube.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.

Class and Category

Chemical class: Hydantoin derivative

Therapeutic class: Anticonvulsant

Pregnancy category: C

Indications and Dosages

↗ *To treat tonic-clonic, simple, or complex partial seizures in patients who have had no prior treatment*

CHEWABLE TABLETS, ORAL SUSPENSION (PHENYTOIN)

Adults and adolescents. *Initial:* 125 mg suspension or 100 to 125 mg tablet t.i.d., adjusted every 7 to 10 days as needed and tolerated.

Children. *Initial:* 5 mg/kg daily in divided doses b.i.d. or t.i.d., adjusted as needed and tolerated. *Maintenance:* 4 to 8 mg/kg daily in divided doses b.i.d. or t.i.d. *Maximum:* 300 mg daily.

EXTENDED CAPSULES (PHENYTOIN SODIUM)

Adults and adolescents. *Initial:* 100 mg t.i.d., adjusted every 7 to 10 days as needed and tolerated. *Maintenance:* Once seizures are controlled, adjusted dosage given daily if needed and tolerated.

DOSAGE ADJUSTMENT For hospitalized patients without hepatic or renal disease, oral loading dose of 400 mg followed in 2 hr by 300 mg and then in 2 more hr by another 300 mg for a total of 1 g.

Children. *Initial:* 5 mg/kg daily in divided doses b.i.d. or t.i.d., adjusted as needed and tolerated. *Maintenance:* 4 to 8 mg/kg daily in divided doses b.i.d. or t.i.d. *Maximum:* 300 mg daily.

PROMPT CAPSULES (PHENYTOIN SODIUM)

Adults and adolescents. 100 mg t.i.d., adjusted every 7 to 10 days as needed and tolerated.

Children. *Initial:* 5 mg/kg daily in divided doses b.i.d. or t.i.d., adjusted as needed and tolerated. *Maintenance:* 4 to 8 mg/kg daily in divided doses b.i.d. or t.i.d. *Maximum:* 300 mg daily.

↗ *To treat status epilepticus*

I.V. INJECTION (PHENYTOIN SODIUM)

Adults and adolescents. *Initial:* 15 to 20 mg/kg by slow push in 50 ml sodium chloride injection at no more than 50 mg/min. *Maintenance:* Beginning within 12 to 24 hr of initial dose, 5 mg/kg daily P.O. in divided doses b.i.d. to q.i.d., or 100 mg I.V. every 6 to 8 hr.

phenytoin

Dilantin-30 (CAN), Dilantin-125, Dilantin Infatabs

phenytoin sodium

Dilantin, Dilantin Kapseals, Phenytext

Children. 15 to 20 mg/kg at no more than 1 mg/kg/min. *Maximum:* 50 mg/min.

DOSAGE ADJUSTMENT For elderly or very ill patients and those with CV or hepatic disease, dosage reduced to 25 mg/min, as prescribed, or possibly as low as 5 to 10 mg/min to reduce the risk of adverse reactions.

➤ *To prevent or treat seizures during neurosurgery*

I.V. INJECTION (PHENYTOIN SODIUM)

Adults. 100 to 200 mg every 4 hr at no more than 50 mg/min during or immediately after neurosurgery.

Mechanism of Action

Limits the spread of seizure activity and the start of new seizures by regulating voltage-dependent sodium and calcium channels in neurons, inhibiting calcium movement across neuronal membranes, and enhancing sodium-potassium ATP activity in neurons and glial cells. These actions all help stabilize the neurons.

Incompatibilities

Don't mix phenytoin in same syringe with any other drugs or with any I.V. solutions other than sodium chloride for injection because precipitate will form.

Contraindications

Adams-Stokes syndrome, hypersensitivity to phenytoin or its components, SA block, second- or third-degree heart block, sinus bradycardia

Interactions

DRUGS

acetaminophen: Possibly hepatotoxicity, decreased acetaminophen effects
activated charcoal, antacids, calcium salts, enteral feedings, sucralfate: Decreased absorption of oral phenytoin
allopurinol, benzodiazepines, chloramphenicol, cimetidine, disulfiram, fluconazole, isoniazid, itraconazole, methylphenidate, metronidazole, miconazole, omeprazole, phenacetamide, ranitidine, sulfonamides, trazodone, trimethoprim: Decreased metabolism and increased effects of phenytoin
amiodarone, ticlopidine: Possibly increased blood phenytoin level
antifungals (azole): Increased blood phenytoin level, decreased blood antifungal level
antineoplastics, nitrofurantoin, pyridoxine: Decreased phenytoin effects

barbiturates: Variable effects on blood phenytoin level

bupropion, clozapine, loxapine, MAO inhibitors, maprotiline, molindone, phenothiazines, pimozide, thioxanthenes, tricyclic antidepressants: Decreased seizure threshold, decreased anticonvulsant effects

calcium channel blockers: Increased metabolism and decreased effects of these drugs, possibly increased blood phenytoin level
carbamazepine: Decreased blood level and effects of carbamazepine, possibly phenytoin toxicity

carbonic anhydrase inhibitors: Increased risk of osteopenia from phenytoin

chlordiazepoxide, diazepam: Possibly increased blood phenytoin level, decreased effects of these drugs

clonazepam: Possibly decreased blood level and effects of clonazepam, possibly phenytoin toxicity

corticosteroids, cyclosporine, dicumarol, digoxin, disopyramide, doxycycline, estrogens, furosemide, lamotrigine, levodopa,

methadone, metyrapone, mexiletine, oral contraceptives, quinidine, sirolimus, tacrolimus, theophylline: Increased metabolism and decreased effects of these drugs

dopamine: Increased risk of severe hypotension and bradycardia (with I.V. phenytoin)

fluoxetine: Increased blood phenytoin level and risk of phenytoin toxicity

folic acid, leucovorin: Decreased blood phenytoin level, increased risk of seizures

haloperidol: Decreased effects of haloperidol, decreased anticonvulsant effect of phenytoin

halothane anesthetics: Increased risk of hepatotoxicity and phenytoin toxicity

ifosfamide: Decreased phenytoin effects, possibly increased toxicity

influenza virus vaccine: Possibly decreased phenytoin effects

insulin, oral antidiabetic drugs: Possibly hyperglycemia, increased blood phenytoin level (with tolbutamide)

levonorgestrel, mebendazole, streptozocin, sulfonyleureas: Decreased effects of these drugs

lidocaine, propranolol (possibly other beta blockers): Increased cardiac depressant effects (with I.V. phenytoin), possibly decreased blood level and increased adverse effects of phenytoin

lithium: Increased risk of lithium toxicity, increased risk of neurologic symptoms with normal blood lithium level

meperidine: Increased metabolism and decreased effects of meperidine, possibly meperidine toxicity

methadone: Possibly increased metabolism of methadone and withdrawal symptoms

neuromuscular blockers: Shorter duration of action and decreased effects of neuromuscular blockers

oral anticoagulants: Decreased metabolism and increased effects of phenytoin; early increase and then decrease in anticoagulation

paroxetine: Decreased bioavailability of both drugs

phenylbutazone, salicylates: Increased phenytoin effects, possibly phenytoin toxicity

primidone: Increased primidone effects, possibly primidone toxicity

rifampin: Increased hepatic metabolism of phenytoin

valproic acid: Possibly decreased phenytoin metabolism, resulting in increased phenytoin effects; possibly decreased blood valproic acid level

vitamin D: Possibly decreased vitamin D effects, resulting in rickets or osteomalacia (with long-term use of phenytoin)

ACTIVITIES

alcohol use: Additive CNS depression, increased phenytoin clearance

Adverse Reactions

CNS: Ataxia, confusion, depression, dizziness, drowsiness, excitement, fever, headache, involuntary motor activity, lethargy, nervousness, peripheral neuropathy, restlessness, slurred speech, suicidal ideation, tremor, weakness

CV: Cardiac arrest, hypotension, vasculitis

EENT: Amblyopia, conjunctivitis, diplopia, earache, epistaxis, eye pain, gingival hyperplasia, hearing loss, loss of taste, nystagmus, pharyngitis, photophobia, rhinitis, sinusitis, taste perversion, tinnitus

ENDO: Gynecomastia, hyperglycemia

GI: Abdominal pain, anorexia, constipation, diarrhea, epigastric pain, hepatic dysfunction, hepatic necrosis, hepatitis, nausea, vomiting

GU: Glycosuria, priapism, renal failure

HEME: Acute intermittent porphyria (exacerbation), agranulocytosis, anemia,

eosinophilia, leukopenia, pancytopenia, thrombocytopenia

MS: Arthralgia, arthropathy, bone fractures, muscle twitching, osteomalacia, polymyositis

RESP: Apnea, asthma, bronchitis, cough, dyspnea, hypoxia, increased sputum production, pneumonia, pneumothorax, pulmonary fibrosis

SKIN: Exfoliative dermatitis, jaundice, maculopapular or morbilliform rash, purpuric dermatitis, Stevens-Johnson syndrome, toxic epidermal necrolysis, unusual hair growth, urticaria

Other: Facial feature enlargement, injection site pain, lupus-like symptoms, lymphadenopathy, polyarteritis, weight gain or loss

Nursing Considerations

WARNING Patients of Asian ancestry who have the genetic allelic variant HLA-B*1502 develop serious and sometimes fatal dermatologic reactions ten times more often than people without this variant when given carbamazepine, another antiepileptic drug. Because early data suggest a similar effect with phenytoin, this drug shouldn't be used as a substitute for carbamazepine in these patients.

- Be aware that preferred administration routes for phenytoin are oral and I.V. injection. With I.M. administration, phenytoin has a variable absorption rate.
- If patient has difficulty swallowing, open prompt (rapid-release) capsules and mix contents with food or fluid.
- Shake oral suspension before measuring dose, and use a calibrated measuring device.
- To minimize GI distress, give phenytoin with or just after meals.
- Inspect I.V. form for particles and discoloration before administering.

WARNING Avoid rapid I.V. injection because it may cause cardiac arrest, CNS depression, or severe hypotension.

- To decrease vein irritation, follow I.V. injection with flush of sodium chloride for injection through same I.V. catheter.
- Continuously monitor ECG tracings and blood pressure when administering I.V. phenytoin.
- Frequently assess I.V. site for signs of extravasation because drug can cause tissue necrosis.

- If patient has an NG tube in place, minimize drug absorption by polyvinyl chloride tubing by diluting suspension threefold with sodium chloride for injection, D₅W, or sterile water. After administration, flush tube with at least 20 ml diluent.
- Separate oral phenytoin administration by at least 2 hours from antacids and calcium salts.
- Expect continuous enteral feedings to disrupt phenytoin absorption and, possibly, reduce blood phenytoin level. Discontinue tube feedings 1 to 2 hours before and after phenytoin administration, as prescribed. Anticipate giving increased phenytoin doses to compensate for reduced bioavailability during continuous tube feedings.
- Monitor phenytoin level. Therapeutic level ranges from 10 to 20 mcg/L.

WARNING Monitor patient's hematologic status during therapy because phenytoin can cause blood dyscrasias. A patient with a history of agranulocytosis, leukopenia, or pancytopenia may have an increased risk of infection because phenytoin can cause myelosuppression.

- Anticipate that drug may worsen intermittent porphyria.
- Frequently monitor blood glucose level of patient with diabetes mellitus because drug can stimulate glucagon secretion and impair insulin secretion, either of which can raise blood glucose level.
- Monitor thyroid hormone levels in patient receiving thyroid replacement therapy because phenytoin may decrease circulating thyroid hormone levels and increase thyroid-stimulating hormone level.
- Be aware that long-term phenytoin therapy may increase patient's requirements for folic acid or vitamin D supplements. However, keep in mind that a diet high in folic acid may decrease seizure control.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

PATIENT TEACHING

- Instruct patient to crush or thoroughly chew phenytoin chewable tablets before swallowing or to shake oral solution well before using.
- Advise patient to take drug exactly as prescribed and not to change brands or dosage or stop taking drug unless instructed

by prescriber.

- Instruct patient to avoid taking antacids or calcium products within 2 hours of phenytoin.
- Urge patient to avoid alcohol during therapy.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Inform patient with diabetes mellitus about the increased risk of hyperglycemia and the possible need for increased antidiabetic drug dosage during therapy. Advise her to check blood glucose level often.
- Stress the importance of good oral hygiene, and encourage patient to inform her dentist that she's taking phenytoin.
- Encourage patient to obtain medical identification that indicates her diagnosis and drug therapy.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes and to report concerns at once to prescriber.
- Encourage woman who becomes pregnant while taking phenytoin to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting information about the safety of antiepileptic drugs during pregnancy.

physostigmine salicylate

Antilirium

Class and Category

Chemical class: Salicylic acid derivative

Therapeutic class: Anticholinergic antidote, cholinesterase inhibitor

Pregnancy category: Not rated

Indications and Dosages

➤ *To counteract toxic anticholinergic effects (anticholinergic syndrome)*

I.V. OR I.M. INJECTION

Adults and adolescents. 0.5 to 2 mg at no more than 1 mg/min; then 1 to 4 mg, repeated every 20 to 30 min as needed and as prescribed.

Children. 0.02 mg/kg I.V., at no more than 0.5 mg/min, repeated every 5 to 10 min as prescribed. *Maximum:* 2 mg/dose.

Mechanism of Action

Inhibits destruction of acetylcholine by acetylcholinesterase. This action increases acetylcholine concentration at cholinergic transmission sites and prolongs and exaggerates effects of acetylcholine that are blocked by toxic doses of anticholinergics.

Route	Onset	Peak	Duration
I.V.	3–8 min	5 min	30–60 min
I.M.	3–8 min	20–30 min	30–60 min

Contraindications

Asthma; cardiovascular disease; diabetes mellitus; gangrene; GI or GU obstruction; hypersensitivity to physostigmine, sulfites, or their components

Interactions

DRUGS

choline esters: Enhanced effects of carbachol and bethanechol with concurrent use of physostigmine, enhanced effects of acetylcholine and methacholine with prior use of physostigmine

succinylcholine: Prolonged neuromuscular paralysis

Adverse Reactions

CNS: CNS stimulation, fatigue, hallucinations, restlessness, seizures (with too-rapid I.V. delivery), weakness

CV: Bradycardia (with too-rapid I.V. delivery), irregular heartbeat, palpitations

EENT: Increased salivation, lacrimation, miosis

GI: Abdominal pain, diarrhea, nausea, vomiting

GU: Urinary urgency

MS: Muscle twitching

RESP: Bronchospasm, chest tightness, dyspnea (with too-rapid I.V. administration), increased bronchial secretions, wheezing

SKIN: Diaphoresis

Nursing Considerations

- Use physostigmine cautiously in patients with bradycardia, epilepsy, or Parkinson's disease.
- Avoid rapid I.V. delivery, which may lead to bradycardia, respiratory distress, or seizures.
- Check pulse and respiratory rates, blood pressure, and neurologic status often.
- Monitor ECG tracing during I.V. use.

- Closely monitor patient with asthma for asthma attack because physostigmine may precipitate attack by causing bronchoconstriction.
- Watch for seizures in patient with a history of seizures because physostigmine can induce seizures by stimulating CNS.

WARNING Be alert for life-threatening cholinergic crisis, which may indicate physostigmine overdose and may include confusion, diaphoresis, hypotension, miosis, muscle weakness, nausea, paralysis (including respiratory paralysis), salivation, seizures, sinus bradycardia, and vomiting. If you detect such signs, prepare to give atropine (the antidote) and use resuscitation equipment. Keep in mind that atropine counteracts only muscarinic cholinergic effects; paralytic effects may continue.

PATIENT TEACHING

- Reassure patient that vital signs will be monitored often to help prevent or detect adverse reactions.
- Instruct patient to notify prescriber at once about evidence of cholinergic crisis.

pindolol

NovoPindol (CAN), SynPindol (CAN), Visken

Class and Category

Chemical class: Nonselective beta blocker

Therapeutic class: Antihypertensive

Pregnancy category: B

Indications and Dosages

➤ *To manage hypertension*

TABLETS

Adults. *Initial*: 5 mg b.i.d., increased by 10 mg daily every 3 to 4 wk, as prescribed.

Maintenance: 10 to 30 mg daily. *Maximum*: 60 mg daily (U.S.), 45 mg daily (Canada).

Route	Onset	Peak	Duration
P.O.	Unknown	1–2 hr	Up to 24 hr

Mechanism of Action

Blocks sympathetic stimulation of beta₁ receptors in the heart and beta₂ receptors in vascular and bronchial smooth muscle by competing with adrenergic neurotransmit-

ters, such as catecholamines. Pindolol's negative chronotropic effects slow the resting heart rate and reduce exercise-induced tachycardia. Its negative inotropic effects reduce cardiac output, myocardial contractility, systolic and diastolic blood pressure, and myocardial oxygen consumption during stress or exercise. Among beta blockers, pindolol has the most intrinsic sympathomimetic activity and nonselective antagonism.

Contraindications

Advanced AV block; asthma; bronchospasm; cardiogenic shock; heart failure; hepatic disease; hypersensitivity to pindolol, other beta blockers, or their components; hypotension (with systolic pressure less than 100 mm Hg); sinus bradycardia

Interactions

DRUGS

allergy extracts or immunotherapy, iodinated contrast media: Increased risk of systemic reaction or anaphylaxis

aluminum salts, barbiturates, calcium salts, certain penicillins, cholestyramine, colestipol, NSAIDs, rifampin, salicylates, sulfipyrazone: Decreased blood level and effects of pindolol

antihypertensives: Additive hypotensive effect

beta blockers, digoxin: Increased risk of bradycardia

calcium channel blockers, quinidine: Possibly increased effects of both drugs, symptomatic bradycardia (with diltiazem or verapamil), excessive hypertension or heart failure (with nifedipine)

cimetidine: Increased blood pindolol level

epinephrine: Possibly hypertension followed by bradycardia

ergotamine: Possibly severe peripheral vasoconstriction with pain and cyanosis

estrogens: Decreased antihypertensive effect
fentanyl, fentanyl derivatives: Risk of bradycardia after anesthesia induction

insulin, oral antidiabetic drugs: Masked symptoms of hypoglycemia, increased risk of hyperglycemia

lidocaine: Increased risk of lidocaine toxicity

MAO inhibitors: Possibly hypertension

neuromuscular blockers: Possibly increased or prolonged neuromuscular blockade

phenothiazines: Increased blood levels of

both drugs

phenytoin: Possibly increased cardiac depressant effects

prazosin, reserpine: Increased risk of orthostatic hypotension, bradycardia (with reserpine)

quinolones: Possibly increased bioavailability of pindolol

xanthines: Possibly decreased effects of both drugs, decreased xanthine clearance

Adverse Reactions

CNS: Anxiety, confusion, depression, dizziness, fatigue, fever, hallucinations, hypothermia, insomnia, memory loss, paresthesia, peripheral neuropathy, stroke, syncope, weakness

CV: Arrhythmias (including AV block and bradycardia), chest pain, decreased peripheral circulation, heart failure, hyperlipidemia, hypotension, MI, orthostatic hypotension, peripheral edema and ischemia, thrombosis of renal or mesenteric artery

EENT: Pharyngitis

ENDO: Hyperglycemia, hypoglycemia

GI: Colitis (ischemic), constipation, diarrhea, elevated liver function test results, gastritis, nausea, pancreatitis, vomiting

GU: Cystitis, decreased libido, renal colic, renal failure, urinary frequency, urine retention, UTI

HEME: Agranulocytosis, bleeding, eosinophilia, leukopenia, nonthrombocytopenic purpura, thrombocytopenia, thrombocytopenic purpura, unusual bleeding or bruising

MS: Arthralgia, back pain

RESP: Bronchospasm, pulmonary edema, pulmonary emboli

SKIN: Acne; alopecia; crusted, red, or scaly skin; diaphoresis; eczema; exfoliative dermatitis; hyperpigmentation; pruritus; purpura; rash

Other: Angioedema, positive ANA titer

Nursing Considerations

- Check blood pressure and pulse rate often, especially at start of pindolol therapy. Also monitor fluid intake and output and daily weight, and assess for evidence of heart failure, such as dyspnea, edema, fatigue, and jugular vein distention.
- Be aware that drug shouldn't be stopped abruptly because MI, myocardial ischemia, severe hypertension, or ventricular arrhythmias may result.

- Expect to discontinue drug up to 2 days before surgery, as prescribed, to reduce the risk of heart failure.
- Assess distal circulation and peripheral pulses in patient with Raynaud's phenomenon or other peripheral vascular disorder because drug can worsen these conditions.
- Be aware that pindolol can mask tachycardia from hyperthyroidism; abrupt withdrawal can cause thyroid storm. Drug also may potentiate diplopia and muscle weakness in patient with myasthenia gravis; decrease blood glucose level, prolong or mask symptoms of hypoglycemia, and promote hyperglycemia in patient with diabetes mellitus; and worsen psoriasis.

PATIENT TEACHING

- Instruct patient to weigh herself daily during pindolol therapy and to notify prescriber if she gains more than 2 lb (0.9 kg) in 1 day or 5 lb (2.3 kg) in 1 week.
- Caution patient not to stop drug abruptly.
- Advise patient to rise slowly from a seated or lying position to minimize effects of orthostatic hypotension.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to contact prescriber about bleeding or bruising, cough at night, depression, dizziness, edema, rash, shortness of breath, slow pulse rate, or sore throat.
- Advise diabetic patient to monitor her blood glucose level more often during pindolol therapy because drug may mask symptoms of hypoglycemia.
- Inform patient with psoriasis that drug may aggravate this condition.

pioglitazone hydrochloride

Actos

Class and Category

Chemical class: Thiazolidinedione

Therapeutic class: Antidiabetic

Pregnancy category: C

Indications and Dosages

↗ *To achieve glucose control in type 2 diabetes mellitus as monotherapy or in combination with insulin, metformin,*

or a sulfonylurea

TABLETS

Adults. *Initial:* 15 or 30 mg daily.

Maximum: 45 mg daily.

DOSAGE ADJUSTMENT For patients taking insulin, insulin dosage decreased by 10% to 25%, as prescribed, once glucose level reaches 100 mg/dl or less. If hypoglycemia occurs, dosage of any concurrent antidiabetic is reduced, as prescribed.

Mechanism of Action

Decreases insulin resistance by enhancing the sensitivity of insulin-dependent tissues, such as adipose tissue, skeletal muscle, and the liver, and reduces glucose output from the liver. Drug activates peroxisome proliferator-activated receptor-gamma (PPAR γ) receptors, which modulate transcription of insulin-responsive genes involved in glucose control and lipid metabolism. In this way, pioglitazone reduces hyperglycemia, hyperinsulinemia, and hypertriglyceridemia in patients with type 2 diabetes mellitus and insulin resistance. However, to work effectively, pioglitazone needs endogenous insulin. Unlike sulfonylureas, it doesn't increase pancreatic insulin secretion.

Contraindications

Diabetic ketoacidosis, hypersensitivity to pioglitazone or its components, New York Heart Association (NYHA) Class III or IV heart failure, severe hepatic dysfunction, type 1 diabetes mellitus

Interactions

DRUGS

gemfibrozil, rifampin: Possibly altered glucose control

ketoconazole: Possibly decreased metabolism of pioglitazone

oral contraceptives: Possibly decreased effectiveness of oral contraceptives

Adverse Reactions

CNS: Headache

CV: Congestive heart failure, edema

EENT: Blurred vision, decreased visual acuity, macular edema, pharyngitis, sinusitis, tooth disorders

HEME: Decreased hemoglobin level and hematocrit

MS: Fractures, myalgia

RESP: Upper respiratory tract infection

Other: Weight gain

Nursing Considerations

- Be aware that pioglitazone isn't recommended for patients with symptomatic heart failure.
- Be prepared to monitor liver function test results before therapy begins, every 2 months during first year, and annually thereafter, as ordered, because drug is extensively metabolized in the liver. Expect to stop drug if jaundice develops or ALT values exceed 2.5 times normal.

WARNING Monitor patient for signs and symptoms of congestive heart failure—such as shortness of breath, rapid weight gain, or edema—because pioglitazone can cause fluid retention that may lead to or worsen heart failure. Notify prescriber immediately of any deterioration in the patient's cardiac status, and expect to discontinue the drug, as ordered.

- Assess for signs and symptoms of hypoglycemia, especially if patient is also taking another antidiabetic drug.
- Monitor fasting glucose level, as ordered, to evaluate effectiveness of therapy.
- Monitor glycosylated hemoglobin level to assess drug's long-term effectiveness.

PATIENT TEACHING

- Stress the need for patient to continue exercise program, diet control, and weight management during pioglitazone therapy.
- Advise patient to notify prescriber immediately if she experiences shortness of breath, fluid retention, or sudden weight gain because drug may need to be discontinued.
- Urge patient to report vision changes promptly and expect to have an eye examination by an ophthalmologist regardless of when the last examination occurred.
- Instruct patient to keep appointments for liver function tests, as ordered, typically every 2 months during first year of therapy and annually thereafter.
- Inform female patient who uses oral contraceptives that drug decreases their effectiveness; suggest that she use another method of contraception while taking pioglitazone.
- Also inform female patient that she may be at risk for fractures during pioglitazone therapy, and urge her to take safety precautions to prevent falls and other injuries.

piperacillin sodium

Pipracil

Class and Category

Chemical class: Piperazine derivative of ampicillin, acylureidopenicillin

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat moderate to severe bacterial infections, including bone and joint infections, gynecologic infections, intra-abdominal infections, lower respiratory tract infections, septicemia, and skin and soft-tissue infections, caused by susceptible strains of Acinetobacter species, anaerobic cocci, Bacteroides species, Enterobacter species, Escherichia coli, Haemophilus influenzae, Klebsiella species, Proteus species, Pseudomonas aeruginosa, and Serratia species*

I.V. INFUSION

Adults and adolescents. 12 to 18 g daily or 200 to 300 mg/kg daily in divided doses every 4 to 6 hr. *Maximum:* 24 g daily.

➤ *To treat bacterial meningitis*

I.V. INFUSION

Adults and adolescents. 4 g every 4 hr or 75 mg/kg every 6 hr. *Maximum:* 24 g daily.

➤ *To treat uncomplicated UTI and community-acquired pneumonia caused by susceptible organisms, including E. coli, Klebsiella species, and Serratia species*

I.V. INFUSION, I.M. INJECTION

Adults. 6 to 8 g daily or 100 to 125 mg/kg daily in divided doses every 6 to 12 hr.

➤ *To treat complicated UTI caused by susceptible organisms, including Acinetobacter species, Klebsiella species, and Serratia species*

I.V. INFUSION

Adults. 8 to 16 g daily or 125 to 200 mg/kg daily in divided doses every 6 to 8 hr.

➤ *To treat uncomplicated gonorrhea caused by susceptible strains of Neisseria gonorrhoeae*

I.M. INJECTION

Adults. 2 g as a single dose 30 min after 1-g dose of probenecid P.O.

➤ *To provide surgical prophylaxis in intra-abdominal procedures, including GI and biliary surgery*

I.V. INFUSION

Adults. 2 g 20 to 30 min before anesthesia, 2 g during surgery, and 2 g every 6 hr for 24 hr after surgery.

↗ *To provide surgical prophylaxis in abdominal hysterectomy*

I.V. INFUSION

Adults. 2 g 20 to 30 min before anesthesia, 2 g just after surgery, and 2 g 6 hr later.

↗ *To provide surgical prophylaxis in vaginal hysterectomy*

I.V. INFUSION

Adults. 2 g 20 to 30 min before anesthesia, then 2 g 6 and 12 hr after initial dose.

↗ *To provide surgical prophylaxis in cesarean section*

I.V. INFUSION

Adults. 2 g after cord is clamped, then 2 g 4 and 8 hr after initial dose.

Mechanism of Action

Binds to specific penicillin-binding proteins and inhibits the third and final stage of bacterial cell wall synthesis by interfering with an autolysin inhibitor. Uninhibited autolytic enzymes destroy the cell wall and result in cell lysis.

Incompatibilities

Don't mix piperacillin sodium in same container with aminoglycosides because of chemical incompatibility (depending on concentrations, diluents, pH, and temperature). Don't mix with solutions that contain only sodium bicarbonate because of chemical instability.

Contraindications

Hypersensitivity to cephalosporins, penicillins, or their components

Interactions**DRUGS**

aminoglycosides: Additive or synergistic effects against some bacteria, possibly mutual inactivation

anti-inflammatory drugs (including aspirin and NSAIDs), heparin, oral anticoagulants, platelet aggregation inhibitors, sulfapyrazone, thrombolytics: Increased risk of bleeding

hepatotoxic drugs (including labetalol and rifampin): Increased risk of hepatotoxicity

methotrexate: Increased blood methotrexate level and risk of toxicity

probenecid: Increased blood piperacillin level and risk of toxicity

vecuronium: Possibly prolonged perioperative neuromuscular blockade of vecuronium

Adverse Reactions

CNS: Dizziness, fever, hallucinations, headache, lethargy, seizures, stroke

CV: Cardiac arrest, hypotension, palpitations, tachycardia, vasodilation, vasovagal reactions

EENT: Oral candidiasis, pharyngitis

GI: Diarrhea, epigastric distress, intestinal necrosis, nausea, pseudomembranous colitis, vomiting

GU: Hematuria, impotence, nephritis, neurogenic bladder, priapism, proteinuria, renal failure, vaginal candidiasis

HEME: Agranulocytosis, eosinophilia, hemolytic anemia, leukopenia, neutropenia, pancytopenia, prolonged bleeding time, thrombocytopenia

MS: Arthralgia

RESP: Dyspnea, pulmonary embolism, pulmonary hypertension

SKIN: Exfoliative dermatitis, mottling, rash, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis; facial edema; hypokalemia; hyponatremia; injection site pain, phlebitis, and skin ulcer; superinfection

Nursing Considerations

- Expect to obtain blood, sputum, or other samples for culture and sensitivity testing before giving piperacillin and to start therapy before results are available.
- Be aware that sunlight may darken piperacillin powder for dilution but won't alter drug potency.
- For initial dilution for I.V. infusion, reconstitute each gram of drug with at least 5 ml sterile water for injection, sodium chloride for injection, D₅W, dextrose 5% in normal saline solution, or bacteriostatic water that contains parabens or benzyl alcohol. Shake solution vigorously after adding diluent, and inspect for particles and discoloration before giving.
- For further dilution, use sodium chloride for injection, D₅W, dextrose 5% in normal saline solution, lactated Ringer's solution, or dextran 6% in normal saline solution. Solutions diluted with lactated Ringer's solution should be given within 2 hours.
- For intermittent infusion, infuse appropriate dose over 20 to 30 minutes.
- Give aminoglycosides 1 hour before or

after piperacillin; use a separate site, I.V. bag, and tubing.

- For I.M. injection, reconstitute each gram of piperacillin with at least 2 ml of an appropriate diluent listed above.
- Don't give more than 2 g I.M. in one site. Use deltoid area cautiously and only if well developed to avoid injuring radial nerve.
- Watch for bleeding or excessive bruising because drug can decrease platelet aggregation, especially in patients with renal failure. If bleeding occurs, notify prescriber and expect to stop piperacillin.
- Monitor CBC regularly, as ordered, to detect hematologic abnormalities, such as leukopenia and neutropenia.
- Monitor serum potassium level to detect hypokalemia from urinary potassium loss.
- Check for diarrhea during and after therapy because it may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold piperacillin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- Watch for hypersensitivity reactions, especially if patient has cystic fibrosis. Notify prescriber, and expect to stop drug.

PATIENT TEACHING

- Advise patient to consult prescriber before using OTC drugs during piperacillin therapy because of the risk of interactions.
- Inform patient that increased bruising may occur if she takes anti-inflammatory drugs during piperacillin therapy.
- Advise patient to notify prescriber about signs of superinfection, such as white patches on tongue or in mouth.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.
- Instruct patient to complete full course of therapy, even if symptoms subside.

pirbuterol acetate

Maxair, Maxair Autohaler

Class and Category

Chemical class: Sympathomimetic amine

Therapeutic class: Bronchodilator

Pregnancy category: C

Indications and Dosages

➤ *To prevent or treat bronchospasm caused by COPD, to treat bronchospasm caused by asthma*

ORAL INHALATION

Adults and adolescents. 1 or 2 inhalations (200 to 400 mcg) every 4 to 6 hr.

Maximum: 12 inhalations (2.4 mg) daily.

Route	Onset	Peak	Duration
Oral inhalation	In 5 min	In 30–90 min	3–6 hr

Mechanism of Action

Attaches to beta₂ receptors on bronchial cell membranes, which stimulates the intracellular enzyme adenyl cyclase to convert adenosine triphosphate (ATP) to cAMP. The increased intracellular level of cAMP relaxes bronchial smooth-muscle cells and inhibits histamine release. Pirbuterol also stabilizes mast cells and inhibits the release of histamine.

Contraindications

Hypersensitivity to pirbuterol or its components, tachycardia

Interactions

DRUGS

beta-adrenergic bronchodilators: Additive effects

beta blockers (ophthalmic): Possibly decreased pirbuterol effects, increased risk of bronchospasm

beta blockers (systemic): Decreased effects of both drugs, increased risk of bronchospasm

MAO inhibitors, tricyclic antidepressants:

Potentiated cardiovascular effects

Adverse Reactions

CNS: Anxiety, confusion, depression, dizziness, headache, nervousness, tiredness, tremor

CV: Arrhythmias (including PVCs and tachycardia), chest pain, ECG changes (including flattening of T waves, prolonged QT interval, and ST-segment depression), hypotension, palpitations

EENT: Dry mouth

GI: Abdominal cramps, diarrhea, nausea, vomiting

RESP: Bronchospasm, cough

SKIN: Alopecia, rash, urticaria

Other: Facial edema, hypokalemia

Nursing Considerations

- For patient with a cardiovascular disorder, such as arrhythmia, hypertension, or ischemic cardiac disease, monitor blood pressure and heart rate and rhythm to detect significant changes after pirbuterol use.
- Be aware that elderly patients have greater risk of adverse reactions than younger adults.

WARNING Stop giving drug and notify prescriber immediately if patient has paradoxical bronchospasm, a life-threatening adverse reaction.

PATIENT TEACHING

- Teach patient how to use an inhaler and spacer correctly, and urge her to keep the inhaler readily available at all times.
- Recommend the use of an autohaler if patient has trouble coordinating inhalations with a regular inhaler.
- Advise patient to clean the inhaler's mouthpiece at least once daily.
- Caution patient against overusing drug because doing so may increase adverse reactions.
- Teach patient how to use peak flow meter and determine her personal best reading.

WARNING Advise patient to notify prescriber if symptoms worsen, if bronchospasm occurs more frequently, if she needs to use the inhaler more often, or if the inhaler becomes less effective.

piroxicam

Apo-Piroxicam (CAN), **Feldene**, **Novo-Pirocam** (CAN), **Nu-Pirox** (CAN), **PMS-Piroxicam** (CAN)

Class and Category

Chemical class: Oxicam derivative

Therapeutic class: Anti-inflammatory, anti-rheumatic

Pregnancy category: Not rated

Indications and Dosages

➤ To treat acute and chronic osteoarthritis and rheumatoid arthritis

CAPSULES

Adults. *Initial:* 20 mg once daily or 10 mg b.i.d.

Mechanism of Action

Blocks the activity of cyclooxygenase, the enzyme needed for prostaglandin synthesis. Prostaglandins, important mediators of the inflammatory response, cause local vasodilation with swelling and pain. By blocking cyclooxygenase activity and inhibiting prostaglandins, this NSAID reduces inflammatory symptoms and pain.

Route	Onset	Peak	Duration
P.O.	Unknown	Several days to 1 wk*	Unknown

Contraindications

Angioedema, asthma, bronchospasm, nasal polyps, rhinitis, or urticaria induced by aspirin, iodides, or other NSAIDs; hypersensitivity to piroxicam or its components

Interactions

DRUGS

acetaminophen: Possibly increased adverse renal effects with long-term use of both drugs

antihypertensives: Possibly decreased or reversed effects of antihypertensives

aspirin, other NSAIDs: Increased risk of bleeding and adverse GI effects, possibly increased blood piroxicam level

cefamandole, cefoperazone, cefotetan: Increased risk of hypoprothrombinemia and bleeding

colchicine: Increased risk of GI bleeding, hemorrhage, and ulcers

corticosteroids, potassium supplements:

Increased risk of adverse GI effects

cyclosporine: Increased risk of nephrotoxicity from both drugs, increased blood cyclosporine level

diuretics: Decreased antihypertensive, diuretic, and natriuretic effects of diuretics

gold compounds, nephrotoxic drugs:

Increased risk of adverse renal effects

heparin, oral anticoagulants, thrombolytics:

Increased anticoagulant effects, increased risk of hemorrhage

insulin, oral antidiabetic drugs: Possibly increased hypoglycemic effect of these drugs

lithium: Possibly increased blood lithium

* With severe inflammation, 2 wk or more.

level and toxicity

methotrexate: Decreased methotrexate clearance and increased risk of methotrexate toxicity

platelet aggregation inhibitors: Increased risk of bleeding and GI ulceration or hemorrhage

plicamycin, valproic acid: Increased risk of hypoprothrombinemia and GI bleeding, hemorrhage, and ulceration

probenecid: Possibly increased blood level, effectiveness, and risk of toxicity of piroxicam

ACTIVITIES

alcohol use: Increased risk of adverse GI effects

Adverse Reactions

CNS: Anxiety, aseptic meningitis, asthenia, cerebral hemorrhage, confusion, depression, dizziness, dream disturbances, drowsiness, fever, headache, insomnia, ischemic stroke, malaise, nervousness, paresthesia, somnolence, syncope, transient ischemic attack, tremor, vertigo

CV: Deep vein thrombosis, edema, heart failure, hypertension, MI, peripheral edema, tachycardia

EENT: Blurred vision, dry mouth, epistaxis, glossitis, stomatitis, tinnitus

ENDO: Hypoglycemia

GI: Abdominal pain; anorexia; constipation; diarrhea; elevated liver function test results; esophagitis; flatulence; gastritis; GI bleeding, perforation, or ulceration; heartburn; hematemesis; hepatitis; indigestion; jaundice; liver failure; melena; nausea; vomiting

GU: Acute renal failure, cystitis, dysuria, elevated serum creatinine level, hematuria, interstitial nephritis, nephrotic syndrome, oliguria, polyuria, proteinuria, renal failure or insufficiency

HEME: Agranulocytosis, anemia, aplastic anemia, coagulation abnormalities, eosinophilia, leukopenia, pancytopenia, thrombocytopenia

RESP: Asthma, dyspnea

SKIN: Alopecia, diaphoresis, ecchymosis, erythema, erythema multiforme, exfoliative dermatitis, photosensitivity, pruritus, purpura, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, flulike symptoms, hyperkalemia, infection, sepsis, weight loss or gain

Nursing Considerations

- Administer piroxicam with food to decrease GI upset.
- Use piroxicam with extreme caution in patients with a history of ulcer disease or GI bleeding because NSAIDs such as piroxicam increase risk of GI bleeding and ulceration. Expect to use piroxicam for the shortest time possible in these patients.
- Be aware that serious GI tract ulceration, bleeding, and perforation may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, withhold drug and notify prescriber at once.
- Use piroxicam cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

WARNING Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

WARNING If patient has bone marrow suppression or is receiving antineoplastic drug therapy, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of piroxicam may mask signs and symptoms, such as fever and pain.

- Especially if patient is elderly or taking drug long-term, watch for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver function test results because, rarely, elevated levels may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure.
- Monitor BUN and serum creatinine levels in patients with heart failure, impaired renal function, or hepatic dysfunction; those taking diuretics or ACE inhibitors; and elderly patients because drug may cause renal failure.
- Monitor CBC for decreased hemoglobin level and hematocrit because drug may worsen anemia.
- Assess patient's skin routinely for rash or other signs of hypersensitivity reaction

because piroxicam and other NSAIDs may cause serious skin reactions without warning, even in patients with no history of NSAID hypersensitivity. Stop drug at first sign of reaction, and notify prescriber.

WARNING Be aware that drug may cause premature closure of ductus arteriosus in growing fetus during third trimester of pregnancy. Be prepared to suggest referral for high-risk pregnancy.

PATIENT TEACHING

- Advise patient to take piroxicam with meals to minimize GI distress. Also direct her to take drug with a full glass of water and to remain upright for 30 minutes afterward to decrease risk of drug lodging in esophagus and causing irritation.
- Instruct patient to swallow capsules whole and not to crush, break, chew, or open them.
- Advise patient to avoid alcohol, aspirin, and other NSAIDs, unless prescribed, while taking piroxicam.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- If patient also takes an anticoagulant, advise her to watch for and immediately report bleeding problems, such as bloody or tarry stools and bloody vomitus.
- If patient also takes insulin or an oral antidiabetic, advise her to closely monitor blood glucose level to prevent hypoglycemia. Urge her to carry candy or other simple sugars to treat mild hypoglycemia. Advise her to notify prescriber if hypoglycemic episodes are frequent or severe.
- Explain that piroxicam may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, weakness, and slurring of speech.
- Tell patient that piroxicam may increase risk of serious adverse GI reactions; stress the need to seek immediate medical attention for such signs and symptoms as epigastric or abdominal pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.
- Alert patient to possibility of rare but serious skin reactions. Urge her to seek immediate medical care for rash, blisters, itching, fever, or other signs of hypersensitivity.
- Instruct female patient to consult pre-

scriber if she becomes pregnant because drug may cause premature closure of ductus arteriosus in growing fetus.

pitavastatin

Livalo

Class and Category

Chemical class: HMG-CoA reductase inhibitor

Therapeutic class: Antihyperlipidemic, statin

Pregnancy category: X

Indications and Dosages

➤ To decrease elevated total cholesterol, LDL, apolipoprotein B, and triglyceride levels and increase HDL level as adjunct to diet in patients with primary hyperlipidemia or mixed dyslipidemia

TABLETS

Adults. *Initial:* 2 mg once daily, increased as needed. *Maximum:* 4 mg once daily

DOSAGE ADJUSTMENT For patients with moderate renal impairment (glomerular filtration rate 30 to 60 ml/min/1.73m²) or patients receiving dialysis, initial dosage reduced to 1 mg once daily, with maximum of 2 mg once daily. For patients taking erythromycin, dosage shouldn't exceed 1 mg daily; for patients taking rifampin, dosage shouldn't exceed 2 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	Unknown

Mechanism of Action

Reduces plasma cholesterol and lipoprotein levels by inhibiting HMG-CoA reductase and cholesterol synthesis in the liver. Consequently, number of LDL receptors on liver cells increases, and LDL uptake and breakdown are enhanced. With sustained inhibition of cholesterol synthesis in the liver, levels of very low-density lipoproteins are decreased.

Contraindications

Active liver disease (including unexplained persistent LFT elevation), breast-feeding, concurrent cyclosporine therapy, hypersensitivity to pitavastatin or its components, women who are pregnant or may become pregnant

Interactions

DRUGS

cyclosporine, erythromycin, lopinavir and ritonavir, rifampin: Increased pitavastatin exposure

fibrates such as gemfibrozil: Increased risk of myopathy

niacin: Increased risk of adverse skeletal muscle effects

Adverse Reactions

CNS: Headache

EENT: Nasopharyngitis

ENDO: Elevated blood glucose level

GI: Constipation, diarrhea, elevated liver enzyme levels

GU: Acute renal failure, myoglobinuria

MS: Arthralgia, back or extremity pain, myopathy, myositis, rhabdomyolysis

SKIN: Pruritus, rash, urticaria

Other: Elevated creatine phosphokinase level, influenza

Nursing Considerations

- Be aware that pitavastatin isn't recommended for patients with severe renal impairment who aren't on dialysis and for patients currently receiving lopinavir and ritonavir therapy because of increased risk of serious adverse effects.
- Note that pravastatin, another HMG-CoA reductase inhibitor, sounds similar to pitavastatin and could be confusing. Make sure of correct drug before giving.
- Use pitavastatin cautiously in patients with risk factors for myopathy, such as age over 65, presence of renal impairment, being inadequately treated for hypothyroidism, or concurrent use of niacin-containing products or fibrates. Monitor patient throughout therapy for muscular complaints and an elevated blood creatine kinase level, as ordered. Drug should be discontinued if patient's creatine kinase level becomes markedly elevated or myopathy is suspected or confirmed.
- Expect liver function tests to be done before pitavastatin starts, after 6 and 12 weeks of therapy, with each dosage increase, and every 6 months thereafter.
- Expect to monitor patient's lipid levels after 4 weeks of therapy to determine drug effectiveness and periodically thereafter, as ordered. Expect dosage to be adjusted if lipid levels remain elevated.

PATIENT TEACHING

- Stress that pitavastatin is an adjunct to, not a substitute for, a low-cholesterol diet.
- Tell patient to take drug at the same time each day to maintain its effects.
- Instruct patient to report unexplained muscle pain, tenderness, or weakness, especially if accompanied by malaise or fever.
- Advise patient to limit alcohol ingestion while taking pitavastatin because alcohol-induced liver dysfunction may be difficult to differentiate from pitavastatin-induced liver dysfunction.
- Instruct patient to consult prescriber before taking OTC niacin products because of increased risk of adverse muscle effects.
- Caution women of childbearing age that drug is contraindicated in pregnancy because drug could be harmful to the baby. If pregnancy is suspected, patient should notify prescriber immediately.

polymyxin B sulfate

Aerosporin

Class and Category

Chemical class: *Bacillus polymyxa* derivative

Therapeutic class: Antibiotic

Pregnancy category: Not rated

Indications and Dosages

➤ *To treat infections resistant to less toxic drugs, such as bacteremia, septicemia, and UTI caused by susceptible organisms, including Enterobacter aerogenes, Escherichia coli, Haemophilus influenzae, and Klebsiella pneumoniae*

I.V. INFUSION

Adults and children age 2 and over.

15,000 to 25,000 units/kg daily in divided doses every 12 hr or as a continuous infusion. *Maximum:* 2 million units daily.

Infants and children under age 2. Up to 40,000 units/kg daily in divided doses every 12 hr or as a continuous infusion.

I.M. INJECTION

Adults and children age 2 and over.

25,000 to 30,000 units/kg daily in divided doses every 4 to 6 hr. *Maximum:* 2 million units daily.

Infants and children under age 2. Up to 40,000 units/kg daily in divided doses every

4 to 6 hr.

DOSE ADJUSTMENT Dosage reduced by 50% for patients with creatinine clearance of 5 to 20 ml/min/1.73 m²; by 85% for patients with creatinine clearance of less than 5 ml/min/1.73 m².

↗ **To prevent bacteriuria and bacteremia in patients with an indwelling catheter**

BLADDER IRRIGATION

Adults and children age 2 and over.

Combination of 200,000 units (20 mg) polymyxin B sulfate and 57 mg neomycin sulfate added to 1,000 ml normal saline solution daily as a continuous bladder irrigation for up to 10 days; rate adjusted as prescribed, based on patient's urine output.

↗ **To treat meningitis caused by susceptible strains of *Pseudomonas aeruginosa* or *H. influenzae***

INTRATHECAL INJECTION

Adults and children age 2 and over.

50,000 units daily for 3 to 4 days, then 50,000 units every other day for at least 2 wk after CSF cultures are negative and glucose content is normal.

Infants and children under age 2.

20,000 units daily for 3 to 4 days, then 25,000 units every other day for at least 2 wk after CSF cultures are negative and glucose content is normal.

Mechanism of Action

Binds to cell membrane phospholipids in gram-negative bacteria, increasing permeability of cell membrane. Polymyxin B also acts as a cationic detergent, altering osmotic barrier of membrane and causing essential intracellular metabolites to leak out. Both actions lead to cell death.

Incompatibilities

Don't mix polymyxin B sulfate with amphotericin B, calcium salts, chloramphenicol, chlorothiazide, heparin sodium, magnesium salts, nitrofurantoin, penicillins, prednisolone, and tetracyclines. They're incompatible.

Contraindications

Hypersensitivity to polymyxin B or its components

Interactions

DRUGS

general anesthetics, neuromuscular blockers,

skeletal muscle relaxants: Increased or prolonged skeletal muscle relaxation, possibly respiratory paralysis

nephrotoxic and neurotoxic drugs (such as aminoglycosides, amphotericin B, colistin, sodium citrate, streptomycin, tobramycin, and vancomycin): Increased risk of nephrotoxicity and neurotoxicity

Adverse Reactions

CNS: Ataxia, confusion, dizziness, drowsiness, fever, giddiness, headache, increased leukocyte and protein levels in CSF, neurotoxicity, paresthesia (circumoral or peripheral), slurred speech

CV: Thrombophlebitis

EENT: Blurred vision, nystagmus

GU: Albuminuria, azotemia, cylindruria, decreased urine output, hematuria, nephrotoxicity

HEME: Eosinophilia

RESP: Respiratory muscle paralysis

SKIN: Rash, urticaria

Other: Anaphylaxis, drug-induced fever, facial flushing, injection site pain, stiff neck (with intrathecal injection), superinfection

Nursing Considerations

- Be aware that patients receiving polymyxin B sulfate are hospitalized to allow appropriate supervision.
- Obtain blood, urine, or other samples for culture and sensitivity tests, as ordered, before giving drug. Expect to start drug before results are known. Keep in mind that baseline renal function tests should have been performed before administration. Check test results, if available, and notify prescriber of abnormalities.
- For I.M. injection, reconstitute sterile powder with 2 ml of sterile water for injection or sodium chloride for injection.
- Be aware that I.M. route isn't usually recommended (especially for infants and children) because it can cause severe pain at injection site.
- For I.V. infusion, dissolve polymyxin B in 300 to 500 ml of D₅W and infuse over 60 to 90 minutes.
- For intrathecal route, add 10 ml sodium chloride for injection to polymyxin B vial.
- Inspect for particles and discoloration before giving drug.
- During therapy, monitor renal function, including BUN and serum creatinine lev-

els, especially in patients with a history of renal insufficiency.

WARNING Be aware that declining urine output and rising BUN level suggest nephrotoxicity, which also is characterized by albuminuria, azotemia, cylindruria, excessive excretion of electrolytes, hematuria, leukocyturia, and rising blood drug level. Notify prescriber immediately if you detect any of these signs.

WARNING Notify prescriber immediately if patient experiences blurred vision, circumoral or peripheral paresthesia, confusion, dizziness, drowsiness, facial flushing, giddiness, myasthenia, nystagmus, or slurred speech. These may be signs of neurotoxicity, a serious adverse reaction that may lead to respiratory arrest or paralysis if untreated.

- Assess for signs of superinfection, such as mouth sores, severe diarrhea, and white patches on tongue or in mouth, especially in debilitated or elderly patients.
- Monitor fluid intake and output and provide adequate fluids to reduce the risk of nephrotoxicity.

PATIENT TEACHING

- Encourage patient to maintain adequate fluid intake during polymyxin B therapy.
- Instruct patient to notify prescriber at once about diarrhea, mouth sores, or vaginitis, possible early signs of superinfection.

posaconazole

Noxafil

Class and Category

Chemical class: Triazole

Therapeutic class: Antifungal

Pregnancy category: C

Indications and Dosages

↗ *To prevent invasive aspergillus and candida infections in patients at high risk because of severe immunocompromise from such conditions as graft-versus-host disease with hematopoietic stem-cell transplant or hematologic malignancies with prolonged neutropenia from chemotherapy*

ORAL SUSPENSION

Adults. 200 mg (5 ml) t.i.d. until recovery from neutropenia or immunosuppression.

↗ *To treat oropharyngeal candidiasis*

ORAL SUSPENSION

Adults. *Initial:* 100 mg (2.5 ml) b.i.d. on first day, followed by 100 mg (2.5 ml) once daily for 13 days.

↗ *To treat oropharyngeal candidiasis refractory to itraconazole and or fluconazole*

ORAL SUSPENSION

Adults. 400 mg (10 ml) b.i.d. until underlying condition improves.

Route	Onset	Peak	Duration
P.O.	Unknown	3–5 hr	Unknown

Mechanism of Action

Blocks synthesis of ergosterol, an essential component of fungal cell membrane, by inhibiting 14 alpha-demethylase, an enzyme needed for conversion of lanosterol to ergosterol. Lack of ergosterol increases cellular permeability, and cell contents leak.

Contraindications

Concurrent therapy with sirolimus; hypersensitivity to posaconazole, its components, or other azole antifungals; use with ergot alkaloids or CYP3A4 substrates such as astemizole, cisapride, halofantrine, pimozone, quinidine, and terfenadine

Interactions

DRUGS

astemizole, cisapride, halofantrine, pimozone, quinidine, terfenadine: Increased risk of prolonged QT interval and torsades de pointes
atazanavir, calcium channel blockers, cyclosporine, midazolam, phenytoin, rifabutin, ritonavir, sirolimus, tacrolimus: Increased plasma levels of these drugs, with increased risk of adverse reactions
cimetidine, efavirenz, phenytoin, rifabutin: Possibly decreased plasma level of posaconazole

digoxin: Increased risk of digitalis toxicity
ergot alkaloids: Increased plasma ergot alkaloid level and increased risk of ergotism
esomeprazole, metoclopramide: Possible breakthrough fungal infections
HMG-CoA reductase inhibitors: Increased plasma statin level and increased risk of rhabdomyolysis
vinca alkaloids: Increased plasma vinca alkaloid level and increased risk of neurotoxicity

Adverse Reactions

CNS: Anxiety, asthenia, dizziness, fatigue, fever, headache, insomnia, rigors, tremor, weakness

CV: Edema, hypertension, hypotension, QT-interval prolongation, tachycardia

EENT: Blurred vision, epistaxis, herpes simplex, mucositis, pharyngitis, taste perversion

ENDO: Hyperglycemia, hypocalcemia

GI: Abdominal pain, anorexia, bilirubinemia, constipation, diarrhea, dyspepsia, elevated liver enzyme levels, hepatomegaly, jaundice, nausea, vomiting

GU: Acute renal failure, elevated blood creatinine level, vaginal hemorrhage

HEME: Anemia, neutropenia, thrombocytopenia

MS: Arthralgia, back or musculoskeletal pain

RESP: Coughing, dyspnea, pneumonia, upper respiratory tract infection

SKIN: Diaphoresis, petechiae, pruritus, rash

Other: Bacteremia, cytomegalovirus infection, dehydration, hypokalemia, hypomagnesemia, weight loss

Nursing Considerations

- Use cautiously in patients who have had a hypersensitivity reaction to other azoles because of risk for cross-sensitivity.
- Use cautiously in patients with renal or hepatic dysfunction.
- Use cautiously in patients with potentially proarrhythmic conditions because posaconazole may prolong QT interval.
- Obtain baseline assessment of liver function and check periodically during therapy. If elevations occur or patient has evidence of abnormal liver function, notify prescriber.

PATIENT TEACHING

- Advise patient to use the measuring spoon supplied by manufacturer and to rinse it with water after each use.
- Instruct patient to take posaconazole with or within 20 minutes after a full meal or liquid nutritional supplement to increase drug absorption. Tell patient that he also may take posaconazole with an acidic carbonated beverage such as gingerale.
- Tell patient to report severe diarrhea or vomiting because these conditions may interfere with drug effectiveness.

potassium acetate

(contains 2 or 4 mEq of elemental potassium per 1 ml of injection)

potassium bicarbonate

(contains 6.5 mEq of elemental potassium per tablet, 20 or 25 mEq of elemental potassium per effervescent tablet for oral solution)

K+Care ET, K-Electrolyte, K-Ide, Klor-Con/EE, K-Lyte, K-Vescent

potassium bicarbonate and potassium chloride

(contains 20 mEq of elemental potassium per 2.8-g granule packet; 20, 25, or 50 mEq of elemental potassium per effervescent tablet for oral solution)

Klorvess Effervescent Granules, K-Lyte/Cl, K-Lyte/Cl 50, Neo-K (CAN), Potassium Sandoz (CAN)

potassium bicarbonate and potassium citrate

(contains 25 or 50 mEq of elemental potassium per effervescent tablet for oral solution)

Effer-K, K-Lyte DS

potassium chloride

(contains 8 or 10 mEq of elemental potassium per E.R. capsule; 6.7, 8, 10, 12, or 20 mEq of elemental potassium per E.R. tablet; 10, 20, 30, or 40 mEq of elemental potassium per 15 ml of oral solution; 10, 15, 20, or 25 mEq of elemental potassium per packet for oral solution; 20 mEq of elemental potassium per packet for oral suspension; 0.1, 0.2, 0.3, 0.4, 1.5, 2, 3, or 10 mEq of elemental potassium per 1 ml of injection)

Apo-K (CAN), Cena-K, Gen-K, K-8,

K-10 (CAN), K+ 10, Kalium Durules (CAN), Kaochlor 10%, Kaochlor S-F 10%, Kaon-Cl, Kato, Kay Ciel, K+ Care, KCL 5% (CAN), K-Dur, K-Ide, K-Lease, K-Long (CAN), K-Lor, Klor-Con 10, Klor-Con Powder, Klor-Con/25 Powder, Klorvess 10% Liquid, Klotrix, K-Lyte/Cl Powder, K-Med 900 (CAN), K-Norm, K-Sol, K-Tab, Micro-K, Micro-K 10, Potasalan, Roychlor 10% (CAN), Rum-K, Slow-K, Ten-K

potassium citrate

(contains 5 mEq or 10 mEq of elemental potassium per tablet)

Urocit-K

potassium gluconate

(contains 20 mEq of elemental potassium per 15 ml of elixir; 2, 2.3, or 2.5 mEq of elemental potassium per tablet)

Glu-K, Kaon, Kaylixir, K-G Elixir, Potassium-Rouquier (CAN)

potassium gluconate and potassium chloride

(contains 20 mEq of elemental potassium per 15 ml of oral solution; 20 mEq of elemental potassium per 5-g packet for oral solution)

Kolyum

potassium gluconate and potassium citrate

(contains 20 mEq of elemental potassium per 15 ml of oral solution)

Twin-K

trikates

(contains 15 mEq of elemental potassium per 5 ml of oral solution)

Tri-K

Class and Category

Chemical class: Electrolyte cation

Therapeutic class: Electrolyte replacement

Pregnancy category: C

Indications and Dosages

➤ To prevent or treat hypokalemia in patients who can't ingest sufficient dietary potassium or who are losing potassium because of a condition (such as hepatic cirrhosis or prolonged vomiting) or drug (such as potassium-wasting diuretics or certain antibiotics)

EFFERVESCENT TABLETS (POTASSIUM BICARBONATE)

Adults and adolescents. 25 to 50 mEq/g once or twice daily, as needed and tolerated. *Maximum:* 100 mEq daily.

EFFERVESCENT TABLETS (POTASSIUM BICARBONATE AND POTASSIUM CHLORIDE)

Adults and adolescents. 20, 25, or 50 mEq once or twice daily, as needed and tolerated. *Maximum:* 100 mEq daily.

EFFERVESCENT TABLETS (POTASSIUM BICARBONATE AND POTASSIUM CITRATE)

Adults and adolescents. 25 or 50 mEq once or twice daily, as needed and tolerated. *Maximum:* 100 mEq daily.

ELIXIR (POTASSIUM GLUCONATE)

Adults and adolescents. 20 mEq b.i.d. to q.i.d., as needed and tolerated. *Maximum:* 100 mEq daily.

Children. 2 to 3 mEq/kg daily in divided doses.

E.R. CAPSULES (POTASSIUM CHLORIDE)

Adults and adolescents. 40 to 100 mEq daily in divided doses b.i.d. or t.i.d. for treatment; 16 to 24 mEq daily in divided doses b.i.d. or t.i.d. for prevention. *Maximum:* 100 mEq daily.

E.R. TABLETS (POTASSIUM CHLORIDE)

Adults and adolescents. 6.7 to 20 mEq t.i.d. *Maximum:* 100 mEq daily.

GRANULE PACKETS (POTASSIUM BICARBONATE AND POTASSIUM CHLORIDE)

Adults and adolescents. 20 mEq once or twice daily, as needed and tolerated. *Maximum:* 100 mEq daily.

GRANULES FOR ORAL SUSPENSION (POTASSIUM CHLORIDE)

Adults and adolescents. 20 mEq 1 to 5 times/day, as needed. *Maximum:* 100 mEq daily.

ORAL SOLUTION (POTASSIUM CHLORIDE)

Adults and adolescents. 20 mEq once daily

to q.i.d., as needed and tolerated.

Maximum: 100 mEq daily.

Children. 1 to 3 mEq/kg daily in divided doses.

ORAL SOLUTION (POTASSIUM GLUCONATE AND POTASSIUM CHLORIDE, POTASSIUM GLUCONATE AND POTASSIUM CITRATE)

Adults and adolescents. 20 mEq b.i.d. to q.i.d., as needed and tolerated. *Maximum:* 100 mEq daily.

Children. 2 to 3 mEq/kg daily in divided doses.

POWDER PACKET FOR ORAL SOLUTION (POTASSIUM CHLORIDE)

Adults. 15 to 25 mEq b.i.d. to q.i.d., as needed and tolerated. *Maximum:* 100 mEq daily.

Children. 1 to 3 mEq/kg daily in divided doses, as needed and tolerated.

POWDER PACKET FOR ORAL SOLUTION (POTASSIUM GLUCONATE AND POTASSIUM CHLORIDE)

Adults and adolescents. 20 mEq b.i.d. to q.i.d., as needed and tolerated. *Maximum:* 100 mEq daily.

Children. 2 to 3 mEq/kg daily in divided doses.

ORAL TRIKATES SOLUTION (POTASSIUM ACETATE, POTASSIUM BICARBONATE, AND POTASSIUM CITRATE)

Adults and adolescents. 15 mEq t.i.d. to q.i.d., as needed and tolerated. *Maximum:* 100 mEq daily.

Children. 2 to 3 mEq/kg daily in divided doses.

TABLETS (POTASSIUM GLUCONATE)

Adults and adolescents. 5 to 10 mEq b.i.d. to q.i.d., as needed and tolerated. *Maximum:* 100 mEq daily.

I.V. INFUSION (POTASSIUM ACETATE AND POTASSIUM CHLORIDE)

Adults and adolescents with serum potassium level above 2.5 mEq/L. Up to 10 mEq/hr. *Maximum:* 200 mEq daily.

Adults and adolescents with serum potassium level below 2 mEq/L, ECG changes, or paralysis. Up to 20 mEq/hr. *Maximum:* 400 mEq daily.

Children. 3 mEq/kg daily.

DOSAGE ADJUSTMENT Dosage adjusted as prescribed based on patient's ECG patterns and serum potassium level.

➤ *To treat renal tubular acidosis with calcium stones, hypocitraturic calcium oxalate nephrolithiasis of any etiology,*

and uric acid lithiasis with or without calcium stones

TABLETS (POTASSIUM CITRATE)

Adults. For patients with severe hypocitraturia, 15 mEq four times daily with meals or 20 mEq three times daily with meals. For patients with mild to moderate hypocitraturia, 10 mEq three times daily with meals.

Mechanism of Action

Acts as the major cation in intracellular fluid, activating many enzymatic reactions essential for physiologic processes, including nerve impulse transmission and cardiac and skeletal muscle contraction. Potassium also helps maintain electroneutrality in cells by controlling exchange of intracellular and extracellular ions. It also helps maintain normal renal function and acid-base balance.

Incompatibilities

Don't mix potassium chloride for injection in same syringe with amino acid solutions, lipid solutions, or mannitol because these drugs may precipitate from solution. Administration with blood or blood products can cause lysis of infused RBCs.

Contraindications

Acute dehydration, Addison's disease (untreated), concurrent use of potassium-sparing diuretics, crush syndrome, disorders that may delay drug passing through GI tract (potassium citrate), heat cramps, hyperkalemia, hypersensitivity to potassium salts or their components, peptic ulcer disease (potassium citrate), renal impairment with azotemia or oliguria, severe hemolytic anemia, UTI (potassium citrate)

Interactions

DRUGS

ACE inhibitors, beta blockers, blood products, cyclosporine, heparin, NSAIDs, potassium-containing drugs, potassium-sparing diuretics: Increased risk of hyperkalemia
amphotericin B, corticosteroids (glucocorticoids, mineralocorticoids), gentamicin, penicillins, polymyxin B: Possibly hypokalemia
anticholinergics, drugs with anticholinergic activity: Increased risk of GI ulceration, stricture, and perforation
calcium salts (parenteral): Possibly arrhythmias
digoxin: Increased risk of digitalis toxicity

insulin, laxatives, sodium bicarbonate:

Decreased serum potassium level
sodium polystyrene sulfonate: Possibly decreased serum potassium level and fluid retention

thiazide diuretics: Possibly hyperkalemia when diuretic is discontinued

FOODS

low-salt milk, salt substitutes: Increased risk of hyperkalemia

Adverse Reactions

CNS: Confusion, paralysis, paresthesia, weakness

CV: Arrhythmias, ECG changes

EENT: Throat pain when swallowing

GI: Abdominal pain; bloody stools; diarrhea; flatulence; GI bleeding, perforation, or ulceration; intestinal obstruction; nausea; vomiting

RESP: Dyspnea

SKIN: Rash

Other: Hyperkalemia

Nursing Considerations

- Administer oral potassium with or immediately after meals.
- Mix potassium chloride for oral solution or potassium gluconate elixir in cold water, orange juice, tomato juice (if patient isn't sodium restricted), or apple juice, and stir for 1 full minute before administering.
- Mix potassium bicarbonate, potassium bicarbonate and potassium chloride, and potassium bicarbonate and potassium citrate effervescent tablets with cold water and allow to dissolve completely.
- Be aware that liquid form of oral potassium is prescribed for patients with delayed gastric emptying, esophageal compression, or intestinal obstruction or stricture to decrease the risk of tissue damage.

WARNING Be aware that direct injection of a potassium concentrate may be immediately fatal. Dilute potassium concentrate for injection with adequate volume of solution before I.V. use. Maximum suggested concentration is 40 mEq/L, although stronger concentrations (up to 80 mEq/L) may be used for severe hypokalemia. Inappropriate solutions or improper technique may cause extravasation, fever, hyperkalemia, hypervolemia, I.V. site infection, phlebitis, venospasm, and

venous thrombosis.

- Infuse potassium slowly to avoid phlebitis and decrease risk of adverse cardiac reactions. Keep in mind that different forms of potassium salts contain different amounts of elemental potassium per gram and that not all forms are dosage equivalent.
 - Monitor serum potassium level before and during administration of I.V. potassium.
- WARNING** Be aware that some forms of potassium contain tartrazine, which may cause an allergic reaction, such as asthma. Some forms may also contain aluminum, which may become toxic in a patient with impaired renal function.
- Regularly assess patient for signs of hypokalemia, such as arrhythmias, fatigue, and weakness, and for signs of hyperkalemia, such as arrhythmias, confusion, dyspnea, and paresthesia.
 - Because adequate renal function is needed for potassium supplementation, monitor serum creatinine level and urine output during administration. Notify prescriber about signs of decreased renal function.

PATIENT TEACHING

- Inform patient that potassium is part of a normal diet and that most meats, seafoods, fruits, and vegetables contain sufficient potassium to meet recommended daily intake. Also advise her not to exceed recommended daily amount of potassium.
- Teach patient the correct way to take prescribed potassium. This can vary from swallowing a tablet with a full glass of water to mixing certain preparations with half to full glass of cold water or juice.
- Caution patient not to crush or chew E.R. forms unless instructed otherwise.
- Instruct patient to take drug with or right after food.
- Teach patient how to take her radial pulse, and advise her to notify prescriber about significant changes in heart rate or rhythm.
- Advise patient to watch stools for changes in color and consistency and to notify prescriber if they become black, tarry, or red.
- Inform patient that although she may see waxy form of E.R. tablet in stools, she has received all of the potassium.
- Urge patient to keep follow-up laboratory appointments as directed by prescriber to determine serum potassium level.

potassium iodide (KI, SSKI)

Pima, Thyro-Block

Class and Category

Chemical class: Iodine

Therapeutic class: Antithyroid, radiation protectant

Pregnancy category: D

Indications and Dosages

↗ *To prepare for thyroidectomy*

ORAL SOLUTION

Adults and children. 50 to 250 mg t.i.d. for 10 to 14 days before surgery.

↗ *To manage thyrotoxic crisis*

ORAL SOLUTION

Adults. 50 to 250 mg t.i.d. or 500 mg every 4 hr.

↗ *To protect thyroid gland during radiation exposure*

ORAL SOLUTION, SYRUP, TABLETS

Adults and adolescents. 100 to 150 mg 24 hr before administration of or exposure to radioactive isotopes of iodine and daily for 3 to 10 days afterward. *Maximum:* 12 g daily.

Children age 1 and over. 130 mg daily for 10 days after administration of or exposure to radioactive isotopes of iodine.

Children under age 1. 65 mg daily for 10 days after administration of or exposure to radioactive isotopes of iodine.

Route	Onset	Peak	Duration
P.O.*	24 hr	10–15 days	Up to 6 wk

Mechanism of Action

Inhibits release of thyroid hormone into circulation, thus alleviating symptoms caused by excessive thyroid hormone stimulation. Potassium iodide also blocks thyroid uptake of radioactive iodine isotopes released as a result of radiation exposure.

Contraindications

Acute bronchitis, Addison's disease, dehydration, heat cramps, hyperkalemia, hypersensitivity to iodides or their components, hyperthyroidism, iodism, renal impairment, tuberculosis

* For antithyroid effects.

Interactions

DRUGS

antithyroid drugs, lithium: Increased risk of hypothyroidism and goiter
captopril, enalapril, lisinopril, potassium-sparing diuretics: Increased risk of hyperkalemia

Adverse Reactions

CNS: Confusion, fatigue, headache, heaviness or weakness in legs, paresthesia

CV: Irregular heartbeat

EENT: Burning in mouth or throat, increased salivation, metallic taste, sore teeth or gums

GI: Diarrhea, epigastric pain, indigestion, nausea, vomiting

HEME: Eosinophilia

MS: Arthralgia

SKIN: Acneiform lesions, urticaria

Other: Angioedema, lymphadenopathy

Nursing Considerations

- Be aware that potassium iodide shouldn't be given to patients with tuberculosis because drug may cause pulmonary irritation and increased secretions.

WARNING Monitor serum potassium level regularly in patients with renal impairment because of the risk of hyperkalemia.

- Monitor thyroid function test results periodically to assess drug's effectiveness.

PATIENT TEACHING

- Advise patient taking potassium iodide oral solution or syrup to use a calibrated measuring device to ensure accurate doses.
- Urge patient to mix solution or syrup in a full glass (8 oz) of water, fruit juice, milk, or broth to improve taste and lessen GI reactions. Advise patient taking tablet form to dissolve each tablet in half a glass (4 oz) of water or milk before ingestion.
- If crystals form in solution, advise patient to place the closed container in warm water and gently shake to dissolve.
- Instruct patient to discard bottle and obtain a new one if solution turns brownish yellow.

potassium phosphates

K-Phos Original, Neutra-Phos-K

potassium and sodium phosphates

K-Phos M.F., K-Phos-Neutral, K-Phos No. 2, Neutra-Phos

sodium phosphates

Class and Category

Chemical class: Anion, soluble salts

Therapeutic class: Antiurolithic, electrolyte replenisher, urinary acidifier

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat UTI, to prevent renal calculus formation*

MONOBASIC TABLETS (POTASSIUM PHOSPHATES)

Adults and adolescents. 1 g in 180 to 240 ml water q.i.d., after meals and at bedtime.

MONOBASIC TABLETS (POTASSIUM AND SODIUM PHOSPHATES)

Adults and adolescents. 250 mg in 240 ml water q.i.d., after meals and at bedtime.

Dosage interval may be increased to every 2 hr if urine is difficult to acidify.

Maximum: 2 g/24 hr.

↗ *To prevent or treat hypophosphatemia*

CAPSULES (POTASSIUM PHOSPHATES)

Adults and children age 4 and over. 1.45 g in 75 ml water or juice q.i.d., after meals and at bedtime.

Children up to age 4. 200 mg in 60 ml water or juice q.i.d., after meals and at bedtime.

CAPSULES (POTASSIUM AND SODIUM PHOSPHATES)

Adults and children age 4 and over. 1.25 g in 75 ml water or juice q.i.d., after meals and at bedtime.

Children up to age 4. 200 mg in 60 ml water or fruit juice q.i.d., after meals and at bedtime.

MONOBASIC TABLETS (POTASSIUM PHOSPHATES)

Adults and children age 4 and over. 1 g in 180 to 240 ml water q.i.d., after meals and at bedtime.

Children up to age 4. 200 mg in 60 ml water q.i.d., after meals and at bedtime.

MONOBASIC TABLETS (POTASSIUM AND SODIUM PHOSPHATES)

Adults and children age 4 and over.

250 mg in 240 ml water q.i.d., after meals

and at bedtime.

Children up to age 4. 200 mg in 60 ml water q.i.d., after meals and at bedtime.

ORAL SOLUTION (POTASSIUM PHOSPHATES, POTASSIUM AND SODIUM PHOSPHATES)

Adults and children age 4 and over. 250 mg q.i.d., after meals and at bedtime.

Children up to age 4. 200 mg q.i.d., after meals and at bedtime.

TABLETS (POTASSIUM AND SODIUM PHOSPHATES)

Adults and children age 4 and over. 250 mg in a full glass of water q.i.d., after meals and at bedtime.

Children up to age 4. 200 mg in 60 ml water q.i.d., after meals and at bedtime.

I.V. INFUSION (SODIUM PHOSPHATES)

Adults and adolescents. 10 to 15 mmol (310 to 465 mg) daily.

Children. 1.5 to 2 mmol (46.5 to 62 mg)/kg daily.

Mechanism of Action

Reverses symptoms of hypophosphatemia by replenishing the body's supply of phosphate; acidifies urine by causing hydrogen to be exchanged for sodium in renal distal tubule; and inhibits formation of calcium renal calculi by preventing solidification of calcium oxalate.

Incompatibilities

Don't add phosphates to calcium- or magnesium-containing solutions because precipitate may form.

Contraindications

Hyperkalemia (potassium formulations), hypernatremia (sodium formulations), hyperphosphatemia, magnesium ammonium phosphate urolithiasis accompanied by infection, severe renal insufficiency, UTI caused by urea-splitting organisms

Interactions

DRUGS

ACE inhibitors, cyclosporine, heparin (long-term use), NSAIDs, potassium-containing drugs, potassium-sparing diuretics: Increased risk of hyperkalemia (potassium forms only)
aluminum- or magnesium-containing antacids: Possibly impaired phosphate absorption

anabolic steroids, androgens, corticosteroids, estrogens: Increased risk of edema (sodium formulations only)

calcium-containing drugs: Increased risk of

calcium deposition in soft tissues

iron supplements: Decreased absorption of oral iron

phosphate-containing drugs, vitamin D:

Increased risk of hyperphosphatemia

salicylates: Increased blood salicylate level

zinc supplements: Reduced zinc absorption

FOODS

low-salt milk, salt substitutes: Increased risk of hyperkalemia

oxalates (in spinach and rhubarb), phytates

(in bran and whole grains): Decreased absorption of phosphate

Adverse Reactions

CNS: Anxiety, confusion, dizziness, fatigue, headache, paresthesia, seizures, tremor, weakness

CV: Arrhythmias, edema of legs, tachycardia

GI: Diarrhea, epigastric pain, nausea, thirst, vomiting

GU: Decreased urine output

MS: Muscle cramps or weakness

RESP: Dyspnea

Other: Hyperkalemia, hypernatremia, hyperphosphatemia, hypocalcemia, weight gain

Nursing Considerations

- Monitor serum phosphorus level, as appropriate, in patient who receives phosphates and has a condition that may be associated with elevated phosphorus level, such as chronic renal disease, hypoparathyroidism, and rhabdomyolysis; phosphates may further increase serum phosphorus level.
- Monitor serum calcium level, as appropriate, in patient who receives phosphates and has a condition that may be associated with a low calcium level, such as acute pancreatitis, chronic renal disease, hypoparathyroidism, osteomalacia, rhabdomyolysis, and rickets; phosphates may further decrease serum calcium level.
- Monitor serum potassium level, as appropriate, if patient who receives potassium phosphate has a condition linked to elevated potassium level, such as acute dehydration, adrenal insufficiency, extensive tissue breakdown (as in severe burns), myotonia congenita, pancreatitis, rhabdomyolysis, and severe renal insufficiency; she may have increased risk of hyperkalemia.
- Monitor serum sodium level in patient

who receives sodium phosphates and has a condition that may be worsened by sodium excess, such as heart failure, hypernatremia, hypertension, peripheral or pulmonary edema, preeclampsia, renal impairment, and severe hepatic disease.

- Monitor urine pH, as ordered, to assess effectiveness of drug used to acidify urine.
- When administering sodium phosphates, monitor ECG tracing frequently during I.V. infusion to detect arrhythmias.

PATIENT TEACHING

- Instruct patient to take phosphates after meals to avoid GI upset and decrease laxative effect.
- Stress importance of not swallowing capsules or tablets whole; instead, advise patient to soak tablets in water or fruit juice for 2 to 3 minutes to dissolve them.
- Suggest chilling diluted drug to improve flavor, but caution against freezing.
- Encourage increased intake of fluids (8 oz/hour, if not contraindicated) to prevent renal calculi.
- Urge patient to notify prescriber immediately about muscle weakness or cramps, unexplained weight gain, or shortness of breath.
- Instruct patient who needs an iron supplement to take it 1 to 2 hours after taking phosphates.

pralidoxime chloride

(2-PAM chloride, 2-pyridine aldoxime methochloride)

Protopam Chloride

Class and Category

Chemical class: Quaternary ammonium oxime

Therapeutic class: Anticholinesterase antidote

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to reverse organophosphate pesticide toxicity*

I.V. INFUSION, I.M. OR SUBCUTANEOUS INJECTION

Adults. *Initial:* 1 to 2 g in 100 ml normal saline solution infused over 15 to 30 min,

given concurrently with atropine 2 to 6 mg every 5 to 60 min until muscarinic signs and symptoms disappear; may be repeated in 1 hr and then every 3 to 8 hr if muscle weakness persists. If I.V. route isn't feasible, administer I.M. or subcutaneously.

Children. *Initial:* 20 mg/kg in 100 ml normal saline solution infused over 15 to 30 min, given concurrently with atropine (dosage individualized); may be repeated in 1 hr and then every 3 to 8 hr if muscle weakness persists. If I.V. route isn't feasible, administer I.M. or subcutaneously.

➤ *To treat anticholinesterase overdose secondary to myasthenic drugs (including ambenonium, neostigmine, and pyridostigmine)*

I.V. INJECTION

Adults. *Initial:* 1 to 2 g, followed by 250 mg every 5 min.

➤ *To treat exposure to nerve agents*

I.V. INJECTION

Adults. *Initial:* 1 atropine-containing autoinjector followed by 1 pralidoxime-containing autoinjector as soon as atropine's effects are evident; both injections repeated every 15 min for 2 additional doses if nerve agent symptoms persist.

DOSAGE ADJUSTMENT Dosage reduced for patients with renal insufficiency.

Mechanism of Action

Reverses muscle paralysis by removing phosphoryl group from inhibited cholinesterase molecules at neuromuscular junction of skeletal and respiratory muscles.

Reactivation of cholinesterase restores body's ability to metabolize acetylcholine, which is inhibited by organophosphate pesticides, anticholinesterase overdose, or nerve agent poisoning.

Contraindications

Hypersensitivity to pralidoxime chloride or its components

Interactions

DRUGS

aminophylline, morphine, phenothiazines, reserpine, succinylcholine, theophylline:

Increased symptoms of organophosphate poisoning

barbiturates: Potentiated barbiturate effects

Adverse Reactions

CNS: Dizziness, drowsiness, headache

CV: Increased systolic and diastolic blood pressure, tachycardia

EENT: Accommodation disturbances, blurred vision, diplopia

GI: Nausea, vomiting

MS: Muscle weakness

RESP: Hyperventilation

Other: Injection site pain

Nursing Considerations

- Be aware that pralidoxime must be given within 36 hours of toxicity to be effective.
- Use drug with extreme caution in patients with myasthenia gravis being treated for organophosphate poisoning because pralidoxime may precipitate myasthenic crisis.
- Reconstitute drug according to manufacturer's guidelines and administration route.
- For intermittent infusion, further dilute with normal saline solution to 100 ml and infuse over 15 to 30 minutes.
- Avoid too-rapid delivery, which may cause hypertension, laryngospasm, muscle spasms, neuromuscular blockade, and tachycardia. Also be sure to avoid intradermal injection.
- Closely monitor neuromuscular status during therapy.
- Monitor BUN and serum creatinine levels, as appropriate, in patients with renal insufficiency because drug is excreted in urine.
- When pralidoxime is administered with atropine, expect signs of atropination, such as dry mouth and nose, flushing, mydriasis, and tachycardia, to occur earlier than might be expected when atropine is given alone.

PATIENT TEACHING

- Inform patient receiving I.M. pralidoxime that she'll experience pain at the injection site for 40 to 60 minutes afterward.
- Reassure patient that she'll be closely monitored throughout therapy.

pramipexole dihydrochloride

Mirapex

Class and Category

Chemical class: Benzothiazolamine derivative

Therapeutic class: Antidyskinetic

Pregnancy category: C

Indications and Dosages

➤ *To treat Parkinson's disease, with or without concurrent levodopa therapy*

TABLETS

Adults. *Initial:* 0.125 mg t.i.d. for 1 wk, increased weekly thereafter as follows: for week 2, 0.25 mg t.i.d.; for week 3, 0.5 mg t.i.d.; for week 4, 0.75 mg t.i.d.; for week 5, 1 mg t.i.d.; for week 6, 1.25 mg t.i.d.; and for week 7, 1.5 mg t.i.d. *Maintenance:* 1.5 to 4.5 mg daily in divided doses t.i.d.

Maximum: 4.5 mg daily.

DOSE ADJUSTMENT For patients with renal impairment, dosage reduced as follows: for creatinine clearance of 35 to 59 ml/min/1.73 m², initial dose of 0.125 mg b.i.d., maximum of 3 mg daily; for creatinine clearance of 15 to 34 ml/min/1.73 m², initial dose of 0.125 mg daily, maximum of 1.5 mg daily. Drug shouldn't be given to patients with creatinine clearance of less than 15 ml/min/1.73 m².

➤ *To treat restless legs syndrome*

TABLETS

Adults. *Initial:* 0.125 mg once daily, 2 to 3 hours before bedtime. Increased in 4 to 7 days to 0.25 mg once daily 2 to 3 hours before bedtime as needed. Further increased in 4 to 7 days to 0.5 mg once daily 2 to 3 hours before bedtime, as needed.

DOSE ADJUSTMENT For patients with moderate to severe renal impairment (creatinine clearance 20 to 60 ml/min/1.73 m²) dosage interval for titration, if needed, increased to 14 days.

Mechanism of Action

May stimulate dopamine receptors in the brain, thereby easing symptoms of Parkinson's disease, which is thought to be caused by a dopamine deficiency.

Contraindications

Hypersensitivity to pramipexole or its components

Interactions

DRUGS

carbidopa, levodopa: Possibly increased peak blood levodopa level and potentiation of levodopa's dopaminergic adverse effects
diltiazem, quinidine, quinine, ranitidine, triamterene, verapamil: Decreased pramipex-

ole clearance

haloperidol, metoclopramide, phenothiazines, thioxanthenes: Decreased pramipexole effectiveness

Adverse Reactions

CNS: Abnormal behavior, amnesia, anxiety, asthenia, confusion, dream disturbances, drowsiness, dyskinesia, dystonia, fatigue, fever, hallucinations, headache, insomnia, malaise, paranoia, restlessness, syncope

CV: Edema, orthostatic hypotension

EENT: Diplopia, dry mouth, rhinitis, vision changes

GI: Anorexia, constipation, dysphagia, nausea

GU: Altered libido, impotence, urinary frequency, urinary incontinence

MS: Arthralgia, myalgia, myasthenia

RESP: Pneumonia

SKIN: Diaphoresis, rash

Other: Eating disorders (binge or compulsive eating, hyperphagia), intense urges for certain activities (such as gambling and sex), weight gain or loss

Nursing Considerations

- Use pramipexole cautiously in patients with hallucinations, hypotension, or retinal problems (such as macular degeneration). Drug may worsen these conditions.
- Also use cautiously in patients with renal impairment because pramipexole elimination may be decreased.
- Take safety precautions per facility policy until drug's CNS effects are known.
- Avoid stopping pramipexole abruptly because doing so may cause a symptom complex resembling neuroleptic malignant syndrome and consisting of hyperpyrexia, muscle rigidity, altered level of consciousness, and autonomic instability.
- Assess patient for skin changes regularly because melanomas may occur at a higher rate in patients with Parkinson's disease. It isn't clear if this is a result of the disease or drugs used to treat it.

PATIENT TEACHING

- Advise patient to take pramipexole with meals if nausea occurs.
- Caution patient about possible dizziness, drowsiness, or light-headedness, which may result from orthostatic hypotension. Advise her not to rise quickly from a lying or sitting position to minimize these effects.

- Instruct patient to notify prescriber immediately about vision problems or urinary frequency or incontinence.
- Inform patient that improvement in motor performance and activities of daily living may take 2 to 3 weeks.
- Urge patient to have regular skin examinations by a dermatologist or other qualified health professional.
- Advise patient to notify prescriber about intense urges, as for gambling or sex. Dosage may need to be reduced or drug discontinued.

pramlintide acetate

Symlin

Class and Category

Chemical class: Synthetic analogue of human amylin, a pancreatic beta cell hormone

Therapeutic class: Antidiabetic

Pregnancy category: C

Indications and Dosages

➤ *To achieve euglycemia in patients with type 1 diabetes who use mealtime insulin therapy but have not achieved desired glucose control*

SUBCUTANEOUS INJECTION

Adults. *Initial:* 15 mcg just before major meals with 50% reduced dosage of preprandial rapid-acting or short-acting insulin, including fixed-mix insulins such as 70/30. When nausea has abated at least 3 days, dosage increased in increments of 15 mcg. *Maintenance:* 30 to 60 mcg before major meals.

DOSAGE ADJUSTMENT Dosage decreased to 30 mcg if nausea occurs and persists at higher dosages.

➤ *To achieve euglycemia in patients with type 2 diabetes who use mealtime insulin, with or without a sulfonyleurea and/or metformin, and have not achieved desired glucose control*

SUBCUTANEOUS INJECTION

Adults. *Initial:* 60 mcg immediately before major meals combined with dosage reduction of preprandial rapid-acting or short-acting insulin, including fixed-mix insulins such as 70/30, by 50%. When nausea has been absent for 3 to 7 days, dosage

increased to 120 mcg before major meals.

DOSAGE ADJUSTMENT Dosage decreased to 60 mcg before major meals if nausea occurs and persists with 120-mcg dosage.

Route	Onset	Peak	Duration
SubQ	Unknown	19–21 min	3 hr

Mechanism of Action

Slows the rate at which food is released from stomach to small intestine, thus reducing initial postprandial rise in serum glucose level. Pramlintide also suppresses glucagon secretion and promotes satiety, thus furthering weight loss, which also lowers serum glucose level.

Pramlintide is a synthetic analogue of amylin, a naturally occurring neuroendocrine hormone secreted with insulin by pancreatic beta cells. In diabetes, secretion of insulin and amylin is reduced or absent.

Contraindications

Gastroparesis, hypersensitivity to pramlintide, cresol or its components; hypoglycemia unawareness

Incompatibilities

Don't mix in same syringe as insulin because pharmacokinetic parameters of pramlintide become altered.

Interactions

DRUGS

drugs that alter GI motility (such as anticholinergics) or slow intestinal absorption of nutrients (such as alpha-glucosidase inhibitors): Altered effects of these drugs
oral drugs: Delayed absorption

Adverse Reactions

CNS: Dizziness, fatigue, headache

EENT: Blurred vision, pharyngitis

ENDO: Insulin-induced hypoglycemia

GI: Abdominal pain, anorexia, nausea, vomiting

MS: Arthralgia

RESP: Coughing

SKIN: Diaphoresis

Other: Hypersensitivity reactions; local injection site reaction, such as redness, swelling, or pruritus

Nursing Considerations

- Because of the risks involved with pramlintide therapy, insulin-using patients with

- type 1 or 2 diabetes must have failed to achieve adequate glycemic control despite individualized insulin management and must be receiving ongoing care with guidance of insulin prescriber and a diabetes educator before pramlintide is prescribed.
- Expect that certain patients won't be prescribed pramlintide because its risks may outweigh its benefits. These include patients with poor compliance with current insulin regimen, poor compliance with monitoring blood glucose level, a glycosylated hemoglobin greater than 9%, recurrent severe hypoglycemia that required assistance during past 6 months, hypoglycemia unawareness, gastroparesis, concurrent therapy with drugs that stimulate GI motility, and pediatric patients.
 - Before pramlintide therapy starts, make sure patient's pre-meal insulin dosage has been reduced by 50%.
 - Give drug immediately before main meals.
 - Monitor patient's pre- and post-meal blood glucose levels regularly to determine effectiveness of pramlintide and insulin therapy and to detect hypoglycemia.
 - For 3 hours after each dose of pramlintide, monitor patient closely for hypoglycemia, which may be severe, especially in patients with type 1 diabetes. Effects may include hunger, headache, sweating, tremor, irritability, and trouble concentrating. They may occur with a rapid decrease in blood glucose level regardless of glucose values.
 - Although pramlintide doesn't cause hypoglycemia, its use with insulin increases the risk of insulin-induced severe hypoglycemia, which can result in loss of consciousness, coma, or seizures. If hypoglycemia occurs, provide supportive care, including glucagon if prescribed, and notify prescriber. Expect insulin dosage accompanying pramlintide to be reduced.
 - Keep in mind that early warning symptoms of hypoglycemia may be different or less severe if patient has had diabetes for a long time; has diabetic nerve disease; takes a beta blocker, clonidine, guanethidine, or reserpine; or is under intensified diabetes control.
 - Closely monitor patients taking oral antidiabetics, ACE inhibitors, disopyramide, fibrates, fluoxetine, MAO inhibitors, pentoxifylline, propoxyphene, salicylates,

or sulfonamide antibiotics because of an increased risk of hypoglycemia.

- Expect pramlintide to be stopped if patient develops recurrent hypoglycemia that requires medical assistance, develops persistent nausea, or becomes noncompliant with therapy or follow-up visits.

PATIENT TEACHING

- Alert patient that insulin-induced hypoglycemia may occur within 3 hours of injecting pramlintide. Review signs and symptoms and appropriate treatment. Tell patient to notify prescriber if hypoglycemia occurs because insulin dosage will need to be reduced.
- Stress need to monitor blood glucose level often, especially before and after eating.
- Tell patient to inject drug subcutaneously immediately before major meals using an insulin syringe to draw up dose and using the same technique as with insulin administration, including rotating sites. Or, if patient has been prescribed the Symlin Pen injector, show her how to use it. Advise patient to inject drug into her abdomen or thigh and not to use her arm as an injection site because absorption may be too variable.
- Warn patient not to mix pramlintide and insulin together in the same syringe.
- Warn patient that nausea is common with pramlintide; urge her to notify prescriber because dosage may need to be decreased.
- Caution patient that if she misses a dose, she should skip the missed dose and continue with the next scheduled dose.
- Instruct patient to keep unopened pramlintide vials in the refrigerator; vials that have been opened may be kept in the refrigerator or at room temperature. Vials should be discarded 28 days after opening.
- Caution patient to avoid hazardous activities that require mental alertness until effects of pramlintide are known.
- Reassure patient that pramlintide won't alter her awareness of or her body's response to insulin-induced hypoglycemia.
- Alert patient that she'll need close follow-up care, at least weekly until a target dose of pramlintide has been reached, she's tolerating the drug well, and her blood glucose level is stable.
- Instruct women of childbearing age to notify prescriber about planned, suspect-

ed, or known pregnancy because drug therapy will need to be adjusted.

- Explain that local injection site reactions, such as redness, swelling or itching, may occur but usually resolve in a few weeks.

prasugrel

Effient

Class and Category

Chemical class: Thienopyridine

Therapeutic class: Platelet activation and aggregation inhibitor, antiplatelet

Pregnancy category: B

Indications and Dosages

➤ *To reduce rate of thrombotic cardiovascular events in patients with acute coronary syndrome who will be managed with percutaneous coronary intervention because of unstable angina, non-ST-elevation MI, or ST-elevation MI*

TABLETS

Adults. *Initial:* 60 mg as a loading dose and then 10 mg once daily. *Maintenance:* 10 mg once daily.

DOSE ADJUSTMENT For patients weighing less than 60 kg (132 lb), daily maintenance dosage may be reduced to 5 mg once daily.

Route	Onset	Peak	Duration
P.O.	2 hr	30 min	7–10 days

Mechanism of Action

After forming active metabolite, irreversibly binds to ADP receptors on platelets to inhibit platelet activation and aggregation for the lifetime of the platelet, which is 7 to 10 days. Without platelet activation and aggregation, thrombus cannot form.

Contraindications

Active bleeding, history of transient ischemic attack or stroke, hypersensitivity to prasugrel or its components

Interactions

DRUGS

fibrinolytic agents, heparin, NSAIDs (chronic use), warfarin: Increased risk of bleeding

Adverse Reactions

CNS: Dizziness, fatigue, fever, headache,

intracranial hemorrhage

CV: Atrial fibrillation, bradycardia, hypercholesterolemia, hyperlipidemia, hypertension, hypotension, peripheral edema

EENT: Epistaxis, retinal hemorrhage

GI: Diarrhea, GI or retroperitoneal hemorrhage, hepatic dysfunction, nausea

HEME: Anemia, leukopenia, mild to life-threatening bleeding, severe thrombocytopenia, thrombotic thrombocytopenic purpura

MS: Back or limb pain

RESP: Cough, dyspnea, hemoptysis

SKIN: Subcutaneous hematoma, rash

Other: Allergic reaction, angioedema, malignancies, noncardiac chest pain

Nursing Considerations

- Be aware that patient should be receiving daily aspirin therapy (75 mg or 325 mg) throughout prasugrel therapy.
- Drug isn't recommended for patients age 75 or older (except in high-risk situations such as the presence of diabetes or history of previous MI) or in patients who have active bleeding or a history of a transient ischemic attack or stroke. Monitor patients closely who have other risk factors for bleeding, which include a body weight less than 60 kg, a history of bleeding, or concurrent use of drugs that increase risk of bleeding, such as warfarin, heparin, fibrinolytic therapy, or chronic use of NSAIDs.
- Prasugrel shouldn't be given to patients likely to undergo emergency coronary artery bypass graft (CABG) surgery because of increased bleeding risk. Drug should be discontinued at least 7 days before any surgery.

WARNING Monitor patient closely for bleeding because prasugrel can cause life-threatening hemorrhage. Report hypotension in patients who have recently undergone coronary angiography, percutaneous coronary intervention, CABG surgery, or other surgical procedures while taking drug. In this setting, expect therapy to continue because stopping prasugrel, especially in first few weeks after acute coronary syndrome, increases the risk of adverse cardiovascular effects.

- Because prasugrel inhibits platelet aggregation for the lifetime of the platelet, which is 7 to 10 days, withholding a dose

is unlikely help in managing a bleeding event or the risk of bleeding associated with an invasive procedure. Expect to administer exogenous platelets but only 6 hours after prasugrel loading dose or 4 hours after maintenance dose was given.

- Monitor patient's CBC regularly, as ordered, watching for evidence of thrombotic thrombocytopenic purpura, such as fever, neurologic abnormalities, renal dysfunction, and abnormal blood counts. Notify prescriber immediately because condition can be fatal. Expect to implement emergency treatment, such as plasmapheresis.

PATIENT TEACHING

- Stress importance of taking prasugrel exactly as prescribed, without lapses in therapy, for drug to be effective and adverse reactions to be reduced.
- Instruct patient to take daily dose of aspirin as prescribed.
- Discourage use of NSAIDs, including OTC products, during prasugrel therapy because of risk of bleeding.
- Caution patient that bleeding may last longer than usual. Instruct him to report unusual bleeding or bruising.
- Instruct patient to inform health care providers that he takes prasugrel.
- Urge patient to take precautions against bleeding, such as using an electric shaver and a soft-bristled toothbrush.
- Advise patient to avoid activities that could cause traumatic injury and bleeding.

pravastatin sodium

Pravachol

Class and Category

Chemical class: Mevinic acid derivative

Therapeutic class: Antihyperlipidemic

Pregnancy category: X

Indications and Dosages

↗ *To prevent coronary and cardiovascular events in patients at risk, to treat hyperlipidemia*

TABLETS

Adults. *Initial:* 10 to 40 mg daily at bedtime, increased every 4 wk, as needed.

Maintenance: 10 to 80 mg at bedtime.

DOSAGE ADJUSTMENT For patients with sig-

nificant renal or hepatic impairment, those taking immunosuppressants, and elderly patients, initial dosage reduced to 10 mg daily at bedtime. For elderly patients and those taking immunosuppressants, maintenance dosage usually limited to 20 mg daily.

↗ *To treat pediatric heterozygous familial hypercholesterolemia*

TABLETS

Adolescents ages 14 to 18. 40 mg daily at bedtime.

Children ages 8 to 14. 20 mg daily at bedtime.

Mechanism of Action

Inhibits cholesterol synthesis in liver by blocking the enzyme needed to convert hydroxymethylglutaryl-CoA (HMG-CoA) to mevalonate, a cholesterol precursor. When cholesterol synthesis is blocked, the liver also increases breakdown of LDL cholesterol.

Contraindications

Active hepatic disease or unexplained, persistent elevated liver function test results; breastfeeding; hypersensitivity to pravastatin or its components; pregnancy

Interactions

DRUGS

cholestyramine, colestipol: Decreased pravastatin bioavailability
cyclosporine, erythromycin, gemfibrozil, immunosuppressants, niacin: Increased risk of rhabdomyolysis and acute renal failure
oral anticoagulants: Increased bleeding or prolonged PT

Adverse Reactions

CNS: Anxiety, depression, dizziness, fatigue, headache, nervousness, sleep disturbance

CV: Angina pectoris, chest pain

EENT: Blurred vision, diplopia, rhinitis

ENDO: Abnormal thyroid function

GI: Abdominal pain, constipation, diarrhea, elevated liver function test results, flatulence, heartburn, indigestion, nausea, pancreatitis, vomiting

GU: Dysuria, nocturia, urinary frequency

MS: Arthralgia, musculoskeletal cramps or pain, myalgia, myopathy, rhabdomyolysis

RESP: Cough, dyspnea, upper respiratory tract infection

SKIN: Rash

Other: Angioedema

Nursing Considerations

- Use pravastatin cautiously in patients with renal or hepatic impairment and in elderly patients.
- Monitor liver function test results before pravastatin therapy starts, before dosage increases, and periodically throughout therapy, as prescribed.
- Give drug 1 hour before or 4 hours after giving cholestyramine or colestipol.
- Report unexplained muscle aches or weakness and significant increases in CK level to prescriber because drug rarely causes rhabdomyolysis with acute renal failure caused by myoglobinuria. Expect to stop drug and provide supportive care.
- Monitor patient's BUN and serum creatinine levels periodically for abnormal elevations.
- Monitor blood lipoprotein level, as indicated, to evaluate response to therapy.

PATIENT TEACHING

- Instruct patient to take drug at bedtime, without regard to meals.
- Advise patient to notify prescriber at once about muscle pain, tenderness, weakness, and other evidence of myopathy.
- Urge woman of childbearing age to use a reliable method of contraception during pravastatin therapy and to notify prescriber at once if she becomes pregnant or thinks she may be pregnant.
- Instruct patient not to stop taking pravastatin without consulting prescriber, even when cholesterol level returns to normal.

prazosin hydrochloride

Minipress

Class and Category

Chemical class: Quinazoline derivative

Therapeutic class: Antihypertensive

Pregnancy category: C

Indications and Dosages

➤ *To manage hypertension*

CAPSULES

Adults. *Initial:* 1 mg b.i.d. or t.i.d.

Maintenance: 6 to 15 mg daily in divided doses b.i.d. or t.i.d. *Maximum:* 40 mg daily.

Children. *Initial:* 50 to 400 mcg/kg daily in

divided doses b.i.d. or t.i.d. *Maximum:* 7 mg/dose, 15 mg daily.

TABLETS

Adults. *Initial:* 0.5 mg b.i.d. or t.i.d. for at least 3 days; then increased to 1 mg b.i.d. or t.i.d., if tolerated, for an additional 3 days. Subsequent dosages adjusted gradually, as needed and tolerated. *Maintenance:* 6 to 15 mg daily in divided doses b.i.d. or t.i.d. *Maximum:* 40 mg daily.

Children. *Initial:* 50 to 400 mcg/kg daily in divided doses b.i.d. or t.i.d. *Maximum:* 7 mg/dose, 15 mg daily.

DOSAGE ADJUSTMENT For elderly patients and those with renal impairment, initial dosage possibly reduced to 1 mg once to twice daily.

Route	Onset	Peak	Duration
P.O.	0.5–1.5 hr	2–4 hr*	7–10 hr

Mechanism of Action

Selectively and competitively inhibits alpha₁-adrenergic receptors. This action promotes peripheral arterial and venous dilation and reduces peripheral vascular resistance, thereby lowering blood pressure.

Contraindications

Hypersensitivity to prazosin, other quinazolines, or their components

Interactions

DRUGS

antihypertensives, beta blockers, diuretics, phosphodiesterase-5 inhibitors: Increased risk of hypotension and syncope

dopamine: Antagonized peripheral vasoconstrictive effect of dopamine (high doses)

ephedrine: Decreased vasopressor response to ephedrine

epinephrine: Possibly severe hypotension and tachycardia

metaraminol: Decreased vasopressor effect of metaraminol

methoxamine, phenylephrine: Possibly decreased vasopressor effect and shortened duration of action of these drugs

NSAIDs, sympathomimetics: Decreased effectiveness of prazosin

Adverse Reactions

CNS: Asthenia, dizziness, drowsiness,

* For a single dose; 3 to 4 wk for multiple doses.

fatigue, headache, insomnia, malaise, nervousness, syncope

CV: Angina, bradycardia, edema, orthostatic hypotension, palpitations, vasculitis

EENT: Dry mouth, eye pain

ENDO: Gynecomastia

GI: Nausea

GU: Urinary frequency, urinary incontinence

SKIN: Urticaria

Other: Hypersensitivity reaction

Nursing Considerations

- Use prazosin cautiously in patients with renal impairment because of increased sensitivity to prazosin's effects; in those with angina pectoris because drug may induce or aggravate angina; in those with narcolepsy because prazosin may worsen cataplexy; and in elderly patients because they're at increased risk for drug-induced hypotension.
- Monitor blood pressure regularly to evaluate effectiveness of therapy.

PATIENT TEACHING

- Instruct patient who is starting prazosin to take drug at bedtime to minimize effects of first-dose hypotension.
- Stress need to take drug even if feeling well.
- Advise patient to avoid drinking alcohol, standing for long periods, and exercising in hot weather because these activities increase risk of orthostatic hypotension.
- Suggest rising slowly from lying or sitting position to minimize orthostatic hypotension.
- Urge patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to notify prescriber immediately about adverse reactions, especially dizziness and fainting.
- Instruct patient not to take any drugs, including OTC forms, without consulting prescriber, to avoid serious interactions.

prednisolone

Cotolone, Delta-Cortef, Prelone

prednisolone acetate

Articulose-50, Flo-Pred, Key-Pred, Predacort 50, Predalone 50, Predate 50,

Predcor-25, Predcor-50, Pred-Ject 50

prednisolone sodium phosphate

Orapred ODT, Pediapred

prednisolone tebutate

Nor-Pred T.B.A., Predalone T.B.A., Predate TBA, Predcor-TBA

Class and Category

Chemical class: Glucocorticoid

Therapeutic class: Anti-inflammatory, immunosuppressant

Pregnancy category: C

Indications and Dosages

↗ *To treat adrenal insufficiency and acute and chronic inflammatory and immunosuppressive disorders*

SYRUP, TABLETS (PREDNISOLONE);

DISINTEGRATING TABLETS, ORAL SOLUTION (PREDNISOLONE SODIUM PHOSPHATE); ORAL SUSPENSION (PREDNISOLONE ACETATE)

Adults and adolescents. 5 to 60 mg daily or in divided doses. *Maximum:* 250 mg daily.

I.M. INJECTION (PREDNISOLONE ACETATE)

Adults and adolescents. 4 to 60 mg daily.

INTRA-ARTICULAR, INTRALESIONAL, OR SOFT-TISSUE INJECTION (PREDNISOLONE ACETATE, PREDNISOLONE TEBUTATE)

Adults and adolescents. 4 to 100 mg of prednisolone acetate, repeated as needed, or 4 to 40 mg of prednisolone tebutate, repeated every 1 to 3 wk, as needed.

↗ *To treat adrenocortical insufficiency in children*

SYRUP, TABLETS (PREDNISOLONE);

DISINTEGRATING TABLETS, ORAL SOLUTION (PREDNISOLONE SODIUM PHOSPHATE); ORAL SUSPENSION (PREDNISOLONE ACETATE)

Children. 0.14 mg/kg daily in divided doses t.i.d.

I.M. INJECTION (PREDNISOLONE ACETATE)

Children. 0.14 mg/kg over a 24-hr period in divided doses t.i.d. every third day.

↗ *To treat acute exacerbations of multiple sclerosis*

SYRUP, TABLETS (PREDNISOLONE);

DISINTEGRATING TABLETS, ORAL SOLUTION

(PREDNISOLONE SODIUM PHOSPHATE); ORAL SUSPENSION (PREDNISOLONE ACETATE)

Adults. 200 mg daily for 1 wk, followed by 80 mg every other day for 1 mo.

Route	Onset	Peak	Duration
P.O.*	Unknown	1–2 hr	1.25–1.5 days
I.M.†	Slow	Unknown	Unknown
Intra-articular, intralesional, soft-tissue injection‡	1–2 days	Unknown	1–3 wk

Mechanism of Action

Binds to intracellular glucocorticoid receptors and suppresses inflammatory and immune responses by:

- inhibiting neutrophil and monocyte accumulation at inflammation site and suppressing their phagocytic and bactericidal activity
- stabilizing lysosomal membranes
- suppressing antigen response of macrophages and helper T cells
- inhibiting synthesis of inflammatory response mediators, such as cytokines, interleukins, and prostaglandins.

Contraindications

Hypersensitivity to prednisolone or its components, idiopathic thrombocytopenic purpura (I.M. form), systemic fungal infection

Interactions**DRUGS**

acetaminophen: Possibly hepatotoxicity (long-term use or high acetaminophen doses)

acetazolamide: Possibly hypernatremia or edema

amphotericin B (parenteral): Possibly severe hypokalemia

anabolic steroids, androgens: Possibly edema and severe acne

anticholinergics: Increased intraocular pressure

asparaginase: Increased hyperglycemic

effect of asparaginase, possibly neuropathy and disturbances in erythropoiesis

carbonic anhydrase inhibitors: Possibly hypocalcemia, hypokalemia, and osteoporosis

digoxin: Possibly arrhythmias and digitalis toxicity from hypokalemia

diuretics: Possibly decreased natriuretic and diuretic effects of diuretics, severe hypokalemia (with potassium-depleting diuretics)

ephedrine: Increased metabolic clearance of prednisolone

estrogens, oral contraceptives: Decreased clearance, increased elimination half-life, and increased therapeutic and toxic effects of prednisolone

folic acid: Increased folic acid requirements (with long-term prednisolone use)

heparin, oral anticoagulants, streptokinase, urokinase: Possibly decreased anticoagulant effect and increased risk of GI ulceration and bleeding

immunosuppressants: Increased risk of infection, lymphomas, and other lymphoproliferative disorders

isoniazid: Decreased blood isoniazid level

mexiletine: Possibly accelerated metabolism and decreased blood level of mexiletine

neuromuscular blockers: Increased neuromuscular blockade

NSAIDs: Increased risk of GI ulceration and bleeding, possibly added therapeutic effect when NSAIDs are used to treat arthritis

potassium supplements: Decreased effectiveness of both drugs

rifampin, other hepatic enzyme inducers: Decreased prednisolone effect

ritodrine: Increased risk of pulmonary edema in pregnant women

salicylates: Possibly decreased blood salicylate level, increased risk of GI ulceration and bleeding

sodium-containing drugs: Possibly edema and hypertension

somatrem, somatropin: Inhibited growth response to somatrem or somatropin

streptozocin: Increased risk of hyperglycemia

toxoids, vaccines: Possibly loss of antibody response, increased risk of neurologic complications

tricyclic antidepressants: Possibly worsened adverse psychiatric effects of prednisolone

troleandomycin: Increased therapeutic and toxic effects of prednisolone

FOODS

* Prednisolone

† Prednisolone acetate

‡ Prednisolone tebutate

sodium-containing foods: Increased risk of edema and hypertension

ACTIVITIES

alcohol use: Increased risk of GI ulceration and bleeding

Adverse Reactions

CNS: Euphoria, headache, insomnia, nervousness, psychosis, restlessness, seizures, vertigo

CV: Edema, heart failure, hypertension

EENT: Cataracts, exophthalmos, glaucoma, increased ocular pressure

ENDO: Adrenal insufficiency, Cushing's syndrome, growth suppression in children, hyperglycemia

GI: Anorexia, GI bleeding and ulceration, increased appetite, indigestion, intestinal perforation, nausea, pancreatitis, vomiting

GU: Menstrual irregularities

MS: Avascular necrosis of joints, bone fractures, muscle atrophy or weakness, myalgia, osteoporosis, tendon rupture (local injection only)

SKIN: Acne; cutaneous or subcutaneous atrophy (with frequent repository injections); diaphoresis; ecchymosis; flushing; petechiae; striae; thin, fragile skin

Other: Delayed wound healing, hypernatremia, hypokalemia, injection site scarring, negative nitrogen balance

Nursing Considerations

WARNING Avoid using prednisolone in patients with a history of active tuberculosis because drug can reactivate the disease.

- Give once-daily doses in the morning to mirror body's normal cortisol secretion.
- Inspect injectable form for particulates and discoloration before administering.
- For I.M. injection, shake suspension well before withdrawing. Keep in mind that I.M. injections are contraindicated in patients with idiopathic thrombocytopenic purpura.
- For intra-articular injection, attach a 20G to 24G needle to empty syringe, using aseptic technique, so prescriber can remove a few drops of synovial fluid to confirm that needle is in the joint. The aspirating syringe is then exchanged with a prednisolone-filled syringe to inject drug into joint.
- Because prednisolone can produce many adverse reactions, assess patient regularly

for evidence of such reactions, including heart failure and hypertension. Also monitor patient's intake, output, and daily weight.

- Monitor growth pattern in children; prednisolone may retard bone growth.
- Prolonged use may cause hypothalamic-pituitary-adrenal suppression.

WARNING Withdraw drug gradually, as ordered, if therapy lasts longer than 2 weeks. Stopping abruptly may cause acute adrenal insufficiency or, possibly, death.

- Be aware that patient may be at risk for emotional instability or psychic disturbance while taking prednisolone, especially if predisposed to them or taking high doses.

PATIENT TEACHING

- Instruct patient to take oral prednisolone with food to decrease stomach upset and to take once-daily dose in the morning.
- Stress need to take drug exactly as prescribed; taking too much increases risk of serious adverse reactions.
- Instruct patient taking orally disintegrating tablets to remove tablet from blister pack only when ready to take drug and to place tablet on tongue. Warn her not to split, cut, or break tablets.
- Caution patient not to discontinue drug abruptly.
- Urge patient to avoid alcohol during therapy because of increased risk of GI ulcers and bleeding.
- Urge patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to avoid people with contagious infections because drug has an immunosuppressant effect. Urge her to notify prescriber immediately about exposure to measles or chickenpox.
- Caution against receiving vaccinations or other immunizations and coming in contact with people who have recently received oral poliovirus vaccine.
- Teach patient about potential side effects of prednisolone therapy, including restlessness, mood swings, nervousness, and delayed wound healing.
- Instruct patient to notify prescriber immediately about joint pain, swelling, tarry stools, and visual disturbances. Also instruct her to report signs of infection or

injury for up to 12 months after therapy.

- Advise patient to restrict joint use after intra-articular injection and to obtain activity guidelines from prescriber.
- Instruct diabetic patient to check her blood glucose level often because prednisolone may cause hyperglycemia.
- Advise patient to comply with follow-up visits to assess drug's effectiveness and detect adverse reactions.
- Urge patient to carry medical identification revealing prednisolone therapy.

prednisone

Apo-Prednisone (CAN), Deltasone Liquid Pred, Meticorten, Orasone 1, Orasone 5, Orasone 10, Prednicen-M, Prednicot, Prednisone Intensol, Sterapred, Sterapred DS, Winpred (CAN)

Class and Category

Chemical class: Glucocorticoid

Therapeutic class: Anti-inflammatory, immunosuppressant

Pregnancy category: Not rated

Indications and Dosages

➤ *To treat adrenal insufficiency and acute and chronic inflammatory and immunosuppressive disorders*

ORAL SOLUTION, SYRUP, TABLETS

Adults and adolescents. 5 to 60 mg daily as a single dose or in divided doses.

Maximum: 250 mg daily.

➤ *To treat adrenogenital syndrome*

ORAL SOLUTION, SYRUP, TABLETS

Adults and adolescents. 5 to 10 mg daily.

Children. 5 mg/m² daily in divided doses b.i.d.

➤ *To treat acute exacerbations of multiple sclerosis*

ORAL SOLUTION, SYRUP, TABLETS

Adults. 200 mg daily for 1 wk, then 80 mg every other day for 1 mo. *Maximum:* 250 mg daily.

➤ *To treat nephrosis in children*

ORAL SOLUTION, SYRUP, TABLETS

Children age 10 and over. 20 mg q.i.d.

Children ages 4 to 10. 15 mg q.i.d.

Children ages 18 months to 4 years. 7.5 to 10 mg q.i.d.

➤ *To treat rheumatic carditis, leukemia,*

and tumors in children

ORAL SOLUTION, SYRUP, TABLETS

Children. 0.5 mg/kg q.i.d. for 2 to 3 wk; then 0.375 mg/kg q.i.d. for 4 to 6 wk.

➤ *As adjunct to treat tuberculosis in children (with concurrent antitubercular therapy)*

ORAL SOLUTION, SYRUP, TABLETS

Children. 0.5 mg/kg q.i.d. for 2 mo.

Route	Onset	Peak	Duration
P.O.	Rapid	1–2 hr	1.25–1.5 days

Mechanism of Action

Binds to intracellular glucocorticoid receptors and suppresses inflammatory and immune responses by:

- inhibiting neutrophil and monocyte accumulation at inflammation site and suppressing their phagocytic and bactericidal activity
- stabilizing lysosomal membranes
- suppressing antigen response of macrophages and helper T cells
- inhibiting synthesis of inflammatory response mediators, such as cytokines, interleukins, and prostaglandins.

Contraindications

Hypersensitivity to prednisone or its components, systemic fungal infection

Interactions

DRUGS

acetaminophen: Possibly hepatotoxicity (long-term use or high acetaminophen doses)

acetazolamide sodium: Possibly hypernatremia or edema

amphotericin B (parenteral): Possibly severe hypokalemia

anabolic steroids, androgens: Possibly edema and severe acne

antacids: Decreased absorption of prednisone (with long-term use)

anticholinergics: Increased intraocular pressure

asparaginase: Increased hyperglycemic effect of asparaginase, possibly neuropathy and disturbances in erythropoiesis

carbonic anhydrase inhibitors: Possibly hypocalcemia, hypokalemia, and osteoporosis

digoxin: Possibly arrhythmias and digitalis toxicity from hypokalemia

diuretics: Possibly decreased natriuretic

and diuretic effects of diuretics, severe hypokalemia (with potassium-depleting diuretics)

ephedrine: Increased metabolic clearance of prednisone

estrogens, oral contraceptives: Decreased clearance, increased elimination half-life, and increased therapeutic and toxic effects of prednisone

folic acid: Increased folic acid requirements (with long-term prednisone use)

heparin, oral anticoagulants, streptokinase, urokinase: Possibly decreased anticoagulant effect and increased risk of GI ulceration and bleeding

immunosuppressants: Increased risk of infection, lymphomas, and other lymphoproliferative disorders

isoniazid: Decreased blood isoniazid level

mexiletine: Possibly accelerated metabolism and decreased blood level of mexiletine

neuromuscular blockers: Increased neuromuscular blockade

NSAIDs: Increased risk of GI ulceration and bleeding, possibly added therapeutic effect when NSAIDs are used to treat arthritis

potassium supplements: Decreased effectiveness of both drugs

ritodrine: Increased risk of pulmonary edema in pregnant women

salicylates: Possibly decreased blood salicylate level, increased risk of GI ulceration and bleeding

sodium-containing drugs: Possibly edema and hypertension

somatrem, somatropin: Inhibited growth response to somatrem or somatropin

streptozocin: Increased risk of hyperglycemia

toxoids, vaccines: Possibly loss of antibody response, increased risk of neurologic complications

tricyclic antidepressants: Possibly exacerbated adverse psychiatric effects of prednisone

troleandomycin: Increased therapeutic and toxic effects of prednisone

FOODS

sodium-containing foods: Increased risk of edema and hypertension

ACTIVITIES

alcohol use: Increased risk of GI ulceration and bleeding

Adverse Reactions

CNS: Euphoria, headache, insomnia, nervousness, psychosis, restlessness, seizures,

vertigo

CV: Edema, heart failure, hypertension

EENT: Cataracts, exophthalmos, glaucoma, increased ocular pressure

ENDO: Adrenal insufficiency, Cushing's syndrome, growth suppression in children, hyperglycemia

GI: Anorexia, GI bleeding and ulceration, increased appetite, indigestion, intestinal perforation, nausea, pancreatitis, vomiting

GU: Menstrual irregularities

MS: Avascular necrosis of joints, bone fractures, muscle atrophy or weakness, myalgia, osteoporosis

SKIN: Acne; diaphoresis; ecchymosis; flushing; petechiae; striae; thin, fragile skin

Other: Delayed wound healing, hypernatremia, hypokalemia, negative nitrogen balance

Nursing Considerations

- Administer once-daily doses of prednisone in the morning to match body's normal cortisol secretion schedule.
- Because prednisone can produce many adverse reactions, assess regularly for signs and symptoms of such reactions as heart failure and hypertension. Also monitor fluid intake and output and daily weight.
- Monitor growth pattern in children. Prednisone may retard bone growth.
- Be aware that prolonged use of prednisone may cause hypothalamic-pituitary-adrenal suppression.

WARNING Withdraw prednisone gradually, as ordered, if therapy lasts longer than 2 weeks. Stopping abruptly may cause acute adrenal insufficiency and, possibly, death.

PATIENT TEACHING

- Instruct patient to take prednisone with food to decrease GI distress and to take once-daily dose in the morning.
- Stress importance of taking drug exactly as prescribed; taking more than prescribed increases risk of serious adverse reactions.
- Caution patient not to stop drug abruptly.
- Urge patient to avoid alcohol during therapy because of increased risk of GI ulcers and bleeding.
- Urge patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to avoid people with contagious infections because drug has an immunosuppressant effect. Urge her to

notify prescriber immediately about possible exposure to measles or chickenpox.

- Caution against receiving vaccinations or other immunizations and coming in contact with people who have recently received oral poliovirus vaccine.
- Instruct patient to notify prescriber immediately about joint pain, swelling, tarry stools, and visual disturbances. Also instruct her to report signs of infection or injury for up to 12 months after therapy.
- Instruct diabetic patient to check blood glucose level often because prednisone may cause hyperglycemia.
- Advise patient to comply with follow-up visits to assess drug effectiveness and detect adverse reactions.
- Urge patient to carry medical identification revealing prednisone therapy.

pregabalin

Lyrica

Class and Category

Chemical class: Structural derivative of gamma-aminobutyric acid (GABA)

Therapeutic class: Analgesic, anticonvulsant

Pregnancy category: C

Indications and Dosages

➤ *To relieve neuropathic pain associated with diabetic peripheral neuropathy*

CAPSULES

Adults. *Initial:* 50 mg t.i.d., increased to 100 mg t.i.d. within 1 wk as needed.

➤ *To relieve postherpetic neuralgia; as adjunct therapy to manage partial onset seizures*

CAPSULES

Adults. *Initial:* 75 mg b.i.d. or 50 mg t.i.d., increased to 150 mg b.i.d. or 100 mg t.i.d. within 1 week as needed. Then increased to 300 mg b.i.d. or 200 mg t.i.d. in 2 to 4 weeks as needed.

➤ *To manage fibromyalgia*

CAPSULES

Adults. *Initial:* 75 mg b.i.d., increased to 150 mg b.i.d. in 1 wk, as needed, and then to 225 mg b.i.d. in 1 wk as needed.

Maximum: 450 mg daily.

DOSAGE ADJUSTMENT If creatinine clearance is 30 to 60 ml/min/1.73 m², daily dosage reduced by 50%. If clearance is 15 to 30 ml/

min/1.73 m², daily dosage reduced by 75% and frequency reduced to once or twice daily. If clearance is less than 15 ml/min/1.73 m², daily dosage reduced to as low as 25 mg daily. If patient is having hemodialysis, daily dosage is reduced and supplemental dose given immediately after every 4-hour hemodialysis session as follows: If reduced daily dosage is 25 mg daily, give supplemental dose of 25 to 50 mg. If reduced daily dosage is 25 to 50 mg daily, give supplemental dose of 50 to 75 mg. If reduced daily dosage is 75 mg, give supplemental dose of 100 to 150 mg.

Route	Onset	Peak	Duration
P.O.	Unknown	1.5 hr	Unknown

Mechanism of Action

Binds to alpha₂-delta site, an auxiliary subunit of voltage calcium channels, in CNS tissue where it may reduce calcium-dependent release of several neurotransmitters, possibly by modulating calcium channel function. With fewer neurotransmitters, pain sensation and seizure activity decline.

Contraindications

Hypersensitivity to pregabalin or its components

Interactions

DRUGS

ACE inhibitors: Increased risk of pregabalin-induced angioedema

CNS depressants: Additive CNS effects such as somnolence

lorazepam, oxycodone: Additive effects on cognitive and gross motor function

thiazolidinedione antidiabetics: Possibly increased risk of peripheral edema and weight gain

ACTIVITIES

alcohol use: Additive effects on cognitive and gross motor function

Adverse Reactions

CNS: Abnormal gait, amnesia, anxiety, asthenia, ataxia, balance disorder, confusion, depression, difficulty concentrating, dizziness, euphoria, extrapyramidal syndrome, fatigue, fever, headache, hypertonia, hypesthesia, incoordination, intracranial hypertension, myoclonus, nervousness, neuropathy, paresthesia, psychotic depres-

sion, schizophrenic reaction, somnolence, stupor, suicidal ideation, tremor, twitching, vertigo

CV: Chest pain, heart failure, peripheral edema, ventricular fibrillation

EENT: Amblyopia, blurred vision, conjunctivitis, decreased visual acuity, diplopia, dry mouth, nystagmus, otitis media, sinusitis, tinnitus, visual field defect

ENDO: Hypoglycemia

GI: Abdominal distention or pain, constipation, diarrhea, flatulence, gastroenteritis, GI hemorrhage, increased appetite, nausea, vomiting

GU: Acute renal failure, anorgasmia, decreased libido, glomerulitis, impotence, nephritis, urinary frequency, urinary incontinence, urine retention

HEME: Decreased platelet count, leukopenia, thrombocytopenia

MS: Arthralgia, back pain, elevated creatine kinase level, leg or muscle cramps, myalgia, myasthenia

RESP: Apnea, dyspnea

SKIN: Ecchymosis, exfoliative dermatitis, pruritus

Other: Anaphylaxis, angioedema, facial edema, hypersensitivity reaction, Stevens-Johnson syndrome, weight gain

Nursing Considerations

- Pregabalin therapy should be stopped gradually over at least 1 week to decrease risk of seizure activity and avoid unpleasant symptoms such as diarrhea, headache, insomnia, and nausea.
- If patient has evidence of hypersensitivity (red skin, urticaria, rash, dyspnea, facial swelling, wheezing), stop drug at once, notify prescriber, and give supportive care.
- Monitor patient closely for adverse reactions. Notify prescriber if significant adverse reactions persist.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

PATIENT TEACHING

- Warn against stopping pregabalin abruptly.
- Urge patient to avoid hazardous activities until she knows how drug affects her.
- Instruct patient to notify prescriber if she has changes in vision or unexplained muscle pain, tenderness, or weakness, especially if these muscle symptoms are accompanied by malaise or fever.

- Alert patient that drug may cause edema and weight gain.
- If patient also takes a thiazolidinedione antidiabetic, tell her these effects may be intensified. If significant, tell patient to notify prescriber.
- Inform male patient who plans to father a child that drug could impair his fertility.
- Instruct diabetic patients to inspect their skin while taking pregabalin.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes and to report concerns at once to prescriber.
- Urge woman who becomes pregnant while taking pregabalin for seizures to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting information about the safety of antiepileptic drugs during pregnancy

primidone

Apo-Primidone (CAN), **Myidone**, **Mysoline**, **PMS Primidone** (CAN), **Sertan** (CAN)

Class and Category

Chemical class: Prodrug of phenobarbital

Therapeutic class: Anticonvulsant

Pregnancy category: Not rated

Indications and Dosages

↗ *To manage generalized tonic-clonic seizures, nocturnal myoclonic seizures, complex partial seizures, and simple partial seizures caused by epilepsy*

CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS

Adults and children age 8 and over. *Initial:*

100 or 125 mg at bedtime for first 3 days; then increased to 100 or 125 mg b.i.d. for next 3 days, followed by 100 or 125 mg t.i.d. for next 3 days. On 10th day, begin maintenance dosage as prescribed.

Maintenance: 250 mg t.i.d. or q.i.d., adjusted as needed. *Maximum:* 2 g daily.

Children up to age 8. *Initial:* 50 mg at bedtime for first 3 days; then increased to 50 mg b.i.d. for next 3 days, followed by increase to 100 mg b.i.d. for next 3 days. On 10th day, begin maintenance dosage.

Maintenance: 125 to 250 mg t.i.d., adjusted as needed.

Mechanism of Action

Prevents seizures by decreasing excitability of neurons and increasing motor cortex's threshold of electrical stimulation.

Contraindications

Hypersensitivity to primidone, phenobarbital, or their components; porphyria

Interactions

DRUGS

acetaminophen: Decreased acetaminophen effectiveness, increased risk of hepatotoxicity
adrenocorticoids, chloramphenicol, cyclosporine, dacarbazine, disopyramide, doxycycline, levothyroxine, metronidazole, mexiletine, oral anticoagulants, oral contraceptives (estrogen-containing), quinidine, tricyclic antidepressants: Decreased effectiveness of these drugs
amphetamines: Possibly delayed absorption of primidone
anticonvulsants: Possibly altered pattern of seizures
carbamazepine: Decreased effectiveness of primidone
carbonic anhydrase inhibitors: Increased risk of osteopenia
CNS depressants: Possibly enhanced CNS and respiratory depressant effects of both drugs
cyclophosphamide: Reduced half-life and increased leukopenic activity of cyclophosphamide
enflurane, halothane, methoxyflurane: Increased risk of hepatotoxicity; increased risk of nephrotoxicity (with methoxyflurane)
fenopropfen: Decreased elimination half-life of fenopropfen
folic acid: Increased folic acid requirements
griseofulvin: Decreased antifungal effects of griseofulvin
guanadrel, guanethidine: Possibly aggravated orthostatic hypotension
haloperidol, loxapine, maprotiline, molidone, phenothiazines, thioxanthenes: Possibly lowered seizure threshold and increased CNS depression
leucovorin: Possibly decreased anticonvulsant effects of primidone (with large doses)
MAO inhibitors: Possibly prolonged primidone effects and altered seizure pattern
methylphenidate: Possibly increased blood primidone level, resulting in toxicity
phenobarbital: Increased sedative effects of

either drug, possibly altered seizure pattern
phenylbutazone: Decreased primidone effectiveness, increased metabolism and decreased half-life of phenylbutazone
rifampin: Decreased blood primidone level
valproic acid: Increased blood primidone level, leading to increased CNS depression and neurotoxicity; decreased valproic acid half-life and increased hepatotoxicity risk
vitamin D: Decreased effects of vitamin D
xanthines: Increased metabolism and clearance of xanthines (except dyphylline)

ACTIVITIES

alcohol use: Possibly increased CNS and respiratory depressant effects of primidone

Adverse Reactions

CNS: Ataxia, confusion, dizziness, drowsiness, excitement, mental changes, mood changes, restlessness

EENT: Diplopia, nystagmus

GI: Anorexia, nausea, vomiting

GU: Impotence

RESP: Dyspnea

Other: Folic acid deficiency

Nursing Considerations

- Monitor blood levels of primidone and phenobarbital (its active metabolite), as ordered, to determine therapeutic level or detect toxic levels.
- Anticipate that drug may cause confusion, excitement, or mood changes in elderly patients and children.
- Assess for signs of folic acid deficiency: mental dysfunction, neuropathy, tiredness, and weakness.

PATIENT TEACHING

- Instruct patient to crush primidone tablets and mix with food or fluids, as needed.
- Advise patient taking oral suspension to shake bottle well and measure doses with a calibrated device.
- Suggest that patient take drug with meals to minimize adverse GI reactions.
- Urge patient not to stop taking primidone abruptly because doing so can precipitate seizures.
- Caution patient about possible decreased alertness.
- Advise her to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to avoid consuming alcohol and other CNS depressants during primidone therapy.

probenecid

Benemid, Benuryl (CAN), Probalan

Class and Category

Chemical class: Sulfonamide derivative

Therapeutic class: Antibiotic adjunct, antigout, uricosuric

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat chronic gouty arthritis and hyperuricemia due to chronic gout*

TABLETS

Adults and adolescents. *Initial:* 250 mg b.i.d. for 1 wk; then increased to maintenance dosage. *Maintenance:* 500 mg b.i.d.; if not effective or 24-hr uric acid excretion isn't greater than 700 mg, dosage increased by 500 mg/day every 4 wk, as needed and prescribed, up to a maximum of 3 g daily. If no acute attacks of gout occur over next 6 mo and serum uric acid level is within normal limits, dosage decreased, as prescribed, by 500 mg every 6 mo until lowest effective maintenance dose is reached. *Maximum:* 3 g daily.

DOSAGE ADJUSTMENT Dosage possibly increased for patients with mild renal dysfunction, except for elderly patients, who require a dosage reduction.

↗ *As adjunct to antibiotic therapy with penicillins and some cephalosporins*

TABLETS

Adults, adolescents age 14 and over, and children weighing more than 50 kg (110 lb). 500 mg q.i.d.; if given with I.V. or I.M. antibiotic, administer at least 30 min before antibiotic.

Children ages 2 to 14 weighing up to 50 kg. 25 mg/kg as single dose, then 10 mg/kg q.i.d.; if given with I.V. or I.M. antibiotic, give at least 30 min before antibiotic.

↗ *As adjunct to treat sexually transmitted diseases*

TABLETS

Adults and adolescents. 1 g as single dose, given with appropriate antibiotic.

↗ *As adjunct to treat pediatric gonorrhea*

TABLETS

Postpubertal children and children weighing more than 45 kg (99 lb). 1 g as single dose, given with appropriate antibiotic.

↗ *As adjunct to treat neurosyphilis*

TABLETS

Adults and adolescents. 500 mg q.i.d. with 1 daily dose (2.4 million units) of penicillin G procaine for 10 to 14 days.

Route	Onset	Peak	Duration
P.O.	Unknown	30 min*	8 hr†

Mechanism of Action

Increases urinary excretion of uric acid and lowers serum uric acid level, which may prevent or resolve urate deposits, tophus formation, and joint changes. Eventually, incidence of acute gout attacks decreases. Probenecid also inhibits renal excretion of penicillins and some cephalosporins, thereby increasing their serum concentration and prolonging their duration of action.

Contraindications

Age less than 2 years, blood dyscrasias, hypersensitivity to probenecid or its components, renal calculi (urate)

Interactions

DRUGS

acyclovir: Decreased renal tubular secretion of acyclovir

allopurinol: Additive antihyperuricemic effects

aminosalicylate sodium, cephalosporins, ciprofloxacin, clofibrate, dapsone, ganciclovir, imipenem, methotrexate, nitrofurantoin, norfloxacin, penicillins: Increased and possibly prolonged blood levels of these drugs, increased risk of toxicity

antineoplastics (rapidly cytolytic): Possibly uric acid nephropathy
diazoxide, mecamlamine, pyrazinamide: Increased risk of hyperuricemia, decreased probenecid effectiveness

dyphylline: Increased half-life of dyphylline
furosemide: Increased blood furosemide level

heparin: Increased and prolonged anticoagulant effect

indomethacin, ketoprofen, other NSAIDs: Possibly increased adverse effects

lorazepam, oxazepam, temazepam: Increased

* For renal clearance of uric acid; 2 hr for effect on blood antibiotic level.

† For effect on blood antibiotic level; unknown for renal clearance of uric acid.

effects of these drugs, possibly excessive sedation

riboflavin: Decreased GI absorption of riboflavin

rifampin, sulfonamides: Increased blood levels of these drugs and, possibly, toxicity

salicylates: Decreased uricosuric effects of probenecid

sodium benzoate and sodium phenylacetate: Decreased renal elimination of these drugs

sulfonylureas: Increased sulfonylurea half-life

thiopental: Prolonged thiopental effect

zidovudine: Increased risk of zidovudine toxicity

ACTIVITIES

alcohol use: Increased risk of hyperuricemia, decreased probenecid effectiveness

Adverse Reactions

CNS: Dizziness, headache

EENT: Sore gums

GI: Anorexia, nausea, vomiting

GU: Hematuria, renal calculi (urate), renal colic, urinary frequency

MS: Costovertebral pain; joint pain, redness, and swelling

SKIN: Facial flushing, pruritus, rash, urticaria

Nursing Considerations

- Be aware that probenecid therapy shouldn't start until acute gout attack has subsided. If acute attack starts during therapy, continue therapy as prescribed.
- Use drug cautiously in patients with peptic ulcer disease.
- Expect to give sodium bicarbonate (3 to 7.5 g daily) or potassium citrate (7.5 g daily), as prescribed, to keep urine alkaline and prevent renal calculus formation.
- Monitor CBC, serum uric acid level, and liver and renal function test results during therapy.
- Closely monitor patients receiving intermittent therapy because they're more likely to develop allergic reactions.
- Check blood glucose level often in diabetic patient who takes a sulfonylurea because of the risk of drug interactions.

PATIENT TEACHING

- Advise patient to take probenecid with meals to minimize GI distress.
- Encourage patient to increase fluid intake (up to 3 L daily, if not contraindicated) to

help prevent renal calculus formation.

- Instruct patient to notify prescriber immediately if she has signs of an acute gout attack (joint pain, swelling, and redness) or of renal calculi (flank pain and blood in urine).
- Caution patient against taking salicylates while taking probenecid. Instead, advise acetaminophen to treat mild pain or fever.

procainamide hydrochloride

Procan SR, Promine, Pronestyl, Pronestyl-SR

Class and Category

Chemical class: Ethyl benzamide monohydrochloride

Therapeutic class: Antiarrhythmic

Pregnancy category: C

Indications and Dosages

➤ *To treat life-threatening ventricular arrhythmias*

CAPSULES, TABLETS

Adults. 50 mg/kg daily in 8 divided doses (every 3 hr), adjusted as needed and tolerated. *Maximum*: 6 g daily (maintenance).

Children. 12.5 mg/kg q.i.d.

E.R. TABLETS

Adults. *Maintenance*: 50 mg/kg daily in divided doses q.i.d. (every 6 hr), adjusted as needed and tolerated. *Maximum*: 6 g daily (maintenance).

I.V. INFUSION OR INJECTION

Adults. *Initial*: 100 mg diluted in D₅W and given at no more than 50 mg/min.

Repeated every 5 min until arrhythmia is controlled or maximum total dose of 1 g is reached. Or, 10 to 15 mg/kg I.V. bolus given at 25 to 50 mg/min. *Maintenance*: 1 to 4 mg/min by continuous infusion.

I.M. INJECTION

Adults. 50 mg/kg daily in divided doses every 3 to 6 hr.

➤ *To treat ventricular extrasystoles and arrhythmias associated with anesthesia and surgery*

I.V. INFUSION OR INJECTION

Adults. *Initial*: 100 mg diluted in D₅W and given at no more than 50 mg/min. Dosage repeated every 5 min until arrhythmia is

controlled or maximum total dose of 1 g is reached. Or, 10 to 15 mg/kg I.V. bolus given at 25 to 50 mg/min. *Maintenance*: 1 to 4 mg/min by continuous infusion.

I.M. INJECTION

Adults. 100 to 500 mg every 3 to 6 hr.

DOSE ADJUSTMENT For elderly patients or those with cardiac or hepatic insufficiency, dosage possibly reduced or dosing intervals increased. For patients with creatinine clearance less than 50 ml/min/1.73 m², initial dosage reduced to 1 to 2 mg/min.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	60–90 min
P.O. (E.R.)	Unknown	60–90 min	Unknown
I.V.	Unknown	Immediate	Unknown
I.M.	10–30 min	15–60 min	Unknown

Mechanism of Action

Prolongs recovery period after myocardial repolarization by inhibiting sodium influx through myocardial cell membranes. This action prolongs refractory period, causing myocardial automaticity, excitability, and conduction velocity to decline.

Contraindications

Complete heart block, hypersensitivity to procainamide or its components, systemic lupus erythematosus, torsades de pointes

Interactions

DRUGS

antiarrhythmics: Additive cardiac effects

anticholinergics, antidiuretics, antihistamines: Possibly intensified atropine-like adverse effects, increased risk of ileus

antihypertensives: Additive hypotensive effects

antimyasthenics: Possibly antagonized effect of antimyasthenic on skeletal muscle

bethanechol: Possibly antagonized cholinergic effect of bethanechol

bone marrow depressants: Possibly increased leukopenic or thrombocytopenic effects

bretylum: Possibly decreased inotropic effect of bretylum and enhanced hypotension

neuromuscular blockers: Possibly increased or prolonged neuromuscular blockade

pimozide: Possibly prolonged QT interval, leading to life-threatening arrhythmias

Adverse Reactions

CNS: Chills, disorientation, dizziness, light-headedness

CV: Heart block (second-degree), hypotension, pericarditis, prolonged QT interval, tachycardia

EENT: Bitter taste

GI: Abdominal distress, anorexia, diarrhea, nausea, vomiting

HEME: Agranulocytosis, neutropenia, thrombocytopenia

MS: Arthralgia, myalgia

RESP: Pleural effusion

SKIN: Pruritus, rash

Other: Drug-induced fever

Nursing Considerations

- Place patient in a supine position before giving procainamide I.M. or I.V. to minimize hypotensive effects. Monitor blood pressure often and ECG tracings continuously during administration and for 30 minutes afterward.
- Inspect parenteral solution for particles and discoloration before giving drug; discard if particles are present or solution is darker than light amber.
- When possible, give drug by I.V. infusion or injection, as prescribed, rather than by I.M. injection.
- If drug is to be given I.M. and patient's platelet count is below 50,000/mm³, notify prescriber at once because patient may develop bleeding, bruising, or hematomas from procainamide-induced bone marrow suppression and thrombocytopenia. Expect to give procainamide I.V.
- For I.V. injection, dilute procainamide with D₅W according to manufacturer's instructions before administration.
- For I.V. infusion, dilute 200 to 1,000 mg of procainamide to a concentration of 2 or 4 mg/ml using 50 to 500 ml of D₅W.
- Administer I.V. infusion with an infusion pump or other controlled-delivery device.
- Don't exceed 500 mg in 30 minutes by I.V. infusion or 50 mg/min by I.V. injection because heart block or cardiac arrest may occur.
- Anticipate that patient has reached maximum clinical response when ventricular tachycardia resolves, hypotension develops, or QRS complex is 50% wider than original width.
- Expect to give first oral dose 3 to 4 hours

after last I.V. dose.

PATIENT TEACHING

- Instruct patient to swallow E.R. procainamide tablets whole, without breaking, crushing, or chewing them.
- If patient has trouble swallowing, tell her to crush regular-release tablets or open capsules and mix contents with food or fluid.
- Instruct patient to take drug 1 hour before or 2 hours after meals with a full glass of water. Inform her that she may take drug with food if GI irritation develops.
- Urge patient to obtain needed dental work before therapy starts or after blood count returns to normal because drug can cause myelosuppression and increased risk of bleeding and infection. Encourage good oral hygiene during therapy, and urge patient to consult prescriber before having dental procedures.
- Advise patient to notify prescriber immediately about bruising, chills, diarrhea, fever, or rash.

prochlorperazine

Compazine, Stemetil (CAN)

prochlorperazine edisylate

Compazine

prochlorperazine maleate

Compazine Spansule, Nu-Prochlor (CAN), Stemetil (CAN)

Class and Category

Chemical class: Phenothiazine, piperazine

Therapeutic class: Antianxiety, antiemetic, antipsychotic

Pregnancy category: Not rated

Indications and Dosages

↗ *To control nausea and vomiting related to surgery*

I.V. INFUSION OR INJECTION (PROCHLORPERAZINE EDISYLATE)

Adults and adolescents. 5 to 10 mg at a rate not to exceed 5 mg/ml 15 to 30 min

before anesthesia or during or after surgery, as needed. Dosage repeated once, if necessary. *Maximum:* 10 mg/dose, 40 mg daily.

I.M. INJECTION (PROCHLORPERAZINE EDISYLATE)

Adults and adolescents. 5 to 10 mg 1 to 2 hr before anesthesia or during or after surgery, as needed. Repeated once in 30 min, if needed. *Maximum:* 10 mg/dose, 40 mg daily.

↗ *To control severe nausea and vomiting*

E.R. CAPSULES (PROCHLORPERAZINE MALEATE)

Adults and adolescents. 15 to 30 mg daily in the morning, or 10 mg every 12 hr.

Maximum: 40 mg daily.

ORAL SOLUTION (PROCHLORPERAZINE EDISYLATE)

Adults and adolescents. 5 to 10 mg t.i.d. or q.i.d. *Maximum:* 40 mg daily.

Children weighing 18 to 39 kg (40 to 86 lb). 2.5 mg t.i.d. or 5 mg b.i.d.

Maximum: 15 mg daily.

Children weighing 14 to 18 kg (31 to 40 lb). 2.5 mg b.i.d. or t.i.d. *Maximum:* 10 mg daily.

Children weighing 9 to 14 kg (20 to 31 lb). 2.5 mg once or twice daily. *Maximum:* 7.5 mg daily.

TABLETS (PROCHLORPERAZINE MALEATE)

Adults and adolescents. 5 to 10 mg t.i.d. or q.i.d. *Maximum:* 40 mg daily.

I.V. INFUSION OR INJECTION (PROCHLORPERAZINE EDISYLATE)

Adults and adolescents. 2.5 to 10 mg at a rate not to exceed 5 mg/min. *Maximum:* 40 mg daily.

I.M. INJECTION (PROCHLORPERAZINE EDISYLATE)

Adults and adolescents. 5 to 10 mg every 3 to 4 hr, p.r.n. *Maximum:* 40 mg daily.

Children ages 2 to 12. 132 mcg/kg/dose to maximum of 10 mg on day 1; then increased as needed. *Maximum:* On day 1, 10 mg; thereafter, 25 mg daily for children ages 6 to 12, 20 mg daily for children ages 2 to 6.

SUPPOSITORIES (PROCHLORPERAZINE)

Adults and adolescents. 25 mg b.i.d.

Children weighing 18 to 39 kg. 2.5 mg t.i.d. or 5 mg b.i.d. *Maximum:* 15 mg daily.

Children weighing 14 to 18 kg. 2.5 mg b.i.d. or t.i.d. *Maximum:* 10 mg daily.

Children weighing 9 to 14 kg. 2.5 mg once or twice daily. *Maximum:* 7.5 mg daily.

↗ *To manage psychotic disorders, such as schizophrenia*

ORAL SOLUTION (PROCHLORPERAZINE EDISYLATE)

Adults and adolescents. 5 to 10 mg t.i.d. or q.i.d., increased gradually every 2 to 3 days, as needed and tolerated. *Maximum:* 150 mg daily.

Children ages 2 to 12. 2.5 mg b.i.d. or t.i.d. *Maximum:* On day 1, 10 mg for all children; thereafter, 25 mg daily for children ages 6 to 12, 20 mg daily for children ages 2 to 6.

TABLETS (PROCHLORPERAZINE MALEATE)

Adults and adolescents. 5 to 10 mg t.i.d. or q.i.d., increased gradually every 2 to 3 days, as needed and tolerated. *Maximum:* 150 mg daily.

I.M. INJECTION (PROCHLORPERAZINE EDISYLATE)

Adults and adolescents. *Initial:* 10 to 20 mg, repeated every 2 to 4 hr, as prescribed, to bring symptoms under control (usually 3 to 4 doses). *Maintenance:* 10 to 20 mg every 4 to 6 hr. *Maximum:* 200 mg daily.

Children ages 2 to 12. 132 mcg/kg/dose on day 1; then increased as needed. *Maximum:* On day 1, 10 mg for all children; thereafter, 25 mg daily for children ages 6 to 12, 20 mg/day for children ages 2 to 6.

↗ *To treat anxiety short-term*

E.R. CAPSULES (PROCHLORPERAZINE MALEATE)

Adults and adolescents. 15 mg daily in the morning, or 10 mg every 12 hr. *Maximum:* 20 mg/day for no longer than 12 wk.

ORAL SOLUTION, TABLETS (PROCHLORPERAZINE EDISYLATE)

Adults and adolescents. 5 mg t.i.d. or q.i.d. *Maximum:* 20 mg daily for no longer than 12 wk.

I.V. INFUSION OR INJECTION (PROCHLORPERAZINE EDISYLATE)

Adults and adolescents. 2.5 to 10 mg at no more than 5 mg/min. *Maximum:* 40 mg daily.

I.M. INJECTION (PROCHLORPERAZINE EDISYLATE)

Adults and adolescents. 5 to 10 mg every 3 to 4 hr, p.r.n.

DOSAGE ADJUSTMENT Initial dose usually reduced and subsequent dosage increased more gradually for elderly, emaciated, and debilitated patients.

Mechanism of Action

Alleviates psychotic symptoms by blocking dopamine receptors, depressing release of selected hormones, and producing alpha-adrenergic blocking effect in the brain.

Prochlorperazine also alleviates nausea and vomiting by centrally blocking dopa-

mine receptors in the medullary chemoreceptor trigger zone and by peripherally blocking the vagus nerve in the GI tract.

Anticholinergic effects and alpha-adrenergic blockade reduce anxiety by decreasing arousal and filtering internal stimuli to the brain stem reticular activating system.

Route	Onset	Peak	Duration
P.O., I.V., I.M., P.R.	Up to several wk*	Up to 6 mo	Unknown

Incompatibilities

Don't mix prochlorperazine in same syringe with other drugs. Precipitate may form when prochlorperazine edisylate is mixed in same syringe with morphine sulfate.

Contraindications

Age less than 2 years, blood dyscrasias, bone marrow depression, cerebral arteriosclerosis, coma, coronary artery disease, hepatic dysfunction, hypersensitivity to phenothiazines, myeloproliferative disorders, pediatric surgery, severe CNS depression, severe hypertension or hypotension, subcortical brain damage, use of large quantities of CNS depressants, weight less than 9 kg (20 lb)

Interactions

DRUGS

aluminum- or magnesium-containing antacids, antidiarrheals (adsorbent): Possibly inhibited absorption of oral prochlorperazine

amantadine, anticholinergics, antidyskinetics, antihistamines: Possibly intensified anticholinergic adverse effects, increased risk of prochlorperazine-induced hyperpyretic effect

amphetamines: Decreased stimulant effect of amphetamines, decreased antipsychotic effect of prochlorperazine

anticonvulsants: Lowered seizure threshold

antithyroid drugs: Increased risk of agranulocytosis

apomorphine: Possibly decreased emetic response to apomorphine, additive CNS depression

appetite suppressants: Possibly antagonized anorectic effect of appetite suppressants

* For antipsychotic effects; unknown for other indications.

(except for phenmetrazine)

astemizole, cisapride, disopyramide, erythromycin, pimozide, probucol, procainamide:

Additive QT interval prolongation, increased risk of ventricular tachycardia
beta blockers: Increased risk of additive hypotensive effects, irreversible retinopathy, arrhythmias, and tardive dyskinesia
bromocriptine: Decreased effectiveness of bromocriptine

CNS depressants: Additive CNS depression
dopamine: Possibly antagonized peripheral vasoconstriction (high doses of dopamine)
ephedrine, epinephrine: Decreased vasopressor effects of these drugs

hepatotoxic drugs: Increased risk of hepatotoxicity

hypotension-producing drugs: Possibly severe hypotension with syncope

levodopa: Inhibited antidyskinetic effect of levodopa

lithium: Reduced absorption of oral prochlorperazine, increased lithium excretion, increased extrapyramidal effects, possibly masking of early symptoms of lithium toxicity

MAO inhibitors, maprotiline, tricyclic antidepressants: Possibly prolonged and intensified anticholinergic and sedative effects, increased antidepressant level, inhibited prochlorperazine metabolism, increased risk of neuroleptic malignant syndrome

mephentermine: Possibly antagonized antipsychotic effect of prochlorperazine and vasopressor effect of mephentermine
metrizamide: Increased risk of seizures

opioid analgesics: Increased risk of CNS and respiratory depression, orthostatic hypotension, severe constipation, urine retention
ototoxic drugs: Possibly masking of some symptoms of ototoxicity, such as dizziness, tinnitus, and vertigo

phenytoin: Possibly inhibited phenytoin metabolism, increased risk of phenytoin toxicity

thiazide diuretics: Possibly potentiated hyponatremia and water intoxication

ACTIVITIES

alcohol use: Additive CNS depression

Adverse Reactions

CNS: Akathisia, altered temperature regulation, dizziness, drowsiness, extrapyramidal reactions (such as dystonia, pseudoparkinsonism, tardive dyskinesia)

CV: Hypotension, orthostatic hypotension, tachycardia

EENT: Blurred vision, dry mouth, nasal congestion, ocular changes, pigmentary retinopathy

ENDO: Galactorrhea, gynecomastia

GI: Constipation, epigastric pain, nausea, vomiting

GU: Dysuria, ejaculation disorders, menstrual irregularities, urine retention

SKIN: Decreased sweating, photosensitivity, pruritus, rash

Other: Weight gain

Nursing Considerations

- Prochlorperazine shouldn't be used to treat dementia-related psychosis in the elderly because of increased mortality risk.
- Avoid contact between skin and solution forms of prochlorperazine because contact dermatitis could result.
- Inject I.M. form slowly, deep into upper outer quadrant of buttocks. Keep patient supine for 30 minutes after injection to minimize hypotensive effects.
- Rotate I.M. injection sites to prevent irritation and sterile abscesses.
- Be aware that I.V. form may be given undiluted as injection or diluted in isotonic solution as infusion (mesylate form requires dilution in at least 1 L). Both forms should be given at no more than 5 mg/minute.
- Protect prochlorperazine from light.
- Parenteral solution may develop slight yellowing that won't affect potency. Don't use if discoloration is pronounced or precipitate is present.
- Expect antipsychotic effects to occur in 2 to 3 weeks, although range is days to months.

WARNING Monitor closely for numerous adverse reactions that may be serious.

- Adverse effects may occur up to 12 weeks after discontinuation of E.R. capsules.

PATIENT TEACHING

- Instruct patient to take prochlorperazine with food or a full glass of milk or water to minimize GI distress.
- Advise patient to swallow E.R. capsules whole, not to crush or chew them.
- Instruct patient using suppository to refrigerate it for 30 minutes or hold it under running cold water before removing the wrapper if it softens during storage.

- Teach patient correct administration technique for suppository.
- Caution patient on long-term therapy not to stop prochlorperazine abruptly; doing so may lead to such adverse reactions as nausea, vomiting, and trembling.
- Urge patient to avoid alcohol and OTC drugs that may contain CNS depressants.
- Advise patient to rise slowly from lying and sitting positions to minimize effects of orthostatic hypotension.
- Urge patient to avoid hazardous activities because of the risk of drowsiness and impaired judgment and coordination.
- Instruct patient to avoid excessive sun exposure and to wear sunscreen outdoors.
- Urge patient to notify prescriber about involuntary movements and restlessness.
- Explain that adverse effects may occur up to 12 weeks after stopping E.R. capsules.

progestins

hydroxyprogesterone caproate

Gesterol LA 250, Hy/Gestrone, Hylutin, Prodrex, Pro-Span

levonorgestrel

Norplant System

medrogestone

Colprone (CAN)

medroxyprogesterone acetate

Alti-MPA (CAN), Amen, Curretab, Cycrin, Depo-Provera, Gen-Medrox (CAN), Novo-Medrone (CAN), Provera

megestrol acetate

Apo-Megestrol (CAN), Megace, Megace OS (CAN)

norethindrone

Aygestin, Norlutate (CAN)

norgestrel

Ovrette

progesterone

Crinone, Gesterol 50, PMS-Progesterone (CAN), Prometrium

Class and Category

Chemical class: Progesterone derivative, steroid hormone

Therapeutic class: Antianorectic, anti-cachectic, antineoplastic, ovarian hormone replacement

Pregnancy category: D (hydroxyprogesterone, megestrol [tablets], progesterone); X (levonorgestrel, medroxyprogesterone [parenteral], megestrol [parenteral and suspension], norethindrone, norgestrel); NR (medrogestone, medroxyprogesterone [tablets])

Indications and Dosages

➤ *To treat renal cancer*

I.M. INJECTION (MEDROXYPROGESTERONE)

Adults and adolescents. *Initial:* 400 mg to 1 g every wk until improvement and stabilization. *Maintenance:* 400 mg or more every mo.

➤ *To treat breast cancer*

TABLETS (MEGESTROL)

Adults and adolescents. 160 mg daily as single dose or in divided doses.

➤ *To treat endometrial cancer*

TABLETS (MEGESTROL)

Adult and adolescent women. 40 to 320 mg daily in divided doses.

I.M. INJECTION (MEDROXYPROGESTERONE)

Adults and adolescents. *Initial:* 400 mg to 1 g every wk until improvement and stabilization. *Maintenance:* 400 mg or more every mo.

➤ *To treat anorexia, cachexia, or significant weight loss in patients who have AIDS*

SUSPENSION (MEGESTROL)

Adults and adolescents. 800 mg daily for the first mo, and then 400 or 800 mg daily for the next 3 mo.

➤ *To treat endometriosis*

TABLETS (NORETHINDRONE ACETATE)

Adult and adolescent women. *Initial:* 5 mg daily for 2 wk, increased by 2.5 mg daily at 2-wk intervals to total dose of 15 mg daily. *Maintenance:* 15 mg daily for 6 to 9 mo unless temporarily discontinued because of breakthrough menstrual bleeding.

➤ *As adjunct to treat endometrial shedding in menopausal women*

TABLETS (MEDROGESTONE)

Adult and adolescent women. 5 to 10 mg daily on days 15 through 25 of menstrual cycle.

➤ *To treat secondary amenorrhea*

TABLETS (MEDROGESTONE)

Adult and adolescent women. 5 to 10 mg daily on days 15 through 25 of menstrual cycle.

TABLETS (MEDROXYPROGESTERONE)

Adult and adolescent women. 5 to 10 mg daily for 5 to 10 days, starting anytime during menstrual cycle.

TABLETS (NORETHINDRONE ACETATE)

Adult and adolescent women. 2.5 to 10 mg daily on days 5 through 25 of menstrual cycle. Or, 2.5 to 10 mg daily for 5 to 10 days during last half of menstrual cycle.

CAPSULES (PROGESTERONE)

Adult and adolescent women. 400 mg daily in evening for 10 days.

I.M. INJECTION (HYDROXYPROGESTERONE)

Adult and adolescent women. 375 mg as one-time dose.

I.M. INJECTION (PROGESTERONE)

Adult and adolescent women. 5 to 10 mg daily for 6 to 10 days. Or, 100 to 150 mg injected as single dose.

VAGINAL GEL (PROGESTERONE)

Adult and adolescent women. 45 mg (1 applicatorful of 4% vaginal gel) every other day for up to 6 doses. Dosage increased, as needed, to 90 mg (1 applicatorful of 8% vaginal gel) every other day for up to 6 doses.

➤ *To treat dysfunctional uterine bleeding*

TABLETS (MEDROGESTONE)

Adult and adolescent women. 5 to 10 mg daily on days 15 through 25 of menstrual cycle.

TABLETS (MEDROXYPROGESTERONE)

Adult and adolescent women. 5 to 10 mg daily for 5 to 10 days, starting on day 16 or 21 of menstrual cycle.

TABLETS (NORETHINDRONE ACETATE)

Adult and adolescent women. 2.5 to 10 mg daily on days 5 through 25 of menstrual cycle. Or, 2.5 to 10 mg daily for 5 to 10 days during last half of menstrual cycle.

I.M. INJECTION (HYDROXYPROGESTERONE)

Adult and adolescent women. 375 mg as one-time dose.

I.M. INJECTION (PROGESTERONE)

Adult and adolescent women. 5 to 10 mg daily for 6 consecutive days.

➤ *To induce menses*

TABLETS (MEDROGESTONE)

Adult and adolescent women. 5 to 10 mg

daily on days 15 through 25 of the menstrual cycle.

TABLETS (MEDROXYPROGESTERONE)

Adult and adolescent women. 10 mg daily for 10 days, starting on day 16 of menstrual cycle. Repeated for 2 or more cycles if bleeding is satisfactorily controlled.

I.M. INJECTION (HYDROXYPROGESTERONE)

Adult and adolescent women. 125 to 250 mg on day 10 of menstrual cycle, repeated every 7 days until suppression is no longer desired.

➤ *To prevent pregnancy (postcoital)*

TABLETS (LEVONORGESTREL)

Adult and adolescent women. 0.75 mg as soon as possible within 72 hr of intercourse. Second dose given 12 hr later.

➤ *To prevent pregnancy*

TABLETS (NORETHINDRONE)

Adult and adolescent women. 0.35 mg daily, starting on day 1 of menstrual cycle and continuing uninterrupted through the year, whether or not menstrual bleeding occurs.

TABLETS (NORGESTREL)

Adult and adolescent women. 0.075 mg daily starting on day 1 of menstrual cycle and continuing uninterrupted throughout the year, whether or not menstrual bleeding occurs.

I.M. INJECTION (MEDROXYPROGESTERONE)

Adult and adolescent women. 150 mg every 3 mo.

SUBDERMAL IMPLANT (LEVONORGESTREL)

Adult and adolescent women. One set of implants surgically inserted every 2 yr.

Mechanism of Action

Progestins may diminish response to endogenous hormones in tumor cells by decreasing the number of steroid hormone receptors, causing a direct cytotoxic or antiproliferative effect on cell cycle growth and increased terminal cell differentiation. At higher doses, some progestins decrease adrenal production of estradiol and androstenedione, which may decrease estrogen- or testosterone-sensitive tumors. Megestrol stimulates appetite and metabolic effects, which promotes weight gain. Progestins also bind to cytosolic receptors that are loosely bound in cell nucleus, increasing protein synthesis and improving cachexia.

Progestins affect other hormones, especially estrogen, by reducing availability or stability of hormone receptor complex,

shutting off estrogen-responsive genes, or causing negative feedback mechanism that decreases number of functioning estrogen receptors. These actions allow menstrual cycle to function normally, alleviating amenorrhea and dysfunctional uterine bleeding and inducing menses. Progestins also act to transform proliferative uterine endometrium into a more differentiated, secretory one, which is the basis for using medroxyprogesterone to treat some types of amenorrhea. In a normal ovulatory cycle not resulting in pregnancy, decline in progesterone secretion caused by degeneration of corpus luteum in late luteal phase results in endometrial sloughing. A similar sloughing occurs after 5 to 10 days of medroxyprogesterone, provided that adequate estrogen-stimulated proliferation has occurred during follicular phase.

Selected progestins also inhibit secretion of gonadotropins from pituitary gland, which prevents ovulation, follicular maturation, thickening of cervical mucus to prevent sperm penetration, and creation of an atrophic endometrium, resulting in contraceptive effect.

Contraindications

Active thromboembolic disorder; thrombophlebitis; significant hepatic disease; hypersensitivity to peanuts (progesterone), progestins, or their components; known or suspected breast cancer; pregnancy; undiagnosed genital, uterine, or urinary tract bleeding

Interactions

DRUGS

aminoglutethimide: Possibly decreased blood level of medroxyprogesterone
carbamazepine, phenobarbital, phenytoin, rifabutin, rifampin: Possibly decreased effectiveness of progestin
thyroid hormone: Decreased thyroid hormone effectiveness

Adverse Reactions

CNS: Altered or reduced coordination or speech, depression, dizziness, drowsiness, fatigue, headache, irritability, migraine, mood changes, nervousness, postmenopausal dementia, syncope, unusual tiredness or weakness

CV: Fluid retention; hypotension; numbness or pain in chest, arm, or leg; thrombo-

embolism

ENDO: Adrenal insufficiency or suppression, breast pain or tenderness, Cushing's syndrome, decreased T_3 resin uptake, delayed return of fertility in women, elevated thyroid-binding globulin, galactorrhea, hyperglycemia, vaginal spotting

EENT: Gingival bleeding, swelling, or tenderness; vision changes or loss

GI: Abdominal cramps or pain, diarrhea, nausea, vomiting

GU: Amenorrhea, breakthrough bleeding or metromenorrhagia, decreased libido, hypermenorrhea, ovarian enlargement or cysts

HEME: Clotting and bleeding abnormalities

MS: Back pain, decreased bone density, osteoporosis, osteoporotic fractures

RESP: Dyspnea

SKIN: Acne, alopecia, melasma, rash

Other: Anaphylaxis; facial fullness; hot flashes; injection or implantation site irritation, pain, or redness; weight gain

Nursing Considerations

- Be aware that progestin/estrogen therapy shouldn't be used to prevent cardiovascular disease or dementia.
- Use progestins cautiously in patients with risk factors for arterial vascular disease, such as hypertension, diabetes mellitus, tobacco use, hypercholesterolemia, obesity, systemic lupus erythematosus, or a family or personal history of venous thromboembolism. Drug worsen these conditions.
- Use progestins cautiously in patients who have CNS disorders, such as seizures or depression, because progestins may worsen these conditions.
- Be aware that drug causes significant loss of bone mineral density in adolescence and early adulthood and isn't recommended for long-term contraception. If other contraceptive methods are inadequate, evaluate bone mineral density routinely, as ordered.
- Confirm that patient isn't pregnant before giving progestin as a contraceptive.
- Shake container vigorously for at least 1 minute before giving medroxyprogesterone acetate injection suspension or megestrol acetate oral suspension.
- Inject parenteral medroxyprogesterone slowly, over 5 to 7 seconds, into deltoid muscle. Don't inject into gluteal muscle to lessen absorption problems that may

occur when patient sits on injection site. Pat site lightly after injection; don't rub it.

- Be aware that cyclical use of progestins is based on a menstrual cycle of 28 days.

WARNING Notify prescriber immediately if patient develops sudden vision loss, abnormal protrusion of eyeball, diplopia, papilledema, migraine, or other signs of thrombotic events. Expect to discontinue progestin if such signs occur.

- Monitor patient for adrenal suppression, especially with megestrol therapy. If suspected, notify prescriber.
- Expect to stop progestin/estrogen therapy in any woman who develops evidence of cancer; cardiovascular disease such as CVA, MI, pulmonary embolism, or venous thrombosis; or dementia.

PATIENT TEACHING

- Explain risks of progestin/estrogen therapy, including breast, endometrial, or ovarian cancer; cardiovascular disease; dementia; and gallbladder disease, especially in postmenopausal women.
- Instruct woman to notify prescriber if uterine bleeding continues longer than 3 months or if menstruation is delayed by 45 days.
- Warn patient taking progestin for noncontraceptive purposes to use a contraceptive method to prevent pregnancy because drug may harm fetus.
- Advise female patient to contact prescriber immediately if she suspects pregnancy or misses a menstrual period.
- Stress importance of using a second method of birth control when taking other drugs that could reduce contraceptive effectiveness of progestins.
- Advise patient that some products may contain peanut oil. If she is allergic to peanuts, tell her to contact pharmacist to find out if prescribed progestin product contains peanut oil.
- Advise female patient who vomits shortly after taking progestin-only oral contraceptive pill not to take another dose immediately thereafter but to wait until next scheduled dose before resuming therapy and to use an additional contraceptive method for 48 hours afterward.
- Caution female patient who vomits within 1 hour of taking progestin for emergency contraception to contact prescriber about

whether to repeat dose.

- Teach woman how to use vaginal gel, if prescribed. Tell her to avoid using other vaginal products for 6 hours before and after to ensure gel's complete absorption.
- Direct patient to alert all prescribers about progestin therapy because certain blood tests may be affected.
- Stress importance of good dental hygiene and regular dental checkups because elevated progestin level increases growth of normal oral flora, which may lead to gum tenderness, bleeding, or swelling.
- Caution postmenopausal women about increased risk of dementia associated with progestin therapy.

promethazine hydrochloride

Anergan 25, Anergan 50, Antinaus 50, Histanil (CAN), Pentazine, Phenazine 25, Phenazine 50, Phencen-50, Phenerzine, Phenoject-50, Pro-50, Promacot, Pro-Med 50, Promet, Prorex-25, Prorex-50, Prothazine, Shogan, V-Gan-25, V-Gan-50

Class and Category

Chemical class: Phenothiazine derivative

Therapeutic class: Antiemetic, antihistamine, antvertigo, sedative-hypnotic

Pregnancy category: C

Indications and Dosages

➤ *To prevent or treat motion sickness*

SYRUP, TABLETS

Adults and adolescents. 25 mg 30 to 60 min before travel and repeated 8 to 12 hr later, if needed. *Maximum:* 150 mg daily.

➤ *To treat vertigo*

SYRUP, TABLETS

Adults and adolescents. 25 mg b.i.d., p.r.n. *Maximum:* 150 mg daily.

Children age 2 and over. 0.5 mg/kg or 10 to 25 mg every 12 hr, p.r.n.

SUPPOSITORIES

Adults and adolescents. 25 mg b.i.d., p.r.n. *Maximum:* 150 mg daily.

Children age 2 and over. 0.5 mg/kg or 12.5 to 25 mg every 12 hr.

➤ *To prevent or treat nausea and vomiting in certain types of anesthesia and surgery*

SYRUP, TABLETS

Adults and adolescents. *Initial:* 25 mg; then 10 to 25 mg every 4 to 6 hr, p.r.n.

Maximum: 150 mg daily.

Children age 2 and over. 0.25 to 0.5 mg/kg or 10 to 25 mg every 4 to 6 hr, p.r.n.

I.V. OR I.M. INJECTION

Adults and adolescents. 12.5 to 25 mg every 4 hr, p.r.n. *Maximum:* 150 mg daily.

I.M. INJECTION

Children age 2 and over. 0.25 to 0.5 mg/kg or 12.5 to 25 mg every 4 to 6 hr, p.r.n.

SUPPOSITORIES

Adults and adolescents. *Initial:* 25 mg; then 12.5 to 25 mg every 4 to 6 hr, p.r.n.

Maximum: 150 mg daily.

Children age 2 and over. 0.25 to 0.5 mg/kg or 12.5 to 25 mg every 4 to 6 hr.

↗ *To treat signs and symptoms of allergic response*

SYRUP, TABLETS

Adults and adolescents. 10 to 12.5 mg q.i.d. before meals and at bedtime, p.r.n. Or, 25 mg at bedtime, p.r.n. *Maximum:* 150 mg daily.

Children age 2 and over. 0.125 mg/kg every 4 to 6 hr or 5 to 12.5 mg t.i.d., p.r.n. Or, 0.5 mg/kg or 25 mg at bedtime, p.r.n.

I.V. INJECTION

Adults and adolescents. 25 mg, repeated within 2 hr, if needed.

I.M. INJECTION, SUPPOSITORIES

Adults and adolescents. 25 mg, repeated in 2 hr, p.r.n. *Maximum:* 150 mg daily.

Children age 2 and over. 0.125 mg/kg every 4 to 6 hr or 6.25 to 12.5 mg t.i.d., p.r.n. Or, 0.5 mg/kg or 25 mg at bedtime, p.r.n.

↗ *To provide nighttime, preoperative, or postoperative sedation*

SYRUP, TABLETS

Adults and adolescents. 25 to 50 mg as a single dose. *Maximum:* 150 mg daily.

Children age 2 and over. 0.5 to 1 mg/kg or 10 to 25 mg as a single dose. Or, for preoperative sedation, 1.1 mg/kg along with 1.1 mg/kg of meperidine and appropriate dose of an atropine-like drug.

I.V. INJECTION

Adults and adolescents. 25 to 50 mg as a single dose. Or, for preoperative and postoperative sedation, 25 to 50 mg combined with appropriately reduced dosages of analgesics and anticholinergics.

I.M. INJECTION, SUPPOSITORIES

Adults and adolescents. 25 to 50 mg as a single dose. Or, for preoperative and postoperative sedation, 25 to 50 mg combined with appropriately reduced dosages of analgesics and anticholinergics.

Children age 2 and over. 0.5 to 1 mg/kg or 12.5 to 25 mg as a single dose. Or, for preoperative sedation, 1.1 mg/kg along with 1.1 mg/kg of meperidine and an appropriate dose of an atropine-like drug.

↗ *To relieve apprehension and promote sleep the night before surgery*

SYRUP, TABLETS, SUPPOSITORIES

Adults and adolescents. 50 mg along with 50 mg of meperidine and an appropriate dose of an atropine-like drug at bedtime on the night before surgery.

DOSAGE ADJUSTMENT Dosage usually decreased for elderly patients.

↗ *To provide obstetric sedation*

I.V. OR I.M. INJECTION

Adults and adolescents. 50 mg for early stages of labor, followed by 1 or 2 doses of 25 to 75 mg after labor is established, repeated every 4 hr during normal labor.

Route	Onset	Peak	Duration
P.O.	15–60 min	Unknown	4–6 hr
I.V.	3–5 min	Unknown	4–6 hr
I.M., P.R.	20 min	Unknown	4–6 hr

Mechanism of Action

Competes with histamine for H₁-receptor sites, thereby antagonizing many histamine effects and reducing allergy signs and symptoms. Promethazine also prevents motion sickness, nausea, and vertigo by acting centrally on medullary chemoreceptive trigger zone and by decreasing vestibular stimulation and labyrinthine function in the inner ear. It also promotes sedation and relieves anxiety by blocking receptor sites in CNS, directly reducing stimuli to the brain.

Contraindications

Angle-closure glaucoma; benign prostatic hyperplasia; bladder neck obstruction; bone marrow depression; breast-feeding; children under age 2; coma; hypersensitivity or history of idiosyncratic reaction to promethazine, other phenothiazines, or their components; hypertensive crisis; lower respiratory tract disorders (including asthma)

when used as an antihistamine; pyloroduodenal obstruction; stenosing peptic ulcer; use of large quantities of CNS depressants

Interactions

DRUGS

amphetamines: Decreased stimulant effect of amphetamines

anticholinergics: Possibly intensified anticholinergic adverse effects

anticonvulsants: Lowered seizure threshold

appetite suppressants: Possibly antagonized anorectic effect of appetite suppressants

beta blockers: Increased risk of additive hypotensive effects, irreversible retinopathy, arrhythmias, and tardive dyskinesia

bromocriptine: Decreased effectiveness of bromocriptine

CNS depressants: Additive CNS depression

dopamine: Possibly antagonized peripheral vasoconstriction (high doses of dopamine)

ephedrine, metaraminol, methoxamine: Decreased vasopressor response to these drugs

epinephrine: Blocked alpha-adrenergic effects of epinephrine, increased risk of hypotension

guanadrel, guanethidine: Decreased antihypertensive effects of these drugs

hepatotoxic drugs: Increased risk of hepatotoxicity

hypotension-producing drugs: Possibly severe hypotension with syncope

levodopa: Inhibited antidyskinetic effects of levodopa

MAO inhibitors: Possibly prolonged and intensified anticholinergic and CNS depressant effects of promethazine

metrizamide: Increased risk of seizures

ototoxic drugs: Possibly masking of some symptoms of ototoxicity, such as dizziness, tinnitus, and vertigo

quinidine: Additive cardiac effects

riboflavin: Increased riboflavin requirement

ACTIVITIES

alcohol use: Additive CNS depression

Adverse Reactions

CNS: Akathisia, CNS stimulation, confusion, dizziness, drowsiness, dystonia, euphoria, excitation, fatigue, hallucinations, hysteria, incoordination, insomnia, irritability, nervousness, neuroleptic malignant syndrome, paradoxical stimulation, pseudoparkinsonism, restlessness, sedation,

seizures, syncope, tardive dyskinesia, tremor

CV: Bradycardia, hypertension, hypotension, tachycardia

EENT: Blurred vision; diplopia; dry mouth, nose, and throat; nasal congestion; tinnitus; vision changes

ENDO: Hyperglycemia

GI: Anorexia, cholestatic jaundice, ileus, nausea, rectal burning or stinging (suppository form), vomiting

GU: Dysuria

HEME: Agranulocytosis, leukopenia, thrombocytopenia, thrombocytopenic purpura

RESP: Apnea, respiratory depression, tenacious bronchial secretions

SKIN: Dermatitis, diaphoresis, jaundice, photosensitivity, rash, urticaria

Other: Angioedema, paradoxical reactions

Nursing Considerations

- Use promethazine cautiously in children and elderly patients because they may be more sensitive to its effects, patients with cardiovascular disease or hepatic dysfunction because of potential adverse effects, patients with asthma because of anticholinergic effects, and patients with seizure disorders or those who take drugs that may affect seizure threshold because drug may lower seizure threshold.
- Inject I.M. form deep into large muscle mass, and rotate sites.

WARNING Avoid inadvertent intra-arterial injection of promethazine because it can cause arteriospasm. Also avoid injecting drug under skin; severe tissue damage and gangrene may develop from impaired circulation.

- Give I.V. injection at no more than 25 mg/min; rapid I.V. administration may produce a transient drop in blood pressure.

WARNING Monitor respiratory function because drug may suppress cough reflex and cause thickening of bronchial secretions, aggravating such conditions as asthma and COPD. Rarely, it may depress respirations and induce apnea.

- Monitor patient's hematologic status as ordered because promethazine may cause bone marrow depression, especially when used with other known marrow-toxic agents. Assess patient for signs and symptoms of infection or bleeding.

WARNING Monitor patient for evidence of

neuroleptic malignant syndrome, such as fever, hypertension or hypotension, involuntary motor activity, mental changes, muscle rigidity, tachycardia, and tachypnea. Be prepared to provide supportive treatment and drug therapy, as prescribed.

- Be aware that patient shouldn't have intradermal allergen tests within 72 hours of receiving promethazine because drug may significantly alter flare response.

PATIENT TEACHING

- Tell patient to use a calibrated device to ensure accurate doses of promethazine syrup.
- Teach patient correct administration technique for suppository, if needed.
- Advise patient to avoid OTC drugs unless approved by prescriber.
- Instruct patient to notify prescriber immediately if she has involuntary movements and restlessness.
- Urge patient to avoid alcohol and other CNS depressants during therapy.
- Instruct patient to avoid hazardous activities until drug's CNS effects are known.
- Suggest rinsing and use of sugarless gum or hard candy to relieve dry mouth.
- Urge patient to avoid excessive sun exposure and to use sunscreen when outdoors.

propafenone hydrochloride

Rythmol

Class and Category

Chemical class: 3-Phenylpropriophenone

Therapeutic class: Class IC antiarrhythmic

Pregnancy category: C

Indications and Dosages

➤ *To treat life-threatening ventricular arrhythmias*

TABLETS

Adults. *Initial:* 150 mg every 8 hr; after 3 or 4 days, increased to 225 mg every 8 hr (U.S.) or 300 mg every 12 hr (Canada), if needed; after an additional 3 or 4 days, further increased to 300 mg every 8 hr, if needed. *Maximum:* 900 mg daily.

Mechanism of Action

Prolongs recovery period after myocardial

repolarization by inhibiting sodium influx through myocardial cell membranes. This action prolongs the refractory period, causing myocardial automaticity, excitability, and conduction velocity to decline.

Contraindications

Bronchospastic disorders, such as asthma; cardiogenic shock; electrolyte imbalances; heart failure (uncontrolled); hypersensitivity to propafenone or its components; severe hypotension; sinus bradycardia or AV conduction disturbances (without artificial pacemaker)

Interactions

DRUGS

amiodarone: Possibly altered cardiac conduction and repolarization; possibly increased blood propafenone level

anesthetics (local): Increased risk of adverse CNS effects

antiarrhythmics, fluoxetine: Increased propafenone level and adverse CV effects

cimetidine, erythromycin, ketoconazole,

paroxetine, ritonavir, saquinavir, sertraline:

Possibly increased blood propafenone level

desipramine: Possibly increased blood level

of desipramine or propafenone

digoxin: Increased risk of digitalis toxicity

haloperidol, imipramine, venlafaxine:

Possibly increased levels of these drugs

metoprolol, propranolol: Increased blood

level and half-life of these drugs

orlistat: Possibly decreased absorption of propafenone

quinidine: Decreased propafenone metabolism

rifampin: Possibly decreased propafenone level

warfarin: Increased blood warfarin level and risk of bleeding

FOODS

grapefruit juice: Possibly increased blood propafenone level

Adverse Reactions

CNS: Dizziness, fatigue, headache

CV: Angina, AV block, bradycardia, heart failure, irregular heartbeat, tachycardia, ventricular arrhythmias

EENT: Altered taste, blurred vision, dry mouth

GI: Constipation, diarrhea, nausea, vomiting

SKIN: Rash

Nursing Considerations

- Assess patient for electrolyte imbalances, such as hyperkalemia, before starting propafenone or any antiarrhythmic to reduce risk of adverse cardiac reactions.
- Use propafenone cautiously in patients with heart failure or myocardial dysfunction because beta-blocking activity may further depress myocardial contractility.
- Monitor ECG tracings, blood pressure, and pulse rate, particularly at start of therapy and with dosage increases.

PATIENT TEACHING

- Instruct patient to take a missed dose if she remembers within 4 hours; otherwise, tell her to skip missed dose and to resume the regular dosing schedule.
- Advise patient not to stop propafenone or change dosage without asking prescriber.
- Urge patient to carry medical identification showing she takes propafenone.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to increase fluid intake and dietary fiber if she becomes constipated.
- Explain that drug may cause an unusual taste. Advise patient to notify prescriber if taste interferes with compliance.

proprantheline bromide

Pro-Banthine, Propanthel (CAN)

Class and Category

Chemical class: Quaternary amine

Therapeutic class: Anticholinergic

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat peptic ulcer disease*

TABLETS

Adults. 15 mg t.i.d. before meals and 30 mg at bedtime, adjusted as needed and tolerated. *Maximum:* 120 mg daily.

Children. 0.375 mg/kg q.i.d., adjusted as needed and tolerated.

DOSAGE ADJUSTMENT For elderly patients with mild symptoms or patients of below-average weight, dosage possibly reduced to 7.5 mg t.i.d. or q.i.d.

Mechanism of Action

Prevents the neurotransmitter acetylcholine

from combining with receptors on postganglionic parasympathetic nerve terminal, thereby reducing smooth-muscle spasms in the GI system, slowing GI motility, and inhibiting gastric acid secretion. All these effects help to heal peptic ulcers.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	6 hr

Contraindications

Adhesions between iris and lens, angle-closure glaucoma, hemorrhage accompanied by hemodynamic instability, hepatic dysfunction, hypersensitivity to proprantheline or its components, ileus, myasthenia gravis, myocardial ischemia, obstructive GI or urinary disease, renal dysfunction, severe ulcerative colitis, tachycardia

Interactions

DRUGS

amantadine, other anticholinergics, tricyclic antidepressants: Additive anticholinergic effects

antacids, antidiarrheals (adsorbent): Possibly reduced absorption of proprantheline
antimythasthenics: Possibly further reduction in intestinal motility

atenolol: Increased effects of atenolol

cyclopropane: Possibly ventricular arrhythmias

digoxin: Possibly digitalis toxicity

haloperidol: Decreased antipsychotic effect of haloperidol in schizophrenic patients

ketoconazole: Decreased ketoconazole absorption

metoclopramide: Possibly decreased metoclopramide effect on GI motility

opioid analgesics: Increased risk of severe constipation and urine retention

phenothiazines: Possibly decreased antipsychotic effects

potassium chloride: Possibly increased severity of potassium chloride-induced GI ulceration, stricture, or perforation

urinary alkalinizers: Delayed urinary excretion of proprantheline

Adverse Reactions

CNS: Dizziness, excitement, insomnia, nervousness, paradoxical CNS stimulation

CV: Palpitations, tachycardia

EENT: Blurred vision; dry mouth, nose, and throat

GI: Constipation, dysphagia, heartburn, ileus, nausea, vomiting

GU: Impotence, urinary hesitancy, urine retention

SKIN: Decreased sweating, dry skin, flushing

Nursing Considerations

- Don't administer propantheline within 1 hour of antacids or antidiarrheals.
- Monitor elderly patients closely; they may respond to usual dose with agitation, confusion, drowsiness, or excitement.

WARNING Drug can interfere with sweating reflex, increasing the risk of heatstroke.

PATIENT TEACHING

- Instruct patient to take propantheline 30 to 60 minutes before meals and at bedtime, as prescribed.
- Inform patient that drug may cause dizziness. Urge her to avoid hazardous activities until drug's CNS effects are known.
- Encourage patient to increase fluid and fiber intake to decrease constipation. Instruct her to report persistent constipation and urine retention.
- Advise patient to avoid excessive exposure to heat to reduce risk of heat prostration and heatstroke.
- Suggest that patient relieve dry mouth with frequent rinsing and sugar-free hard candy or gum.

propofol (disoprofol)

Diprivan

Class and Category

Chemical class: 2,6-diisopropylphenol derivative

Therapeutic class: Sedative-hypnotic

Pregnancy category: B

Indications and Dosages

➤ To provide sedation for critically ill patients in intensive care

I.V. INFUSION

Adults. 2.8 to 130 mcg/kg/min. *Usual:* 27 mcg/kg/min.

DOSAGE ADJUSTMENT For elderly, debilitated, or American Society of Anesthesiologists Physical Status (ASA-PS) III or IV patients, induction dose decreased and maintenance rate slower.

Mechanism of Action

Decreases cerebral blood flow, cerebral metabolic oxygen consumption, and intracranial pressure and increases cerebrovascular resistance, which may play a role in propofol's hypnotic effects.

Route	Onset	Peak	Duration
I.V.	Within 40 sec	Unknown	3–5 min

Incompatibilities

Don't mix propofol with other drugs before giving. Don't give propofol through same I.V. line as blood or plasma products because globular component of emulsion will aggregate.

Contraindications

Hypersensitivity to propofol or its components, to eggs or egg products, or to soybeans or soy products

Interactions

DRUGS

CNS depressants: Additive CNS depressant, respiratory depressant, and hypotensive effects; possibly decreased emetic effects of opioids

droperidol: Possibly decreased control of nausea and vomiting

ACTIVITIES

alcohol use: Additive CNS depressant, respiratory depressant, and hypotensive effects

Adverse Reactions

CV: Bradycardia, hypotension

GI: Nausea, vomiting

MS: Involuntary muscle movement (transient)

RESP: Apnea

Other: Anaphylaxis, injection site burning, pain, or stinging

Nursing Considerations

- Use propofol cautiously in patients with cardiac disease, peripheral vascular disease, impaired cerebral circulation, or increased intracranial pressure because drug may aggravate these disorders.
- To dilute before administration, use only D₅W for final solution of 2 mg/ml or more.
- Consult prescriber about pretreating injection site with 1 ml of 1% lidocaine to minimize pain, burning, or stinging that may occur. If ordered, lidocaine shouldn't

be added to propofol solution in quantities greater than 20 mg/200 mg propofol because emulsion may become unstable. Giving drug through a larger vein in forearm or antecubital fossa also may minimize injection site discomfort.

- Shake container well before using, administer drug promptly after opening, and use vial for a single patient. Use prefilled syringes within 6 hours of opening.
- Use a drop counter, syringe pump, or volumetric pump to safely control infusion rate. Don't infuse drug through filter with a pore size of less than 5 microns; doing so could cause emulsion to break down.
- Discard unused portion of propofol solution plus reservoirs, I.V. tubing, and solutions immediately after or within 12 hours of administration (6 hours if propofol was transferred from original container) to prevent bacterial growth in stagnant solution. Also, protect solution from light.
- Dosage must be tapered before stopping therapy. Stopping abruptly will cause rapid awakening, anxiety, agitation and resistance to mechanical ventilation.
- Expect patient to recover from sedation within 8 minutes.

WARNING Monitor patient for propofol infusion syndrome, especially with prolonged high-dose infusions. It may cause severe metabolic acidosis, hyperkalemia, lipemia, rhabdomyolysis, hepatomegaly and cardiac and renal failure. Alert prescriber at once and be prepared to provide emergency supportive care as ordered.

PATIENT TEACHING

- Urge patient and family to voice concerns and ask questions before administration.
- Reassure patient that she'll be monitored closely during administration and that vital functions will be supported as needed.

propoxyphene hydrochloride

Cotanol-65, Darvon, PP-Cap

propoxyphene napsylate

Darvon-N

Class, Category, and Schedule

Chemical class: Synthetic opioid

Therapeutic class: Analgesic

Pregnancy category: Not rated

Controlled substance schedule: IV

Indications and Dosages

➤ *To relieve mild to moderate pain*

CAPSULES, ORAL SUSPENSION, TABLETS (PROPOXYPHENE NAPSYLATE)

Adults. 100 mg every 4 hr, p.r.n. *Maximum:* 600 mg daily.

CAPSULES, TABLETS (PROPOXYPHENE HYDROCHLORIDE)

Adults. 65 mg every 4 hr, p.r.n. *Maximum:* 390 mg daily.

Route	Onset	Peak	Duration
P.O.	15–60 min	2 hr	4–6 hr

Mechanism of Action

Produces analgesia through a synergistic analgesic effect. Propoxyphene strongly agonizes mu receptors, blocking release of such inhibitory neurotransmitters as gamma-aminobutyric acid (GABA) and acetylcholine. It also mediates analgesia by changing pain perception at spinal cord and higher CNS levels and by altering emotional response to pain.

Contraindications

Hypersensitivity to propoxyphene or its components (including acetaminophen and aspirin), respiratory depression, severe asthma, upper airway obstruction, use within 14 days of MAO inhibitor therapy

Interactions

DRUGS

amphetamines: Possibly fatal seizures (with propoxyphene overdose)

anticholinergics: Increased risk of severe constipation and urine retention

antidiarrheals: Severe constipation, possibly increased CNS depression

antihypertensives: Possibly exaggerated antihypertensive response

buprenorphine: Possibly decreased propoxyphene effectiveness, increased respiratory depression

carbamazepine: Possibly carbamazepine toxicity

CNS depressants: Increased CNS and respiratory depression, hypotensive effects, and

risk of habituation

hydroxyzine: Increased analgesic, CNS depressant, and hypotensive effects

MAO inhibitors: Severe, possibly fatal reactions, including hypertensive crisis

metoclopramide: Possibly antagonized effects of metoclopramide on GI motility

naloxone: Antagonized analgesic and CNS and respiratory depressant effects of propoxyphene

naltrexone: Risk of withdrawal symptoms in patients dependent on propoxyphene, possibly decreased analgesic effect

neuromuscular blockers: Additive respiratory depressant effects

opioid analgesics: Additive CNS and respiratory depressant and hypotensive effects

warfarin: Increased anticoagulation effects

ACTIVITIES

alcohol use: Increased CNS and respiratory depression, hypotensive effects, and risk of habituation

nicotine chewing gum, other smoking deterrents, smoking cessation: Decreased effectiveness of propoxyphene

Adverse Reactions

CNS: Dizziness, drowsiness, fatigue, insomnia, light-headedness, malaise, nervousness, sedation, tremor

CV: Orthostatic hypotension, tachycardia

EENT: Blurred vision, diplopia, dry mouth, tinnitus

GI: Abdominal cramps, anorexia, constipation, nausea, vomiting

GU: Decreased urine output

MS: Muscle weakness

RESP: Dyspnea, respiratory depression, wheezing

SKIN: Facial flushing, pruritus, rash, urticaria

Other: Psychological dependence

Nursing Considerations

- Be aware that propoxyphene shouldn't be used in patients who are suicidal or prone to addiction because of risk of overdose.
- Use drug cautiously in patients who take CNS depressants such as tranquilizers or antidepressants and patients who use alcohol in excess because of risk of overdose.
- Use propoxyphene cautiously in patients with hepatic or renal dysfunction because delayed elimination may occur. Monitor hepatic and renal function test results.

WARNING Be aware that long-term, high-dose propoxyphene therapy may lead to psychological dependence in some people. Assess for opioid and alcohol use, which increase risk of drug abuse or dependence.

- Be aware drug is also available in combination products with aspirin or acetaminophen and caffeine.
- Be aware that abruptly discontinuing drug can result in withdrawal symptoms.

PATIENT TEACHING

- Inform patient that she may take propoxyphene with food if she has GI distress.
- Caution patient not to take more than prescribed amount because drug may be addictive or cause accidental overdose.
- Inform patient that drug may cause blurred vision, drowsiness, dizziness, and impaired judgment and coordination. Urge her to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to avoid alcohol and other sedatives while taking drug.
- Advise smokers to inform prescriber if they try to stop smoking during propoxyphene therapy because increased dosage may be needed for effective analgesia.
- Urge patient to notify prescriber immediately if pain isn't relieved or worsens.

propranolol hydrochloride

Apo-Propranolol (CAN),
Detensol (CAN), Inderal, Inderal LA,
Innopran XL, Novopropranol (CAN),
pms Propranolol (CAN)

Class and Category

Chemical class: Beta-adrenergic blocker

Therapeutic class: Antianginal, antiarrhythmic, antihypertensive, anti-MI, anti-migraine, antitremor, hypertrophic cardiomyopathy and pheochromocytoma therapy adjunct

Pregnancy category: C

Indications and Dosages

↗ *To manage hypertension*

E.R. TABLETS

Adults. *Initial*: 80 mg daily, increased gradually up to 160 mg daily *Maximum*: 640 mg daily.

XL TABLETS (INNOPRAN XL)

Adults. *Initial:* 80 mg once daily at bedtime, increased, as needed, to 120 mg once daily at bedtime.

ORAL SOLUTION, TABLETS

Adults. *Initial:* 40 mg b.i.d., increased gradually to 120 to 240 mg daily, as needed.

Maximum: 640 mg daily.

Children. *Initial:* 0.5 to 1 mg/kg daily in divided doses b.i.d. to q.i.d., adjusted as needed. *Maintenance:* 2 to 4 mg/kg daily in divided doses b.i.d.

➤ *To treat chronic angina*

E.R. TABLETS

Adults. *Initial:* 80 mg daily, increased every 3 to 7 days, as prescribed. *Maximum:* 320 mg/day.

ORAL SOLUTION, TABLETS

Adults. 80 to 320 mg daily in divided doses b.i.d., t.i.d., or q.i.d.

➤ *To treat supraventricular arrhythmias and ventricular tachycardia*

ORAL SOLUTION, TABLETS

Adults. 10 to 30 mg t.i.d. or q.i.d., adjusted as needed.

I.V. INJECTION

Adults. 1 to 3 mg at a rate not to exceed 1 mg/min; repeated after 2 min and again after 4 hr, if needed.

Children. 0.01 to 0.1 mg/kg at a rate not to exceed 1 mg/min; repeated every 6 to 8 hr, as needed. *Maximum:* 1 mg/dose.

➤ *To control tremor*

ORAL SOLUTION, TABLETS

Adults. *Initial:* 40 mg b.i.d., adjusted as needed and prescribed. *Maximum:* 320 mg daily.

➤ *To prevent vascular migraine headaches*

E.R. TABLETS

Adults. *Initial:* 80 mg daily, increased gradually, as needed. *Maximum:* 240 mg daily.

ORAL SOLUTION, TABLETS

Adults. *Initial:* 20 mg q.i.d., increased gradually, as needed. *Maximum:* 240 mg daily.

➤ *As adjunct to treat hypertrophic cardiomyopathy*

ORAL SOLUTION, TABLETS

Adults. 20 to 40 mg t.i.d. or q.i.d., adjusted as needed.

➤ *As adjunct to manage pheochromocytoma*

ORAL SOLUTION, TABLETS

Adults. For operable tumors, 20 mg t.i.d. to 40 mg t.i.d. or q.i.d. for 3 days before sur-

gery, concurrently with an alpha blocker. For inoperable tumors, 30 to 160 mg daily in divided doses.

➤ *To prevent MI*

ORAL SOLUTION, TABLETS

Adults. 180 to 240 mg daily in divided doses.

DOSAGE ADJUSTMENT Dosage increased or decreased for elderly patients, depending on sensitivity to propranolol.

Route	Onset	Peak	Duration
P.O.	Unknown	1–1.5 hr*	Unknown

Mechanism of Action

Through beta-blocking action, propranolol:

- prevents arterial dilation and inhibits renin secretion, resulting in decreased blood pressure (in hypertension and pheochromocytoma) and relief of migraine headaches
- decreases heart rate, which helps resolve tachyarrhythmias
- improves myocardial contractility, which helps ease symptoms of hypertrophic cardiomyopathy
- decreases myocardial oxygen demand, which helps prevent anginal pain and death of myocardial tissue.

In addition, peripheral beta-adrenergic blockade may play a role in propranolol's ability to alleviate tremor.

Contraindications

Asthma, cardiogenic shock, greater than first-degree AV block, sick sinus syndrome, or sinus bradycardia (unless pacemaker in place); heart failure (unless secondary to tachyarrhythmia responsive to propranolol), hypersensitivity to propranolol or its components

Interactions

DRUGS

ACE inhibitors: Increased risk of hypotension, especially in presence of acute MI
allergen immunotherapy, allergenic extracts for skin testing: Increased risk of serious systemic adverse reactions or anaphylaxis
amiodarone: Additive depressant effects on conduction, negative inotropic effects
anesthetics (hydrocarbon inhalation):

* For regular-release form; unknown for E.R. form.

Increased risk of myocardial depression and hypotension

beta blockers: Additive beta blockade effects
bupivacaine, lidocaine, mepivacaine:

Decreased clearance of these drugs, possibly increased risk of toxicity

calcium channel blockers, clonidine, diazoxide, guanabenz, reserpine, other hypotension-producing drugs: Additive hypotensive effect and, possibly, other beta blockade effects

catecholamine-depleting drugs, such as reserpine: Increased risk of hypotension, bradycardia, vertigo, syncope, and orthostatic hypotension

cimetidine: Possibly interference with propranolol clearance

digitalis glycosides: Increased risk of bradycardia

diltiazem: Increased risk of bradycardia, hypotension, high-degree heart block, and heart failure

dobutamine, isoproterenol: Reversed effects of propranolol

doxazosin, terazosin: Increased risk of orthostatic hypotension

epinephrine: Increased risk of uncontrolled hypertension

estrogens: Decreased antihypertensive effect of propranolol

fentanyl, fentanyl derivatives: Possibly increased risk of initial bradycardia after induction doses of fentanyl or a derivative (with long-term propranolol use)

glucagon: Possibly blunted hyperglycemic response

insulin, oral antidiabetic drugs: Possibly impaired glucose control, masking of tachycardia in response to hypoglycemia

MAO inhibitors, tricyclic antidepressants: Increased risk of significant hypertension

neuroleptic drugs: Increased risk of hypotension and cardiac arrest

neuromuscular blockers: Possibly potentiated and prolonged action of these drugs

NSAIDs: Possibly decreased hypotensive effects

phenothiazines: Increased blood levels of both drugs

phenytoin: Additive cardiac depressant effects (with parenteral phenytoin)

prazosin: Increased risk of first-dose hypotension

propafenone: Increased blood level and half-

life of propranolol

quinidine: Increased propranolol level, resulting in higher degrees of beta blockade and orthostatic hypotension

sympathomimetics, xanthines: Possibly mutual inhibition of therapeutic effects

thyroxine: Possibly decreased T₃ level

verapamil: Increased risk of bradycardia, heart failure, and cardiovascular collapse

warfarin: Increased risk of bleeding

ACTIVITIES

alcohol: Possibly increased plasma propranolol level

nicotine chewing gum, smoking cessation, smoking deterrents: Increased therapeutic effects of propranolol

Adverse Reactions

CNS: Anxiety, depression, dizziness, drowsiness, fatigue, fever, insomnia, lethargy, nervousness, weakness

CV: AV conduction disorders, cold limbs, heart failure, hypotension, sinus bradycardia

EENT: Dry eyes, laryngospasm, nasal congestion, pharyngitis

GI: Abdominal pain, constipation, diarrhea, nausea, vomiting

GU: Impotence, peyronie's disease, sexual dysfunction

HEME: Agranulocytosis

MS: Muscle weakness

RESP: Bronchospasm, dyspnea, respiratory distress, wheezing

SKIN: Alopecia, erythema multiforme, erythematous rash, exfoliative dermatitis, psoriasiform rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, flulike symptoms, systemic lupuslike reaction

Nursing Considerations

- Use propranolol cautiously in patients with bronchospastic lung disease because it may induce asthmatic attack.
- Monitor blood pressure, apical and radial pulses, fluid intake and output, daily weight, respiration, and circulation in extremities before and during therapy.
- Give I.V. injection at no more than 1 mg/minute.

WARNING Monitor ECG continuously, as ordered, when giving I.V. injection. Have emergency drugs and equipment available in case of hypotension or cardiac arrest.

- Protect injection solution from light.

- Because drug's negative inotropic effect can depress cardiac output, monitor cardiac output in patients with heart failure, particularly those with severely compromised left ventricular dysfunction.
- Be aware that propranolol can mask tachycardia in hyperthyroidism and that abrupt withdrawal in patients with hyperthyroidism or thyrotoxicosis can cause thyroid storm.
- Monitor diabetic patient taking an anti-diabetic because propranolol can prolong hypoglycemia or promote hyperglycemia. It also can mask signs of hypoglycemia, especially tachycardia, palpitations, and tremor, but it doesn't suppress diaphoresis or hypertensive response to hypoglycemia.

WARNING Be aware that stopping drug abruptly may cause myocardial ischemia, MI, ventricular arrhythmias, or severe hypertension, especially in patients with cardiac disease. It also may cause increased intraocular pressure to return. Dosage should be reduced gradually.

PATIENT TEACHING

- Instruct patient to take propranolol at the same time every day.
- Caution patient not to change dosage without consulting prescriber and not to stop taking drug abruptly.
- Advise patient to notify prescriber immediately if she has shortness of breath.
- Instruct diabetic patient to regularly check blood glucose level and urine for ketones.
- Advise patient to consult prescriber before taking OTC drugs, especially cold products.
- Urge patient to avoid hazardous activities until CNS effects of drug are known.
- Advise smoker to notify prescriber immediately if she stops smoking because cessation may decrease drug metabolism, calling for dosage adjustments.
- Tell patient to notify prescriber if she is or could be pregnant because drug may need to be discontinued.

propylthiouracil (PTU)

Propyl-Thyracil (CAN)

Class and Category

Chemical class: Thiourea derivative

Therapeutic class: Antithyroid
Pregnancy category: D

Indications and Dosages

➤ *To treat hyperthyroidism*

TABLETS

Adults and adolescents. *Initial:* For mild to moderate hyperthyroidism, 300 to 900 mg daily in 1 to 4 divided doses until patient becomes euthyroid; for severe hyperthyroidism, 300 to 1,200 mg daily in 1 to 4 divided doses until patient becomes euthyroid. *Maintenance:* 50 to 600 mg daily in 1 to 4 divided doses.

Children age 10 and over. *Initial:* 50 to 300 mg daily in 1 to 4 divided doses.

Maintenance: Adjusted based on response to initial dosage.

Children ages 6 to 10. *Initial:* 50 to 150 mg/day in 1 to 4 divided doses. *Maintenance:* Adjusted based on response to initial dosage.

Neonates. 10 mg/kg daily in divided doses.

➤ *As adjunct to treat thyrotoxic crisis*

TABLETS

Adults and adolescents. 200 to 400 mg every 4 hr on day 1 plus other measures. Dosage gradually decreased as crisis subsides.

DOSAGE ADJUSTMENT If creatinine clearance is 10 to 50 ml/min/1.73 m², recommended dosage reduced by 25%; if creatinine clearance is less than 10 ml/min/1.73 m², recommended dosage reduced by 50%.

Route	Onset	Peak	Duration
P.O.	Unknown	17 wk	Unknown

Mechanism of Action

Inhibits conversion of peripheral thyroxine to triiodothyronine by interfering with incorporation of iodide into thyroglobulin; drug remains iodinated and degraded in thyroid gland. Diversion of oxidized iodine away from thyroglobulin diminishes thyroid hormone synthesis and levels of circulating thyroid hormone.

Contraindications

Breast-feeding, hypersensitivity to propylthiouracil or its components

Interactions

DRUGS

amiodarone, iodinated glycerol, iodine, potas-

sium iodide: Decreased efficacy of propylthiouracil
digoxin: Risk of digitalis toxicity
oral anticoagulants: Possibly enhanced anticoagulant effect
sodium iodide 131 (radioactive iodine, ¹³¹I): Decreased thyroid uptake of ¹³¹I

Adverse Reactions

CNS: Dizziness, paresthesia, peripheral neuropathy
CV: Vasculitis
ENDO: Hypothyroidism
GI: Abdominal pain, hepatotoxicity, nausea, vomiting
HEME: Agranulocytosis, leukopenia
MS: Arthralgia, joint redness or swelling
SKIN: Pruritus, rash, urticaria
Other: Lupuslike symptoms

Nursing Considerations

- Monitor CBC, PT, and liver and thyroid function test results in patients taking propylthiouracil. Elevated serum triiodothyronine (T₃) level may be the sole indicator of inadequate treatment.
- Expect to stop drug 3 to 4 days before ¹³¹I treatment to prevent decreased thyroid uptake of ¹³¹I; therapy may be resumed 3 to 5 days after radiation, if needed.
- Serum T₃ and thyroxine levels should decrease after about 3 weeks of therapy.
- Expect to decrease beta blocker or theophylline dosage once patient is euthyroid.
- Monitor liver function, especially during first 6 months of therapy, because drug may cause liver failure, need for liver transplant, or death. Expect to stop drug at first sign of liver dysfunction (fatigue, weakness, vague abdominal pain, loss of appetite, itching, easy bruising, jaundice).

PATIENT TEACHING

- Instruct patient to take drug with meals to decrease risk of adverse GI reactions.
- Urge patient to avoid dietary sources of iodine, such as iodized salt and shellfish.
- Tell patient to check pulse rate and weight daily and to report increased heart rate and excessive weight loss to prescriber.
- Urge patient to report signs and symptoms of infection, such as fever and sore throat, or signs and symptoms that could reflect hepatic dysfunction, such as anorexia and right-upper-quadrant pain.
- Instruct patient to notify prescriber immediately if she becomes pregnant.

- Advise patient to report signs and symptoms of hypothyroidism, such as cold intolerance, depression, and increased fatigue.
- Tell patient to ask prescriber before using OTC cold drugs (some contain iodides).
- Advise patient to notify prescriber immediately if he has fatigue, weakness, vague abdominal pain, loss of appetite, itching, easy bruising, or yellowing of eyes or skin.

protamine sulfate

Class and Category

Chemical class: Simple low-molecular-weight protein

Therapeutic class: Heparin antagonist

Pregnancy category: C

Indications and Dosages

↗ *To treat heparin toxicity or hemorrhage associated with heparin therapy*

I.V. INJECTION

Adults and children. 1 mg for each 100 units of heparin to be neutralized, or as indicated by coagulation test results.
Maximum: 100 mg (within 2-hr period).

Route	Onset	Peak	Duration
I.V.	5 min	Unknown	2 hr

Mechanism of Action

Neutralizes anticoagulant activity. A strong basic polypeptide, protamine combines with strongly acidic heparin complex to form an inactive stable salt, thereby neutralizing anticoagulant activity of both drugs.

Incompatibilities

Don't mix protamine sulfate in same syringe with other drugs unless they're known to be compatible. Several cephalosporins, penicillins, and other antibiotics are incompatible.

Contraindications

Allergy to fish, hypersensitivity to protamine or its components

Interactions

DRUGS

heparin: Neutralized anticoagulant effect of both drugs

Adverse Reactions

- CNS:** Weakness
- CV:** Bradycardia, hypertension, hypotension, shock
- GI:** Nausea, vomiting
- HEME:** Unusual bleeding or bruising
- RESP:** Dyspnea, pulmonary edema (non-cardiogenic), pulmonary hypertension
- SKIN:** Flushing, sensation of warmth
- Other:** Anaphylaxis

Nursing Considerations

- Expect to administer I.V. protamine undiluted. However, dilute drug if needed (for patients other than neonates) with 5 ml of bacteriostatic water for injection containing 0.9% benzyl alcohol. For neonates, reconstitute with preservative-free sterile water for injection.
- Inject drug slowly at 5 mg/minute; administer no more than 50 mg in 10 minutes or 100 mg in 2 hours.

WARNING Be aware that rapid delivery may cause severe hypotension and anaphylaxis.

- Be prepared to obtain coagulation studies (APTT, activated clotting time) 5 to 15 minutes after giving drug and to repeat them in 2 to 8 hours to detect heparin-rebound hypotension, shock, and bleeding.
- Monitor vital signs, hemodynamic parameters, and fluid intake and output, and assess for flushing sensation.
- Have fluids—epinephrine 1:1,000, dobutamine, or dopamine—available for allergic or hypotensive reactions.
- Be aware that men with vasectomy have an increased risk of hypersensitivity reaction because of possible accumulation of antiprotamine antibodies.

PATIENT TEACHING

- Instruct patient to report adverse reactions immediately.

protriptyline hydrochloride

Triptil (CAN), Vivactil

Class and Category

Chemical class: Dibenzocycloheptene derivative
Therapeutic class: Antidepressant
Pregnancy category: Not rated

Indications and Dosages

➤ *To treat depression*

TABLETS

Adults. *Initial:* 5 to 10 mg t.i.d. or q.i.d., increased every wk by 10 mg daily, as needed. *Maximum:* 60 mg daily.
Children age 12 and over. *Initial:* 5 mg t.i.d., increased as needed.

DOSAGE ADJUSTMENT For elderly patients, initial dosage limited to 5 mg t.i.d., then adjusted as needed.

Route	Onset	Peak	Duration
P.O.	2–3 wk	Unknown	Unknown

Mechanism of Action

May block reuptake of norepinephrine and serotonin (and possibly other neurotransmitters) at neuronal membranes, thus enhancing their effects at postsynaptic receptors. These neurotransmitters may play a role in relieving depression symptoms.

Contraindications

Acute recovery phase after MI, hypersensitivity to protriptyline or its components, use within 14 days of MAO inhibitor therapy

Interactions

DRUGS

amantadine, anticholinergics, antidyskinetics, antihistamines: Additive anticholinergic effects, potentiated effects of antihistamines or protriptyline, possibly impaired detoxification of atropine and related drugs
anticonvulsants: Possibly lowered seizure threshold and decreased anticonvulsant effectiveness; enhanced CNS depression
antithyroid drugs: Possibly agranulocytosis
barbiturates, carbamazepine: Decreased therapeutic effects of protriptyline
bupropion, clozapine, cyclobenzaprine, haloperidol, loxapine, maprotiline, molindone, phenothiazines, thioxanthenes: Prolonged and intensified anticholinergic and sedative effects, lowered seizure threshold, increased risk of neuroleptic malignant syndrome; increased blood protriptyline level and inhibited phenothiazine metabolism (with phenothiazine use)
cimetidine: Increased risk of protriptyline toxicity
clonidine, guanadrel, guanethidine: Decreased hypotensive effects; increased

CNS depression (with clonidine use)

CNS depressants: Possibly serious potentiation of CNS and respiratory depression and hypotensive effect

disulfiram, ethchlorvynol: Possibly transient delirium; increased CNS depression (with ethchlorvynol use)

fluoxetine: Increased protriptyline level

MAO inhibitors: Increased risk of hyperpyretic crisis, severe seizures, and death

methylphenidate: Possibly antagonized effects of methylphenidate and increased blood protriptyline level

metrizamide: Increased risk of seizures

naphazoline, oxymetazoline, phenylephrine, xylometazoline: Possibly increased vasopressor effects of these drugs

oral anticoagulants: Possibly increased anticoagulant activity

pimozide, probucol: Possibly prolonged QT interval and ventricular tachycardia

sympathomimetics: Possibly potentiated cardiovascular effects, decreased vasopressor effects of ephedrine and mephentermine

thyroid hormones: Increased therapeutic and toxic effects of both drugs

ACTIVITIES

alcohol use: Possibly increased response to alcohol

Adverse Reactions

CNS: Agitation, ataxia, confusion, dizziness, drowsiness, exacerbation of psychosis, extrapyramidal reactions, fatigue, lack of coordination, paresthesia, peripheral neuropathy, suicidal ideation, tremor, weakness

CV: Arrhythmias, including heart block and tachycardia; hypertension; hypotension; MI; orthostatic hypotension; palpitations; stroke

EENT: Black tongue, blurred vision, dry mouth, increased intraocular pressure, lacrimation, stomatitis, tongue swelling

ENDO: Hyperglycemia, hypoglycemia

GI: Abdominal cramps, anorexia, constipation, diarrhea, epigastric discomfort, hepatic dysfunction, nausea, vomiting

GU: Impotence, libido changes, nocturia, urinary frequency and hesitancy, urine retention

SKIN: Diaphoresis, petechiae, photosensitivity, rash, urticaria

Other: Facial edema, weight gain or loss

Nursing Considerations

- Use protriptyline cautiously in patients

with a history of seizures because drug can lower seizure threshold.

- Use cautiously in patients with a history of urine retention or increased intraocular pressure because of drug's autonomic activity.

WARNING Avoid giving protriptyline with an MAO inhibitor. If patient is being switched from an MAO inhibitor to protriptyline, make sure MAO inhibitor has been discontinued for 14 days before starting protriptyline.

- Watch patients closely (especially children, adolescents, and young adults) for suicidal tendencies, particularly when therapy starts or dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.

PATIENT TEACHING

- Inform patient that protriptyline therapy may take several weeks to reach full effect.
- Instruct patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to change position slowly to minimize orthostatic hypotension.
- Urge patient to avoid alcohol while taking drug.
- Suggest drinking water and using sugarless gum or hard candy to relieve dry mouth.
- Advise patient to avoid sunlight and tanning booths and to wear protective clothing, a hat, and sunscreen when outdoors.
- Instruct diabetic patient to check blood glucose level frequently during first few weeks of protriptyline therapy.
- Urge family or caregiver to watch patient for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.

pyrazinamide

pms-Pyrazinamide (CAN),
Tebrazid (CAN)

Class and Category

Chemical class: Pyrazine analogue of nicotinamide

Therapeutic class: Antitubercular

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat tuberculosis, along*

with other antitubercular drugs

TABLETS

Adults and children. 15 to 30 mg/kg daily; or, 50 to 70 mg/kg 2 or 3 times/wk.

Maximum: For daily regimen, 2 g daily; for twice/wk regimen, 4 g daily; for 3-times/wk regimen, 3 g daily.

DOSAGE ADJUSTMENT For patients with HIV infection, 20 to 30 mg/kg daily for first 2 mo of therapy.

Mechanism of Action

Inhibits growth of *Mycobacterium tuberculosis* by decreasing pH level; exhibits bactericidal or bacteriostatic action, depending on blood pyrazinamide level.

Contraindications

Acute gout, hypersensitivity to pyrazinamide or its components, severe hepatic damage

Interactions

DRUGS

allopurinol, colchicine, probenecid, sulfipyrazone: Possibly increased blood uric acid level and decreased antigout efficacy
cyclosporine: Possibly decreased blood level and therapeutic effects of cyclosporine

Adverse Reactions

CNS: Fever

GI: Anorexia, hepatotoxicity, nausea, vomiting

GU: Dysuria

HEME: Porphyria

MS: Arthralgia, gout, myalgia

SKIN: Acne, photosensitivity, pruritus, rash, urticaria

Nursing Considerations

- Review liver function test results before and every 2 to 4 weeks during therapy.
- Be aware that drug can affect the accuracy of certain urine ketone strip test results.
- Because drug is metabolized by liver, monitor patient for evidence of hepatotoxicity, such as darkened urine, fever, jaundice, malaise, nausea, severe pain in feet or toes, and vomiting.

PATIENT TEACHING

- Explain importance of complying with long-term pyrazinamide therapy.
- Tell diabetic patient about possible changes in ketone measurement during therapy.

- Instruct patient to report dark urine, fever, malaise, nausea, severe pain in feet or toes, vomiting, and yellowing of skin or eyes.
- Inform patient of need for regular blood tests and follow-up visits with prescriber.
- Urge patient to minimize exposure to sun and to wear protective clothing, hat, sunglasses, and sunscreen when outdoors.

pyridostigmine bromide

Mestinon, Mestinon-SR (CAN), Mestinon Timespans, Regonol (CAN)

Class and Category

Chemical class: Bromide dimethylcarbamate

Therapeutic class: Antimyasthenic

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat symptoms of myasthenia gravis*

E.R. TABLETS

Adults and adolescents. 180 to 540 mg once or twice daily (at least 6 hr between doses).

SYRUP, TABLETS

Adults and adolescents. *Initial:* 30 to 60 mg every 3 to 4 hr, adjusted as needed.

Maintenance: 60 mg to 1.5 g daily.

Children. 7 mg/kg daily in 5 or 6 divided doses.

I.V. OR I.M. INJECTION

Adults and adolescents. 2 mg every 2 to 3 hr.

I.M. INJECTION

Neonates of myasthenic mothers. 0.05 to 0.15 mg/kg every 4 to 6 hr.

↗ *To reverse the effects of neuromuscular blockers*

I.V. INJECTION

Adults and adolescents. 10 to 20 mg after 0.6 to 1.2 mg of I.V. atropine has been given.

DOSAGE ADJUSTMENT Dosage possibly reduced for patients with renal impairment.

Mechanism of Action

Improves muscle strength compromised by myasthenia gravis or neuromuscular blockade by competing with acetylcholine for its binding site on acetylcholinesterase. This action potentiates the effects of acetylcho-

line on skeletal muscle and the GI tract. Inhibited destruction of acetylcholine allows freer transmission of nerve impulses across the neuromuscular junction.

Route	Onset	Peak	Duration
P.O.	30–45 min	1–2 hr	3–6 hr
P.O. (E.R.)	30–60 min	1–2 hr	6–12 hr
I.V.	2–5 min	Unknown	2–4 hr
I.M.	15 min	Unknown	2–4 hr

Contraindications

Hypersensitivity to pyridostigmine or its components, mechanical obstruction of GI or urinary tract

Interactions

DRUGS

aminoglycosides (systemic), anesthetics (hydrocarbon inhalation), capreomycin, lidocaine (I.V.), lincomycins, polymyxins, quinine: Possibly antagonized effect of pyridostigmine on skeletal muscle; possibly decreased neuromuscular blocking activity of these drugs (with large doses of pyridostigmine)

anesthetics (local): Inhibited neuronal transmission, increased anesthesia effects

anticholinergics: Possibly masked pyridostigmine overdose; reduced intestinal motility

cholinesterase inhibitors: Increased risk of additive toxicity

edrophonium, guanadrel, guanethidine, mecaminylamine, neuromuscular blockers, procainamide:

Possibly prolonged phase I blocking effect or reversal of nondepolarization blockade
quinidine, trimethaphan: Possibly antagonized effects of pyridostigmine

Adverse Reactions

EENT: Increased salivation, lacrimation, miosis

GI: Abdominal cramps, diarrhea, increased peristalsis, nausea, vomiting

GU: Urinary frequency, incontinence, or urgency

MS: Fasciculations, muscle spasms or weakness

RESP: Increased tracheobronchial secretions

SKIN: Diaphoresis

Nursing Considerations

- Use pyridostigmine cautiously in patients with renal disease because drug is mainly excreted unchanged by kidneys. Monitor BUN and serum creatinine levels.

WARNING Maintain a rigid dosing schedule because a missed or late dose can precipitate myasthenic crisis.

- Observe for cholinergic reactions when administering drug I.V. or I.M.

WARNING Pyridostigmine overdose may obscure diagnosis of myasthenic crisis because main symptom in both is muscle weakness. Treat cholinergic crisis by stopping anticholinesterase, giving atropine as prescribed, and helping with endotracheal intubation and mechanical ventilation, if needed.

- Be aware that reversal of neuromuscular blockade usually occurs in 15 to 30 minutes. Be prepared to maintain patent airway and ventilation until normal voluntary respiration returns completely. Assess respiratory measurements and muscle tone with peripheral nerve stimulator device, as indicated.

PATIENT TEACHING

- Instruct patient to take pyridostigmine as directed and on schedule. Explain that a late or missed dose can precipitate a crisis. Suggest the use of a battery-operated alarm clock as a reminder.
- Tell patient to take drug with a full glass of water or with food or milk if GI distress occurs.
- Warn patient not to crush or chew E.R. tablets.
- Ask patient to record pyridostigmine dosage, times taken, and drug effects to help determine optimal dosage and schedule.
- Urge patient to carry medical identification describing her condition and drug regimen.

Q R S

quazepam

Doral

Class, Category, and Schedule

Chemical class: Benzodiazepine

Therapeutic class: Sedative-hypnotic

Pregnancy category: X

Controlled substance schedule: IV

Indications and Dosages

↗ *To treat insomnia*

TABLETS

Adults. 15 mg at bedtime.

DOSE ADJUSTMENT In elderly and debilitated patients, dosage may be reduced to 7.5 mg at bedtime after 1 or 2 nights of therapy.

Mechanism of Action

May antagonize mu receptors at limbic, thalamic, and hypothalamic regions of the brain, blocking release of such inhibitory neurotransmitters as gamma-aminobutyric acid (GABA) and acetylcholine. Central receptors interact with GABA receptors, allowing for greater influx of chloride into the neuron, thereby suppressing neuronal excitability. GABA effects may inhibit spinal afferent pathways and block the cortical and limbic arousal that normally occurs when reticular pathways are stimulated. These effects result in various levels of CNS depression, including sleep.

Contraindications

Hypersensitivity to quazepam or its components, pregnancy, sleep apnea (known or suspected)

Interactions

DRUGS

addictive drugs: Possibly habituation

carbamazepine: Decreased blood quazepam level, possibly increased blood carbamazepine level

cimetidine, diltiazem, disulfiram, erythromycin, fluoxetine, fluvoxamine, isoniazid, itraconazole, ketoconazole, nefazodone, oral contraceptives, propoxyphene, ranitidine, vera-

pamil: Possibly potentiated effects of quazepam

clozapine: Possibly syncope, with respiratory depression or arrest

CNS depressants, tricyclic antidepressants:

Increased CNS depression

CYP2B6 substrates such as bupropion and

efavirenz: Possibly increased plasma levels of these agents leading to increased risk of adverse effects

digoxin: Possibly increased blood digoxin level and risk of digitalis toxicity

levodopa: Possibly decreased therapeutic effects of levodopa

phenytoin: Increased risk of phenytoin toxicity

theophyllines: Possibly antagonized effects of quazepam

zidovudine: Increased risk of zidovudine toxicity

FOODS

grapefruit juice: Increased quazepam level

ACTIVITIES

alcohol use: Additive CNS depression

smoking: Possibly decreased effectiveness of quazepam

Adverse Reactions

CNS: Abnormal complex behaviors, such as sleep driving; amnesia (anterograde); anxiety; ataxia; confusion; depression; dizziness; drowsiness; euphoria; fatigue; headache; light-headedness; paresthesia; slurred speech; suicidal ideation; tremor; weakness

CV: Chest pain, palpitations, tachycardia

EENT: Blurred vision, dry mouth, hyperacusis, photophobia, throat tightness, worsening of glaucoma

GI: Abdominal cramps, constipation, diarrhea, heartburn, nausea, thirst, vomiting

GU: Renal dysfunction, urinary incontinence, urine retention

MS: Muscle spasms

RESP: Dyspnea, increased tracheobronchial secretions

Other: Anaphylaxis, angioedema

Nursing Considerations

- Use quazepam cautiously in patients with angle-closure glaucoma because of drug's anticholinergic effects; in patients with hepatic dysfunction because this condition may prolong quazepam's half-life; in patients with myasthenia gravis because drug may worsen condition; in patients

with severe COPD because adverse effects of quazepam may compromise respiratory function; in patients with renal dysfunction because accumulation of metabolites may result in toxicity; and in elderly patients because of age-related decreases in hepatic, renal, and cardiac function.

WARNING Monitor patient closely for signs and symptoms of hypersensitivity reactions, such as dyspnea, throat tightness, nausea, vomiting, and swelling. If present, discontinue quazepam immediately, notify prescriber, and provide supportive care.

WARNING Notify prescriber if eye pain develops in patient with angle-closure glaucoma.

WARNING Be aware that quazepam may intensify signs and symptoms of depression. Monitor patient closely for evidence of suicidal ideation, and institute suicide precautions, as needed.

PATIENT TEACHING

- Instruct patient to stop taking quazepam and seek emergency care if she has trouble breathing, throat tightness, nausea, vomiting, or abnormal swelling.
- Advise patient that drug may cause abnormal behaviors during sleep, such as driving a car, eating, talking on the phone, or having sex without recall of the event. If family members notice such behavior, or if patient sees evidence of it upon awakening, prescriber should be notified.
- Urge patient to avoid consuming alcohol during quazepam therapy because sedation and risk of abnormal behaviors, such as sleep driving, may increase.
- Instruct patient not to stop drug abruptly after prolonged use (6 weeks or more).
- Instruct female patient of childbearing age to use effective contraception during therapy and to notify prescriber immediately of known or suspected pregnancy.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.

quetiapine fumarate

Seroquel, Seroquel XR

Class and Category

Chemical class: Dibenzothiazepine derivative

Therapeutic class: Antipsychotic
Pregnancy category: C

Indications and Dosages

↗ *To treat schizophrenia*

TABLETS

Adults. *Initial:* 25 mg b.i.d. on day 1. Increased by 25 to 50 b.i.d. or t.i.d. on days 2 and 3. *Usual:* 300 to 400 mg daily by day 4, in divided doses b.i.d. or t.i.d. Increased every 2 days in increments of 25 to 50 mg b.i.d., as needed. *Maximum:* 800 mg daily.

E.R. TABLETS

Adults. *Initial:* 300 mg once daily in evening. Dosage increased daily in increments up to 300 mg, as needed. *Maximum:* 800 mg daily.

↗ *To manage psychotic disorders other than schizophrenia*

TABLETS

Adults. *Initial:* 25 mg b.i.d. on day 1. Dosage increased by 25 to 50 mg b.i.d. or t.i.d. on days 2 and 3. *Usual:* 300 to 400 mg daily by day 4, in divided doses b.i.d. or t.i.d. Dosage increased every 2 days in increments of 25 to 50 mg b.i.d., as needed. *Maximum:* 800 mg daily.

↗ *To treat depressive episodes in bipolar disorder*

TABLETS

Adults. *Initial:* On day one, 50 mg once at bedtime; day two, 100 mg once at bedtime; day three, 200 mg once at bedtime; day four, 300 mg once at bedtime. *Maintenance:* 300 mg once daily at bedtime.

E.R. TABLETS

Adults. *Initial:* 50 mg once daily in evening on day 1, followed by 100 mg once daily in evening on day 2, 200 mg once daily in evening on day 3, and 300 mg once daily in evening on day 4 and thereafter.

↗ *As adjunct therapy with antidepressants to treat major depressive disorder*

E.R. TABLETS

Adults. *Initial:* 50 mg once daily in evening, increased to 150 mg once daily in evening on day 3. *Maximum:* 300 mg daily in evening.

↗ *To treat acute manic episodes in bipolar I disorder*

TABLETS

Adults. 50 mg b.i.d., increased to 200 mg b.i.d. on day 4 (in increments no greater than 100 mg daily) and then further

increased to 400 mg b.i.d. on day 6 (in increments no greater than 200 mg daily), as needed.

➤ *To treat acute manic episodes in bipolar I disorder as monotherapy; as adjunct with lithium or divalproex to treat acute manic episodes in bipolar I disorder*

E.R. TABLETS

Adults. *Initial:* 300 mg once daily in evening on day 1, followed by 600 mg once daily in evening on day 2 and 200 to 400 mg b.i.d. on day 3 and thereafter.

Maintenance: 200 to 400 mg b.i.d.

DOSAGE ADJUSTMENT For elderly patients and patients with hepatic impairment, initial dosage no higher than 50 mg once daily and increased in increments of 50 mg/day depending on response and tolerance.

Mechanism of Action

May produce antipsychotic effects by interfering with dopamine binding to dopamine type 2 (D₂)-receptor sites in the brain and by antagonizing serotonin 5-HT₂, dopamine type 1 (D₁), histamine H₁, and adrenergic alpha₁ and alpha₂ receptors.

Contraindications

Hypersensitivity to quetiapine or its components

Interactions

DRUGS

antihypertensives: Possibly enhanced antihypertensive effects of these drugs

cimetidine, erythromycin, fluconazole, itraconazole, ketoconazole: Decreased clearance and possibly increased effects of quetiapine

CNS depressants: Possibly increased CNS depression

lorazepam: Possibly increased effects of lorazepam

phenytoin, thioridazine: Increased clearance and possibly decreased effectiveness of quetiapine

ACTIVITIES

alcohol use: Possibly enhanced CNS depression

Adverse Reactions

CNS: Depression, dizziness, drowsiness, dystonia, extrapyramidal reactions, hypertonia, lethargy, restless leg syndrome, somnolence, suicidal ideation, tardive dyskinesia

CV: Cardiomyopathy, hypercholesterolemia,

myocarditis, orthostatic hypotension, palpitations

EENT: Dry mouth, nasal congestion, pharyngitis, rhinitis

ENDO: Hyperglycemia, syndrome of inappropriate ADH secretion

GI: Anorexia, constipation, indigestion

HEME: Agranulocytosis, leukopenia, neutropenia

MS: Dysarthria, muscle weakness, rhabdomyolysis

RESP: Cough, dyspnea

SKIN: Diaphoresis, Stevens-Johnson syndrome

Other: Anaphylaxis, flulike symptoms, weight gain

Nursing Considerations

WARNING Quetiapine shouldn't be used for elderly patients with dementia-related psychosis because drug increases the risk of death in these patients.

- Monitor patients (particularly young adults) closely for suicidal tendencies, especially when therapy starts or dosage changes, because depression may worsen temporarily during these times.

WARNING Monitor patient taking quetiapine for predisposing factors for neuroleptic malignant syndrome, such as heat stress, physical exhaustion, dehydration, and organic brain disease. Neuroleptic malignant syndrome includes hyperpyrexia, muscle rigidity, altered mental status, and autonomic instability (which may include irregular pulse or blood pressure, tachycardia, diaphoresis, and arrhythmias).

- Monitor patient for signs of tardive dyskinesia, a potentially irreversible complication characterized by involuntary, dyskinesic movements of tongue, mouth, jaw, eyelids, or face. Notify prescriber if such signs develop because quetiapine therapy may need to be stopped.

- Monitor patient for orthostatic hypotension, especially during initial dosage titration period. Be prepared to correct underlying conditions, such as hypovolemia and dehydration, before starting quetiapine therapy, as prescribed.

- Monitor patient for prolonged abnormal muscle contractions, especially during the first few days of quetiapine therapy, in male patients, and in younger patients.

- Assess patient for hypothyroidism because drug can cause dose-dependent decreases in total and free thyroxine (T_4) levels.
- Monitor laboratory results during first 3 weeks of therapy for transient elevations in hepatic enzyme levels. Notify prescriber if they persist or worsen.
- Monitor patient's blood glucose and lipid levels routinely, as ordered, because drug increases the risk of hyperglycemia and hypercholesterolemia.
- Check CBC often during the first few months of therapy, as ordered, in patients with a low white blood cell count or a history of drug-induced hematologic problems. If counts drop or patient develops a fever or other signs of infection, notify prescriber and expect to discontinue drug and provide supportive care.

PATIENT TEACHING

- Instruct patient to take quetiapine with food to reduce stomach upset.
- Advise patient not to stop taking quetiapine suddenly because doing so may exacerbate his symptoms.
- Inform patient that quetiapine therapy may cause dizziness or drowsiness. Advise him not to drive or perform other activities that require alertness until drug's full CNS effects are known.
- Instruct patient to rise slowly from a seated or lying position to reduce the risk of dizziness or fainting.
- Caution patient to avoid consuming alcoholic beverages because they can increase dizziness and drowsiness.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a young adult.
- Encourage patient on long-term therapy to have regular eye examinations so that cataracts can be detected.

quinapril hydrochloride

Accupril

Class and Category

Chemical class: Ethylester of quinaprilat

Therapeutic class: Antihypertensive

Pregnancy category: C (first trimester), D (later trimesters)

Indications and Dosages

↗ *To treat hypertension*

TABLETS

Adults. *Initial:* 10 or 20 mg daily, adjusted every 2 wk based on clinical response.

Maintenance: 20 to 80 mg daily or in divided doses b.i.d.

DOSAGE ADJUSTMENT Initial dosage reduced to 5 mg daily for patients who are dehydrated from previous diuretic therapy, those who are still receiving diuretic therapy, and those with creatinine clearance of 30 to 60 ml/min/1.73 m². Dosage reduced to 2.5 mg daily for patients with creatinine clearance of 10 to 30 ml/min/1.73 m².

Route	Onset	Peak	Duration
P.O.	In 1 hr	2–4 hr	Up to 24 hr

Mechanism of Action

Blocks conversion of angiotensin I to angiotensin II, leading to vasodilation, and reduces aldosterone secretion, which prevents water retention. Quinapril also reduces peripheral arterial resistance. These combined actions lead to a reduction in blood pressure.

Contraindications

History of angioedema related to previous treatment with ACE inhibitor, hypersensitivity to quinapril or its components

Interactions**DRUGS**

allopurinol, bone marrow depressants, corticosteroids (systemic), procainamide:

Increased risk of fatal neutropenia or agranulocytosis

CNS depressants, other hypotension-producing drugs: Additive hypotensive effects

cyclosporine, potassium preparations, potassium-sparing diuretics: Possibly hyperkalemia
lithium: Possibly increased blood lithium level and risk of toxicity

NSAIDs, sympathomimetics: Decreased anti-hypertensive effect of quinapril

sodium aurothiomalate: Possibly nitritoid reactions such as facial flushing, nausea, vomiting, and hypotension

tetracyclines: Reduced tetracycline absorption

FOODS

low-salt milk, salt substitutes: Increased risk of hyperkalemia

ACTIVITIES

alcohol use: Additive hypotensive effects

Adverse Reactions

CNS: Depression, dizziness, drowsiness, fatigue, fever, headache, insomnia, light-headedness, malaise, paresthesia, sleep disturbance, syncope, vertigo

CV: Chest pain, hypotension, orthostatic hypotension, palpitations, tachycardia

EENT: Amblyopia, dry mouth, loss of taste, pharyngitis

GI: Abdominal pain, constipation, diarrhea, indigestion, nausea, vomiting

GU: Impotence

MS: Arthralgia, back pain, myalgia

RESP: Cough, dyspnea

SKIN: Alopecia, diaphoresis, flushing, photosensitivity, pruritus, rash, urticaria

Other: Anaphylaxis, angioedema

Nursing Considerations

- Use quinapril cautiously in patients with renal impairment.

WARNING Patients with heart failure, hyponatremia, or severe volume or salt depletion; those who've recently received intensive diuresis or an increase in diuretic dosage; and those undergoing dialysis may be at risk for excessive hypotension. Monitor blood pressure often for first 2 weeks of therapy and whenever quinapril or diuretic dosage increases. If excessive hypotension occurs, notify prescriber immediately, place patient in a supine position, and, if prescribed, infuse normal saline solution.

WARNING Because of the risk of angioedema, be prepared to discontinue drug and administer emergency measures, including subcutaneous epinephrine 1:1,000 (0.3 to 0.5 ml), if swelling of tongue, glottis, or larynx causes airway obstruction.

- Monitor blood pressure often to assess drug's effectiveness.

PATIENT TEACHING

- Instruct patient to notify prescriber immediately and stop taking quinapril if he has swelling of the face, eyes, lips, or tongue or difficulty breathing.
- Explain that drug may cause dizziness and

light-headedness, especially for first few days of therapy. Advise patient to avoid hazardous activities until drug's CNS effects are known and to notify prescriber if he faints.

- Inform woman of childbearing age of risks of taking quinapril during pregnancy, especially during the second and third trimesters. Caution her to use effective contraception and to notify prescriber immediately of known or suspected pregnancy.
- Advise patient having surgery or anesthesia to tell specialist that he takes quinapril.
- Instruct patient to consult prescriber before using potassium supplements or salt substitutes that contain potassium.

quinidine gluconate

Quinaglute Dura-tabs, Quinate (CAN), Quin-Release

quinidine**polygalacturonate**

Cardioquin

quinidine sulfate

Apo-Quinidine (CAN), Novoquinidin (CAN), Quinidex Extentabs

Class and Category

Chemical class: Dextrorotatory isomer of quinine

Therapeutic class: Class IA antiarrhythmic

Pregnancy category: C

Indications and Dosages

➤ To prevent or treat cardiac arrhythmias, including established atrial fibrillation, atrial flutter, paroxysmal atrial fibrillation, paroxysmal atrial tachycardia, paroxysmal atrioventricular junctional rhythm, paroxysmal ventricular tachycardia not associated with complete heart block, and premature atrial and ventricular contractions

E.R. TABLETS (QUINIDINE GLUCONATE)

Adults. 324 to 660 mg every 8 to 12 hr.
Maximum: 1,944 mg daily.

E.R. TABLETS (QUINIDINE SULFATE)

Adults. 300 to 600 mg every 8 to 12 hr.

TABLETS (QUINIDINE GLUCONATE)

Adults. *Initial:* 325 mg every 2 to 3 hr for 5 to 8 doses, gradually increasing dosage as needed and prescribed. *Maintenance:* 325 to 488 mg t.i.d. or q.i.d.

TABLETS (QUINIDINE POLYGALACTURONATE)

Adults. *Initial:* 275 to 825 mg every 3 to 4 hr for 3 or 4 doses, then increased by 137.5 to 275 mg every 3rd or 4th dose until rhythm is restored or toxic effects occur. *Maintenance:* 275 mg b.i.d. or t.i.d.

TABLETS (QUINIDINE SULFATE)

Adults. *Initial:* For premature atrial and ventricular contractions, 200 to 300 mg t.i.d. or q.i.d.; for paroxysmal supraventricular tachycardia, 400 to 600 mg every 2 to 3 hr until terminated; for atrial flutter, individual titration after digitalization; for conversion of atrial fibrillation, 200 mg every 2 to 3 hr for 5 to 8 doses, followed by subsequent daily increases, as needed.

Maintenance: 200 to 400 mg t.i.d. or q.i.d.

Children. 6 mg/kg 5 times daily.

I.V. INFUSION (QUINIDINE GLUCONATE)

Adults. 800 mg in 40 ml of D₅W at up to 0.25 mg/kg/min.

I.M. INJECTION (QUINIDINE SULFATE)

Adults. 190 to 380 mg every 2 to 4 hr. *Maximum:* 3 g daily.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	6–8 hr
P.O. (E.R.)	Unknown	Unknown	12 hr

Mechanism of Action

Depresses excitability, conduction velocity, and contractility of the myocardium and increases the effective refractory period, thus suppressing arrhythmic activity in the atria, ventricles, and His-Purkinje system.

Contraindications

Digitalis toxicity; history of quinidine-induced thrombocytopenic purpura or torsades de pointes; hypersensitivity to quinidine, other cinchona derivatives, or their components; long-QT syndrome; myasthenia gravis; pacemaker-dependent conduction disturbances

Interactions**DRUGS**

antiarrhythmics, phenothiazines, rauwolfia alkaloids: Additive cardiac effects

anticholinergics: Possibly intensified atropine-like adverse effects

antimyasthenics: Antagonized antimyasthenic effects on skeletal muscle

barbiturates, rifampin: Possibly accelerated elimination and decreased effectiveness of quinidine

cimetidine: Increased elimination half-life, possibly leading to quinidine toxicity

digoxin: Possibly digitalis toxicity

hepatic enzyme inducers: Possibly decreased blood quinidine level

neuromuscular blockers: Possibly potentiated neuromuscular blockade

oral anticoagulants: Additive hypoprothrombinemia, increased risk of bleeding

pimozide: Risk of arrhythmias

quinine: Increased risk of quinidine toxicity

urinary alkalinizers (such as antacids, carbonic anhydrase inhibitors, citrates, sodium bicarbonate, thiazide diuretics): Increased renal tubular reabsorption of quinidine, possibly leading to quinidine toxicity

verapamil: Possibly AV block, bradycardia, pulmonary edema, significant hypotension, and ventricular tachycardia

Adverse Reactions

CNS: Anxiety, asthenia, ataxia, confusion, delirium, difficulty speaking, dizziness, drowsiness, extrapyramidal reactions, fever, headache, hypertonia, syncope, vertigo

CV: Complete heart block, orthostatic hypotension, palpitations, peripheral edema, prolonged QT interval, torsades de pointes, vasculitis, ventricular arrhythmias, widening QRS complex

EENT: Blurred vision, change in color perception, diplopia, dry mouth, hearing loss (high-frequency), pharyngitis, photophobia, rhinitis, tinnitus

GI: Abdominal pain, anorexia, constipation, diarrhea, indigestion, nausea, vomiting

HEME: Agranulocytosis, hemolytic anemia, leukopenia, neutropenia, thrombocytopenia, thrombocytopenic purpura

MS: Arthralgia, myalgia

RESP: Dyspnea

SKIN: Diaphoresis, eczema, exfoliative dermatitis, flushing, hyperpigmentation, photosensitivity, pruritus, psoriasis, purpura, rash, urticaria

Other: Angioedema, flulike symptoms, weight gain

Nursing Considerations

- Give I.M. form of quinidine undiluted.
- For intermittent I.V. infusion, dilute drug in 40 ml of D₅W and administer using an infusion pump at a rate of 0.25 mg/kg/min or less. Rapid administration may cause hypotension. Monitor ECG tracings and blood pressure throughout administration.
- Monitor therapeutic blood level of quinidine, as ordered.
- Monitor heart rate and rhythm closely because quinidine may cause serious adverse reactions and can be cardiotoxic, especially at dosages exceeding 2.4 g daily. Implement continuous cardiac monitoring, as ordered.
- Assess for early signs and symptoms of cinchonism, including blurred vision, change in color perception, confusion, diplopia, headache, and tinnitus, which may indicate quinidine toxicity.

PATIENT TEACHING

- Advise patient to take quinidine at the same times every day and at evenly spaced intervals.
- Instruct patient to swallow E.R. tablets whole, with a full glass of water, preferably while sitting upright.
- Advise patient to take drug with food if GI upset occurs.
- Urge patient to inform prescriber immediately of blurred or double vision, change in color perception, confusion, diarrhea, fever, headache, loss of hearing, or tinnitus.

quinine sulfate

Class and Category

Chemical class: Cinchona alkaloid

Therapeutic class: Antimalarial

Pregnancy category: X

Indications and Dosages

↗ *As adjunct to treat chloroquine-resistant malaria caused by Plasmodium falciparum*

CAPSULES, TABLETS

Adults. 600 to 650 mg every 8 hr for at least 3 days with one of the following: 250 mg of tetracycline every 6 hr for 7 days; 1.5 g of

sulfadoxine and 75 mg of pyrimethamine combined as a single dose; 900 mg of clindamycin every 8 hr for 3 days; or 100 mg of doxycycline every 12 hr for 7 days.

Children over age 8. 8.3 mg/kg every 8 hr for at least 3 days with one of the following: 5 mg/kg of tetracycline every 6 hr for 7 days; 6.7 to 13.3 mg/kg of clindamycin every 8 hr for 3 days; or 1.25 mg/kg of pyrimethamine and 25 mg/kg of sulfadoxine combined as a single dose.

Mechanism of Action

May disrupt function in malarial parasite by elevating intracellular pH in parasitic acid vesicles.

Contraindications

G6PD deficiency, history of quinine-induced blackwater fever or thrombocytopenic purpura, hypersensitivity to quinine or its components, optic neuritis, pregnancy, tinnitus

Interactions

DRUGS

acetazolamide, sodium bicarbonate:

Increased risk of quinine toxicity
aluminum-containing antacids: Possibly delayed or decreased quinine absorption
aminophylline, theophylline: Possibly increased quinine adverse effects

antimythasthenics: Possibly antagonized antimythasthenic effect on skeletal muscle
astemizole, cisapride, halofantrine, mefloquine, pimoizide, quinidine, terfenadine:

Increased risk of prolonged QT interval
atorvastatin: Increased blood atorvastatin level; increased risk of myopathy or rhabdomyolysis

carbamazepine, phenobarbital, phenytoin: Possibly increased blood level of these drugs; possibly decreased blood quinine level

cimetidine: Possibly reduced quinine clearance

debrisoquine, desipramine, dextromethorphan, flecainide, metoprolol, paroxetine: Possibly increased blood levels of these drugs; increased risk of adverse reactions

digoxin: Increased blood digoxin level
erythromycin, ketoconazole, troleandomycin: Possibly increased blood quinine level
hemolytics, neurotoxic drugs, ototoxic drugs:

Increased risk of toxicity of these drugs
hepatic enzyme inducers, rifampin: Possibly decreased blood quinine level
mefloquine: Increased risk of seizures
neuromuscular blockers: Potentiated neuromuscular blockade
oral anticoagulants: Possibly increased anti-coagulant effects and risk of bleeding

Adverse Reactions

CNS: Headache

EENT: Blurred vision, hearing loss, tinnitus, vision changes

ENDO: Hypoglycemia

GI: Abdominal or epigastric pain, diarrhea, nausea, vomiting

HEME: Thrombocytopenia

Nursing Considerations

- Be aware that quinine shouldn't be used in patients with blackwater fever, which can follow chronic malaria, because they're at increased risk for anemia and hemolysis with renal failure. Quinine also isn't recommended for treating or preventing nocturnal leg cramps because life-threatening hematologic reactions have occurred with potential for chronic renal impairment.
- Be aware that quinine shouldn't be given I.M. Doing so may cause bleeding, bruising, or hematomas because of quinine's effect on platelets.
- Monitor patient with type 2 diabetes mellitus for alterations in blood glucose level because quinine stimulates release of insulin and may promote hypoglycemia.
- Be aware that quinine can exacerbate optic neuritis or tinnitus. It may also exacerbate muscle weakness and cause dysphagia and respiratory distress in myasthenic patients.
- Assess for early signs and symptoms of cinchonism, including blurred vision, confusion, diplopia, fever, headache, loss of hearing, and tinnitus, which may indicate quinine toxicity.
- Be aware that patients who develop quinine-dependent antibodies could develop thrombocytopenia more rapidly and more severely upon re-exposure to quinine from any source.

PATIENT TEACHING

- Instruct patient not to crush or chew quinine tablets; they taste bitter and can irritate the mouth and throat.
- Advise patient to take drug with food or

after meals to minimize GI irritation.

- Urge patient to notify prescriber immediately if he experiences blurred or double vision, confusion, fever, headache, loss of hearing, or tinnitus, which are indicators of quinine toxicity.
- Advise patient to avoid hazardous activities until he knows how quinine affects him.

rabeprazole sodium

AcipHex

Class and Category

Chemical class: Substituted benzimidazole

Therapeutic class: Antiulcer

Pregnancy category: B

Indications and Dosages

↗ *To provide short-term treatment of erosive esophagitis or ulcerative gastroesophageal reflux disease (GERD)*

DELAYED-RELEASE TABLETS

Adults. For mild to moderate disease, 20 mg daily for 4 to 8 wk; course may be repeated if healing has not occurred at the end of 8 wk. For severe reflux with ulceration or stricture formation, 40 mg daily for 4 to 8 wk.

↗ *To treat symptomatic GERD*

DELAYED-RELEASE TABLETS

Adults and adolescents age 12 and over.

20 mg daily for 4 wk. Course may be repeated if symptoms aren't completely resolved.

↗ *To provide maintenance treatment of erosive esophagitis or GERD*

DELAYED-RELEASE TABLETS

Adults. 20 mg daily.

↗ *To promote healing of duodenal ulcer, as adjunct to treat Helicobacter pylori-positive duodenal ulcer*

DELAYED-RELEASE TABLETS

Adults. 20 mg daily after breakfast for up to 4 wk for ulcer healing and 2 wk when used with antibiotic therapy for *H. pylori*.

↗ *As adjunct to reduce the risk of duodenal ulcer recurrence by eradicating *H. pylori**

DELAYED-RELEASE TABLETS

Adults. 20 mg b.i.d with morning and evening meals in conjunction with amoxi-

cillin 1000 mg b.i.d for 7 days and clarithromycin 500 mg b.i.d. for 7 days.

➤ *To treat hypersecretory conditions, such as Zollinger-Ellison syndrome*

DELAYED-RELEASE TABLETS

Adults. *Initial:* 60 mg daily; may be increased, if needed, to 100 mg daily or 60 mg b.i.d.

DOSE ADJUSTMENT Dosage reduction may be needed in severe hepatic dysfunction.

Mechanism of Action

Decreases gastric acid secretion by suppressing its release at the secretory surface of gastric parietal cells. Rabeprazole also increases gastric pH and decreases basal acid output, which helps to heal ulcerated areas. In gastric parietal cells, it's transformed to an active sulfonamide, which increases the clearance rate of *Helicobacter pylori*.

Contraindications

Hypersensitivity to rabeprazole, other substituted benzimidazoles (omeprazole, lansoprazole), or their components

Interactions

DRUGS

cyclosporine: Possibly inhibited cyclosporine metabolism

digoxin: Increased risk of digitalis toxicity

warfarin: Possibly increased PT, INR

Adverse Reactions

CNS: Coma, delirium, disorientation, dizziness, headache, malaise

GI: Abdominal pain, diarrhea, jaundice, nausea, vomiting

GU: Interstitial nephritis

HEME: Agranulocytosis, hemolytic anemia, leukopenia, pancytopenia, thrombocytopenia

MS: Rhabdomyolysis

RESP: Interstitial pneumonia

SKIN: Erythema multiforme, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, angioedema, hyperamonemia

Nursing Considerations

- Use rabeprazole cautiously in patients with hepatic dysfunction.
- Expect to monitor serum gastrin level in long-term therapy to detect elevation.

- Closely monitor Japanese men receiving rabeprazole for adverse reactions because they're more likely than other patients to have increased blood drug levels.

PATIENT TEACHING

- Instruct patient to swallow delayed-release rabeprazole tablets whole.
- Inform patients with hypersecretory conditions, such as Zollinger-Ellison syndrome, that treatment can last as long as 1 year.

raloxifene hydrochloride (keoxifene hydrochloride)

Evista

Class and Category

Chemical class: Benzothiophene derivative

Therapeutic class: Osteoporosis prophylactic

Pregnancy category: X

Indications and Dosages

➤ *To prevent osteoporosis in postmenopausal women; to reduce risk of invasive breast cancer in postmenopausal women with osteoporosis; to reduce risk of invasive breast cancer in postmenopausal women at high risk*

TABLETS

Adults. 60 mg daily.

Mechanism of Action

Prevents osteoporosis by binding to estrogen receptors, which decreases bone resorption and increases bone mineral density in postmenopausal women.

Contraindications

History of thromboembolic disease, hypersensitivity to raloxifene or its components, pregnancy

Interactions

DRUGS

ampicillin, cholestyramine: Decreased raloxifene absorption

warfarin: Possibly decreased PT

Adverse Reactions

CNS: Depression, fever, insomnia, migraine, stroke

CV: Chest pain, hot flashes, peripheral edema, thromboembolism, thrombophlebitis

EENT: Laryngitis, pharyngitis, sinusitis

ENDO: Hot flashes

GI: Abdominal pain, cholelithiasis, flatulence, indigestion, nausea, vomiting

GU: Cystitis, infertility, leukorrhea, UTI, vaginitis

MS: Arthralgia, arthritis, leg cramps or spasms, myalgia

RESP: Cough, pneumonia, pulmonary embolism

SKIN: Diaphoresis, rash

Other: Flulike symptoms, weight gain

Nursing Considerations

- Use cautiously in patients who smoke or have a history of stroke, TIA, atrial fibrillation, or hypertension because raloxifene may increase the risk of stroke.
- Use cautiously in patients with renal impairment because effects of raloxifene on renal system are unknown.

WARNING Monitor patient's limbs for impaired circulation and pain (possible thromboembolism).

- Expect prescriber to stop drug at least 72 hours before and during periods of prolonged immobilization. Resume raloxifene therapy as prescribed after patient is fully ambulatory.

PATIENT TEACHING

- Advise patient to avoid lengthy immobility during travel while taking raloxifene because of the increased risk of thromboembolism.
- Instruct patient to report adverse reactions to prescriber immediately, especially leg pain or swelling, sudden chest pain, shortness of breath, coughing up blood, or a sudden change in vision.
- Stress the importance of compliance with long-term raloxifene therapy.
- Advise patient that postmenopausal women require an average of 1,500 mg of elemental calcium and 400 to 800 international units of vitamin D daily. Vitamin D requirement is increased in women over age 70, women with GI malabsorption syndromes, and women who are chronically ill or nursing home bound. Review dietary sources of calcium and vitamin D, and have patient discuss supplements with prescriber, as needed.

ramelteon

Zorozerem

Class and Category

Chemical class: Melatonin receptor agonist

Therapeutic class: Hypnotic

Pregnancy category: C

Indications and Dosages

↗ To treat insomnia in patients having difficulty falling asleep

TABLETS

Adults. 8 mg 30 min before at bedtime.

Route	Onset	Peak	Duration
P.O.	Unknown	0.5–1.5 hr	Unknown

Mechanism of Action

Binds to melatonin receptors MT1 and MT2 in the suprachiasmatic nucleus (SCN) of the hypothalamus. The SCN regulates the sleep-wake cycle, and endogenous melatonin probably is involved in maintaining the circadian rhythm underlying that cycle.

Contraindications

Concurrent therapy with fluvoxamine, history of angioedema with previous ramelteon treatment, hypersensitivity to ramelteon or its components, severe hepatic dysfunction

Interactions

DRUGS

benzodiazepines, melatonin, other sedative-hypnotics: Possible additive sedative effects

fluconazole, fluvoxamine, ketoconazole:

Increased plasma ramelteon levels

rifampin: Decreased ramelteon effectiveness

ACTIVITIES

alcohol use: Possibly additive CNS effect

Adverse Reactions

CNS: Agitation, amnesia, anxiety, bizarre behavior, complex behaviors such as sleep driving, depression, dizziness, fatigue, hallucinations, headache, insomnia exacerbation, mania, somnolence, suicidal ideation

EENT: Throat tightness

ENDO: Decreased testosterone level, increased prolactin level

GI: Diarrhea, dysgeusia, nausea, vomiting

MS: Arthralgia, myalgia

RESP: Dyspnea, upper respiratory tract

infection

Other: Anaphylaxis, angioedema

Nursing Considerations

- Be aware that ramelteon therapy is not recommended for patients with severe sleep apnea or COPD because its effects have not been studied in these patient populations.
- Use cautiously in patients with mild to moderate hepatic dysfunction. Drug is contraindicated in severe hepatic dysfunction.

- Ramelteon is the first approved hypnotic not classified as a controlled substance.

WARNING Monitor patient closely for hypersensitivity reactions such as dyspnea, throat tightness, nausea, vomiting, and swelling. If present, discontinue ramelteon immediately, notify prescriber, and provide supportive care.

- Watch patient closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.

PATIENT TEACHING

- Instruct patient not to take ramelteon with or immediately after eating a high-fat meal.
- Caution patient to avoid potentially hazardous activities after taking ramelteon; drug's intended effect is to decrease alertness.
- Advise patient that drug may cause abnormal behaviors during sleep, such as driving a car, eating, talking on the phone, or having sex without any recall of the event. If family members notice any such behavior or patient sees evidence of such behavior upon awakening, prescriber should be notified.
- Advise limiting alcohol during therapy.
- Tell patient to notify prescriber if insomnia worsens or new signs or symptoms occur.
- Inform patient that drug may affect reproductive hormones; urge patient to report cessation of menses or galactorrhea (females) or decreased libido or problems with infertility.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.

ramipril

Altace

Class and Category

Chemical class: Ethylester of ramiprilat

Therapeutic class: Antihypertensive

Pregnancy category: C (first trimester), D (later trimesters)

Indications and Dosages

↗ *To treat heart failure after MI*

CAPSULES

Adults. *Initial:* 1.25 to 2.5 mg b.i.d.

Maintenance: 5 mg b.i.d.

↗ *To treat hypertension*

CAPSULES

Adults. *Initial:* 2.5 mg daily. *Maintenance:* 2.5 to 20 mg once daily or in divided doses b.i.d.

DOSE ADJUSTMENT Initial dosage reduced to 1.25 mg daily for patients dehydrated from diuretics, those receiving diuretics, and those with creatinine clearance less than 40 ml/min/1.73 m²; dosage then slowly increased until blood pressure is under control or maximum daily dose of 5 mg is reached.

Route	Onset	Peak	Duration
P.O.	1–2 hr	4–6.5 hr	24 hr

Mechanism of Action

Blocks conversion of angiotensin I to angiotensin II, causing vasodilation, and reduces aldosterone secretion, which prevents water retention. Ramipril also reduces peripheral arterial resistance. Combined, these actions reduce blood pressure.

Contraindications

Hypersensitivity to ramipril, its components, or any other ACE inhibitors

Interactions

DRUGS

allopurinol, bone marrow depressants, corticosteroids (systemic), procainamide:

Increased risk of fatal neutropenia or agranulocytosis

CNS depressants, other hypotension-producing drugs: Additive hypotensive effect

cyclosporine, potassium preparations,

potassium-sparing diuretics: Possibly hyperkalemia

insulin, oral antidiabetics: Increased risk of hypoglycemia

lithium: Increased risk of lithium toxicity

NSAIDs, sympathomimetics: Decreased antihypertensive effect of ramipril

sodium aurothiomalate: Increased risk of nitritoid reaction (facial flushing, nausea, vomiting, hypotension)

telmisartan: Possibly increased risk of adverse effects, especially renal dysfunction

tetracyclines: Reduced tetracycline absorption

FOODS

low-salt milk, salt substitutes: Increased risk of hyperkalemia

ACTIVITIES

alcohol use: Additive hypotensive effects

Adverse Reactions

CNS: Depression, dizziness, drowsiness, fatigue, fever, headache, insomnia, light-headedness, malaise, paresthesia, sleep disturbance, syncope, vertigo

CV: Chest pain, hypotension, orthostatic hypotension, palpitations, tachycardia

EENT: Amblyopia, dry mouth, loss of taste, pharyngitis

GI: Abdominal pain, constipation, diarrhea, elevated liver function test results, hepatic failure, hepatitis, nausea, vomiting

GU: Acute renal failure, elevated BUN and serum creatinine levels, impotence, oliguria, progressive azotemia

HEME: Agranulocytosis, anemia, bone marrow depression, pancytopenia

MS: Arthralgia, back pain, myalgia

RESP: Cough, dyspnea

SKIN: Alopecia, diaphoresis, flushing, jaundice, onycholysis, pemphigoid, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Angioedema

Nursing Considerations

- Use ramipril cautiously in patients with renal or hepatic impairment.

WARNING Patients with dehydration, heart failure, or hyponatremia; those who've recently received intensive diuresis or an increase in diuretic dosage; and those having dialysis may risk excessive hypotension. Monitor such patients closely the first 2 weeks of therapy and whenever ramipril or diuretic dosage increases. If

excessive hypotension occurs, notify prescriber immediately, place patient in a supine position, and, if prescribed, infuse normal saline solution.

WARNING Because of the risk of angioedema, be prepared to stop drug and provide emergency measures, including subcutaneous epinephrine 1:1,000 (0.3 to 0.5 ml), if swelling of tongue, glottis, or larynx causes airway obstruction.

- Monitor blood pressure frequently during therapy to assess drug's effectiveness.

- Monitor patient's renal and hepatic function closely during therapy.

PATIENT TEACHING

- Advise patient to stop taking ramipril and inform prescriber immediately if she experiences swelling of the face, eyes, lips, or tongue or has difficulty breathing.

- Explain that drug may cause dizziness and light-headedness, especially during first few days of therapy. Instruct patient to notify prescriber immediately if she faints.

- Inform female patient of childbearing age of the risks of taking ramipril during pregnancy. Caution patient to use effective contraception and to report known or suspected pregnancy immediately.

- Urge patient to tell providers that she takes ramipril before having surgery or anesthesia.

- Tell patient to ask prescriber before using supplements or salt substitutes that contain potassium.

ranitidine hydrochloride

Apo-Ranitidine (CAN), Gen-Ranitidine (CAN), Novo-Ranitidine (CAN), Nu-Ranit (CAN), Zantac, Zantac EFFERdose Tablets, Zantac 150 GELdose, Zantac 300 GELdose

Class and Category

Chemical class: Aminoalkyl-substituted furan derivative

Therapeutic class: Antiulcer agent, gastric acid secretion inhibitor

Pregnancy category: B

Indications and Dosages

↗ To prevent duodenal and gastric ulcers

CAPSULES, EFFERVESCENT GRANULES, EFFERVESCENT TABLETS, SYRUP, TABLETS

Adults and adolescents. 150 mg at bedtime.

↗ *To provide short-term treatment of active duodenal and benign gastric ulcers*

CAPSULES, EFFERVESCENT GRANULES, EFFERVESCENT TABLETS, SYRUP, TABLETS

Adults and adolescents. 150 mg b.i.d. for gastric ulcers; 150 mg b.i.d. or 300 mg at bedtime for duodenal ulcers.

Children ages 1 month to 16 years. 2 to 4 mg/kg b.i.d. up to 300 mg daily.

Maintenance: 2 to 4 mg/kg daily up to 150 mg daily.

CONTINUOUS I.V. INFUSION

Adults and adolescents. 6.25 mg/hr.

Maximum: 400 mg daily.

INTERMITTENT I.V. INFUSION

Adults and adolescents. 50 mg diluted to total volume of 100 ml and infused over 15 to 20 min every 6 to 8 hr. Maximum: 400 mg daily.

Children. 2 to 4 mg/kg daily diluted to a suitable volume and infused over 15 to 20 min.

I.V. INJECTION

Adults and adolescents. 50 mg diluted to total volume of 20 ml and injected slowly over no less than 5 min every 6 to 8 hr.

Maximum: 400 mg daily.

I.M. INJECTION

Adults and adolescents. 50 mg every 6 to 8 hr. Maximum: 400 mg daily.

↗ *To treat acute gastroesophageal reflux disease*

CAPSULES, EFFERVESCENT GRANULES, EFFERVESCENT TABLETS, SYRUP, TABLETS

Adults and adolescents. 150 mg b.i.d.

EFFERVESCENT TABLETS

Children ages 1 month to 16 years. 2.5 to 5 mg/kg b.i.d.

INTERMITTENT I.V. INFUSION

Children. 2 to 8 mg/kg diluted to suitable volume and infused over 15 to 20 min t.i.d.

↗ *To treat erosive esophagitis*

CAPSULES, EFFERVESCENT GRANULES, EFFERVESCENT TABLETS, SYRUP, TABLETS

Adults and adolescents. 150 mg q.i.d.

EFFERVESCENT TABLETS

Children ages 1 month to 16 years. 2.5 to 5 mg/kg b.i.d.

↗ *To treat hypersecretory GI conditions,*

such as Zollinger-Ellison syndrome, systemic mastocytosis, and multiple endocrine adenoma syndrome

CAPSULES, EFFERVESCENT GRANULES, EFFERVESCENT TABLETS, SYRUP, TABLETS

Adults and adolescents. Initial: 150 mg b.i.d., adjusted as needed. Maximum: 6 g daily in divided doses.

CONTINUOUS I.V. INFUSION

Adults and adolescents. Initial: 1 mg/kg/hr, increased by 0.5 mg/kg/hr up to 2.5 mg/kg/hr. Maximum: 400 mg daily.

INTERMITTENT I.V. INFUSION

Adults. 50 mg diluted to total volume of 100 ml and infused over 15 to 20 min every 6 to 8 hr. Maximum: 400 mg daily.

I.V. INJECTION

Adults and adolescents. 50 mg diluted to total of 20 ml and injected slowly over at least 5 min every 6 to 8 hr. Maximum: 400 mg daily.

I.M. INJECTION

Adults. 50 mg every 6 to 8 hr.

↗ *To prevent acid indigestion, heartburn, and sour stomach caused by eating certain foods or drinking certain beverages*

TABLETS

Adults and adolescents. 75 mg 30 to 60 min before food or beverages expected to cause symptoms. Maximum: 150 mg daily over no more than 2 continuous wk.

↗ *To treat acid indigestion, heartburn, and sour stomach*

TABLETS

Adults and adolescents. 75 mg when symptoms start; repeated once within 24 hr, if needed.

DOSAGE ADJUSTMENT For patients whose creatinine clearance is less than 50 ml/min/1.73 m², 150 mg P.O. every 24 hr with dosage interval increased thereafter to every 12 hr, as needed. Or 50 mg I.V. every 18 to 24 hr with dosage interval increased to every 12 hr, as needed. Dosage reduction may also be necessary for patients with hepatic dysfunction.

Route	Onset	Peak	Duration
P.O., I.V., I.M.	Unknown	1–3 hr	13 hr

Mechanism of Action

Inhibits basal and nocturnal secretion of

gastric acid and pepsin by competitively inhibiting the action of histamine at H₂ receptors on gastric parietal cells. This action reduces total volume of gastric juices and, thus, irritation of GI mucosa.

Contraindications

Acute porphyria, hypersensitivity to ranitidine or its components

Interactions

DRUGS

antacids: Decreased ranitidine absorption
atazanavir, delavirdine, diazepam, gefitinib, itraconazole, ketoconazole, sucralfate: Decreased absorption of these drugs

bone marrow depressants: Increased risk of neutropenia or other blood dyscrasias
glipizide, glyburide, metoprolol, midazolam, nifedipine, phenytoin, theophylline, triazolam: Increased effects of these drugs, possibly leading to toxic reactions

procainamide: Possibly increased risk of procainamide toxicity

warfarin: Possibly altered PT

ACTIVITIES

alcohol use: Increased blood alcohol level (with oral ranitidine)

Adverse Reactions

CNS: Dizziness, drowsiness, fever, headache, insomnia

CV: Vasculitis

GI: Abdominal distress, constipation, diarrhea, nausea, vomiting

GU: Acute interstitial nephritis, impotence

MS: Arthralgia, myalgia

RESP: Bronchospasm

SKIN: Alopecia, erythema multiforme, rash

Other: Anaphylaxis, angioedema

Nursing Considerations

- Be aware that ranitidine must be diluted for I.V. use if not using premixed solution. For I.V. injection, dilute to total of 20 ml with normal saline solution, D₅W, D₁₀W, lactated Ringer's solution, or 5% sodium bicarbonate. For I.V. infusion, dilute to total volume of 100 ml of same solutions.
- Give I.V. injection at no more than 4 ml/min, intermittent I.V. infusion at 5 to 7 ml/min, and continuous I.V. infusion at 6.25 mg/hr (except with hypersecretory conditions, when initial infusion rate is 1 mg/kg/hr, gradually increased after 4 hours, as needed, in increments of

0.5 mg/kg/hr).

- Don't add additives to premixed solution.
- Stop primary I.V. solution infusion during piggyback administration.

PATIENT TEACHING

- Tell patient to dissolve 150-mg effervescent tablets or granules in 6 to 8 oz water or 25-mg effervescent tablets in at least 5 ml water.
- Advise patient (or parent) to wait until effervescent tablet is completely dissolved before taking (or giving to child or infant).
- Caution patient not to chew effervescent tablets, swallow them whole, or let them dissolve on the tongue.
- Alert patients with phenylketonuria that effervescent tablets and granules contain phenylalanine.
- Tell patient that she may take drug with food.
- Tell patient to stop taking ranitidine and contact prescriber if she has trouble swallowing, vomits blood, or passes black or bloody stools.
- If needed, advise patient to take antacids, 2 hours before or after ranitidine; advise against taking other acid reducers with drug.
- If patient takes drug to prevent heartburn, tell her to contact prescriber about frequent chest pain or wheezing with heartburn; stomach pain; unexplained weight loss; nausea; vomiting; heartburn lasting more than 3 months; heartburn with light-headedness, dizziness, or sweating; chest or shoulder pain with shortness of breath, sweating, light-headedness, or pain spreading to arms, neck, or shoulders. These problems may be serious.
- Inform patient that healing of an ulcer may require 4 to 8 weeks of therapy.

ranolazine

Ranexa

Class and Category

Chemical class: Piperazineacetamide

Therapeutic class: Antianginal

Pregnancy category: C

Indications and Dosages

↗ *To treat chronic angina*

E.R. TABLETS

Adults. *Initial:* 500 mg b.i.d., increased to 1,000 mg b.i.d., as needed. *Maximum:* 1,000 mg b.i.d.

DOSE ADJUSTMENT For patients taking a moderate CYP3A inhibitor, such as diltiazem or verapamil, maximum dosage reduced to 500 mg b.i.d. For patients taking cyclosporine, dosage reduced according to clinical response

Route	Onset	Peak	Duration
P.O.	Unknown	2–5 hr	Unknown

Mechanism of Action

Exerts anti-ischemic and antianginal effects by an unknown mechanism not dependent on reductions in heart rate or blood pressure. Ranolazine inhibits cardiac late sodium current, but how this action inhibits angina symptoms is also unknown.

Contraindications

Hypersensitivity to ranolazine or its components, hepatic impairment, QT-interval prolongation, torsades de pointes, use of CYP3A inducers or strong inhibitors

Interactions**DRUGS**

CYP3A inducers, such as carbamazepine, phenobarbital, phenytoin, rifabutin, rifampin, rifapentin, St. John's wort: Decreased blood ranolazine level and decreased effectiveness

CYP3A substrates, such as cyclosporine: Possibly increased cyclosporine level
CYP3A inhibitors, such as clarithromycin, diltiazem, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, verapamil: Increased blood ranolazine level and increased risk of adverse reactions
digoxin: Increased blood digoxin level

Adverse Reactions

CNS: Asthenia, confusion, dizziness, headache, hypoesthesia, paresthesia, tremor, vertigo

CV: Bradycardia, hypotension, orthostatic hypotension, palpitations, peripheral edema, QT-interval prolongation

EENT: Blurred vision, dry mouth, tinnitus

GI: Abdominal pain, constipation, nausea, vomiting

GU: Elevated creatinine level, hematuria, renal failure

HEME: Eosinophilia, leukopenia, pancytopenia, thrombocytopenia

RESP: Dyspnea, pulmonary fibrosis

Other: Angioedema

Nursing Considerations

- Monitor patient's QT interval, as ordered, because ranolazine prolongs it in a dose-related manner.
- Assess effectiveness of ranolazine in preventing anginal pain.
- Monitor patient's serum creatinine, BUN, magnesium, potassium, and liver enzyme levels.

PATIENT TEACHING

- Instruct patient to take ranolazine exactly as prescribed.
- Inform patient that drug may be taken with or without food.
- Caution patient to swallow tablets whole and not to crush, break, or chew them.
- Advise patient to limit the amount of grapefruit and grapefruit juice consumed while taking this drug.
- Advise patient to notify prescriber if serious or persistent adverse reactions occur.

rasagiline

Azilect

Class and Category

Chemical class: Propargylamine

Therapeutic class: Irreversible MAO inhibitor

Pregnancy category: C

Indications and Dosages

➤ *To treat idiopathic Parkinson's disease as initial monotherapy in early-stage disease*

TABLETS

Adults. 1 mg once daily.

➤ *As adjunct with levodopa or levodopa and carbidopa in treatment of later-stage idiopathic Parkinson's disease*

TABLETS

Adults. 0.5 mg once daily increased to 1 mg once daily, as needed.

DOSE ADJUSTMENT For patients with mild hepatic failure, dosage shouldn't exceed 0.5 mg daily.

Mechanism of Action

Inhibits metabolic degradation of catecholamines and serotonin in the CNS and peripheral tissues, increasing extracellular dopamine level in the striatum. The increased dopamine level helps control alterations in voluntary muscle movement (such as tremors and rigidity) in Parkinson's disease because dopamine, a neurotransmitter, is essential for normal motor function. By stimulating peripheral and central dopaminergic 2 (D_2) receptors on postsynaptic cells, dopamine inhibits firing of striatal neurons (such as cholinergic neurons), improving motor function.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	Unknown

Contraindications

Acute MI; angina; cardiac arrhythmias; coronary artery disease; cerebrovascular disease; elective surgery that requires general anesthesia; hypersensitivity to rasagiline or its components; pheochromocytoma; moderate to severe hepatic impairment; stroke; use within 14 days of cyclobenzaprine, dextromethorphan, MAO inhibitors, meperidine, mirtazapine, tramadol, methadone, propoxyphene, St. John's wort, or sympathomimetic amines

Interactions

DRUGS

ciprofloxacin and other CYP1A2 inhibitors:

Increased rasagiline plasma level

dextromethorphan: Increased risk of psychosis or bizarre behavior

levodopa, levodopa and carbidopa: Increased risk of dyskinesias

MAO inhibitors, sympathomimetics:

Increased risk of hypertensive crisis

meperidine, methadone, propoxyphene, tramadol: Increased risk of life-threatening adverse reactions characterized by coma,

severe hypertension or hypotension, severe respiratory depression, seizures, malignant hyperpyrexia, excitation, and peripheral vascular collapse

selective serotonin reuptake inhibitors, tetracyclic antidepressants, tricyclic antidepressants: Increased risk of severe CNS toxicity with hyperpyrexia, behavioral and mental status changes, diaphoresis, muscle rigidity,

hypertension, syncope, and possible death

Adverse Reactions

CNS: Abnormal dreams, amnesia, anxiety, asthenia, ataxia, cerebral ischemia, coma, confusion, depression, difficulty thinking, dizziness, dyskinesia, dystonia, fever, hallucinations, headache, malaise, manic depressive reaction, nightmares, paresthesia, seizures, somnolence, stroke, stupor, syncope, vertigo

CV: Angina, bundle branch heart block, chest pain, heart failure, MI, hypertensive crisis, postural hypotension, thrombophlebitis, ventricular tachycardia or fibrillation

EENT: Blurred vision, conjunctivitis, dry mouth, gingivitis, hemorrhage, laryngeal edema, retinal detachment or hemorrhage, rhinitis

GI: Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, dysphagia, epistaxia, gastroenteritis, gastrointestinal hemorrhage, intestinal obstruction or perforation, liver function test abnormalities, nausea, vomiting

GU: Acute renal failure, albuminuria, decreased libido, hematuria, impotence, incontinence, priapism

HEME: Anemia, leukopenia, thrombocytopenia

MS: Arthralgia, arthritis, bone necrosis, bursitis, leg cramps, myasthenia, neck pain or stiffness, tenosynovitis

RESP: Apnea, asthma, cough, dyspnea, pleural effusion, pneumothorax, interstitial pneumonia

SKIN: Alopecia, carcinoma, diaphoresis, ecchymosis, exfoliative dermatitis, pruritus, ulcer, vesiculobullous rash

Other: Angioedema, flu syndrome, hypersensitivity reaction, hypocalcemia, weight loss

Nursing Considerations

WARNING Notify prescriber immediately if patient has evidence of hypertensive crisis, such as blurred vision, chest pain, difficulty thinking, stupor or coma, seizures, severe headache, neck stiffness, nausea, vomiting, palpitations or signs and symptoms suggesting a stroke. Expect to stop drug immediately if these occur.

- Keep phentolamine readily available to treat hypertensive crisis. Give 5 mg by slow

I.V. infusion, as prescribed, to reduce blood pressure without causing excessive hypotension. Use external cooling measures, as prescribed, to manage fever.

- Monitor patient receiving rasagline with levodopa for worsening of pre-existing dyskinesia. If it occurs, notify prescriber and expect levodopa dosage to be decreased.

PATIENT TEACHING

WARNING Inform patient taking recommended dosage of rasagline that dietary tyramine restriction is no longer needed except for avoidance of very tyramine-rich foods such as aged cheese (e.g., Stilton), which may increase blood pressure greatly. If patient doesn't feel well soon after eating a suspected high-tyramine meal, he should contact prescriber immediately.

- Advise patient to stop taking rasagline and to notify prescriber immediately if he develops blurred vision, chest pain, trouble thinking, stupor or coma, seizures, severe headache, stiff neck, nausea, vomiting, palpitations, or evidence of stroke.
- Suggest that patient change position slowly to minimize orthostatic hypotension.
- Alert patient that drug may cause hallucinations. If they occur, tell patient to notify prescriber promptly.
- Instruct patient to notify all prescribers of rasagline therapy, especially if antidepressants or antibiotics such as ciprofloxacin or a similar drug are being considered, and to avoid taking any over the counter cold medications.

rasburicase

Elitek

Class and Category

Chemical class: Tetrameric protein

Therapeutic class: Uric acid reducer

Pregnancy category: C

Indications and Dosages

➤ *To manage plasma uric acid levels initially in patients with leukemia, lymphoma, or solid tumor malignancies who receive anticancer therapy that elevates plasma uric acid*

I.V. INFUSION

Adults and children. 0.20 mg/kg infused

over 30 min daily for 5 days.

Mechanism of Action

Converts uric acid into an inactive and soluble metabolite at the end of the purine catabolic pathway. This prevents plasma uric acid levels from rising due to tumor lysis from anticancer therapy.

Contraindications

Glucose-6-phosphatase dehydrogenase (G6PD) deficiency; history of anaphylaxis or hypersensitivity reactions, hemolytic reactions, or methemoglobinemia reactions; hypersensitivity to rasburicase or its components

Adverse Reactions

CNS: Anxiety, fever, headache, paresthesia, rigors, seizures

CV: Arrhythmia, cardiac failure or arrest, cerebrovascular disorder, chest pain, hemorrhage, hypotension, myocardial infarction, pulmonary edema, thrombophlebitis, thrombosis

EENT: Mucositis, retinal hemorrhage

ENDO: Hot flashes

GI: Abdominal pain, constipation, diarrhea, ileus, intestinal obstruction, nausea, vomiting

GU: Acute renal failure

HEME: Anemia, hemolysis, methemoglobinemia, neutropenia, pancytopenia

RESP: Cyanosis, dyspnea, pneumonia, pulmonary hypertension, respiratory distress

SKIN: Cellulitis, rash

Other: Anaphylaxis, dehydration, infection, sepsis

Nursing Considerations

- Be aware that children at high risk for G6PD deficiency, such as patients of African or Mediterranean ancestry, should be screened before administering rasburicase because severe hemolysis can occur.
- Expect to give only one course of therapy because of risk of severe allergic reactions.
- Reconstitute rasburicase using only diluent provided. Add 1 ml of diluent to each vial needed, and mix by swirling very gently. Don't shake or invert vial.
- Inject reconstituted solution into an infusion bag containing the appropriate volume of normal saline solution to obtain a final volume of 50 ml. Infuse over 30 minutes in a different line than for infusion of

other drugs. If a separate line isn't possible, flush the line with at least 15 ml of normal saline solution before and after rasburicase infusion. Don't use filters.

- Store reconstituted solution at 2° to 8° C (36° to 46° F) for no longer than 24 hours. Protect drug from light.

WARNING Monitor patient closely for severe hypersensitivity reactions, including anaphylaxis (chest pain, dyspnea, hypotension, urticaria), hemolysis (severe anxiety, pain, dyspnea), and methemoglobinemia (anxiety, hypoxemia, shortness of breath). If such a reaction occurs, discontinue rasburicase immediately, notify prescriber, and start emergency treatment. Rasburicase shouldn't be restarted after such a reaction occurs.

- Ensure that blood samples to measure uric acid levels are collected in chilled tubes containing heparin anticoagulant and are immediately placed in ice water until analysis is done (within 4 hours); blood samples left at room temperature will result in low uric acid levels because of enzyme degradation of uric acid at room temperature.

PATIENT TEACHING

- Explain to child and parents that chemotherapy will start 4 to 24 hours after rasburicase.
- Stress the importance of reporting any adverse reaction immediately.

remifentanyl hydrochloride

Ultiva

Class, Category, and Schedule

Chemical class: Fentanyl analogue

Therapeutic class: Anesthesia adjunct

Pregnancy category: C

Controlled substance schedule: II

Indications and Dosages

↗ *As adjunct to induce general anesthesia*

INTERMITTENT I.V. INFUSION

Adults and children age 2 and over. 0.5 to 1 mcg/kg plus inhalation or I.V. anesthetic.

↗ *To maintain general anesthesia*

INTERMITTENT I.V. INFUSION

Adults and children age 2 and over. 0.05 to

0.2 mcg/kg, followed by 0.5 to 1 mcg/kg every 2 to 5 min, as needed.

↗ *To continue analgesic effect in immediate postoperative period*

CONTINUOUS I.V. INFUSION

Adults and children age 2 and over. *Initial:* 0.1 mcg/kg/min, adjusted by 0.025 mcg/kg/min every 5 min, as prescribed, to balance level of analgesia and respiratory rate.

Maximum: 0.2 mcg/kg/min.

↗ *To supplement local or regional anesthesia in a monitored anesthetic setting*

I.V. INFUSION

Adults and children age 2 and over. *With a benzodiazepine:* 0.05 mcg/kg/min, starting 5 min before placement of local or regional block; after placement of block, decreased to 0.025 mcg/kg/min and then further adjusted every 5 min in increments of 0.025 mcg/kg/min, as needed. *Without a benzodiazepine:* 0.1 mcg/kg/min, starting 5 min before placement of local or regional block; after placement of block, decreased to 0.05 mcg/kg/min and then further adjusted every 5 min in increments of 0.025 mcg/kg/min, as needed.

I.V. INJECTION

Adults and children age 2 and over. *With a benzodiazepine:* 0.5 mcg/kg over 30 to 60 sec as a single dose 60 to 90 sec before local anesthetic is administered. *Without a benzodiazepine:* 1 mcg/kg administered over 30 to 60 sec as a single dose 60 to 90 sec before local anesthetic is administered.

DOSAGE ADJUSTMENT For elderly patients, starting dose possibly reduced by half. If patient is more than 30% over ideal body weight, starting dose based on ideal body weight.

Route	Onset	Peak	Duration
I.V.	1 min	1–2 min	5–10 min

Incompatibilities

Don't give remifentanyl through same I.V. line as blood because nonspecific esterases in blood products may inactivate drug.

Contraindications

Epidural or intrathecal administration, hypersensitivity to fentanyl analogues

Interactions

DRUGS

anesthetics (barbiturate, inhalation), benzo-

Mechanism of Action

Remifentanil decreases transmission and perception of pain by stimulating mu-opioid receptors in neurons. This action decreases the activity of adenylyl cyclase in neurons, which in turn decreases cAMP production. With less cAMP available, potassium (K^+) is forced out of neurons, and calcium (Ca^{++}) is prevented from entering neurons. As a result, neuron excitability declines, and fewer neurotransmitters (such as substance P) leave the neurons, thereby decreasing pain transmission.

diazepines, propofol: Possibly synergistic effects, increasing risk of hypotension and respiratory depression

atropine, glycopyrrolate: Possibly reversal of remifentanil-induced bradycardia

ephedrine, epinephrine, norepinephrine:

Possibly reversal of remifentanil-induced hypotension

neuromuscular blockers: Prolonged skeletal muscle rigidity caused by remifentanil

opioid antagonists: Possibly reversal of remifentanil's effects

Adverse Reactions

CNS: Headache, shivering

CV: Asystole, bradycardia, hypotension

GI: Nausea, vomiting

MS: Skeletal muscle rigidity

RESP: Apnea, cough, dyspnea, respiratory depression, stridor, wheezing

Other: Anaphylaxis

Nursing Considerations

- Inject remifentanil into I.V. tubing at or as close as possible to venous cannula.
- Use infusion device to deliver continuous infusion.
- Monitor vital signs and oxygenation continuously during administration.
- Expect analgesic effects to dissipate rapidly when drug is discontinued. Expect to start adequate postoperative analgesia, as prescribed, before stopping drug.

WARNING After stopping drug, clear I.V. tubing to prevent inadvertent later delivery.

- Monitor respiratory status continuously

because of risk of respiratory depression from residual effects of other anesthetics for up to 30 minutes after infusion stops.

PATIENT TEACHING

- Explain expected drug effects to patient, and reassure her that she'll be monitored continuously during drug administration.

repaglinide

Prandin

Class and Category

Chemical class: Meglitinide

Therapeutic class: Antidiabetic

Pregnancy category: C

Indications and Dosages

➤ To achieve glucose control in type 2 diabetes mellitus as monotherapy in patients whose glycosylated hemoglobin (HbA_{1c}) level is less than 8%

TABLETS

Adults. *Initial*: 0.5 mg 15 to 30 min before meals b.i.d. Dosage doubled, as needed, every wk until adequate glucose response obtained. *Maintenance*: 0.5 to 4 mg/dose up to q.i.d. *Maximum*: 16 mg daily in divided doses of not more than 4 mg/dose.

➤ To achieve glucose control in type 2 diabetes mellitus as monotherapy in patients whose HbA_{1c} is 8% or greater and in combination with metformin or thiazolidinedione (pioglitazone

hydrochloride, rosiglitazone maleate)
therapy

TABLETS

Adults, Initial: 1 or 2 mg 15 to 30 min before meals b.i.d. Dosage doubled, as needed, every wk until adequate glucose response obtained. **Maintenance:** 1 to 4 mg/dose up to q.i.d. **Maximum:** 16 mg daily in divided doses of not more than 4 mg/dose.

DOSAGE ADJUSTMENT For patients with moderate to severe hepatic or renal impairment, increased time between dosage adjustments.

Mechanism of Action

Stimulates release of insulin from functioning pancreatic beta cells. In patients with type 2 diabetes mellitus, a shortage of these cells decreases blood insulin levels and causes glucose intolerance. By interacting with the adenosine triphosphatase (ATP)-potassium channel on the beta cell membrane, repaglinide prevents potassium from leaving the cell. This causes the beta cell to depolarize and the cell membrane's calcium channel to open. As a result, calcium moves into the cell and insulin moves out. The extent of insulin release is glucose dependent; the lower the glucose level, the less insulin is secreted from the cell.

Contraindications

Concurrent therapy with gemfibrozil, diabetic ketoacidosis, hypersensitivity to repaglinide or its components, severe hepatic or renal impairment, type 1 diabetes mellitus

Interactions**DRUGS**

barbiturates, carbamazepine, rifampin, troglitazone: Possibly increased repaglinide metabolism

beta blockers, chloramphenicol, clarithromycin, MAO inhibitors, NSAIDs, oral anticoagulants, probenecid, salicylates, sulfonamides: Enhanced hypoglycemic effects

calcium channel blockers, corticosteroids, diuretics, estrogens, isoniazid, niacin, oral contraceptives, phenothiazines, phenytoin, sympathomimetics, thyroid hormones: Possibly loss of glucose control

erythromycin, ketoconazole, miconazole: Possibly inhibited repaglinide metabolism

gemfibrozil: Increased blood repaglinide

level, resulting in enhanced and prolonged blood glucose-lowering effects

NPH insulin: Possibly increased risk of angina

OATP1B1 inhibitors such as cyclosporine, trimethoprim: Increased plasma repaglinide level

Adverse Reactions

CNS: Headache

CV: Angina

EENT: Rhinitis, sinusitis

ENDO: Hypoglycemia

GI: Diarrhea, elevated liver enzymes, hepatitis, nausea, pancreatitis

HEME: Hemolytic anemia, leukopenia, thrombocytopenia

MS: Arthralgia, back pain

RESP: Bronchitis, upper respiratory tract infection

SKIN: Alopecia, Stevens-Johnson syndrome

Other: Anaphylaxis

Nursing Considerations

- Be aware that repaglinide shouldn't be used with NPH insulin because the combination may increase the risk of angina.
- Expect to check HbA_{1c} level every 3 months, as ordered, to assess patient's long-term control of blood glucose level.
- During times of increased stress, such as from infection, surgery, or trauma, monitor blood glucose level often and assess need for additional insulin.

PATIENT TEACHING

- Instruct patient to take repaglinide 15 to 30 minutes before meals and to skip dose whenever she skips a meal.
- Explain that repaglinide is an adjunct to diet in managing type 2 diabetes mellitus.
- Inform patient that changes in blood glucose level may cause blurred vision or visual disturbances, especially when repaglinide therapy starts. Reassure him that these changes are usually transient.
- Teach patient how to monitor her blood glucose level and when to notify prescriber about changes.
- Review signs and symptoms of hyperglycemia and hypoglycemia with patient and family. Instruct patient to notify prescriber immediately if she experiences anxiety, confusion, dizziness, excessive sweating, headache, increased thirst, increased urination, or nausea.

- Advise patient to wear or carry identification indicating that she has diabetes. Encourage her to carry candy or other simple carbohydrates with her to treat mild episodes of hypoglycemia.
- Inform patient that her HbA_{1c} level will be tested every 3 to 6 months until her blood glucose level is controlled.

reserpine

Novoreserpine (CAN), **Reserfia** (CAN), **Serpalan**, **Serpasil** (CAN)

Class and Category

Chemical class: Rauwolfia alkaloid

Therapeutic class: Antihypertensive

Pregnancy category: C

Indications and Dosages

➤ *To treat hypertension*

TABLETS

Adults. 0.1 to 0.25 mg daily.

Children. 0.005 to 0.02 mg/kg daily once daily or in divided doses b.i.d.

DOSAGE ADJUSTMENT Lower dosage possibly required for elderly or severely debilitated patients.

Route	Onset	Peak	Duration
P.O.	Days–3 wk	3–6 wk	1–6 wk

Contraindications

Active peptic ulcer, electroconvulsive therapy, hypersensitivity to reserpine or its components, mental depression (current or history of), ulcerative colitis

Interactions

DRUGS

anticholinergics: Decreased effectiveness of anticholinergics

barbiturates: Increased CNS depression

beta blockers: Additive and, possibly, excessive beta-adrenergic blockade

bromocriptine: Possibly interference with

Mechanism of Action

Reserpine reduces blood pressure by decreasing norepinephrine stores in presynaptic sympathetic neurons.

Normally, when a nerve impulse activates a sympathetic neuron, the nerve ending releases norepinephrine, which stimulates alpha or beta receptors on target cell membranes, as shown below left. Stimulation of alpha receptors may produce vasoconstriction; stimulation of beta receptors may increase heart rate and force of myocardial contraction,

which raises cardiac output. Through a reuptake mechanism, some norepinephrine returns to the neuron and is stored in vesicles for reuse.

Reserpine displaces norepinephrine from vesicles in the nerve fiber, and MAO degrades the displaced norepinephrine, as shown below right. These actions reduce the amount of norepinephrine available to stimulate postsynaptic alpha and beta receptors, reducing vasoconstriction, cardiac output, and blood pressure.

bromocriptine's effects

digoxin, procainamide, quinidine: Increased risk of arrhythmias

hypotension-producing drugs: Increased antihypertensive effect; increased risk of orthostatic hypotension or bradycardia (with guanadrel or guanethidine)

levodopa: Decreased levodopa effectiveness
MAO inhibitors: Increased risk of severe hypertension and hyperpyrexia, additive CNS depression

NSAIDs: Decreased antihypertensive effect

sympathomimetics: Increased vasopressor effects, decreased antihypertensive effect

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Anxiety, depression, dizziness, drowsiness, headache, nervousness, nightmares, sleep disturbance, syncope, weakness

CV: Arrhythmias, such as bradycardia; chest pain; peripheral edema

EENT: Conjunctival injection, dry mouth, epistaxis, glaucoma, hearing loss, nasal congestion, optic atrophy, uveitis

ENDO: Breast engorgement

GI: Abdominal cramps or pain, anorexia, diarrhea, increased gastric secretions, melena, nausea, vomiting

GU: Decreased libido, galactorrhea, gynecomastia, impotence

MS: Myalgia

RESP: Dyspnea

SKIN: Purpura

Other: Weight gain

Nursing Considerations

- If patient has a history of depression, use reserpine cautiously because it may cause depression masked as somatic complaints.
- Monitor blood pressure frequently during drug therapy.
- Alert anesthesiologist if patient is scheduled for surgery. Drug may cause circulatory instability even if withheld before procedure.

PATIENT TEACHING

- Instruct patient to take reserpine with food or milk to minimize stomach upset.
- Caution patient about possible drowsiness, and advise her to avoid potentially hazardous activities until drug's CNS effects are known.
- Explain the need for frequent appoint-

ments to monitor blood pressure and adjust dosage at start of therapy.

reteplase

Retavase

Class and Category

Chemical class: Recombinant plasminogen activator (r-PA)

Therapeutic class: Thrombolytic

Pregnancy category: C

Indications and Dosages

↗ *To improve ventricular function, prevent heart failure, and reduce mortality after acute MI*

I.V. INJECTION

Adults. 10 units over 2 min; repeated after 30 min.

Mechanism of Action

Converts plasminogen to plasmin, which works to break up fibrin clots that have formed in the coronary arteries. Elimination of the clots improves cardiac blood and oxygen flow to the area, thus improving ventricular function.

Incompatibilities

Don't add other drugs to reteplase injection solution or administer them through same I.V. line as reteplase.

Contraindications

Active internal bleeding, aneurysm, arteriovenous malformation, bleeding diathesis, brain tumor, history of stroke or other cerebrovascular disease, hypersensitivity to reteplase or its components, intracranial or intraspinal surgery or trauma during previous 2 months, severe uncontrolled hypertension (systolic 200 mm Hg or higher, diastolic 110 mm Hg or higher)

Interactions

DRUGS

antifibrinolytics (including aminocaproic acid, aprotinin, and tranexamic acid):

Decreased effectiveness of reteplase

antineoplastics, antithymocyte globulin, certain cephalosporins (such as cefamandole, cefoperazone, and cefotetan), heparin, oral anticoagulants, platelet aggregation inhibitors (such as abciximab, aspirin, and

dipyridamole), *strontium-89 chloride*, *sulfipyrazone*, *valproic acid*: Increased risk of bleeding

Adverse Reactions

CNS: Intracranial hemorrhage

GI: GI bleeding, nausea, vomiting

HEME: Thrombocytopenia

RESP: Hemoptysis

SKIN: Bleeding from wounds, ecchymosis, hematoma, purpura

Other: Allergic reaction, injection site bleeding

Nursing Considerations

- Expect to start reteplase, as prescribed, as soon as possible after MI symptoms begin.
- Closely monitor patient with atrial fibrillation, severe hypertension, or other cardiac disease for signs and symptoms of cerebral embolism.
- To reconstitute, use diluent, syringe, needle, and dispensing pin provided. Withdraw 10 ml of preservative-free sterile water for injection. Remove and discard needle from syringe, and connect dispensing pin to syringe. Remove protective cap from spike end of dispensing pin, and insert spike into reteplase vial. Inject 10 ml of sterile water into the vial. With the spike still in the vial, swirl gently to dissolve the powder. Don't shake. Expect to see slight foaming. Let the vial stand for several minutes. When the bubbles dissipate, withdraw 10 ml of reconstituted solution into the syringe (about 0.7 ml may remain in the vial). Now detach the syringe from the dispensing pin and attach the 20G needle.

- Use the solution within 4 hours. Discard if it's discolored or contains particulates.
- Don't give heparin and reteplase in the same solution. Instead, flush the heparin line with normal saline solution or D₅W before and after reteplase injection.
- Because fibrin is lysed during therapy, closely monitor all possible bleeding sites (catheter insertions, arterial and venous punctures, cutdowns, and needle punctures).
- Avoid I.M. injections, venipunctures, and nonessential handling of patient during therapy.
- If arterial puncture is needed, use an arm vessel that can be compressed, if possible.

After sample is obtained, apply pressure for at least 30 minutes; then apply a pressure dressing. Check site often for bleeding.

- If bleeding occurs and can't be controlled by local pressure, notify prescriber immediately. Be prepared to stop anticoagulant therapy immediately and to discontinue second reteplase bolus, as prescribed.
- Anticipate that reperfusion arrhythmias, such as premature ventricular contractions or ventricular tachycardia, may follow coronary thrombolysis.

PATIENT TEACHING

- Advise patient to report adverse reactions immediately.

rifabutin

Mycobutin

Class and Category

Chemical class: Spiropiperidyl derivative

Therapeutic class: Antimycobacterial antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To prevent disseminated Mycobacterium avium complex in patients with advanced HIV infection*

CAPSULES

Adults. 300 mg once daily or 150 mg b.i.d.

Mechanism of Action

Suppresses RNA synthesis by inhibiting DNA-dependent RNA polymerase in a wide variety of bacteria, including *Mycobacterium avium*. Exhibits dose-dependent bactericidal or bacteriostatic action.

Contraindications

Hypersensitivity to rifabutin or rifamycins

Interactions

DRUGS

aminophylline, barbiturates, beta blockers, chloramphenicol, clofibrate, corticosteroids, cyclosporine, dapsone, diazepam, digoxin, disopyramide, estramustine, estrogens, ketoconazole, mexiletine, oral anticoagulants, oral antidiabetic drugs, oral contraceptives (containing estrogen), oxtriphylline, phenytoin, quinidine, theophylline, tocainide, verapamil (oral): Reduced effects of these drugs

fluconazole: Increased blood rifabutin level
methadone: Possibly withdrawal symptoms
zidovudine: Decreased blood zidovudine level

Adverse Reactions

CNS: Asthenia, fever, headache, insomnia
CV: Chest pain
EENT: Discolored saliva, tears, and sputum
GI: Abdominal pain, anorexia, diarrhea, discolored feces, elevated liver function test results, eructation, flatulence, indigestion, nausea, pseudomembranous colitis, vomiting
GU: Discolored urine
HEME: Neutropenia, thrombocytopenia
MS: Myalgia
SKIN: Discolored skin and sweat, rash

Nursing Considerations

- Monitor laboratory values during rifabutin therapy to detect neutropenia and thrombocytopenia.
- Expect drug to cause reddish orange to reddish brown discoloration of skin and body fluids.
- Be aware that drug may cause myelosuppression and increased risk of infection. Notify prescriber immediately if signs of infection, such as fever, develop.
- Monitor patient for diarrhea during therapy and for at least 2 months afterward; diarrhea may signal pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold rifabutin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

PATIENT TEACHING

- Advise patient to take rifabutin with food if GI distress develops.
- Encourage patient to have needed dental work done before rifabutin therapy starts to reduce the risk of bleeding or infection.
- Explain that drug may turn urine, feces, saliva, sputum, sweat, tears, and skin reddish orange to reddish brown.
- Caution patient against wearing soft contact lenses during therapy because drug may permanently stain them.
- Advise patient to notify prescriber about signs of *Mycobacterium avium* complex (chills, fever, night sweats, weight loss), tuberculosis, myositis, or uveitis.
- Advise woman of childbearing age that

rifabutin may decrease effectiveness of oral contraceptives; advise her to use a nonhormonal method of birth control.

- Urge patient to tell prescriber about diarrhea that's severe or prolonged. Remind patient that watery or bloody stools can occur 2 months or more after antibiotic therapy ends and can be serious, requiring prompt treatment.

rifampin (rifampicin)

Rifadin, Rifadin IV, Rimactane, Rofact (CAN)

Class and Category

Chemical class: Semisynthetic antibiotic derivative of rifamycin

Therapeutic class: Antimycobacterial antitubercular

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat tuberculosis caused by all strains of Mycobacterium tuberculosis*

CAPSULES , ORAL SUSPENSION, I.V. INFUSION

Adults. 10 mg/kg daily with other antitubercular drugs for 2 mo. *Maximum:* 600 mg daily.

Infants and children. 10 to 20 mg/kg daily in combination with other antitubercular drugs for 2 mo. *Maximum:* 600 mg daily.

↗ *To eliminate meningococci from nasopharynx of asymptomatic carriers of Neisseria meningitidis*

CAPSULES , ORAL SUSPENSION, I.V. INFUSION

Adults. 600 mg every 12 hr for 2 days (total of 4 doses).

Infants age 1 month and over and children. 10 mg/kg every 12 hr for 2 days (total of 4 doses). *Maximum:* 600 mg daily.

Infants under age 1 month. 5 mg/kg every 12 hr for 2 days (total of 4 doses).

Maximum: 600 mg daily.

DOSAGE ADJUSTMENT For patients with hepatic impairment, maximum of 8 mg/kg daily. For patients with creatinine clearance of 10 ml/min/1.73 m² or less, recommended dosage usually decreased by 50%.

Mechanism of Action

Inhibits bacterial and mycobacterial RNA

synthesis by binding to DNA-dependent RNA polymerase, thereby blocking RNA transcription. Exhibits dose-dependent bactericidal or bacteriostatic action. Rifampin is highly effective against rapidly dividing bacilli in extracellular cavitory lesions, such as those found in the nasopharynx.

Incompatibilities

Don't administer rifampin in the same I.V. line as diltiazem.

Contraindications

Concurrent use of nonnucleoside reverse transcriptase inhibitors or protease inhibitors by patients with HIV, hypersensitivity to rifamycins

Interactions

DRUGS

aminophylline, oxtriphylline, theophylline:

Increased metabolism and clearance of these theophylline preparations
anesthetics (hydrocarbon inhalation, except isoflurane), hepatotoxic drugs, isoniazid:

Increased risk of hepatotoxicity
beta blockers, chloramphenicol, clofibrate, corticosteroids, cyclosporine, dapsone, digitalis glycosides, disopyramide, hexobarbital, itraconazole, ketoconazole, mexiletine, oral anticoagulants, oral antidiabetic drugs, phenytoin, propafenone, quinidine, tocainide, verapamil (oral): Increased metabolism, resulting in lower blood levels of these drugs

bone marrow depressants: Increased leukopenic or thrombocytopenic effects

clofazimine: Reduced absorption of rifampin, delaying its peak concentration and increasing its half-life

diazepam: Enhanced diazepam elimination, resulting in decreased drug effectiveness

estramustine, estrogens, oral contraceptives: Decreased estrogenic effects

methadone: Possibly impaired absorption of methadone, leading to withdrawal symptoms

probenecid: Increased blood level or prolonged duration of rifampin, increasing risk of toxicity

nonnucleoside reverse transcriptase inhibitors, protease inhibitors (indinavir, nelfinavir, ritonavir, saquinavir): Accelerated metabolism of these drugs (by patients with HIV), resulting in subtherapeutic levels;

delayed metabolism of rifampin, increasing risk of toxicity

trimethoprim: Increased elimination and shortened elimination half-life of trimethoprim

vitamin D: Increased metabolism and decreased efficacy of vitamin D, leading to decreased serum calcium and phosphate levels and increased parathyroid hormone levels

ACTIVITIES

alcohol use: Increased risk of hepatotoxicity

Adverse Reactions

CNS: Chills, dizziness, drowsiness, fatigue, headache, paresthesia

EENT: Discolored saliva, tears, and sputum; mouth or tongue soreness; periorbital edema

GI: Abdominal cramps, anorexia, diarrhea, discolored feces, elevated liver function test results, epigastric discomfort, flatulence, heartburn, hepatitis, nausea, pseudomembranous colitis, vomiting

GU: Discolored urine

MS: Arthralgia, myalgia

SKIN: Discolored skin and sweat

Other: Facial edema, flulike symptoms

Nursing Considerations

- Obtain blood samples or other specimens for culture and sensitivity testing, as ordered, before giving rifampin and throughout therapy to monitor response to drug.
- Expect to monitor liver function test results before and every 2 to 4 weeks during therapy. Immediately report abnormalities.
- For I.V. infusion, reconstitute by adding 10 ml sterile water for injection to 600-mg vial of rifampin. Swirl gently to dissolve. Withdraw appropriate dose and add to 500 ml D₅W (preferred solution) or normal saline solution and infuse over 3 hours. Or, withdraw appropriate dose and add to 100 ml D₅W (preferred solution) or normal saline solution and infuse over 30 minutes. Use reconstituted drug promptly because rifampin may precipitate out of D₅W solution after 4 hours. In normal saline solution, drug is stable up to 24 hours at room temperature.
- Be aware that patient receiving intermittent therapy (once or twice weekly) is at

increased risk for adverse reactions.

- Expect drug to discolor skin and body fluids reddish orange to reddish brown.
- Be aware that rifampin can cause myelosuppression and increase risk of infection. Notify prescriber immediately if signs of infection, such as fever, develop.

PATIENT TEACHING

- Instruct patient to take rifampin 1 hour before or 2 hours after a meal with a full glass of water.
- Stress the need to take drug exactly as prescribed. Explain that interruptions can lead to increased adverse reactions.
- Explain that drug may turn urine, feces, saliva, sputum, sweat, tears, and skin reddish orange to reddish brown.
- Caution patient against wearing soft contact lenses during therapy because drug may permanently stain them.
- Advise patient who takes an oral contraceptive to use an additional form of birth control during rifampin therapy.
- Urge patient to notify prescriber about flulike symptoms, anorexia, darkened urine, fever, joint pain or swelling, malaise, nausea, vomiting, and yellowish skin or eyes, which may indicate hepatitis.
- Advise patient to avoid alcohol during rifampin therapy.
- Instruct patient to notify prescriber if no improvement occurs within 2 to 3 weeks.

riluzole

Rilutek

Class and Category

Chemical class: Benzothiazole

Therapeutic class: Amyotrophic lateral sclerosis treatment agent

Pregnancy category: C

Indications and Dosages

↗ *To treat amyotrophic lateral sclerosis*

TABLETS

Adults. 50 mg every 12 hr.

Mechanism of Action

Inhibits release of glutamic acid, an excitatory amino acid neurotransmitter, in the CNS, thus reducing its effects on target cells. Glutamic acid affects degeneration of neurons; reducing its level may help slow

amyotrophic lateral sclerosis.

Contraindications

Hypersensitivity to riluzole or its components

Interactions

DRUGS

allopurinol, hepatotoxic drugs, methyldopa, sulfasalazine: Increased risk of hepatotoxicity

amitriptyline, phenacetin, quinolones, tacrine, theophylline: Delayed elimination of riluzole

omeprazole, rifampin: Increased riluzole clearance

FOODS

charbroiled foods: Increased riluzole elimination

ACTIVITIES

alcohol use: Increased risk of hepatotoxicity
smoking: Increased riluzole elimination

Adverse Reactions

CNS: Asthenia, dizziness, headache, insomnia, paresthesia (circumoral), somnolence, spasticity, vertigo

CV: Peripheral edema

EENT: Dry mouth, rhinitis, stomatitis

GI: Abdominal pain, anorexia, constipation, diarrhea, elevated liver function test results, flatulence, hepatitis, indigestion, nausea, vomiting

HEME: Neutropenia

MS: Back or muscle pain or stiffness

RESP: Dyspnea, hypersensitivity pneumonitis, increased cough, interstitial lung disorder, pneumonia

SKIN: Alopecia, eczema, pruritus

Other: Anaphylaxis

Nursing Considerations

- Use riluzole cautiously in patients with impaired hepatic or renal function.
- Also use cautiously in elderly patients, women, and Japanese patients because of increased risk of toxicity from decreased drug clearance.
- Monitor liver function test results before and during riluzole therapy.
- Monitor patient for respiratory symptoms, such as dry cough or dyspnea. Notify prescriber if present, and expect patient to have a chest X-ray, as ordered. If evidence of interstitial lung disease or hypersensitivity pneumonitis is present, expect rilu-

zole to be discontinued immediately.

PATIENT TEACHING

- Instruct patient to take riluzole regularly, every 12 hours, either 1 hour before or 2 hours after a meal, and at the same time each day.
- Instruct patient to store riluzole at room temperature, protected from bright light.
- Urge patient to minimize alcohol, smoking, and charred foods because they speed drug excretion.
- Tell patient to report fever, cough, or difficulty breathing.

risedronate sodium

Actonel

Class and Category

Chemical class: Pyridinyl bisphosphonate

Therapeutic class: Bone resorption inhibitor

Pregnancy category: C

Indications and Dosages

↗ *To treat Paget's disease of bone when serum alkaline phosphatase level is at least twice normal and patient is symptomatic or at risk for complications*

TABLETS

Adults. 30 mg daily for 2 mo. Repeated after 2 mo if relapse occurs or if serum alkaline phosphatase level fails to normalize.

↗ *To prevent or treat glucocorticoid-induced osteoporosis*

TABLETS

Adults. 5 mg daily. Or, for postmenopausal osteoporosis, 35 mg once/wk or 75 mg taken on 2 consecutive days once/mo.

↗ *To prevent or treat postmenopausal osteoporosis*

TABLETS

Adults. 5 mg daily. Or, 35 mg once weekly, 75 mg taken on 2 consecutive days once a month, or 150 mg once a month

↗ *To treat osteoporosis in men*

TABLETS

Adults. 35 mg once/wk.

Route	Onset	Peak	Duration
P.O.	Unknown	3 mo	16 mo

Mechanism of Action

Hinders excessive bone remodeling charac-

teristic of Paget's disease by binding to bone and reducing the rate at which osteoclasts are resorbed by bone.

Contraindications

Esophageal abnormalities that delay esophageal emptying, such as stricture or achalasia; hypersensitivity to risedronate or its components; inability to stand or sit upright for at least 30 minutes; hypocalcemia

Interactions

DRUGS

aspirin, NSAIDs: Increased risk of GI irritation

calcium-containing preparations, including antacids: Impaired absorption of risedronate

FOODS

all foods: Decreased risedronate bioavailability

Adverse Reactions

CNS: Anxiety, asthenia, depression, dizziness, fatigue, headache, insomnia, sciatica, syncope, vertigo, weakness

CV: Chest pain, hypercholesterolemia, hypertension, peripheral edema, vasodilation

EENT: Amblyopia, cataract, dry eyes, nasopharyngitis, pharyngitis, rhinitis, sinusitis, tinnitus

GI: Abdominal pain, colitis, constipation, diarrhea, dyspepsia, dysphagia, eructation, esophagitis, esophageal or gastric ulcers, flatulence, gastritis, nausea, vomiting

GU: UTI

MS: Arthralgia; back, limb, neck, or shoulder pain; jaw osteonecrosis; leg cramps or spasms; myasthenia; myalgia; osteoarthritis

RESP: Bronchitis, cough, pneumonia, upper respiratory tract infection

SKIN: Bullous reaction, pruritus, rash

Other: Angioedema, flulike symptoms, hypersensitivity reaction, hypocalcemia

Nursing Considerations

- Risedronate isn't recommended for patients with severe renal impairment.
- Make sure patient has had a dental check-up before having invasive dental procedures during risedronate therapy, especially if patient has cancer; is receiving chemotherapy, head or neck radiation, or a corticosteroid; or has poor oral hygiene

because risk of osteonecrosis is increased in these patients.

- Give supplemental calcium and vitamin D, as prescribed, during risperidone therapy if patient's dietary intake is inadequate.
- Give calcium supplements and antacids at different time of day than risperidone administration to avoid impaired drug absorption and altered effectiveness.
- Watch for rare but possibly severe rash, bullous skin reactions, and angioedema.

PATIENT TEACHING

- Instruct patient to take risperidone at least 1 hour before first food or drink of day (except water) while in an upright position and with 6 to 8 oz of water. Caution against lying down for at least 30 minutes after taking drug to keep it from lodging in esophagus and causing irritation. Also instruct patient not to chew or suck on tablet because doing so may irritate mouth or throat.
- Advise patient to stop taking risperidone and to notify prescriber if GI symptoms appear or become worse.
- Alert patient that drugs in the same class as risperidone have caused severe bone, joint, or muscle pain. If such symptoms appear while taking risperidone, advise patient to contact prescriber.
- If patient takes 35 mg once weekly and misses a dose, tell her to take it the morning after she remembers and then to take the next dose on its usual day. If patient takes 75 mg on 2 consecutive days once monthly and she misses both doses with more than 7 days until the next scheduled dose, tell her to take the first missed dose on the morning after she remembers and the second dose the following day. If she misses only one of the two doses, tell her to take it the morning after she remembers and then resume her normal schedule. If patient takes 150 mg once monthly and misses a dose, urge her to contact prescriber for instructions. Caution patient not to take more than 150 mg within a 7-day period and not to take two tablets of any strength on the same day.
- Tell patient to take calcium supplements or antacids at different times than risperidone.
- Urge women of childbearing age to tell prescriber about planned, suspected, or

known pregnancy because of risk to fetal skeleton.

- Tell patient to stop risperidone and contact prescriber about swelling or skin abnormalities.
- Instruct patient on proper oral hygiene and on the need to notify prescriber about invasive dental procedures.

risperidone

Risperdal, Risperdal Consta

Class and Category

Chemical class: Benzisoxazole derivative

Therapeutic class: Antipsychotic

Pregnancy category: C

Indications and Dosages

↗ *To manage psychotic disorders*

ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS

Adults. 1 mg b.i.d. on day 1; 2 mg b.i.d. on day 2; 3 mg b.i.d. on day 3. Or, 2 mg daily on day one; 4 mg daily on day two; 6 mg daily on day 3. Then increased by 1 to 2 mg daily at 1- to 2-wk intervals, as needed.

Maximum: 16 mg daily.

Adolescents ages 13 to 17. *Initial:* 0.5 mg once daily, increased as needed every 24 hr in 0.5- to 1-mg increments. *Maximum:* 3 mg once daily.

I.M. INJECTION (RISPERDAL CONSTA)

Adults. *Initial:* 25 mg every 2 wk, increased as needed every 4 wk to 37.5 or 50 mg.

Maximum: 50 mg every 2 wk.

↗ *To treat bipolar mania*

ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS

Adults. *Initial:* 2 or 3 mg daily, increased as needed by 1 mg daily up to 6 mg.

Maximum: 6 mg daily for no more than 3 wk.

Children and adolescents ages 10 to 17.

Initial: 0.5 mg once daily, increased as needed every 24 hr in 0.5- to 1-mg increments.

Maximum: 2.5 mg once daily.

↗ *To treat bipolar mania as monotherapy or as adjunct to lithium or valproate therapy*

I.M. INJECTION (RISPERDAL CONSTA)

Adults. 25 mg every 2 wk., increased, as needed to 37.5 mg or 50 mg. *Maximum:*

50 mg every 2 wk.

DOSE ADJUSTMENT Initially 0.5 mg b.i.d. for elderly or debilitated patients, those with renal or hepatic impairment, and those at risk for hypotension. Increased by 0.5 mg b.i.d. every wk, as needed. Given daily after target dosage maintained for 2 or 3 days. Maximum for patients with severe hepatic dysfunction, 4 mg daily; for elderly patients, 3 mg daily. Initially 12.5 mg for patients receiving drug I.M. who have renal or hepatic impairment, take other drugs that increase risperidone blood level, or have a history of tolerating psychotropic drugs poorly. For adolescents and children with persistent somnolence, dose may be split and given twice daily.

↗ *To treat irritability associated with autistic disorder*

ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS

Children age 5 and over and adolescents weighing less than 20 kg (44 lb). *Initial:* 0.25 mg daily, increased after 4 days to 0.5 mg daily. Dosage further increased, as needed in 2 wk intervals in 0.25 mg increments.

Children age 5 and over and adolescents weighing 20 kg or more. *Initial:* 0.5 mg daily, increased after 4 days to 1 mg daily. Dosage further increased, as needed in 2 wk intervals in 0.5 mg increments.

Mechanism of Action

Selectively blocks serotonin and dopamine receptors in the mesocortical tract of the CNS to suppress psychotic symptoms.

Incompatibilities

Don't mix oral solution with cola or tea.

Contraindications

Hypersensitivity to risperidone or its components

Interactions

DRUGS

antihypertensives: Increased antihypertensive effects
bromocriptine, levodopa, pergolide: Possibly antagonized effects of these drugs
carbamazepine: Increased risperidone clearance with long-term concurrent use
clozapine: Decreased risperidone clearance with long-term concurrent use
CNS depressants: Additive CNS depression

fluoxetine, paroxetine: Increased plasma risperidone level

ACTIVITIES

alcohol use: Additive CNS depression

Adverse Reactions

CNS: Aggressiveness, agitation, akathisia, anxiety, asthenia, confusion, decreased concentration, dizziness, dream disturbances, drowsiness, dyskinesia, dystonia, fatigue, fever, headache, lassitude, memory loss, nervousness, neuroleptic malignant syndrome, parkinsonism, restlessness, seizures, somnolence, tremor

CV: Atrial fibrillation, chest pain, hypercholesterolemia, orthostatic hypotension, palpitations, QT-interval prolongation, tachycardia

EENT: Decreased or increased salivation, dry mouth, pharyngitis, retinal artery occlusion, rhinitis, sinusitis, vision changes

ENDO: Diabetic ketoacidosis (patients with diabetes), elevated prolactin level, galactorrhea, hyperglycemia, pituitary adenoma

GI: Abdominal pain, anorexia, constipation, diarrhea, indigestion, intestinal obstruction, nausea, vomiting

GU: Amenorrhea, decreased libido, dysmenorrhea, dysuria, hypermenorrhea, incontinence, increased appetite, polyuria, sexual dysfunction, UTI

HEME: Agranulocytosis, leukopenia, neutropenia

MS: Arthralgia, back pain, myalgia

RESP: Cough, dyspnea, sleep apnea, upper respiratory tract infection

SKIN: Diaphoresis, dry skin, hyperpigmentation, photosensitivity, pruritus, rash, seborrhea

Other: Anaphylaxis, angioedema, injection site induration, pain, redness, or swelling; weight gain or loss

Nursing Considerations

- Use risperidone cautiously in debilitated patients, elderly patients, and patients with hepatic or renal dysfunction or hypotension because of their increased sensitivity to drug. Also use risperidone cautiously in patients with a history of seizures; although rare, seizures may occur in those with schizophrenia.

WARNING Be aware that risperidone should not be used to treat elderly patients with dementia-related psychosis because it

increases risk of death in these patients.

- Be aware that oral risperidone or another antipsychotic should be continued for 3 weeks after long-acting I.M. form of risperidone is first administered to provide an adequate therapeutic plasma level until risperidone release from injection site has begun. If the patient has never received oral risperidone, an oral trial should be prescribed before use of I.M. form to determine patient's tolerance of the drug.
- Remove I.M. form from refrigerator and allow it to come to room temperature before reconstitution. Follow manufacturer's guidelines for reconstitution, using only the diluent supplied in the dose pack.
- Give I.M. form using only the needle supplied in the dose pack. Inject entire contents of syringe into the upper outer quadrant of gluteal area within 2 minutes of reconstitution. If drug can't be given right after reconstitution, shake the upright vial vigorously back and forth until particles are resuspended. Discard reconstituted drug if not used within 6 hours. Never administer I.M. form intravenously.
- Monitor for orthostatic hypotension, especially in patients with cardiac or cerebrovascular disease.

WARNING Immediately notify prescriber and expect to stop giving risperidone if patient shows evidence of neuroleptic malignant syndrome (altered mental status, autonomic instability, hyperpyrexia, muscle rigidity), which can be fatal.

- Monitor patient's blood glucose and lipid levels as ordered because drug increases the risk of hyperglycemia and hypercholesterolemia.
- Monitor patient's CBC, as ordered, because serious adverse hematologic reactions may occur, such as agranulocytosis, leukopenia, or neutropenia. More frequent monitoring during the first few months of risperidone therapy is recommended for patients with a history of drug-induced leukopenia or neutropenia or who have had a significantly low WBC count in the past. If abnormalities occur during therapy, monitor patient for fever or other signs of infection, notify prescriber, and expect drug to be discontinued if severe.

PATIENT TEACHING

- Instruct patient to dilute risperidone oral

solution with water, coffee, orange juice, or low-fat milk but not with cola or tea.

- Tell patient prescribed orally disintegrating tablets to break open the blister unit with dry hands by peeling the foil back to expose the tablet. Stress the importance of not pushing tablet through the foil because this could damage the tablet. Once patient has removed tablet, she should place immediately on her tongue, where it will dissolve within seconds. Tell patient not to chew orally disintegrating tablet or attempt to spit it out of her mouth.
- Urge patient to avoid alcohol because of its additive CNS effects.
- Caution diabetic patient to monitor blood glucose level closely because risperidone may increase it.

rivastigmine tartrate

Exelon, Exelon Patch

Class and Category

Chemical class: Carbamate derivative

Therapeutic class: Antidementia

Pregnancy category: B

Indications and Dosages

↗ *To treat mild to moderate Alzheimer's-type dementia*

CAPSULES , ORAL SOLUTION

Adults. *Initial:* 1.5 mg b.i.d. Dosage increased by 3 mg daily every 2 wk, as needed. *Maximum:* 12 mg daily.

TRANSDERMAL

Adults. *Initial:* 4.6 mg/24 hr. After 4 wk, increased to 9.5 mg/24 hr.

↗ *To treat mild to moderate dementia in Parkinson's disease*

CAPSULES , ORAL SOLUTION

Adults. *Initial:* 1.5 mg b.i.d. Dosage increased by 3 mg daily every 4 wk, as needed. *Maximum:* 12 mg daily.

TRANSDERMAL

Adults. *Initial:* 4.6 mg/24 hr. After 4 wk, increased to 9.5 mg/24 hr.

↗ *To convert patient from oral to transdermal rivastigmine therapy*

TRANSDERMAL

Adults. If total oral dosage was less than

6 mg daily, use 4.6 mg/24 hr, with first transdermal patch applied the day after the last oral dose. If total oral dosage was 6 to 12 mg daily, use 9.5 mg/24 hr, with first transdermal patch applied the day after the last oral dose.

DOSE ADJUSTMENT If patient develops adverse effects (such as nausea or vomiting) during oral therapy, treatment should be stopped for several doses, as prescribed, restarted at lowest dose, and increased by 3 mg daily every 2 wk, as needed. If patient develops adverse effects during transdermal therapy, treatment should be discontinued for several days and restarted at same or next lower dose level.

Mechanism of Action

May slow the decline of cognitive function in patients with Alzheimer's disease by increasing acetylcholine concentration at cholinergic transmission sites. This action prolongs and exaggerates the effects of acetylcholine that are otherwise blocked by toxic levels of anticholinergics. The cognitive decline in these patients is partially related to cholinergic deficits along neuronal pathways projecting from the basal forebrain to the cerebral cortex and hippocampus that are involved in memory, attention, learning, and cognition.

Contraindications

Hypersensitivity to carbamate derivatives, rivastigmine, or their components

Interactions

DRUGS

anticholinergics: Possibly decreased effectiveness of anticholinergics

bethanechol, succinylcholine: Possibly synergistic effects

Adverse Reactions

CNS: Aggression, anxiety, asthenia, confusion, depression, dizziness, extrapyramidal movements, fatigue, fever, hallucinations, headache, insomnia, malaise, parkinsonism, seizures, somnolence, tremor

CV: Hypertension

EENT: Rhinitis

GI: Abdominal pain, anorexia, constipation, diarrhea, flatulence, indigestion, nausea, vomiting

GU: UTI

SKIN: Increased sweating, reaction at patch

application site (pruritus, redness, swelling)

Other: Dehydration, flulike symptoms, weight loss

Nursing Considerations

WARNING Be aware that rivastigmine should be started at lowest recommended dosage and adjusted to effective maintenance dosage because initial therapy at high dosage can cause serious adverse GI reactions, including anorexia, nausea, and weight loss. Also, higher than recommended starting dosage may cause severe vomiting and possibly esophageal rupture. If treatment is interrupted for longer than several days, expect to restart at lowest recommended dosage.

- Be aware that drug shouldn't be stopped abruptly because doing so may increase behavioral disturbances and precipitate a further decline in cognitive function.
- Monitor respiratory status of patients with pulmonary disease, including asthma, chronic bronchitis, and emphysema, because rivastigmine has a weak affinity for peripheral cholinesterase, which may increase bronchoconstriction and bronchial secretions.
- Monitor patient for adequate urine output because cholinomimetics, such as rivastigmine, may induce or exacerbate urinary tract or bladder obstruction.
- Monitor patients with Parkinson's disease for exaggerated parkinsonian symptoms, which may result from drug's increased cholinergic effects on CNS.

PATIENT TEACHING

- Explain to patient and family that rivastigmine can't cure Alzheimer's or Parkinson's disease but may slow the progressive deterioration of memory and improve patient's ability to perform activities of daily living.
- Teach patient and family how to administer oral solution, if prescribed, emphasizing need to use the oral dosing syringe provided. Explain that dose may be swallowed directly from the syringe or mixed into a small glass of water, cold fruit juice, or soda; stirred; and then drunk.
- Explain that oral drug should be taken with food to reduce adverse GI effects.
- For transdermal patch, instruct patient or caregiver to apply it to clean, dry, hairless,

intact skin in a location, such as the back, that won't be rubbed by tight clothing and won't be affected by lotion, cream, or powder. Tell patient to remove the old patch before applying a new one and to use a new application site daily. Caution against using the same site within 14 days.

- To apply transdermal patch, tell patient to press patch firmly against skin until the edges stick well. Reassure patient that patch may be worn while swimming or bathing.
- Instruct a family member to supervise patient's use of rivastigmine.
- Urge caregiver to contact prescriber and to withhold drug if patient stops taking it for more than several days.

rizatriptan benzoate

Maxalt, Maxalt-MLT

Class and Category

Chemical class: Selective 5-hydroxytryptamine

Therapeutic class: Antimigraine

Pregnancy category: C

Indications and Dosages

↗ *To relieve acute migraine headache*

DISINTEGRATING TABLETS, TABLETS

Adults. 5 to 10 mg when migraine headache starts; repeated every 2 hr, p.r.n.
Maximum: 30 mg daily.

DOSAGE ADJUSTMENT For patients taking propranolol, initial dosage reduced to 5 mg, then repeated every 2 hr, p.r.n., up to maximum of 15 mg daily.

Mechanism of Action

Binds to selective 5-hydroxytryptamine receptor sites on cerebral blood vessels, causing vessels to constrict. This may decrease the characteristic pulsing sensation and thus relieve the pain of migraine headaches. Rizatriptan also may relieve pain by inhibiting the release of proinflammatory neuropeptides and reducing transmission of trigeminal nerve impulses from sensory nerve endings during a migraine attack.

Contraindications

Basilar or hemiplegic migraine, hypersensitivity to rizatriptan or its components,

ischemic coronary artery disease, uncontrolled hypertension, use within 14 days of MAO inhibitor therapy, use within 24 hours of other serotonin-receptor agonists or ergotamine-containing or ergot-type drugs

Interactions

DRUGS

ergot-containing drugs: Prolonged vasospastic reactions

MAO inhibitors, propranolol: Increased blood rizatriptan level

selective serotonin-reuptake inhibitors:

Increased risk of weakness, hyperreflexia, and lack of coordination

serotonin-receptor agonists: Additive vasospastic effects

Adverse Reactions

CNS: Altered temperature sensation, anxiety, asthenia, ataxia, chills, confusion, depression, disorientation, dizziness, dream disturbances, drowsiness, euphoria, fatigue, hangover, headache, hypoesthesia, insomnia, mental impairment, nervousness, paresthesia, somnolence, tremor, vertigo
CV: Arrhythmias, such as bradycardia and tachycardia; chest pain; hot flashes; hypertension; palpitations

EENT: Blurred vision; burning eyes; dry eyes, mouth, and throat; earache; eye pain or irritation; lacrimation; nasal congestion and irritation; pharyngeal edema; pharyngitis; tinnitus; tongue swelling

GI: Abdominal distention, constipation, diarrhea, dysphagia, flatulence, heartburn, indigestion, nausea, thirst, vomiting

GU: Menstrual irregularities, polyuria, urinary frequency

MS: Arthralgia; dysarthria; muscle spasms, stiffness, or weakness; myalgia

RESP: Dyspnea, upper respiratory tract infection, wheezing

SKIN: Diaphoresis, flushing, pruritus, rash, urticaria

Other: Angioedema, dehydration, facial edema

Nursing Considerations

- Use rizatriptan cautiously in patients with renal or hepatic dysfunction because of impaired drug metabolism or excretion. Monitor patient's BUN and serum creatinine levels and liver function test results, as appropriate.
- Also use cautiously in patients with

peripheral vascular disease because drug may cause vasospastic reactions, leading to vascular and colonic ischemia with abdominal pain and bloody diarrhea.

Assess peripheral circulation and bowel sounds frequently during therapy.

- Assess patient's cardiovascular status and institute continuous ECG monitoring, as ordered, immediately after giving rizatriptan in patients with cardiovascular risk factors because of possible asymptomatic cardiac ischemia.
- Monitor blood pressure regularly in patients with hypertension because rizatriptan may increase blood pressure.

PATIENT TEACHING

- Instruct patient taking rizatriptan disintegrating tablets to remove tablet from blister pack with dry hands just before taking, to place tablet on tongue, and to allow it to dissolve and be swallowed with saliva.
- Advise phenylketonuric patient not to use disintegrating tablet form because it contains phenylalanine.
- Instruct patient to seek emergency care immediately if cardiac symptoms, such as chest pain, occur after administration.
- Caution patient about possible adverse CNS reactions, and advise her to avoid potentially hazardous activities until drug's CNS effects are known.

romiplostim

Nplate

Class and Category

Chemical class: Fc-peptide fusion protein

Therapeutic class: Platelet production enhancer

Pregnancy category: C

Indications and Dosages

➤ *To treat thrombocytopenia in patients with chronic immune (idiopathic) thrombocytopenic purpura (ITP) who have had an insufficient response to corticosteroids, immunoglobulins, or splenectomy*

SUBCUTANEOUS INJECTION

Adults. *Initial:* 1 mcg/kg based on actual body weight, followed by weekly doses adjusted in increments of 1 mcg/kg to keep platelet count at or above $50 \times 10^9/L$.

Maximum: 10 mcg/kg weekly.

DOSAGE ADJUSTMENT If platelet count is less than $50 \times 10^9/L$, dosage increased by 1 mcg/kg. If platelet count exceeds $200 \times 10^9/L$ for 2 consecutive weeks, dosage reduced by 1 mcg/kg. If platelet count exceeds $400 \times 10^9/L$, dose held until count has fallen to less than $200 \times 10^9/L$ and then resumed at a weekly dosage reduced by 1 mcg/kg.

Route	Onset	Peak	Duration
SubQ	Unknown	7–50 hr	Unknown

Mechanism of Action

Increases platelet production by binding and activating the thrombopoietin receptor in the same manner as endogenous thrombopoietin to prevent bleeding.

Contraindications

Hypersensitivity to romiplostim or its components

Adverse Reactions

CNS: Dizziness, headache, insomnia, paresthesia

CV: Thrombosis

GI: Abdominal pain, dyspepsia

HEME: Bone marrow reticulin deposition

MS: Arthralgia, extremity or shoulder pain, myalgia

Other: Antibody formation to romiplostim

Nursing Considerations

- Be aware that romiplostim can be administered only by prescribers or healthcare providers under their direction who are enrolled in the NEXUS program.
- Romiplostim therapy is used to reduce the risk of bleeding and not as a therapy to normalize platelet counts.
- Be aware that romiplostim may increase patient's risk for hematologic malignancies.
- Obtain a CBC, including platelet count and peripheral blood smears, before starting therapy, weekly until dosage is stable, monthly throughout therapy, and for at least 2 weeks after stopping therapy, as ordered. Detection of peripheral blood cell abnormalities may require a bone marrow examination to identify specific abnormality.
- Expect dosage to be adjusted based on

weekly platelet count response because, if dosage is too high, thrombotic and thromboembolic complications may occur..

- Reconstitute drug using only preservative-free sterile water for injection, adding 0.72 ml to 250-mcg vial or 1.2 ml to 500-mcg vial. Gently swirl and invert vial to dissolve powder, which normally occurs within 2 minutes. Don't shake or agitate vigorously. Protect reconstituted drug from light.
- To determine amount of reconstituted drug to administer, first identify patient's total dose in micrograms based on actual body weight. For example, a patient starting therapy at 1 mcg/kg who weighs 75 kg will receive 75 mcg. Then, divide ordered microgram dose by concentration of reconstituted drug solution (500 mcg/ml). For example, a 75-mcg dose divided by 500 mcg/ml will result in 0.15 ml of drug being administered. Discard any unused portion, and don't administer more than one dose from a vial because reconstituted drug can only be stored 24 hours, and drug is given only weekly.
- Administer drug using a syringe that contains 0.01-ml graduations to ensure accurate dosage because volume to be administered may be quite small.
- Be aware that drug may be given with other ITP therapies, such as corticosteroids, danazol, azathioprine, I.V. immunoglobulin and anti-D immunoglobulin.
- Expect therapy to be discontinued after 4 weeks at maximum dosage if platelet count doesn't increase enough to prevent serious bleeding or if patient develops new or worsening abnormalities or cytopenias.
- Monitor patient closely for bleeding after drug has been discontinued because thrombocytopenia may occur at greater severity than when therapy was started.

PATIENT TEACHING

- Inform patient about increased risk of hematologic malignancies before starting romiplostim therapy.
- Stress importance of weekly blood tests to ensure accurate dosing and early detection of serious blood adverse reactions.
- Urge patient to take precautions to prevent bleeding and to avoid aspirin, NSAIDs, and other drugs that may

increase bleeding risk.

- Instruct patient to seek emergency care immediately if unusual signs and symptoms occur that suggest a blood clot, such as shortness of breath, anxiety, change in skin color or mental status, or development of abnormal sensory or motor function.
- When therapy ends, warn patient to report any serious or prolonged bleeding episodes because additional therapy may be needed to control bleeding.

ropinirole hydrochloride

Requip

Class and Category

Chemical class: Non-ergot alkaloid dopamine agonist

Therapeutic class: Antidyskinetic

Pregnancy category: C

Indications and Dosages

↗ *To treat signs and symptoms of Parkinson's disease*

TABLETS

Adults. *Initial:* 0.25 mg t.i.d. Dosage titrated upward every wk according to the following schedule: 0.25 mg t.i.d. in wk 1; 0.5 mg t.i.d. in wk 2; 0.75 mg t.i.d. in wk 3; 1 mg t.i.d. in wk 4. After wk 4, dosage increased by 1.5 mg daily every wk up to 9 mg daily, then by 3 mg/day up to 24 mg daily. *Maximum:* 24 mg/day.

E.R. TABLETS

Adults. *Initial:* 2 mg once daily for 1 to 2 wk, increased, as needed, in increments of 2 mg/day at 1 wk or longer intervals. *Maximum:* 24 mg/day.

↗ *To treat moderate to severe primary restless legs syndrome*

TABLETS

Adults. *Initial:* 0.25 mg 1 to 3 hr before bedtime. Dosage increased after 2 days to 0.5 mg and then to 1 mg at the end of the first wk. If needed, dosage further increased in 0.5-mg increments every wk. *Maximum:* 4 mg daily.

Mechanism of Action

Directly stimulates postsynaptic dopamine

type 2 (D_2) receptors within the brain and acts as an agonist at peripheral D_2 receptors. These actions inhibit the firing of striatal cholinergic neurons, thus helping to control alterations in voluntary muscle movement (such as tremors and rigidity) associated with Parkinson's disease.

Contraindications

Hypersensitivity to ropinirole or its components

Interactions

DRUGS

carbamazepine, cimetidine, ciprofloxacin, clarithromycin, diltiazem, enoxacin, erythromycin, fluvoxamine, mexiletine, norfloxacin, omeprazole, phenobarbital, phenytoin, rifampin, ritonavir, troleandomycin: Altered drug clearance and increased blood level of ropinirole

chlorprothixene, domperidone, droperidol, haloperidol, metoclopramide, phenothiazines, thiothixene: Possibly decreased effectiveness of ropinirole

CNS depressants: Additive effects

ethinyl estradiol: Possibly reduced clearance of ropinirole

ACTIVITIES

alcohol use: Additive effects

Adverse Reactions

CNS: Asthenia, confusion, dizziness, falling asleep during activities of daily living, fatigue, hallucinations, headache, hyposthesia, malaise, neuralgia, paresthesia, rigors, somnolence, syncope, transient ischemic attack, vertigo

CV: Acute coronary syndrome, angina, bradycardia, cardiac failure, chest pain, hypertension, MI, orthostatic hypotension, palpitations, peripheral edema, sick sinus syndrome, tachycardia

EENT: Abnormal vision, dry mouth, nasal congestion, nasopharyngitis, rhinitis, toothache

GI: Abdominal pain, constipation, diarrhea, dyspepsia, gastric hemorrhage, gastroenteritis, indigestion, intestinal obstruction, ischemic hepatitis, nausea, pancreatitis, vomiting

GU: Elevated BUN level, erectile dysfunction, UTI

HEME: Anemia

MS: Arthralgia; arthritis; exacerbation of

restless leg syndrome in the early-morning hours; limb pain; muscle cramps, spasms, or stiffness; myalgia; neck pain; osteoarthritis; tendinitis

RESP: Asthma, bronchitis, cough, upper respiratory tract infection

SKIN: Diaphoresis, flushing, hot flashes, night sweats, rash

Other: Influenza, intense urges to perform certain activities (such as gambling or sex), viral infection, weight loss

Nursing Considerations

WARNING Expect to reassess patient for excessive sedation periodically during therapy. Excessive, acute drowsiness may arise as late as 1 year after starting therapy.

- When ropinirole is given as adjunct to levodopa, expect concurrent dosage of levodopa to be gradually decreased as tolerated.
- Expect to stop ropinirole gradually over 7 days, as follows: over first 4 days, reduce from t.i.d to b.i.d.; during last 3 days, reduce to once daily, followed by complete withdrawal of drug.

WARNING Watch for altered mental status during drug withdrawal. Rapid dose reduction may lead to a symptom complex resembling neuroleptic malignant syndrome that includes fever, muscle rigidity, altered level of consciousness, and autonomic instability.

- Watch for orthostatic hypotension, especially in patient with early Parkinson's disease. Orthostatic hypotension can occur more than 4 weeks after start of therapy or after a dosage reduction because ropinirole may impair systemic regulation of blood pressure.
- Monitor patient for hallucinations, especially if patient has Parkinson's disease, is elderly, or takes levodopa.
- Monitor patient for worsening of preexisting dyskinesia; ropinirole may potentiate dopaminergic adverse effects of levodopa.
- Avoid giving CNS depressants, sleep aids, and other CNS-interacting drugs during ropinirole therapy because they increase the risk of somnolence.
- Assess patient for skin changes regularly because risk of melanoma is higher in patients with Parkinson's disease. It isn't clear whether this results from disease or drugs used to treat it.

PATIENT TEACHING

- Inform patient with Parkinson's disease that ropinirole helps to improve muscle control and movement but doesn't cure Parkinson's disease.
- Encourage patient to take ropinirole with food to decrease risk of adverse GI effects.
- Caution patient to avoid hazardous activities until CNS effects of drug—including sedation—are known.
- If patient falls asleep during normal activities, advise her to notify prescriber.
- Urge patient to avoid consuming alcohol and other sedating drugs (such as sleep aids) during therapy because they may increase drug's CNS depressant effects.
- If patient has restless legs syndrome, explain that symptoms might appear in early morning during ropinirole therapy and could be worse or spread to other limbs. Urge patient to notify prescriber if this occurs.
- Instruct patient to change positions slowly to minimize effect on blood pressure.
- Urge patient to have regular skin examinations by a dermatologist or other qualified health professional.
- Advise patient to notify prescriber about intense urges (as for gambling or sex) because dosage may need to be reduced or drug discontinued.

rosiglitazone maleate

Avandia

Class and Category

Chemical class: Thiazolidinedione

Therapeutic class: Antidiabetic drug

Pregnancy category: C

Indications and Dosages

➤ *To achieve glucose control in type 2 diabetes mellitus as monotherapy or in combination with metformin*

TABLETS

Adults. *Initial:* 4 mg once daily or 2 mg b.i.d., increased to 8 mg once daily or 4 mg b.i.d. if glucose control is inadequate after 12 wk. *Maximum:* 8 mg daily.

➤ *To achieve glucose control in type 2 diabetes mellitus in combination with*

*insulin therapy***TABLETS**

Adults. 4 mg daily with no change in insulin dosage. Insulin dosage decreased by 10% to 25% if hypoglycemia occurs or fasting plasma concentrations decrease to less than 100 mg/dl with combination therapy.

Mechanism of Action

Increases tissue sensitivity to insulin. This peroxisome proliferator-activated receptor agonist regulates the transcription of insulin-responsive genes found in key target tissues, such as adipose tissue, skeletal muscle, and the liver. Enhanced tissue sensitivity to insulin lowers the blood glucose level.

Contraindications

Hypersensitivity to rosiglitazone or its components, New York Heart Association (NYHA) class III or IV heart failure

Interactions**DRUGS**

CYP2C8 inducers, such as rifampin: Possibly decreased effects of rosiglitazone

CYP2C8 inhibitors, such as gemfibrozil:

Possibly increased effects of rosiglitazone

Adverse Reactions

CNS: Fatigue, headache

CV: Angina, congestive heart failure, edema, hypertension, myocardial ischemia or infarction

EENT: Blurred vision, decreased visual acuity, macular edema, nasopharyngitis, sinusitis

ENDO: Hyperglycemia, hypoglycemia

GI: Diarrhea, elevated liver enzymes, hepatotoxicity

HEME: Anemia

MS: Arthralgia, back pain, fracture (women)

RESP: Dyspnea, upper respiratory tract infection

SKIN: Pruritus, rash, Stevens-Johnson syndrome, urticaria

Other: Anaphylaxis, angioedema, weight gain

Nursing Considerations

- Give rosiglitazone cautiously in patients with edema, heart failure, or hepatic impairment because of potential adverse reactions.
- Be aware that drug isn't recommended for

patients with symptomatic heart failure.

- Evaluate patient's liver function before starting drug and periodically throughout therapy, as ordered. Notify prescriber about abnormalities, such as nausea, vomiting, abdominal pain, fatigue, anorexia, and dark urine. Drug may need to be stopped.

WARNING Monitor patient for evidence of congestive heart failure—such as shortness of breath, rapid weight gain, or edema—because rosiglitazone can cause fluid retention that may lead to or worsen heart failure. Notify prescriber immediately if the patient's cardiac status deteriorates, and expect to stop the drug, as ordered.

- Monitor fasting glucose and glycosylated hemoglobin A_{1c} levels periodically, as ordered, to evaluate rosiglitazone effectiveness.
- Be aware that drug is effective only in the presence of endogenous insulin.

PATIENT TEACHING

- Stress the need to follow an exercise program and a diet control program during rosiglitazone therapy.
- Advise patient to notify prescriber immediately if she has shortness of breath, fluid retention, or sudden weight gain because drug may need to be discontinued.
- Instruct patient to have liver function tests, as prescribed, about every 2 months for first year and then annually.
- Inform premenopausal, anovulatory patient that drug may induce ovulation, increasing risk of pregnancy.
- Urge women to take precautions against falling; drug increases risk of fractures.

rosuvastatin calcium

Crestor

Class and Category

Chemical class: HMG-CoA reductase inhibitor

Therapeutic class: Antihyperlipidemic

Pregnancy category: X

Indications and Dosages

↗ *To treat hyperlipidemia, mixed dyslipidemia, hypertriglyceridemia, and pri-*

mary dysbetalipoproteinemia (Type III hyperlipoproteinemia); to slow the progression of atherosclerosis

TABLETS

Adults with LDL-C level of 190 mg/dl or below. *Initial:* 10 mg daily, increased every 2 to 4 wk, as needed. *Maximum:* 40 mg daily.

Adults with LDL-C level greater than 190 mg/dl. *Initial:* 20 mg daily, increased every 2 to 4 wk, as needed. *Maximum:* 40 mg daily.

↗ *To treat homozygous familial hypercholesterolemia*

TABLETS

Adults. *Initial:* 20 mg daily, increased every 2 to 4 wk, as needed. *Maximum:* 40 mg daily.

↗ *To treat heterozygous familial hypercholesterolemia*

TABLETS

Children age 10 and over and adolescents at least 1 year post-menarche. 5 to 20 mg daily, increased q 4 wk, as needed. *Maximum:* 20 mg daily.

DOSAGE ADJUSTMENT For patients taking cyclosporine, dosage shouldn't exceed 5 mg daily. For Asian patients, initial dosage should be limited to 5 mg daily. For patients taking gemfibrozil or combined lopinavir and ritonavir, 10 mg daily. For patients with severe renal impairment (creatinine clearance greater than 30 ml/min/1.73 m²) who aren't having hemodialysis, dosage should start at 5 mg daily but not exceed 10 mg daily. For patients taking niacin or fenofibrate, dosage reduction should be considered.

Route	Onset	Peak	Duration
P.O.	Unknown	3–5 hr	Unknown

Q
R
S

Mechanism of Action

Cholesterol and triglycerides circulate in the blood as part of lipoprotein complexes. Rosuvastatin inhibits the enzyme 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase. This inhibition reduces lipid levels by increasing the number of hepatic low-density-lipoprotein (LDL) receptors on the cell surface to increase uptake and catabolism of LDL. It also inhibits hepatic synthesis of very-low-density lipoprotein (VLDL), which decreases

es the total number of VLDL and LDL particles.

Contraindications

Active liver disease, breast-feeding, hypersensitivity to rosuvastatin or its components, pregnancy, unexplained persistent elevations of serum transaminase levels

Interactions

DRUGS

antacids: Decreased blood rosuvastatin level if given within 2 hours of rosuvastatin
cyclosporine, gemfibrozil, lopinavir/ritonavir, niacin, other lipid-lowering drugs: Increased rosuvastatin level and risk of myopathy
oral contraceptives: Increased blood ethinyl estradiol and norgestrel levels
warfarin: Increased INR

Adverse Reactions

CNS: Asthenia, depression, dizziness, headache, hypertonia, insomnia, memory loss, paresthesia

CV: Chest pain, hypertension, peripheral edema

EENT: Pharyngitis, rhinitis, sinusitis

ENDO: Thyroid function abnormalities

GI: Abdominal pain, constipation, diarrhea, elevated liver function test results, gastroenteritis, hepatic failure, hepatitis, jaundice, nausea, pancreatitis

GU: Acute renal failure, proteinuria, UTI

MS: Arthralgia, arthritis, back pain, myalgia, myopathy, rhabdomyolysis

RESP: Bronchitis, increased cough

SKIN: Rash, urticaria

Other: Angioedema, flulike symptoms, generalized pain, infection

Nursing Considerations

- Use rosuvastatin cautiously in patients who consume large quantities of alcohol or have a history of liver disease because drug is contraindicated in patients with active liver disease or unexplained persistent elevations of transaminase levels.
- Also use cautiously in patients with risk factors for myopathy, such as renal impairment, advanced age, and hypothyroidism.
- Obtain baseline liver function test results and expect to monitor them every 3 months for abnormal elevations. Notify prescriber if elevations occur. If ALT or AST levels increase to more than three times the normal range, expect dosage to

be reduced or drug discontinued.

- Monitor serum lipoprotein level, as ordered, to evaluate response to therapy.
- Expect rosuvastatin to be temporarily withheld if patient develops any condition that may be related to myopathy or that predisposes her to renal failure, such as sepsis, hypotension, major surgery, trauma, uncontrolled seizures, or severe metabolic, endocrine, or electrolyte disorders.
- Notify prescriber if proteinuria or hematuria appears on patient's routine urinalysis because rosuvastatin dosage may need to be reduced.

PATIENT TEACHING

- Encourage patient to follow a low-fat, low-cholesterol diet.
- Tell patient to wait at least 2 hours after taking rosuvastatin before taking antacids.
- Instruct patient to notify prescriber immediately about muscle pain, tenderness, or weakness, especially if accompanied by malaise or fever.
- Tell woman of childbearing age about the need to use reliable contraceptive method while taking drug. Instruct her to notify prescriber at once if she suspects she may be pregnant.

rufinamide

Banzel

Class and Category

Chemical class: Triazole derivative

Therapeutic class: Anticonvulsant

Pregnancy category: C

Indications and Dosages

↗ *As adjunct treatment of seizures associated with Lennox-Gastaut syndrome*

TABLETS

Adults. *Initial*: 200 to 400 mg b.i.d., increased in daily increments of 200 to 400 mg b.i.d. every 2 days until reaching 1,600 mg b.i.d. *Maximum*: 1,600 mg b.i.d.

Children age 4 and over. *Initial*: 5 mg/kg b.i.d., increased in daily increments of 5 mg/kg b.i.d. every 2 days until reaching 22.5 mg/kg b.i.d. or 1600 mg b.i.d., whichever is less.

DOSAGE ADJUSTMENT For patients undergoing dialysis, dosage may need to be increased. For patients also receiving val-

proate, initial dosage reduced to less than 400 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	4–6 hr	Unknown

Mechanism of Action

Unknown, although rufinamide is known to slow sodium channel recovery from inactivation after a prolonged prepulse and to limit repetitive firing of sodium-dependent action potentials in neurons in the brain. These actions may help limit seizure activity.

Contraindications

Familial short-QT syndrome, hypersensitivity to rufinamide or its components

Interactions

DRUGS

contraceptives containing ethinyl estradiol and norethindrone: Decreased effectiveness of the oral contraceptive

phenytoin: Increased plasma phenytoin level and risk of adverse reactions

valproate: Increased plasma rufinamide level and risk of adverse reactions

ACTIVITIES

alcohol use: Increased CNS effects

Adverse Reactions

CNS: Aggression, anxiety, ataxia, attention disturbance, dizziness, fatigue, headache, hyperactivity, seizures, somnolence, status epilepticus, suicidal ideation, tremor, vertigo

CV: First-degree AV block, right bundle branch block

EENT: Sinusitis

ENDO: Blurred vision, diplopia, nasopharyngitis, nystagmus

GI: Abdominal pain, anorexia, constipation, dyspepsia, nausea, vomiting

GU: Dysuria, enuresis, hematuria, incontinence, nephrolithiasis, pollakiuria, polyuria

HEME: Anemia, leukopenia, lymphadenopathy, neutropenia, thrombocytopenia

MS: Back pain

RESP: Bronchitis

SKIN: Pruritus, rash

Other: Multi-organ hypersensitivity

Nursing Considerations

- Administer rufinamide with food because absorption is increased.
- Monitor patient's QT interval regularly, as ordered, because rufinamide may shorten

the QT interval and possibly predispose patient to ventricular fibrillation if the interval falls below 300 msec.

WARNING Watch closely for multi-organ hypersensitivity, especially if patient develops a rash. Although uncommon, it may cause serious adverse effects, such as urticaria, facial edema, fever, elevated eosinophils or liver enzymes, hematuria, stupor, lymphadenopathy and severe hepatitis, in addition to rash. Notify prescriber at once if such changes appear, and expect to stop drug and provide supportive care.

- Watch closely for suicidal tendencies, especially when therapy starts and dosage changes and particularly in children and adolescents.
- To stop therapy, expect to taper dosage to minimize adverse effects rather than stopping abruptly.

PATIENT TEACHING

- Make sure patient receives medication guide describing drug use and possible suicidal tendencies.
- Instruct patient to take drug exactly as prescribed and to take each dose with food. If patient has trouble swallowing tablets, tell him they may be crushed.
- Inform woman that rufinamide decreases effectiveness of contraceptives containing ethinyl estradiol and norethindrone. Tell her to use a different contraceptive during therapy and to contact prescriber immediately if she thinks she's pregnant.
- Tell patient to report a rash accompanied by fever or other symptoms immediately.
- Warn family or caregiver to watch patient for suicidal tendencies, especially when therapy starts or dosage changes, and particularly if patient is a child or adolescent.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Caution patient not to stop taking drug abruptly. Explain that gradual tapering helps to avoid withdrawal symptoms.
- Explain that alcohol consumption may intensify drug effects.

**salmeterol
xinafoate**

Serevent Diskus

Class and Category

Chemical class: Sympathomimetic amine

Therapeutic class: Bronchodilator

Pregnancy category: C

Indications and Dosages

➤ *To prevent asthma-induced bronchospasm*

ORAL INHALATION POWDER

Adults and children age 4 and over.

1 inhalation (50 mcg) every 12 hr.

➤ *To prevent COPD-induced bronchospasm*

ORAL INHALATION POWDER

Adults. 1 inhalation (50 mcg) every 12 hr.

➤ *To prevent exercise-induced bronchospasm*

ORAL INHALATION POWDER

Adults and children age 4 and over.

1 inhalation (50 mcg) at least 30 min before exercise.

Route	Onset	Peak	Duration
Inhalation	10–20 min	3–4 hr	12 hr

Mechanism of Action

Attaches to beta₂ receptors on bronchial cell membranes, stimulating the intracellular enzyme adenylate cyclase to convert adenosine triphosphate to cAMP. The resulting increase in intracellular cAMP level relaxes bronchial smooth-muscle cells, stabilizes mast cells, and inhibits histamine release.

Contraindications

Hypersensitivity to salmeterol or its components

Interactions

DRUGS

atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin: Possibly increased risk of adverse cardiovascular effects

beta blockers: Mutual inhibition of therapeutic effects

loop or thiazide diuretics: Increased risk of hypokalemia and potentially life-threatening arrhythmias

MAO inhibitors, tricyclic antidepressants: Potentiated adverse vascular effects, such as hypertensive crisis

Adverse Reactions

CNS: Dizziness, fever, headache, nervous-

ness, paresthesia, tremor

CV: Palpitations, tachycardia

EENT: Dry mouth, nose, and throat; sinus problems

GI: Nausea

MS: Arthralgia

RESP: Cough, paradoxical bronchospasm

SKIN: Contact dermatitis, eczema, rash, urticaria

Other: Angioedema, generalized aches and pains

Nursing Considerations

- Be aware that salmeterol shouldn't be used to relieve bronchospasm quickly because of its prolonged onset of action and that patients already taking drug twice daily shouldn't take additional doses for exercise-induced bronchospasm.

WARNING Be aware that a recent study suggests that asthma-related deaths may increase in asthmatics receiving salmeterol. Monitor this patient population closely throughout salmeterol therapy, and notify prescriber immediately of any changes in patient's respiratory status.

- Watch for arrhythmias and changes in blood pressure after use in patients with cardiovascular disorders, including ischemic cardiac disease, hypertension, and arrhythmias, because of drug's beta-adrenergic effects.
- Be aware that Serevent Diskus delivers full dose of salmeterol in only one inhalation.

WARNING Stop salmeterol immediately and notify prescriber if patient develops paradoxical bronchospasm. Risk is greatest with first use of a new canister or vial used as an inhalant.

PATIENT TEACHING

- Advise patient who is using salmeterol to prevent asthma-induced bronchospasm to take doses 12 hours apart for optimum effect. Caution against using drug more than every 12 hours.
- Teach patient how to use the diskus by instructing him to slide the lever only once when preparing dose to avoid wasting doses. Advise him to exhale immediately before using the diskus and then to place mouthpiece to his lips and inhale through his mouth, not his nose. Then he should remove mouthpiece from his mouth, hold his breath for at least 10 sec-

onds, and exhale slowly.

- Advise patient to rinse mouth with water after each dose to minimize dry mouth.
- Advise patient to discard diskus 6 weeks after removing it from overwrap or when dose indicator reads zero.
- Instruct patient to notify prescriber if he needs four or more oral inhalations of rapid-acting inhaled bronchodilator a day for 2 or more consecutive days, or if he uses more than one canister of rapid-acting bronchodilator in an 8-week period.
- Caution patient not to use other drugs to treat his underlying respiratory condition without consulting prescriber and to let all prescribers know that he takes salmeterol.

salsalate (salicylsalicylic acid)

Amigesic, Anaflex 750, Argesic-SA, Disalcid, Marthritic, Mono-Gesic, Salflex, Salsitab

Class and Category

Chemical class: Salicylic acid ester

Therapeutic class: Analgesic, anti-inflammatory

Pregnancy category: C

Indications and Dosages

↗ *To relieve symptoms of rheumatoid arthritis and related rheumatic disorders*

CAPSULES

Adults and adolescents. *Initial:* 1 g t.i.d.; dosage then titrated, as needed.

TABLETS

Adults and adolescents. *Initial:* 0.5 to 1 g b.i.d. or t.i.d.; dosage then titrated, as needed.

Route	Onset	Peak	Duration
P.O.	Unknown	2–3 wk	Unknown

Mechanism of Action

Exerts peripherally induced analgesic and anti-inflammatory effects by blocking pain impulses and inhibiting prostaglandin synthesis.

Contraindications

Bleeding disorders; hypersensitivity to NSAIDs, salicylates, or their components

Interactions

DRUGS

acetaminophen: Increased risk of renal dysfunction with prolonged use of both drugs
anticoagulants, thrombolytics: Increased risk and severity of GI bleeding

antiemetics: Masked symptoms of salicylate-induced ototoxicity

bismuth subsalicylate: Increased risk of salicylate toxicity with large doses of salsalate
cefamandole, cefoperazone, cefotetan, platelet aggregation inhibitors, plicamycin, valproic acid: Possibly hypoprothrombinemia

corticosteroids: Possibly decreased blood salicylate level; additive therapeutic effects when both drugs are used to treat arthritis
furosemide: Increased risk of ototoxicity and salicylate toxicity

hydantoins: Possibly decreased hydantoin metabolism, leading to toxicity

insulin, oral antidiabetic drugs: Potentiated hypoglycemic effect

laxatives (cellulose-containing): Possibly reduced salsalate effectiveness due to impaired absorption

methotrexate: Increased risk of methotrexate toxicity

NSAIDs: Increased risk of adverse GI effects
ototoxic drugs, vancomycin: Increased risk of ototoxicity

probenecid, sulfapyrazone: Decreased uricosuric effects

topical salicylic acid, other salicylates:

Increased risk of salicylate toxicity if significant quantities are absorbed

urinary acidifiers (ammonium chloride, ascorbic acid, potassium or sodium phosphates): Decreased salicylate excretion, possibly leading to salicylate toxicity

urinary alkalizers (antacids [long-term high-dose use], carbonic anhydrase inhibitors, citrates, sodium bicarbonate): Increased salicylate excretion, leading to reduced effectiveness and shortened half-life; increased risk of salicylate toxicity with carbonic anhydrase inhibitor–induced metabolic acidosis

vitamin K: Increased vitamin K requirements

ACTIVITIES

alcohol use: Increased risk of GI bleeding

Adverse Reactions

CNS: CNS depression, confusion, dizziness, drowsiness, fever, headache, lassitude

EENT: Hearing loss, tinnitus, vision changes

GI: Anorexia, diarrhea, epigastric discomfort, GI bleeding, heartburn, hepatotoxicity, indigestion, nausea, thirst, vomiting

HEME: Hemolytic anemia, leukopenia, prolonged bleeding time, thrombocytopenia

SKIN: Diaphoresis, purpura, rash, urticaria
Other: Angioedema, Reye's syndrome

Nursing Considerations

- Avoid using salsalate in patients with hypoprothrombinemia or vitamin K deficiency because drug's hypoprothrombinemic effect may precipitate bleeding.
- Monitor hepatic and renal function, as appropriate, during long-term therapy.
- Assess for signs and symptoms of GI bleeding, such as abdominal pain or black, tarry stools, especially in patient with peptic ulcer disease.
- Assess for symptoms of ototoxicity, such as ringing or roaring in ears.

PATIENT TEACHING

- Instruct patient to take salsalate with food or a full glass of water and to remain upright for 1 hour after administration to prevent drug from lodging in esophagus and causing irritation.
- Inform patient that therapeutic response may not occur for 2 to 3 weeks.
- Urge patient to notify prescriber immediately of abdominal pain or black, tarry stools; these symptoms may indicate GI bleeding or drug toxicity.

sapropterin dihydrochloride

Kuvan

Class and Category

Chemical class: Synthetic tetrahydropterin salt

Therapeutic class: Phenylalanine reducer

Pregnancy category: C

Indications and Dosages

➤ *To reduce blood phenylalanine level in patients with hyperphenylalaninemia from tetrahydrobiopterin-responsive phenylketonuria, with phenylalanine-restricted diet*

TABLETS

Adults and children age 4 and over. *Initial:* 10 mg/kg daily with dosage increased or decreased after 1 wk based on response and then periodically adjusted, as needed. Expect to discontinue drug if levels fail to increase after 1 mo of therapy at 20 mg/kg/day. *Maintenance:* 5 to 20 mg/kg daily. *Maximum:* 20 mg/kg daily.

Mechanism of Action

As a synthetic form of tetrahydrobiopterin, the cofactor of the enzyme phenylalanine hydroxylase (PAH), sapropterin hydroxylates phenylalanine to form tyrosine. This improves the oxidative metabolism of phenylalanine, which decreases blood phenylalanine.

Contraindications

Hypersensitivity to sapropterin or its components

Interactions

DRUGS

folate metabolism inhibitors, such as

methotrexate: Possibly decreased effectiveness of sapropterin

levodopa: Possibly increased risk of irritability, over stimulation or seizures

sildenafil, tadalafil, vardenafil: Possibly additive vasorelaxation effect leading to hypotension

Adverse Reactions

CNS: Agitation, dizziness, fever, headache, irritability, over stimulation, seizures

CV: MI, peripheral edema

EENT: Nasal congestion, pharyngolaryngeal pain, rhinorrhea

GI: Abdominal pain, diarrhea, elevated liver enzymes, gastrointestinal bleeding, nausea, vomiting

GU: Polyuria

HEME: Bleeding, neutropenia

MS: Arthralgia

RESP: Cough, respiratory failure, upper respiratory infection

SKIN: Rash

Nursing Considerations

- Use cautiously in patients with hepatic impairment because impaired phenylalanine metabolism may be linked to hepatic damage.
- Administer drug at same time each day.

- Dissolve tablets in 4 to 8 ounces of water or apple juice, which may take a few minutes. Stirring or crushing tablets will hasten process. Know that tablets may not dissolve completely. Give solution within 15 minutes with food. If there are particles left in glass after administration, add more water or apple juice and have patient drink again to ensure a complete dose.
- Monitor patient's blood phenylalanine level regularly, as ordered.
- Expect drug to be discontinued if patient's blood phenylalanine level doesn't decrease after 1 month at maximum dosage.
- Continue to restrict dietary phenylalanine intake.

PATIENT TEACHING

- Tell patient to dissolve tablets in 4 to 8 ounces water or apple juice, which may take a few minutes. Advise him to stir or crush tablets to hasten process and to drink solution within 15 minutes of dissolving. Explain that tablets may not completely dissolve but that solution is alright to drink with particles floating in solution. After drinking solution, tell him to add more water or apple juice if any particles are clinging to glass and drink again.
- Stress to patient or caregiver importance of continuing dietary restriction of phenylalanine intake.
- Stress continued need for periodic blood tests to determine drug effectiveness.
- Tell patient to a missed dose as soon as he remembers, unless it's almost time for the next dose. Warn patient not to take more than 1 dose per day.

saxagliptin monohydrate

Onglyza

Class and Category

Chemical class: Dipeptidyl peptidase-4 inhibitor

Therapeutic class: Antidiabetic

Pregnancy category: B

Indications and Dosages

↗ *To improve blood glucose control in type 2 diabetes mellitus as adjunct to diet and exercise*

TABLETS

Adults. 2.5 mg or 5 mg once daily

DOSAGE ADJUSTMENT For patients with moderate or severe renal impairment (creatinine clearance 50 ml/min/1.73 m² or less), patients with end-stage renal disease, patients having hemodialysis, and patients receiving strong CYP3A4/5 inhibitors, dosage shouldn't exceed 2.5 mg once daily.

Route	Onset	Peak	Duration
P.O.	Unknown	2 hr	24 hr

Mechanism of Action

Incretin hormones, such as glucose-dependent insulintropic polypeptide (GIP) and glucagons-like peptide-1 (GLP-1), are released into bloodstream from small intestine in response to meals. Upon arrival at the pancreas, they stimulate pancreatic beta cells to release insulin. GLP-1 also reduces glucagon secretion from pancreatic alpha cells, which reduces hepatic glucose production. Incretin hormones become inactivated within minutes of release by the enzyme, dipeptidyl peptidase-4. Saxagliptin inhibits this enzyme, thereby slowing inactivation of incretin hormones, which provides more time for them to increase insulin levels and blunt glucagon secretion. More insulin and less hepatic glucose production work together to lower blood glucose levels.

Contraindications

Hypersensitivity to saxagliptin or its components

Interactions

DRUGS

aprepitant, diltiazem, erythromycin, fluconazole, fosamprenavir, verapamil: Possibly increased plasma saxagliptin level
atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin: Increased plasma saxagliptin level
sulfonyleureas: Increased risk of hypoglycemia

FOODS

grapefruit juice: Possibly increased plasma saxagliptin levels

Adverse Reactions

CNS: Headache

EENT: Sinusitis, nasopharyngitis

ENDO: Hypoglycemia

GI: Abdominal pain, gastroenteritis, vomiting

GU: Elevated plasma creatinine level, UTI

HEME: Lymphopenia

RESP: Upper respiratory tract infection

SKIN: Rash, urticaria

Other: Periphal edema, facial edema

Nursing Considerations

- Saxagliptin shouldn't be used to treat type 1 diabetes mellitus or diabetic ketoacidosis. It hasn't been studied with insulin.
- Obtain a serum creatinine level, as ordered, before starting saxagliptin therapy and then periodically thereafter to monitor patient's renal function.
- Monitor patient's blood glucose level and hemoglobin A_{1C} to assess effectiveness of saxagliptin therapy.
- Watch for hypoglycemia in patients taking antidiabetics, such as sulfonylureas. Expect dosage of insulin secretagogues (such as sulfonylureas) to be reduced to reduce risk of hypoglycemia.

PATIENT TEACHING

- Stress that saxagliptin isn't a replacement for diet and exercise therapy.
- Explain importance of self-monitoring glucose levels during saxagliptin therapy.
- Teach patient to recognize hypoglycemia and how to treat it if it should occur. Urge him to carry glucose with him at all times in case hypoglycemia occurs.
- Instruct patient to notify prescriber if fever, trauma, infection, illness, surgery, or other stress occurs because blood glucose control may be altered requiring temporary insulin therapy.

scopolamine hydrobromide

scopolamine transdermal system

Transderm-Scōp, Transderm-V (CAN)

Class and Category

Chemical class: Belladonna alkaloid,

tertiary amine

Therapeutic class: Anesthesia adjunct, anticholinergic, antiemetic, antispasmodic, anti-vertigo

Pregnancy category: C

Indications and Dosages

↗ *To treat biliary tract disorders, enuresis, nausea and vomiting, and nocturia*

I.V., I.M., OR SUBCUTANEOUS INJECTION (HYDROBROMIDE)

Adults and adolescents. 300 to 600 mcg (0.3 to 0.6 mg) as a single dose.

Children. 6 mcg (0.006 mg)/kg as a single dose.

↗ *To prevent excessive salivation and respiratory tract secretions during anesthesia*

I.M. INJECTION (HYDROBROMIDE)

Adults and adolescents. 0.2 to 0.6 mg 30 to 60 min before induction of anesthesia.

Children ages 8 to 12. 0.3 mg 45 to 60 min before induction of anesthesia.

Children ages 3 to 8. 0.2 mg 45 to 60 min before induction of anesthesia.

Children ages 7 months to 3 years. 0.15 mg 45 to 60 min before induction of anesthesia.

Infants ages 4 to 7 months. 0.1 mg 45 to 60 min before induction of anesthesia.

↗ *As adjunct to anesthesia to induce sleep and calmness*

I.V., I.M., OR SUBCUTANEOUS INJECTION (HYDROBROMIDE)

Adults and adolescents. 0.6 mg t.i.d. or q.i.d.

↗ *As adjunct to anesthesia to induce amnesia*

I.V., I.M., OR SUBCUTANEOUS INJECTION (HYDROBROMIDE)

Adults and adolescents. 0.32 to 0.65 mg.

↗ *To prevent nausea, vomiting, and vertigo associated with motion sickness*

TRANSDERMAL SYSTEM

Adults and adolescents. 1 U.S. transdermal system (0.5 mg) applied behind ear for 3-day period, beginning at least 4 hr before antiemetic effect is required. Or, 1 Canadian transdermal system (1 mg) applied behind ear for 3-day period, beginning at least 12 hr before antiemetic effect is required.

DOSAGE ADJUSTMENT Dosage reduction possible for elderly patients because of their increased sensitivity to scopolamine.

Contraindications

Angle-closure glaucoma; hemorrhage with hemodynamic instability; hepatic dysfunction; hypersensitivity to barbiturates, scopolamine, other belladonna alkaloids, or their components; ileus; intestinal atony; myasthenia gravis; myocardial ischemia; obstructive GI disease, such as pyloric stenosis; obstructive uropathy, as in prostatic hyperplasia; renal impairment; tachycardia; toxic megacolon; ulcerative colitis

Route	Onset	Peak	Duration
I.V., I.M., SubQ*	30 min	1–2 hr	4–6 hr
I.V.†	10 min	50–80 min	2 hr
I.M.‡	15–30 min	Unknown	4 hr
Transdermal	4 hr	Unknown	72 hr

Mechanism of Action

Competitively inhibits acetylcholine at autonomic postganglionic cholinergic receptors. Because the most sensitive receptors are in the salivary, bronchial, and sweat glands, this action reduces secretions from these glands. Scopolamine reduces GI smooth-muscle tone; decreases gastric secretions and GI motility; reduces bladder detrusor muscle tone; reduces nasal, oropharyngeal, and bronchial secretions; and decreases airway resistance by relaxing smooth muscles in the bronchi and bronchioles.

Scopolamine also blocks neural pathways in the inner ear to relieve motion sickness and depresses the cerebral cortex to produce sedation and hypnotic effects.

Interactions

DRUGS

adsorbent antidiarrheals, antacids:

Decreased absorption and therapeutic effects of scopolamine

anticholinergics (other): Possibly intensified anticholinergic effects

antimyasthenics: Possibly reduced intestinal motility

CNS depressants: Possibly potentiated

* For inhibition of saliva.

† For amnesia.

‡ For antiemesis.

effects of either drug, resulting in additive sedation

cyclopropane: Increased risk of ventricular arrhythmias (with I.V. scopolamine)

haloperidol: Decreased antipsychotic effect of haloperidol

ketoconazole: Decreased ketoconazole absorption

lorazepam (parenteral): Possibly hallucinations, irrational behavior, and sedation

metoclopramide: Possibly antagonized effect of metoclopramide on GI motility

opioid analgesics: Increased risk of severe constipation and ileus

potassium chloride: Possibly increased severity of potassium chloride–induced GI lesions

urinary alkalinizers (antacids, carbonic anhydrase inhibitors, citrates, sodium bicarbonate): Delayed excretion of scopolamine, possibly leading to increased therapeutic and adverse effects

ACTIVITIES

alcohol use: Additive CNS effects

Adverse Reactions

CNS: Dizziness, drowsiness, euphoria, insomnia, memory loss, paradoxical stimulation

CV: Palpitations, tachycardia

EENT: Blurred vision; dry eyes, mouth, nose, and throat; mydriasis

GI: Constipation, dysphagia

GU: Urinary hesitancy, urine retention

SKIN: Decreased sweating, dry skin, flushing

Other: Injection site irritation or redness

Nursing Considerations

- For I.V. injection, dilute scopolamine with sterile water for injection.
- Assess for bladder distention and monitor urine output because drug's antimuscarinic effects can cause urine retention.
- Monitor for pain. In presence of pain, drug may act as a stimulant and produce delirium if used without morphine or meperidine.
- Monitor heart rate for transient tachycardia, which may occur with high doses of drug. Rate should return to normal within 30 minutes.

PATIENT TEACHING

- Instruct patient to apply scopolamine transdermal patch on hairless area behind

- ear and to wash hands thoroughly with soap and water before and after applying.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
 - Instruct patient to avoid alcohol while taking oral forms of scopolamine.
 - If patient complains of dry eyes, suggest lubricating drops.

secobarbital sodium

Novosecobarb (CAN), Seconal

Class, Category, and Schedule

Chemical class: Barbiturate

Therapeutic class: Sedative-hypnotic

Pregnancy category: D

Controlled substance schedule: II

Indications and Dosages

➤ *To induce sedation before surgery*

CAPSULES

Adults. 200 to 300 mg 1 to 2 hr before surgery.

Children. 2 to 6 mg/kg 1 to 2 hr before surgery. *Maximum:* 100 mg.

➤ *To provide short-term treatment of insomnia*

CAPSULES

Adults. 100 mg at bedtime.

➤ *To relieve apprehension, daytime anxiety, and tension*

CAPSULES

Adults. 30 to 50 mg t.i.d. or q.i.d.

Children. 2 mg/kg t.i.d.

DOSAGE ADJUSTMENT Reduced dosage required for elderly or debilitated patients and those with renal or hepatic dysfunction.

Route	Onset	Peak	Duration
P.O.	10–15 min	15–30 min	1–4 hr

Mechanism of Action

Inhibits upward conduction of nerve impulses to the reticular formation of the brain, thereby disrupting impulse transmission to the cortex. This action depresses the CNS, producing drowsiness, hypnosis, and sedation.

Contraindications

History of barbiturate addiction; hypersensitivity to secobarbital, other barbiturates,

or their components; nephritis; porphyria; severe hepatic or respiratory impairment

Interactions

DRUGS

acetaminophen, adrenocorticoids, beta blockers, chloramphenicol, cyclosporine, dacarbazine, digoxin, disopyramide, estrogens, metronidazole, oral anticoagulants, oral contraceptives, quinidine, thyroid hormones, tricyclic antidepressants: Decreased effectiveness of these drugs

addictive drugs: Increased risk of addiction
calcium channel blockers: Possibly excessive hypotension

carbamazepine, succinimide anticonvulsants: Decreased blood levels and increased elimination of these drugs

carbonic anhydrase inhibitors: Increased risk of osteopenia

CNS depressants: Increased CNS depressant effects

cyclophosphamide: Increased risk of leukopenic activity and reduced half-life of cyclophosphamide

divalproex sodium, valproic acid: Increased CNS depression and neurologic toxicity

doxycycline, fenopropfen: Increased elimination of these drugs

general anesthetics (enflurane, halothane, methoxyflurane): Increased risk of hepatotoxicity; increased risk of nephrotoxicity (with methoxyflurane)

griseofulvin: Decreased griseofulvin absorption

guanadrel, guanethidine: Possibly increased orthostatic hypotension

haloperidol: Possibly altered pattern or frequency of seizures, decreased blood haloperidol level

ketamine: Increased risk of hypotension or respiratory depression (when secobarbital is used as preanesthetic)

leucovorin (large doses): Decreased anticonvulsant effect of secobarbital

loxapine, phenothiazines, thioxanthenes: Possibly lowered seizure threshold

MAO inhibitors: Possibly prolonged CNS depressant effects of secobarbital

maprotiline: Increased CNS depressant effect; possibly lowered seizure threshold and decreased anticonvulsant effect with high doses of maprotiline

methylphenidate: Increased risk of barbitu-

rate toxicity

mexiletine: Decreased blood mexiletine level

phenylbutazone: Decreased effectiveness of secobarbital

posterior pituitary hormones: Increased risk of arrhythmias and coronary insufficiency

primidone: Increased sedative effect of

either drug, change in seizure pattern

vitamin D: Decreased vitamin D effects

xanthines (aminophylline, oxtriphylline, theophylline): Increased metabolism of xanthines (except dyphylline), decreased hypnotic effect of secobarbital

FOODS

caffeine: Increased caffeine metabolism, decreased hypnotic effect of secobarbital

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Anxiety, clumsiness, confusion, depression, dizziness, drowsiness, hangover, headache, insomnia, irritability, lethargy, nervousness, nightmares, paradoxical stimulation, syncope

CV: Hypotension

EENT: Laryngospasm

GI: Anorexia, constipation, nausea, vomiting

MS: Arthralgia, muscle weakness

RESP: Apnea, bronchospasm, respiratory depression

SKIN: Jaundice

Other: Drug dependence, weight loss

Nursing Considerations

- Be aware that prolonged use of secobarbital may lead to tolerance and physical and psychological dependence.

WARNING To avoid withdrawal symptoms, expect to taper drug after long-term therapy. Withdrawal symptoms usually appear 8 to 12 hours after stopping drug and may include anxiety, insomnia, muscle twitching, nausea, orthostatic hypotension, vomiting, weakness, and weight loss. Severe symptoms may include delirium, hallucinations, and seizures. Generalized tonic-clonic seizures may occur within 16 hours or up to 5 days after last dose.

- Assess patient for signs and symptoms of barbiturate toxicity, including dyspnea, severe confusion, and severe drowsiness. Notify prescriber immediately if they appear because barbiturate toxicity may be life-threatening.

- Expect prescriber to provide patient with the least possible quantity of secobarbital to minimize the risk of acute or chronic overdose. For patients who are depressed, suicidal, or drug-dependent or who have a history of drug abuse, institute precautions to prevent drug hoarding and overdose.

PATIENT TEACHING

- Instruct patient to take secobarbital exactly as prescribed because of the risk of addiction.
- Inform patient that taking drug with food may reduce adverse GI effects.
- Advise patient to avoid alcohol and caffeine and potentially hazardous activities during therapy.
- Inform patient about possible hangover effect.
- If patient takes an oral contraceptive, recommend using an additional form of birth control during therapy.
- Caution patient not to stop taking drug abruptly.
- Instruct patient to notify prescriber of bone pain, muscle weakness, or unexplained weight loss during therapy.

selegiline hydrochloride

Apo-Selegiline (CAN), Carbox, Eldepryl, Gen-Selegiline (CAN), Novo-Selegiline (CAN), Nu-Selegiline (CAN), SD Deprenyl (CAN), Selegiline-5 (CAN), Zelapar

selegiline transdermal system

Emsam

Class and Category

Chemical class: Phenethylamine derivative
Therapeutic class: Antidepressant (Emsam), antidyskinetic

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to carbidopa-levodopa therapy to treat Parkinson's disease*

CAPSULES, TABLETS

Adults. 10 mg once daily, or 5 mg b.i.d.

with breakfast and lunch.

DOSE ADJUSTMENT For patient with levodopa-induced adverse effects, 2.5 mg q.i.d.

↗ *As adjunct to carbidopa-levodopa therapy to treat Parkinson's disease in patients whose response to therapy has deteriorated*

ORALLY DISINTEGRATING TABLETS (ZELAPAR)

Adults. *Initial:* 1.25 mg once daily before breakfast for at least 6 wk; then increased to 2.5 mg once daily, if needed.

↗ *To treat depression*

TRANSDERMAL SYSTEM (EMSAM)

Adults. *Initial:* 6 mg/24 hr with patch applied daily to upper torso, upper thigh, or outer surface of upper arm. Increased every 2 wk in increments of 3 mg/24 hr, as needed. *Maximum:* 12 mg/24 hr.

Mechanism of Action

Reduces dopamine metabolism by non-competitively inhibiting the brain enzyme monoamine oxidase type B. This increases the amount of dopamine available to relieve symptoms of parkinsonism. Selegiline's metabolites may also enhance dopamine transmission by inhibiting its reuptake at synapses.

Contraindications

Hypersensitivity to selegiline or its components; pheochromocytoma; use within 14 days of meperidine; use within 10 days of general anesthesia; use with carbamazepine, oxcarbazepine, selective serotonin reuptake inhibitors (fluoxetine, paroxetine, sertraline), dual serotonin and norepinephrine reuptake inhibitors (duloxetine, venlafaxine), tricyclic antidepressants (amitriptyline, bupropion, imipramine), analgesics (tramadol, propoxyphene), dextromethorphan; use with St. John's wort, mirtazapine, cyclobenzaprine, oral selegiline, other MAO inhibitors, sympathomimetic amines (Emsam only)

Interactions

DRUGS

carbamazepine, oxcarbazepine: Increased blood selegiline level
fluoxetine, fluvoxamine, nefazodone, paroxetine, sertraline, venlafaxine: Increased risk of adverse reactions similar to those of sero-

tonin syndrome (confusion, hypomania, restlessness, myoclonus), autonomic instability, delirium, muscle rigidity, and severe agitation

levodopa: Increased risk of confusion, dyskinesia, hallucinations, nausea, and orthostatic hypotension

meperidine, possibly other opioid agonists:

Increased risk of diaphoresis, excitation, muscle rigidity, and severe hypertension

sympathomimetics: Increased risk of severe hypertension

tricyclic antidepressants: Possibly serious CNS reactions, including decreased level of consciousness, hyperpyrexia, hypertension, muscle rigidity, seizures, and syncope

FOODS

caffeine: Increased risk of hypertension
foods that contain tyramine or other high-pressor amines: Increased risk of sudden and severe hypertension

ACTIVITIES

alcohol use: Increased risk of hypertension

Adverse Reactions

CNS: Anxiety, chills, confusion, dizziness, drowsiness, dyskinesia, euphoria, extrapyramidal reactions, fatigue, hallucinations, headache, insomnia, irritability, lethargy, memory loss, mood changes, nervousness, paresthesia, restlessness, suicidal ideation, syncope, tremor, weakness

CV: Arrhythmias, chest pain, hypertension, orthostatic hypotension, palpitations, peripheral edema

EENT: Altered taste, blepharospasm, blurred vision, burning lips or mouth, diplopia, dry mouth, pharyngitis, sinusitis, tinnitus

GI: Abdominal pain, anorexia, constipation, diarrhea, GI bleeding, heartburn, nausea, vomiting

GU: Dysuria, urinary hesitancy, urinary urgency, urine retention

MS: Arthralgia, back and leg pain, muscle fatigue and spasms, neck stiffness

RESP: Asthma

SKIN: Diaphoresis, photosensitivity, rash

Other: Application site reactions (Emsam), intense urges to perform certain activities (such as gambling or sex)

Nursing Considerations

- Assess patient for mental status and mood changes because selegiline can worsen

such conditions as dementia, severe psychosis, tardive dyskinesia, and tremor. Be especially alert for suicidal tendencies, particularly when therapy starts or dosage changes.

- Monitor patient who is also taking levodopa for levodopa-induced adverse reactions, including confusion, dyskinesia, hallucinations, nausea, and orthostatic hypotension.
- Monitor for decreased symptoms of Parkinson's disease to evaluate drug's effectiveness.
- Be aware that drug can reactivate gastric ulcers because it prevents breakdown of gastric histamine. Assess for related signs and symptoms, such as abdominal pain.
- Assess patient for skin changes regularly because risk of melanoma is increased in patients with Parkinson's disease. It isn't clear whether increase results from disease or drugs used to treat it.

PATIENT TEACHING

- Caution patient to take only prescribed amount because increased dosage may cause severe adverse reactions.
- Advise patient to avoid taking selegiline in the late afternoon or evening because it may interfere with sleep.
- For orally disintegrating tablets, tell patient to take it before breakfast without any liquid. Caution him not to push tablet through the foil on the blister pack but instead to peel back the foil with dry hands and gently remove the tablet. He should then immediately place the tablets on top of his tongue and let it disintegrate. Advise him not to drink or ingest any food for 5 minutes before and after taking the drug.
- If patient will use transdermal form, explain how and where to apply patch, stressing need to rotate sites. Tell patient to wash hands well after application and to dispose of removed patch immediately.
- Stress that only one patch may be worn at a time. If a patch falls off, tell patient to apply a new patch to a new site and to resume previous schedule.
- Urge patient to avoid tyramine-rich foods and beverages during and for 2 weeks after stopping selegiline therapy unless patient is prescribed the lowest dosage of transdermal system (6 mg per 24 hours), which

doesn't require diet modification. Review which foods are considered tyramine-rich.

- Instruct patient to immediately report severe headache, neck stiffness, racing heart, palpitations, or other sudden or unusual symptoms.
- Caution patient to avoid exposing transdermal patch to sources of direct heat, such as heating pads, electric blankets, heat lamps, saunas, hot tubs, and prolonged sunlight exposure.
- Tell patient not to cut transdermal patch into smaller pieces.
- Urge caregiver to monitor patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Urge patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to change positions slowly to minimize the effects of orthostatic hypotension.
- Suggest that patient elevate his legs when sitting to reduce ankle swelling.
- Urge patient to avoid excessive sun exposure.
- Instruct patient to notify prescriber if symptoms develop that could indicate overdose, including muscle twitching and eye spasms.
- Urge patient to notify prescriber if dry mouth lasts longer than 2 weeks. Advise him to have routine dental checkups.
- Urge patient to have regular skin examinations done by a dermatologist or other qualified health professional.
- Advise patient to notify prescriber about intense urges (as for gambling or sex) because dosage may need to be reduced or drug discontinued.

sertraline hydrochloride

Zoloft

Class and Category

Chemical class: Naphthylamine derivative

Therapeutic class: Antidepressant, anti-obsessant, antipanic

Pregnancy category: C

Indications and Dosages

➤ *To treat major depression*

ORAL CONCENTRATE, TABLETS

Adults. *Initial:* 50 mg daily, increased after several wk in increments of 50 mg daily every wk, as needed. *Maximum:* 200 mg daily.

↗ *To treat obsessive-compulsive disorder*

ORAL CONCENTRATE, TABLETS

Adults and adolescents. *Initial:* 50 mg daily, increased after several wk in increments of 50 mg daily every wk, as needed. *Maximum:* 200 mg daily.

Children ages 6 to 12. *Initial:* 25 mg daily, increased every wk, as needed. *Maximum:* 200 mg daily.

↗ *To treat panic disorder, with or without agoraphobia; to treat posttraumatic stress disorder*

ORAL CONCENTRATE, TABLETS

Adults. *Initial:* 25 mg daily, increased to 50 mg daily after 1 wk; then increased by 50 mg daily every wk, as needed.

Maximum: 200 mg daily.

DOSAGE ADJUSTMENT Initial dosage reduction recommended for elderly patients and those with hepatic impairment.

↗ *To treat premenstrual dysphoric disorder (PMDD)*

ORAL CONCENTRATE, TABLETS

Adult women. *Initial:* 50 mg daily in morning or evening throughout menstrual cycle; or, 50 mg daily in morning or evening during luteal phase of menstrual cycle only. Dosage increased each menstrual cycle in 50-mg increments up to 150 mg daily, or each luteal phase up to 100 mg daily, as needed. Once 100-mg daily dosage established for luteal phase, each successive cycle requires a 50-mg titration step for 3 days at the beginning of each luteal phase.

Maximum: 150 mg daily for dosing throughout menstrual cycle, or 100 mg daily for dosing during luteal phase only.

Route	Onset	Peak	Duration
P.O.	2–4 wk*	Unknown	Unknown

Mechanism of Action

Inhibits reuptake of the neurotransmitter serotonin by CNS neurons, thereby increasing the amount of serotonin available in nerve synapses. An elevated serotonin level

* For antidepressant and antipanic effects; for antiobsessant effect, longer than 4 wk.

may result in elevated mood and reduced depression. This action may also relieve symptoms of other psychiatric conditions attributed to serotonin deficiency.

Contraindications

Concurrent use of disulfiram (oral concentrate) or pimozide; hypersensitivity to sertraline or its components; use within 14 days of an MAO inhibitor

Interactions**DRUGS**

aspirin, NSAIDs, warfarin: Increased anticoagulant activity and risk of bleeding
astemizole, terfenadine: Possibly increased blood levels of these drugs, leading to increased risk of arrhythmias

cimetidine: Increased sertraline half-life
MAO inhibitors: Possibly hyperpyretic episodes, hypertensive crisis, serotonin syndrome, and severe seizures

moclobemide, serotonergics: Increased risk of potentially fatal serotonin syndrome
serotonin and norepinephrine reuptake inhibitors: Increased risk of bleeding, especially GI bleeding

tolbutamide: Possibly hypoglycemia

tricyclic antidepressants: Possibly impaired metabolism of tricyclic antidepressants, resulting in increased risk of toxicity

Adverse Reactions

CNS: Aggressiveness, agitation, anxiety, dizziness, drowsiness, fatigue, fever, headache, hyperkinesia, insomnia, nervousness, neuroleptic malignant syndrome–like reaction, paresthesia, serotonin syndrome, suicidal ideation, tremor, weakness, yawning

CV: Palpitations

EENT: Dry mouth, epistaxis, sinusitis, vision changes

ENDO: Syndrome of inappropriate ADH secretion

GI: Abdominal cramps, anorexia, constipation, diarrhea, flatulence, increased appetite, indigestion, nausea, vomiting

GU: Anorgasmia, decreased libido, ejaculation disorders, impotence, urinary incontinence

SKIN: Diaphoresis, flushing, purpura, rash

Other: Weight loss

Nursing Considerations

- Monitor liver function test results and BUN and serum creatinine levels, as

appropriate, in patients with hepatic or renal dysfunction.

WARNING Monitor patient closely for evidence of serotonin syndrome, such as agitation, hallucinations, coma, tachycardia, labile blood pressure, hyperthermia, hyperreflexia, incoordination, nausea, vomiting, and diarrhea. Serotonin syndrome in its most severe form can resemble neuroleptic malignant syndrome, which includes hyperthermia, muscle rigidity, autonomic instability, possibly rapid changes in vital signs, and mental status changes. Notify prescriber immediately because serotonin syndrome reactions that resemble neuroleptic malignant syndrome may be life-threatening. Be prepared to provide supportive care.

- Monitor patient for hypo-osmolarity of serum and urine and for hyponatremia, which may indicate sertraline-induced syndrome of inappropriate ADH secretion.
- Be aware that effective antidepressant therapy can promote development of mania in predisposed people. If mania develops, notify prescriber immediately and expect to withhold sertraline.
- Watch closely for suicidal tendencies, especially when therapy starts and dosage changes and especially in children and adolescents.
- Monitor patient closely for evidence of GI bleeding, especially if patient takes a drug known to cause it, such as aspirin, an NSAID, a serotonin or norepinephrine reuptake inhibitor, or warfarin.
- When therapy stops, expect to taper dosage to minimize adverse effects rather than stopping drug abruptly.

PATIENT TEACHING

WARNING Tell patient that sertraline increases the risk of serotonin syndrome and reactions that resemble neuroleptic malignant syndrome, rare but serious complications, when taken with some other drugs. Teach patient to recognize signs and symptoms of serotonin syndrome and neuroleptic malignant syndrome, and advise him to notify prescriber immediately if they occur.

- Teach patient to dilute oral concentrate before taking it. Tell him to use supplied dropper to remove prescribed amount and

mix it with 4 oz (one-half cup) of water, ginger ale, lemon or lime soda, lemonade, or orange juice. Warn him not to mix oral concentrate with anything else. Explain that it's normal for mixture to be slightly hazy.

- Tell patient to take dose immediately after mixing it.
- If patient has latex sensitivity, advise him to use an alternate dispenser because the supplied dropper dispenser contains dry natural rubber.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Warn family or caregiver to watch patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes, and especially if patient is a child or adolescent.
- Caution patient not to stop taking drug abruptly. Explain that gradual tapering helps to avoid withdrawal symptoms.
- Instruct female patients to notify prescriber if they are or could be pregnant and to discuss benefits and risks of continuing sertraline therapy throughout the pregnancy.
- Advise patient to consult prescriber before taking any OTC product, especially aspirin products or NSAIDs.

sevelamer hydrochloride

Renagel

sevelamer carbonate

Renvela

Class and Category

Chemical class: Polyallylamine-epichlorhydrin polymer

Therapeutic class: Antihyperphosphatemic

Pregnancy category: C

Indications and Dosages

➤ To lower serum phosphate level during end-stage renal disease

CAPSULES (RENAGEL)

Adults. 2 capsules (806 mg) t.i.d. if serum phosphorus level is 6 to 7.5 mg/dl; 3 cap-

sules (1,209 mg) t.i.d. if serum phosphorus level is 7.6 to 8.9 mg/dl; or 4 capsules (1,612 mg) t.i.d. if serum phosphorus level is 9 mg/dl or more. Dosage increased or decreased gradually by 1 capsule (403 mg)/meal, as needed. *Maximum*: 30 capsules (12.1 g) daily.

TABLETS (RENEVELA)

Adults. 1 tablet (800 mg) t.i.d. with meals if serum phosphorus level is 5.5 mg/dl to 7.5 mg/dl; or 2 tablets (1,600 mg) if serum phosphorus level is 7.5 mg/dl or greater. Dosage increased or decreased gradually by 1 tablet (800 mg)/meal at 2-wk intervals, as needed.

DOSAGE ADJUSTMENT For patients being switched from calcium acetate to sevelamer carbonate, 1 tablet of sevelamer (800 mg) can be substituted for every 1 tablet of calcium (667 mg) being taken.

Mechanism of Action

Inhibits phosphate absorption in the intestine by binding dietary phosphate, thereby lowering serum phosphorus level.

Contraindications

Fecal impaction, GI obstruction, hypersensitivity to sevelamer or its components, hypophosphatemia, ileus

Interactions

DRUGS

antiarrhythmics, anticonvulsants, digoxin, levothyroxine, liothyronine, quinolones, tetracyclines, theophylline, warfarin: Possibly altered absorption of these drugs
phosphate salts, phosphorus salts:

Neutralized therapeutic effects of sevelamer
ciprofloxacin: Decreased ciprofloxacin effectiveness

Adverse Reactions

CNS: Headache, fever

CV: Hypertension, hypotension, thrombosis

EENT: Nasopharyngitis

GI: Abdominal pain, constipation (severe), diarrhea, fecal impaction, flatulence, ileus, indigestion, intestinal obstruction or perforation, nausea, vomiting

RESP: Bronchitis, dyspnea, increased cough, upper respiratory tract infection

MS: Arthralgia, back or limb pain

SKIN: Pruritus, rash

Other: Infection

Nursing Considerations

- Give other drugs at least 1 hour before or 3 hours after sevelamer to prevent interaction.
- Be aware that severe hypophosphatemia may occur in patient with dysphagia, major GI tract surgery, or severe GI motility disorder (including severe constipation) because drug prevents phosphate absorption.
- Monitor blood pressure frequently.
- Monitor serum phosphorus level to determine drug's effectiveness; monitor other serum electrolyte levels, especially bicarbonate and chloride, to detect imbalances.

PATIENT TEACHING

- Tell patient to take drug with meals and to swallow capsules or tablets whole with water and not to open, break, or chew them.
- Caution patient to take other drugs 1 hour before or 3 hours after sevelamer.
- Review symptoms of thrombosis, and advise patient to report them immediately.
- Instruct patient to report severe or prolonged constipation to prescriber because additional treatment may be needed to prevent serious complications.

sibutramine hydrochloride monohydrate

Meridia

Class, Category, and Schedule

Chemical class: Cyclobutanemethanamine

Therapeutic class: Antiobesity

Pregnancy category: C

Controlled substance schedule: IV

Indications and Dosages

↗ *As adjunct to calorie-controlled diet to manage obesity*

CAPSULES

Adults. *Initial*: 10 mg daily, increased to 15 mg daily after 4 wk if weight loss is inadequate. *Maximum*: 15 mg daily.

DOSAGE ADJUSTMENT Reduction to 5 mg daily may be needed if patient can't tolerate 10-mg dose.

Mechanism of Action

Inhibits central reuptake of dopamine, norepinephrine, and serotonin, thereby suppressing appetite and lowering food intake, leading to weight loss.

Contraindications

Anorexia nervosa, concurrent use of other centrally acting appetite suppressants, history of cardiovascular disease, hypersensitivity to sibutramine or its components, use within 14 days of MAO inhibitor therapy

Interactions

DRUGS

certain decongestants and cough, cold, and allergy drugs; ephedrine; phenylpropanolamine; pseudoephedrine: Increased risk of elevated blood pressure or heart rate
certain opioid analgesics (dextromethorphan, fentanyl, meperidine, pentazocine), dihydroergotamine, lithium, MAO inhibitors, serotonergics, sumatriptan, tryptophan, zolmitriptan: Increased risk of serotonin syndrome
erythromycin, ketoconazole: Possibly decreased sibutramine clearance

Adverse Reactions

CNS: Abnormal dreams, amnesia, anger, anxiety, confusion, depression, dizziness, drowsiness, gait dysfunction, Gilles de la Tourette's syndrome, headache, hypesthesia, impaired concentration, increased intraocular pressure, insomnia, mania, mood changes, neuroleptic malignant syndrome, nervousness, nightmares, paresthesia, psychosis, serotonin syndrome, short term memory loss, somnolence, speech disorder, stroke, suicidal ideation, transient ischemic attack, tremor, twitching, vertigo

CV: Chest pain, edema, hypertension, MI, palpitations, tachycardia

EENT: Blurred vision, dry eyes or mouth, earache, epistaxis, nasal congestion, rhinitis, sinusitis, taste perversion

GI: Abdominal pain, anorexia, constipation, diarrhea, gastritis, increased appetite, indigestion, nausea, thirst, vomiting

GU: Decreased or increased libido, dysmenorrhea, impotence, urinary frequency, urine retention, UTI, vaginal candidiasis

HEME: Bleeding

MS: Arthralgia, back or neck pain, myalgia, tenosynovitis

SKIN: Acne, alopecia, dermatitis, diaphore-

sis, ecchymosis, flushing, photosensitivity, urticaria

Other: Anaphylaxis, angioedema, flulike symptoms

Nursing Considerations

- Administer sibutramine cautiously in patients with mild to moderate renal impairment, and expect to not use it in patients with severe renal impairment, including those with end-stage renal disease receiving hemodialysis.

WARNING Use drug cautiously in patients with a history of substance abuse, and watch for signs of misuse.

- Measure blood pressure and pulse rate before and during sibutramine therapy. Notify prescriber about sustained increases, and expect drug to be discontinued
- Because serotonin release from nerve terminals has been linked to cardiac valve dysfunction, assess for development of third heart sound.

WARNING If patient takes drugs for migraine, notify prescriber immediately if evidence of serotonin syndrome develops: agitation, anxiety, ataxia, chills, confusion, diaphoresis, disorientation, dysarthria, emesis, excitement, hemiballismus, hyperreflexia, hyperthermia, hypomania, lack of coordination, loss of consciousness, mydriasis, myoclonus, restlessness, tachycardia, tremor, and weakness.

- Because drug decreases salivary flow, monitor patient for adverse dental effects.

WARNING Watch closely for evidence of serotonin syndrome, such as agitation, hallucinations, coma, tachycardia, labile blood pressure, hyperthermia, hyperreflexia, incoordination, nausea, vomiting, and diarrhea. In its most severe form, serotonin syndrome can resemble neuroleptic malignant syndrome, which includes hyperthermia, muscle rigidity, autonomic instability, possibly rapid changes in vital signs, and mental status changes. Notify prescriber immediately because serotonin syndrome reactions that resemble neuroleptic malignant syndrome may be life-threatening. Be prepared to provide supportive care.

- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

- Monitor patient for weight loss to determine drug effectiveness. Expect to discontinue drug if patient has not lost at least 5% of baseline body weight within the first 6 months of treatment.

PATIENT TEACHING

- Caution patient not to take sibutramine more often than prescribed.
- Teach patient how to measure his blood pressure and pulse rate during therapy.
- Explain that sibutramine is an adjunct to reduced-calorie diet, not a replacement for it.
- Advise patient to report unusual bleeding or bruising.
- Caution against taking OTC products that contain ephedrine because of the increased risk of hypertension.
- Urge patient to avoid potentially hazardous activities until drug's CNS effects are known.
- If patient reports dry mouth, suggest sugar-free hard candy or gum or a saliva substitute.

WARNING Tell patient to report any sudden, severe, or persistent symptoms at once.

- Urge caregivers to monitor patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes and to report concerns immediately to prescriber.

sildenafil citrate

Revatio, Viagra

Class and Category

Chemical class: Pyrazolopyrimidinone derivative

Therapeutic class: Antihypertensive (pulmonary arterial), anti-impotence

Pregnancy category: B

Indications and Dosages

↗ *To treat erectile dysfunction*

TABLETS

Adults. 50 mg daily, taken 1 hr before sexual activity; increased as prescribed, based on clinical response. *Maximum:* 100 mg daily.

DOSE ADJUSTMENT Initially 25 mg for elderly patients, those with hepatic cirrhosis or creatinine clearance less than 30 ml/min/1.73 m², and those taking potent cytochrome P-450 3A4 inhibitors or ritonavir.

Dosage reduced to 25 mg if taken within 4 hr of an alpha blocker. *Maximum:* 25 mg/48 hr.

↗ *To treat pulmonary arterial hypertension in order to improve exercise ability and delay clinical worsening of condition in patients classified as group 1 by the World Health Organization*

TABLETS

Adults. 20 mg t.i.d.

I.V. INJECTION

Adults. 10 mg administered as bolus t.i.d.

Route	Onset	Peak	Duration
P.O.	In 30 min	Unknown	4 hr

Mechanism of Action

Enhances the effect of nitric oxide released in the penis by stimulation. Nitric oxide increases cGMP level, relaxes smooth muscle, and increases blood flow to the corpus cavernosum, thus producing an erection.

Contraindications

Continuous or intermittent nitrate therapy, hypersensitivity to sildenafil or components

Interactions**DRUGS**

barbiturates, bosentan, carbamazepine, efavirenza, nevirapine, phenytoin, rifabutin, rifampin: Altered plasma level of either drug

cimetidine, erythromycin, itraconazole, ketoconazole, mibefradil: Prolonged sildenafil effect

doxazosin and other alpha-blockers:

Increased risk of symptomatic hypotension

nitrates: Profound hypotension

protease inhibitors: Increased sildenafil effect

rifampin: Decreased sildenafil effect

FOODS

high-fat meals: Drug absorption delayed by up to 60 minutes

Adverse Reactions

CNS: Cerebrovascular, intracerebral, or subarachnoid hemorrhage; dizziness; headache; migraine; seizures; syncope; transient global amnesia, transient ischemic attack

CV: Heart failure, hypertension, hypotension, myocardial infarction or ischemia, orthostatic hypotension, palpitations, sudden cardiac death, tachycardia, ventricular arrhythmias

EENT: Blurred vision; change in color perception; diplopia; epistaxis; hearing loss; increased intraocular pressure; nasal congestion; nonarteritic anterior ischemic optic neuropathy; ocular burning, pressure, redness or swelling; paramacular edema; photophobia; retinal vascular bleeding or disease; tinnitus, visual decrease or temporary vision loss; vitreous detachment

ENDO: Uncontrolled diabetes mellitus

GI: Diarrhea, indigestion

GU: Cystitis, dysuria, painful erection, priapism, UTI

MS: Arthralgia, back pain

RESP: Pulmonary hemorrhage, upper respiratory tract infection

SKIN: Flushing, photosensitivity

Nursing Considerations

- Use sildenafil cautiously in patients with renal or hepatic dysfunction, elderly patients, and men with penile abnormalities that may predispose them to priapism.
- Also use cautiously in patients with left ventricular outflow obstruction, such as aortic stenosis and idiopathic hypertrophic subaortic stenosis, and those with severely impaired autonomic control of blood pressure because these conditions increase patient's sensitivity to vasodilators such as sildenafil.
- Monitor patient's blood pressure and heart rate and rhythm before and often during therapy.
- Monitor vision, especially in patients over age 50; who have diabetes, hypertension, coronary artery disease, or hyperlipidemia; or who smoke because sildenafil rarely may cause nonarteritic anterior ischemic optic neuropathy that may lead to decreased vision or permanent vision loss.

PATIENT TEACHING

- Explain that sildenafil used to treat erectile dysfunction may be taken up to 4 hours before sexual activity but that taking it 1 hour beforehand provides the most effective results.

WARNING Warn patient not to take sildenafil if he also takes any form of organic nitrate, either continuously or intermittently, because profound hypotension and death could result. Also caution patient taking sildenafil for erectile dysfunction not to take more than 25 mg within

4 hours of an alpha blocker, such as doxazosin, because symptomatic orthostatic hypotension can occur.

- Tell patient to stop taking drug and contact prescriber if vision decreases suddenly in one or both eyes or if he has a loss of hearing, possibly with tinnitus and dizziness.
- Advise patient taking sildenafil for erectile dysfunction to seek sexual counseling to enhance the drug's effects.
- To avoid possible penile damage and permanent loss of erectile function, urge patient to notify prescriber immediately if erection is painful or lasts longer than 4 hours.
- Instruct diabetic patient to monitor his blood glucose level frequently because drug may affect glucose control.

silodosin

Rapaflo

Class and Category

Chemical class: Highly selective α_1 -adrenergic receptor blocker

Therapeutic class: Benign prostatic anti-hyperplasia agent

Pregnancy category: B

Indications and Dosages

➤ To treat symptomatic benign prostatic hyperplasia

CAPSULES

Adult men. 8 mg daily. *Maximum:* 8 mg daily.

DOSAGE ADJUSTMENT For patients with moderate renal impairment (creatinine clearance between 30 and 50 ml/min), dosage reduced to 4 mg daily.

Mechanism of Action

Binds to postsynaptic α_1 adrenoceptors located in the prostate gland, bladder base and neck, and prostatic capsule and urethra. Blocking action at these adrenoceptor sites causes relaxation of smooth muscle in the local area, which improves urine flow and reduces other benign prostatic hyperplasia symptoms.

Contraindications

Hypersensitivity to silodosin and its com-

ponents, severe hepatic insufficiency (Child-Pugh score 10 or above), severe renal insufficiency (creatinine clearance less than 30 ml/min/1.73 m²), use with strong CYP3A4 inhibitors such as clarithromycin, ketoconazole, itraconazole, and ritonavir

Interactions

DRUGS

alpha blockers: Possibly increased effects and risk of adverse reactions
antihypertensives: Increased risk of dizziness and orthostatic hypotension
cyclosporin, CYP3A4 inhibitors such as clarithromycin, diltiazem, erythromycin, itraconazole, ketoconazole, ritonavir: Possibly increased serum silodosin levels and risk of adverse reactions

Adverse Reactions

CNS: Asthenia, dizziness, headache, insomnia, syncope

CV: Orthostatic hypotension

EENT: Nasal congestion, nasopharyngitis, rhinorrhea, sinusitis

GI: Abdominal pain, diarrhea, elevated liver enzymes, impaired hepatic function, jaundice

GU: Elevated prostate specific antigen level, retrograde ejaculation

SKIN: Purpura, toxic skin eruption

Nursing Considerations

- Use cautiously in patients with mild renal impairment and mild or moderate hepatic impairment. Patients with moderate renal impairment need dosage adjustment.
- Monitor patient's blood pressure for reduction, especially if he takes an antihypertensive with silodosin.

PATIENT TEACHING

- Instruct patient to take drug with a meal.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient planning cataract surgery or other ocular procedure to tell ophthalmologist that he takes silodosin or has taken it in the past because of potential adverse reactions.

simvastatin

Zocor

Class and Category

Chemical class: Synthetically derived fer-

mentation product of *Aspergillus terreus*

Therapeutic class: Antihyperlipidemic

Pregnancy category: X

Indications and Dosages

↗ To treat hyperlipidemia

TABLETS

Adults. *Initial*: 20 to 40 mg daily in the evening. Dosage adjusted at 4-wk intervals, as needed, to achieve target LDL-cholesterol level. *Maintenance*: 5 to 80 mg daily.

Maximum: 80 mg daily.

↗ To treat homozygous familial hypercholesterolemia

TABLETS

Adults. 40 mg daily in the evening, or 80 mg/day in 3 divided doses—20 mg, 20 mg, and 40 mg (in the evening). Dosage adjusted every 4 wk, as needed, to achieve target LDL-cholesterol level. *Maintenance*: 5 to 40 mg/day. *Maximum*: 80 mg daily.

DOSAGE ADJUSTMENT Patients taking cyclosporine or who have severe renal insufficiency should initially receive 5 mg simvastatin daily and be increased as needed to no more than 10 mg daily. Maximum dosage of 10 mg daily should also not be exceeded in patients who are also taking fibrates or niacin.

↗ To treat adolescent heterozygous familial hypercholesterolemia

TABLETS

Children ages 10 to 17 at least 1 year post-menarche. *Initial*: 10 mg daily in the evening. Adjusted every 4 wk, as needed, to achieve target LDL-cholesterol level. *Maintenance*: 10 to 40 mg daily. *Maximum*: 40 mg daily.

DOSAGE ADJUSTMENT For patients who take cyclosporine, initial dosage reduced to 5 mg/day and maximum dosage reduced to 10 mg/day. For elderly patients and those with renal impairment, initial dosage reduced to 5 mg daily. For patients who take danazol, fibric-acid derivative lipid-lowering drugs, such as gemfibrozil, or lipid-lowering doses of niacin (1 g daily or more), maximum dosage reduced to 10 mg daily. For patients who take amiodarone or verapamil, maximum dosage shouldn't exceed 20 mg daily.

Mechanism of Action

Interferes with the hepatic enzyme hydroxymethylglutaryl-coenzyme A reductase.

This action reduces the formation of mevalonic acid, a cholesterol precursor, thus interrupting the pathway necessary for cholesterol synthesis. When the cholesterol level declines in hepatic cells, LDLs are consumed, which in turn reduces the levels of circulating total cholesterol and serum triglycerides.

Route	Onset	Peak	Duration
P.O.	2 wk	4–6 wk	Unknown

Contraindications

Active hepatic disease; breast-feeding; concurrent use with clarithromycin, erythromycin, more than 1 quart of grapefruit juice daily, HIV protease inhibitors, itraconazole, ketoconazole, nefazodone, or telithromycin; hypersensitivity to simvastatin or its components; pregnancy

Interactions

DRUGS

amiodarone, antiretroviral protease inhibitors (amprenavir, indinavir, nelfinavir, ritonavir, saquinavir), clarithromycin, cyclosporine, danazol, gemfibrozil and other fibrates, itraconazole, ketoconazole, erythromycin, nefazodone, niacin (1 g daily or more), telithromycin, verapamil: Increased risk of myopathy or rhabdomyolysis
azole antifungals, cyclosporine, gemfibrozil, immunosuppressants, macrolide antibiotics (including erythromycin), niacin, verapamil: Increased risk of acute renal failure
bile acid sequestrants, cholestyramine, colestipol: Decreased simvastatin bioavailability

digoxin: Possibly slight elevation in blood digoxin level

diltiazem, verapamil: Possibly increased blood simvastatin level, increased risk of myopathy

oral anticoagulants: Increased bleeding or prolonged PT

FOODS

grapefruit juice (1 or more quarts daily): Possibly increased blood simvastatin level

Adverse Reactions

CNS: Asthenia, dizziness, fatigue, headache

CV: Chest pain

EENT: Cataracts, rhinitis

GI: Abdominal pain, constipation, diarrhea, elevated liver function test results, flatu-

lence, heartburn, hepatic failure, indigestion, nausea, pancreatitis, vomiting

MS: Myalgia, myopathy, rhabdomyolysis

RESP: Upper respiratory tract infection

SKIN: Eczema, pruritus, rash

Nursing Considerations

- Use simvastatin cautiously in elderly patients and those with renal or hepatic impairment.
- Give drug 1 hour before or 4 hours after giving bile acid sequestrant, cholestyramine, or colestipol.
- Expect to monitor liver function test results every 3 to 6 months for abnormal elevations.
- Monitor serum lipoprotein level, as ordered, to evaluate response to therapy.

PATIENT TEACHING

- Urge patient to take drug in the evening.
- Urge patient to follow low-fat, cholesterol-lowering diet.
- Urge patient to notify prescriber immediately about muscle pain, tenderness, or weakness and other symptoms of myopathy.
- Inform female patient of childbearing age of need to use reliable contraceptive method while taking drug. Instruct her to notify prescriber at once if she suspects pregnancy.
- Advise patient to avoid grapefruit juice to decrease risk of drug toxicity.

sirolimus (rapamycin)

Rapamune

Class and Category

Chemical class: Macrocyclic lactone

Therapeutic class: Immunosuppressant

Pregnancy category: C

Indications and Dosages

➤ *To prevent rejection of kidney transplantation*

ORAL SOLUTION

Adults and adolescents over age 13 weighing 40 kg (88 lb) or more. *Initial:* 6-mg loading dose. *Maintenance:* 2 mg daily.

Adolescents over age 13 weighing less than 40 kg. *Initial:* 3-mg/m² loading dose.

Maintenance: 1 mg/m² daily.

DOSAGE ADJUSTMENT Maintenance dosage reduced by one-third for patients with impaired hepatic function. Maintenance dosage increased by as much as 400% for patients discontinuing concomitant cyclosporine therapy in order to maintain blood sirolimus trough level of 12 to 24 nanograms/ml.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	Up to 6 mo after discontinuation

Mechanism of Action

Inhibits activation and proliferation of T lymphocytes and antibody production. Sirolimus also inhibits cell cycle progression from the G1 to the S phase, possibly by inhibiting a key regulatory kinase believed to suppress cytokine-driven T-cell proliferation.

Contraindications

Hypersensitivity to sirolimus or its components, malignancy

Interactions

DRUGS

aminoglycosides, amphotericin B, cyclosporine: Possibly impaired renal function
bromocriptine, cimetidine, cisapride, clarithromycin, clotrimazole, cyclosporine, danazol, diltiazem, erythromycin, fluconazole, indinavir, itraconazole, ketoconazole, metoclopramide, nicardipine, ritonavir, troleanomycin, verapamil: Possibly increased blood sirolimus level and toxicity
calcineurin inhibitors, corticosteroids: Increased risk of deteriorating renal function, serum lipid abnormalities, and UTI
carbamazepine, phenobarbital, phenytoin, rifabutin, rifapentine, St. John's wort: Possibly decreased blood sirolimus level
HMG-CoA reductase inhibitors: Increased risk of rhabdomyolysis when administered concurrently with sirolimus and cyclosporine
rifampin: Significantly increased sirolimus clearance
vaccines (killed virus): Possibly decreased immune response to vaccines
vaccines (live virus): Increased risk of contracting disease from live virus

FOODS

grapefruit juice: Possibly decreased metabolism of sirolimus

high-fat diet: Reduced rate of sirolimus absorption

Adverse Reactions

CNS: Asthenia, fever, headache, insomnia, tremor

CV: Atrial fibrillation, chest pain, hyperlipidemia, hypersensitivity vasculitis, hypertension, pericardial effusion, peripheral edema

ENDO: Hyperglycemia

GI: Abdominal pain, constipation, diarrhea, elevated liver enzymes, hepatotoxicity, nausea, vomiting

GU: Azoospermia, BK viral nephritis, elevated serum creatinine level, nephrotic syndrome, proteinuria, UTI

HEME: Anemia, lymphoma, neutropenia, pancytopenia, thrombocytopenia

MS: Arthralgia, low back or flank pain, joint abnormality

RESP: Dyspnea on exertion, interstitial lung disease, pleural effusion, pulmonary hemorrhage

SKIN: Acne, exfoliative dermatitis, rash

Other: Anaphylaxis; angioedema; delayed wound healing; hypercholesterolemia; hypokalemia; hypophosphatemia; increased susceptibility to infection, including opportunistic infections such as tuberculosis and activation of latent viral infections; lymphedema; weight gain or loss

Nursing Considerations

- Be aware that sirolimus isn't recommended in liver or lung transplant patients.
- Use sirolimus cautiously in patients who are receiving other drugs known to adversely affect renal function, such as aminoglycosides and amphotericin B; together, they may further decrease renal function.
- Monitor patients with existing or recent (including recent exposure to) chickenpox and patients with herpes zoster for worsening symptoms because they have an increased risk of developing severe generalized disease while taking sirolimus.
- Mix oral sirolimus with at least 2 oz (60 ml) of water or orange juice in a glass or plastic container. Don't dilute drug in grapefruit juice or any other liquid.
- Stir well and have patient drink solution

immediately. Then rinse glass with at least 4 oz (120 ml) of additional liquid, stir well, and have patient drink that liquid to make sure that all of drug is taken.

- Give initial dose as soon after transplantation as possible and daily dose 4 hours after cyclosporine, as prescribed.
- Monitor whole blood sirolimus concentrations, as ordered, in patients receiving concentrated form of drug, patients weighing less than 40 kg (88 lb), patients with hepatic impairment, and those receiving potent CYP3A4 inducers or inhibitors concurrently.
- When using trough level to determine drug's effectiveness, keep in mind that dosage adjustment should be made only after other factors are taken into account, such as signs, symptoms, and tissue biopsy findings. Keep in mind that interpretation methods vary among laboratories and values aren't interchangeable.
- Monitor serum creatinine level, as ordered, because BK virus associated nephropathy has occurred with sirolimus therapy. In addition, patients receiving sirolimus and cyclosporine may develop impaired renal function. Notify prescriber of any increases in serum creatinine level because sirolimus or cyclosporine dosage may need to be adjusted or drug discontinued.
- Monitor patient for urinary protein excretion, as ordered. If protein appears in urine, sirolimus may be discontinued.
- Monitor patient for signs and symptoms of infection and check CBC results, as ordered, to detect sirolimus-induced blood dyscrasias or changes in neutrophil count, which may indicate infection.
- For patients with hyperlipidemia, be prepared to institute dietary changes, an exercise program, or a lipid-lowering drug regimen if blood cholesterol or triglyceride levels increase because drug may aggravate hyperlipidemia.

PATIENT TEACHING

- Advise patient to take sirolimus consistently either with or without food (but not food high in fat) to prevent changes in absorption rate.
- Instruct patient to take daily dose with at least 2 oz (60 ml) of water or orange juice. Caution him not to dilute drug in grape-

fruit juice or any other liquid. Advise him to stir mixture well and drink immediately, then to add at least another 4 oz (120 ml) of liquid to empty container, stir mixture again, and drink that liquid to ensure that he has swallowed all of drug.

- Urge patient to avoid people with colds, flu, or other infections because immunosuppression makes him more vulnerable.
- Instruct patient not to take live vaccines, such as measles, mumps, rubella, oral polio, bacille Calmette-Guérin, yellow fever, varicella, and TY21a typhoid, during sirolimus therapy.
- Advise patient to keep follow-up appointments for blood tests, as ordered.

sitagliptin

Januvia

Class and Category

Chemical class: Beta amino acid derivative

Therapeutic class: Antidiabetic

Pregnancy category: C

Indications and Dosages

➤ *To achieve control of glucose level in type 2 diabetes mellitus as monotherapy or with metformin or other thiazolidinediones*

TABLETS

Adults. 100 mg once daily.

DOSAGE ADJUSTMENT For patients with moderate renal insufficiency (creatinine clearance 30 to 50 ml/min/1.73 m²), dosage reduced to 50 mg once daily; for patients with severe renal insufficiency (creatinine clearance less than 30 ml/min/1.73 m²) or end-stage renal disease requiring hemodialysis or peritoneal dialysis, dosage reduced to 25 mg once daily.

Route	Onset	Peak	Duration
P.O.	Unknown	1–4 hr	Unknown

Mechanism of Action

Inhibits the dipeptidyl peptidase-4 enzyme to slow inactivation of incretin hormones. These hormones are released by the intestine throughout the day but increase in response to a meal. When blood glucose level is normal or increased, incretin hor-

mones increase insulin synthesis and release from pancreatic beta cells. One type of incretin hormone, glucagon-like peptide (GLP-1) also lowers glucagon secretion from pancreatic alpha cells which reduces hepatic glucose production. These combined actions decrease blood glucose level in type 2 diabetes.

Contraindications

Diabetic ketoacidosis, hypersensitivity to sitagliptin or its components, type 1 diabetes

Interactions

DRUGS

ACE inhibitors, disopyramide, fibric acid derivatives, fluoxetine, sulfonylureas: Possibly increased hypoglycemic effects

beta blockers: Possibly prolonged hypoglycemia or promotion of hyperglycemia
digoxin: Slightly increased plasma digoxin level

estrogens, oral contraceptives, phenytoin, progestins, thiazide diuretics, triamterene: Possibly decreased hypoglycemic effects

Adverse Reactions

CNS: Headache

EENT: Nasopharyngitis

GI: Abdominal pain, acute pancreatitis, diarrhea, elevated hepatic enzymes, nausea, vomiting

RESP: Upper respiratory tract infection

SKIN: Cutaneous vasculitis, rash, Stevens-Johnson syndrome, urticaria

Other: Anaphylaxis, angioedema

Nursing Considerations

- Assess patient's renal function before starting sitagliptin therapy, as ordered, and periodically thereafter. In moderate to severe renal dysfunction, dosage will be reduced.
- Monitor patient for hypersensitivity reactions that, although uncommon, may be severe. If present, notify prescriber and expect sitagliptin to be discontinued.
- Monitor patient's blood glucose level, as ordered, to determine effectiveness of sitagliptin therapy.

PATIENT TEACHING

- Stress the need to follow an exercise program and a diet control program during sitagliptin therapy.
- Advise patient to notify prescriber immediately if she has trouble breathing, hives, rash, or swelling.

diately if she has trouble breathing, hives, rash, or swelling.

- Inform patient that periodic blood tests will be done to determine effectiveness of drug and assess kidney function.
- Teach patient how to monitor blood glucose level and when to report changes.
- Caution patient that taking other drugs in addition to sitagliptin to control his diabetes may lead to hypoglycemia. Review signs, symptoms, and appropriate prescribed treatment with him.
- Instruct patient to contact prescriber if he develops other illnesses, such as infection, or experiences trauma or surgery because his diabetes medication may need adjustment.
- Advise patient to carry identification indicating that she has diabetes.
- Instruct patient to stop taking sitagliptin and report persistent severe abdominal pain, possibly radiating to the back and accompanied by vomiting.

sodium bicarbonate

Arm and Hammer Pure Baking Soda, Bell/ans, Citrocarbonate, Soda Mint

Class and Category

Chemical class: Electrolyte

Therapeutic class: Antacid, electrolyte replenisher, systemic and urinary alkalizer

Pregnancy category: C

Indications and Dosages

↗ *To treat hyperacidity*

EFFERVESCENT POWDER

Adults and adolescents. 3.9 to 10 g in a glass of water after meals. *Maximum:* 19.5 g daily.

Children ages 6 to 12. 1 to 1.9 g in a glass of water after meals.

ORAL POWDER

Adults and adolescents. One-half tsp in a glass of water every 2 hr, p.r.n. *Maximum:* 4 tsp daily in patients up to age 60.

TABLETS

Adults and adolescents. 325 mg to 2 g daily to q.i.d., p.r.n. *Maximum:* 16 g daily.

Children ages 6 to 12. 520 mg, repeated once after 30 min, p.r.n.

↗ *To provide urinary alkalization*

ORAL POWDER

Adults and adolescents. 1 tsp in a glass of water every 4 hr. *Maximum:* 4 tsp daily in patients up to age 60.

TABLETS

Adults and adolescents. *Initial:* 4 g, then 1 to 2 g every 4 hr. *Maximum:* 16 g daily.

Children. 23 to 230 mg/kg daily, adjusted p.r.n.

I.V. INFUSION

Adults and children. 2 to 5 mEq/kg over 4 to 8 hr.

↗ *To treat metabolic acidosis during cardiac arrest*

I.V. INJECTION

Adults and children. *Initial:* 1 mEq/kg, followed by 0.5 mEq/kg every 10 min while arrest continues.

↗ *To treat less urgent forms of metabolic acidosis*

I.V. INFUSION

Adults and children. 2 to 5 mEq/kg over 4 to 8 hr.

DOSAGE ADJUSTMENT Dosage reduction possible for elderly patients because of age-related renal impairment.

Mechanism of Action

Increases plasma bicarbonate level, buffers excess hydrogen ions, and raises blood pH, thereby reversing metabolic acidosis. Sodium bicarbonate also increases the excretion of free bicarbonate ions in urine, raising urine pH; increased alkalinity of urine may help to dissolve uric acid calculi. In addition, it relieves symptoms of hyperacidity by neutralizing or buffering existing stomach acid, thereby increasing the pH of stomach contents.

Incompatibilities

Don't admix I.V. form of sodium bicarbonate in same solution or administer through same I.V. line as other drugs because precipitate may form.

Contraindications

Hypocalcemia in which alkalosis may lead to tetany; hypochloremic alkalosis secondary to vomiting, diuretics, or nasogastric suction; preexisting metabolic or respiratory alkalosis

Interactions**DRUGS**

amphetamines, quinidine: Decreased uri-

nary excretion of these drugs, possibly resulting in toxicity

anticholinergics: Decreased anticholinergic absorption and effectiveness

calcium-containing products: Increased risk of milk-alkali syndrome

chlorpropamide, lithium, salicylates, tetracyclines: Increased renal excretion and decreased absorption of these drugs

ciprofloxacin, norfloxacin, ofloxacin:

Decreased solubility of these drugs, leading to crystalluria and nephrotoxicity

citrate: Increased risk of systemic alkalosis; increased risk of calcium calculus formation and hypernatremia in patients with history of uric acid calculi

digoxin: Possibly elevated digoxin level

enteric-coated drugs: Increased risk of gastric or duodenal irritation from rapid removal of enteric coating

ephedrine: Increased ephedrine half-life and duration of action

H₂-receptor antagonists, iron supplements or preparations, ketoconazole: Decreased absorption of these drugs

mecamylamine: Decreased excretion and prolonged effect of mecamylamine

methenamine: Decreased methenamine effectiveness

mexiletine: Possibly mexiletine toxicity

potassium supplements: Decreased serum potassium level

sucralfate: Interference with binding of sucralfate to gastric mucosa

urinary acidifiers (ammonium chloride, ascorbic acid, potassium and sodium phosphates): Counteracted effects of urinary acidifiers

FOODS

dairy products: Increased risk of milk-alkali syndrome with prolonged use of sodium bicarbonate

Adverse Reactions

CNS: Mental or mood changes

CV: Irregular heartbeat, peripheral edema (with large doses), weak pulse

EENT: Dry mouth

GI: Abdominal cramps, thirst

MS: Muscle spasms, myalgia

SKIN: Extravasation with necrosis, tissue sloughing, or ulceration

Nursing Considerations

• Monitor sodium intake of patient taking

sodium bicarbonate because effervescent powder contains 700.6 mg of sodium/3.9 g; oral powder contains 952 mg of sodium/tsp; and tablets contain 325 mg/3.9-mEq tablet, 520 mg/6.2-mEq tablet, and 650 mg/7.7-mEq tablet.

- For I.V. infusion, dilute drug with normal saline solution, D₅W, or other standard electrolyte solution before administration.
- Avoid rapid I.V. infusion, which can cause severe alkalosis. Be aware that during cardiac arrest, risk of death from acidosis may outweigh risks of rapid infusion.
- Monitor urine pH, as ordered, to determine drug's effectiveness as urine alkaliizer.
- If patient on long-term sodium bicarbonate therapy is consuming calcium or milk, watch for milk-alkali syndrome, characterized by anorexia, confusion, headache, hypercalcemia, metabolic acidosis, nausea, renal insufficiency, and vomiting.
- Be aware that parenteral forms are hypertonic and that increased sodium intake can produce edema and weight gain.
- Assess I.V. site often for evidence of extravasation. If it occurs, notify prescriber at once and remove I.V. catheter. Elevate the limb, apply warm compresses, and expect prescriber to administer a local injection of hyaluronidase or lidocaine.

PATIENT TEACHING

- Advise patient not to take sodium bicarbonate with large amounts of dairy products or for longer than 2 weeks, unless directed by prescriber.
- Caution patient not to take more drug than prescribed to avoid adverse reactions.
- Direct patient not to take drug within 2 hours of other oral drugs.
- Advise patient to avoid taking other prescribed or OTC drugs without prescriber's approval because many drugs interact with sodium bicarbonate.

sodium ferric gluconate

(contains 62.5 mg elemental iron per 5 ml)

Ferrlecit

Class and Category

Chemical class: Iron salt, mineral

Therapeutic class: Antianemic

Pregnancy category: B

Indications and Dosages

↗ *To treat iron deficiency anemia in patients receiving long-term hemodialysis and erythropoietin*

I.V. INFUSION OR INJECTION

Adults. 125 mg of elemental iron. *Usual:* Minimum cumulative dose of 1 g elemental iron given over eight sequential dialysis treatments. Dosage repeated at lowest dosage needed to maintain target levels of hemoglobin and hematocrit and acceptable limits of blood iron level.

Mechanism of Action

Acts to replenish iron stores lost during hemodialysis as a result of increased blood loss or increased iron utilization from epoetin therapy. Iron is an essential component of hemoglobin, myoglobin, and several enzymes, including cytochromes, catalase, and peroxidase, and is needed for catecholamine metabolism and normal neutrophil function. Sodium ferric gluconate also normalizes RBC production by binding with hemoglobin or being stored as ferritin in reticuloendothelial cells of the liver, spleen, and bone marrow.

Incompatibilities

Don't mix sodium ferric gluconate with other drugs or parenteral nutrition solutions for I.V. infusion.

Contraindications

Anemia other than iron deficiency, hypersensitivity to iron salts or their components, iron overload

Interactions

DRUGS

oral iron preparations: Possibly reduced absorption of oral iron supplements

Adverse Reactions

CNS: Asthenia, dizziness, fatigue, fever, headache, hypertonionia, nervousness, paresthesia, syncope

CV: Chest pain, generalized edema, hypertension, hypotension, tachycardia

EENT: Dry mouth

GI: Abdominal pain, diarrhea, nausea, vomiting

HEME: Hemorrhage

MS: Back pain, leg cramps

RESP: Cough, dyspnea, upper respiratory tract infection, wheezing

SKIN: Diaphoresis, pruritus

Other: Anaphylaxis, generalized pain, hyperkalemia, hypersensitivity, infusion or injection site reaction

Nursing Considerations

- To reconstitute sodium ferric gluconate for I.V. infusion, dilute prescribed dosage in 100 ml of normal saline solution immediately before infusion. Infuse over 1 hour. Discard any unused diluted solution.
- Inspect drug for particles and discoloration before administration and discard if present.
- Give undiluted drug by slow I.V. injection at up to 12.5 mg/min, not to exceed 125 mg per injection.
- Be aware that most patients need a minimum cumulative dose of 1 gram of elemental iron administered over eight sequential dialysis treatments.

WARNING Assess patient for evidence of allergic reaction, including chills, facial flushing, pruritus, and rash, and of a hypersensitivity reaction, including diaphoresis, dyspnea, nausea, severe lower back pain, vomiting, and wheezing.

Discontinue drug and notify prescriber immediately if patient develops an allergic or hypersensitivity reaction, and be prepared to provide emergency interventions.

WARNING Assess blood pressure often after drug administration because hypotension may occur and may be related to infusion rate or total cumulative dose. Avoid rapid infusion, and be prepared to provide I.V. fluids for volume expansion.

- Expect to monitor blood hemoglobin level, hematocrit, serum ferritin level, and transferrin saturation, as ordered, before, during, and after sodium ferric gluconate therapy. Make sure serum iron level is tested 48 hours after last dose. To prevent iron toxicity, notify prescriber and expect to end therapy if blood iron level is normal or elevated.
- Assess patient for possible iron overload, characterized by bleeding in GI tract and lungs, decreased activity, pale conjunctivae, and sedation.

PATIENT TEACHING

- Warn patient not to take any oral iron

preparations during sodium ferric gluconate therapy without first consulting prescriber.

- Inform patient that symptoms of iron deficiency may include decreased stamina, learning problems, shortness of breath, and fatigue.

sodium phenylbutyrate

Buphenyl

Class and Category

Chemical class: Phenylacetate prodrug

Therapeutic class: Antihyperammonemic

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat urea cycle disorders in combination with low-protein diet*

POWDER, TABLETS

Adults and children weighing more than 20 kg (44 lb). 9.9 to 13 g/m² daily in 4 to 6 divided doses with meals.

Children weighing up to 20 kg. 450 to 600 mg/kg daily in 4 to 6 divided doses with meals.

Mechanism of Action

Provides alternate pathway for eliminating waste nitrogen by forming phenylacetate, an active metabolite that conjugates with glutamine to produce phenylacetylglutamine, which is excreted by the kidneys.

Contraindications

Acute hyperammonemia, hypersensitivity to sodium phenylbutyrate or its components

Interactions

DRUGS

corticosteroids: Increased serum ammonia level

haloperidol, valproate: Increased risk of hyperammonemia

probenecid: Decreased excretion of conjugated product of sodium phenylbutyrate

Adverse Reactions

CNS: Depression, disorientation, fatigue, headache, light-headedness, memory loss, syncope

CV: Arrhythmias

EENT: Hypoacusis, taste perversion
GI: Abdominal pain, anorexia, constipation, elevated liver function test results, gastritis, nausea, peptic ulcer, rectal bleeding, vomiting
GU: Amenorrhea, menstrual irregularities
HEME: Anemia, aplastic anemia, leukocytosis, leukopenia, thrombocytopenia
SKIN: Rash

Other: Body odor, hyperchloremia, hypoalbuminemia, hypophosphatemia, metabolic acidosis, metabolic alkalosis, weight gain

Nursing Considerations

- Mix powder form of sodium phenylbutyrate with food or liquid, but not with acidic beverages such as coffee and tea.
- Be aware that drug shouldn't be used to treat acute hyperammonemia, which is a medical emergency.
- Monitor patient with history of heart failure or severe renal failure for fluid retention because of drug's sodium content.

PATIENT TEACHING

- Instruct patient to take sodium phenylbutyrate with meals but not to mix it with acidic beverages such as coffee and tea.
- Advise patient to comply with follow-up laboratory tests, as prescribed.
- Urge patient to notify prescriber immediately about changes in body odor because they may signal metabolic imbalance.

sodium polystyrene sulfonate

Kayexalate, K-Exit (CAN), Kionex, PMS-Sodium Polystyrene Sulfonate (CAN), SPS Suspension

Class and Category

Chemical class: Sulfonated cation-exchange resin

Therapeutic class: Antihyperkalemic

Pregnancy category: C

Indications and Dosages

➤ *To treat hyperkalemia*

ORAL POWDER, SUSPENSION

Adults. 15 g (4 level tsp) once daily to q.i.d.

Maximum: 40 g q.i.d.

Children. 1 g/kg/dose, as needed.

RECTAL POWDER, SUSPENSION

Adults. 25 to 100 g as retention enema, as needed.

Children. 1 g/kg/dose as retention enema, as needed.

Route	Onset	Peak	Duration
P.O.	2–12 hr	Unknown	Unknown

Mechanism of Action

Releases sodium ions in exchange for other cations in intestines. Resin enters large intestine and releases sodium ions in exchange for hydrogen ions. As the resin moves through the intestines, hydrogen ions are then exchanged for potassium ions, which are in greater concentration. Bound resin leaves the body in feces, carrying potassium and other ions with it, thereby reducing serum potassium level.

Contraindications

Hypersensitivity to sodium polystyrene sulfonate or its components, hypokalemia, obstructive bowel disease, reduced intestinal motility in neonates, oral administration in neonates

Interactions

DRUGS

antacids, laxatives: Increased risk of metabolic alkalosis

potassium-sparing diuretics, potassium supplements: Increased risk of fluid retention

Adverse Reactions

CV: Peripheral edema

GI: Abdominal cramps, anorexia, colonic necrosis, constipation, epigastric pain, fecal impaction, GI bleeding, indigestion, ischemic colitis, nausea, perforation, vomiting

GU: Decreased urine output

Other: Hyponatremia, hypocalcemia, hypokalemia, weight gain

Nursing Considerations

- Use sodium polystyrene sulfonate cautiously in patients with heart failure, hypertension, or marked edema.
- Be aware that drug is available as powdered resin or as solution that contains sorbitol to facilitate movement of resin through intestines. As a result, patient may experience abdominal cramps, diarrhea, nausea, and vomiting.
- Because the drug doesn't take effect for

several hours, be aware that it's inappropriate for treating acute, life-threatening hyperkalemia.

- If patient has hypokalemia or hypocalcemia, notify prescriber immediately and expect to withhold drug because it reduces potassium and calcium levels. Evidence of hypokalemia includes abdominal cramps, acidic urine, anorexia, drowsiness, ECG changes, hypotension, hypoventilation, muscle weakness, and tachycardia. Evidence of hypocalcemia includes abdominal pain, agitation, anxiety, ECG changes, hypotension, muscle twitching, psychosis, seizures, and tetany.
- To give powdered resin as oral suspension, mix powder in water, syrup, or food and give promptly, being sure to follow full aspiration precautions (such as keeping patient in an upright position while giving drug). If needed, administer through gastric feeding tube.
- Precede rectal administration with a cleansing enema, as ordered.
- When giving rectally, suspend powdered resin in 100 ml of aqueous solution warmed to body temperature, in bag connected to soft, large (French 28) catheter. Have patient lie on his left side with his lower leg straight and upper leg flexed or with his knees to his chest. Gently insert the tube into the rectum and well into the sigmoid colon. The solution should flow into the colon by way of gravity and be retained for 30 to 60 minutes or longer, if possible. After patient is unable to retain the solution any longer, administer a non-sodium-containing cleansing enema, as prescribed.
- Use of sorbitol with sodium polystyrene sulfonate isn't recommended because of increased risk of colonic necrosis and other serious GI effects, such as bleeding, ischemic colitis, and perforation.
- After administration, assess for constipation and fecal impaction.

PATIENT TEACHING

- Instruct patient not to mix oral form of sodium polystyrene sulfonate with foods and liquids high in potassium content, such as bananas and orange juice.
- If patient will self-administer rectal solution, teach the correct technique and body position. Remind him to let the solution

flow into the colon by gravity and to retain it for at least 30 to 60 minutes, longer if possible.

- Advise patient to notify prescriber immediately about abdominal cramps, nausea, and vomiting.

sodium thiosalicylate

Rexolate, Tusal

Class and Category

Chemical class: Salicylic acid derivative

Therapeutic class: Analgesic, anti-inflammatory

Pregnancy category: Not rated

Indications and Dosages

➤ *To relieve symptoms of acute gout*

I.V. OR I.M. INJECTION

Adults. Initial: 100 mg every 3 to 4 hr for 2 days; then 100 mg daily.

➤ *To relieve pain from musculoskeletal conditions*

I.V. OR I.M. INJECTION

Adults. 50 to 100 mg daily or every other day.

➤ *To relieve symptoms of osteoarthritis*

I.V. OR I.M. INJECTION

Adults. 100 mg 3 times/wk for several wk, then once/wk, usually up to a total dosage of 2.5 g. After 1 to 2 wk, another course of treatment may be given.

➤ *To treat rheumatic fever*

I.V. OR I.M. INJECTION

Adults. Initial: 100 to 150 mg every 4 to 8 hr for 3 days, then 100 mg b.i.d.

Mechanism of Action

Exerts peripherally induced analgesic and anti-inflammatory effects by blocking pain impulses and inhibiting prostaglandin synthesis.

Contraindications

GI bleeding; hemophilia; hemorrhage; hypersensitivity to sodium thiosalicylate, NSAIDs, or their components; Reye's syndrome

Interactions

DRUGS

ACE inhibitors, beta blockers: Decreased

antihypertensive effect of these drugs
activated charcoal: Decreased sodium thiosalicylate absorption
antacids, urinary alkalisers: Increased excretion of sodium thiosalicylate, leading to reduced drug effectiveness and shortened half-life
carbonic anhydrase inhibitors (such as acetazolamide): Increased risk of salicylate toxicity; possibly displacement of acetazolamide from protein-binding sites, resulting in toxicity
corticosteroids: Possibly increased sodium thiosalicylate excretion
insulin, oral antidiabetic drugs: Altered glucose control (with large sodium thiosalicylate doses)
loop diuretics: Possibly decreased effectiveness of loop diuretics in patients with renal or hepatic impairment
methotrexate: Increased risk of methotrexate toxicity
nizatidine: Increased blood sodium thiosalicylate level
probenecid, sulfipyrazone: Decreased uricosuric effects
spironolactone: Possibly inhibited diuretic effect of spironolactone
urinary acidifiers (including ammonium chloride, ascorbic acid, methionine): Decreased sodium thiosalicylate excretion, possibly leading to salicylate toxicity

ACTIVITIES

alcohol use: Increased risk of gastrointestinal ulceration

Adverse Reactions

GI: Anorexia, diarrhea, GI bleeding, heartburn, hepatotoxicity, indigestion, nausea, thirst, vomiting

HEME: Leukopenia, platelet dysfunction, prolonged bleeding time, thrombocytopenia

RESP: Bronchospasm

SKIN: Rash, urticaria

Other: Angioedema

Nursing Considerations

- Use drug cautiously in patients with asthma, chronic urticaria, or nasal polyps because these patients are more prone to hypersensitivity.
- Expect to monitor hepatic and renal function during long-term drug therapy.
- After repeated use or large doses, look for

signs of salicylate toxicity: CNS depression, confusion, diaphoresis, diarrhea, difficulty hearing, dizziness, headache, hyperventilation, lassitude, tinnitus, and vomiting.

- Be aware that tinnitus usually means that the blood sodium thiosalicylate level has reached or exceeded the upper limit for therapeutic effects.

PATIENT TEACHING

- Instruct patient to notify prescriber immediately about bleeding or symptoms of salicylate toxicity.

solifenacin succinate

VESIcare

Class and Category

Chemical class: Muscarinic receptor antagonist

Therapeutic class: Bladder antispasmodic

Pregnancy category: C

Indications and Dosages

↗ *To treat overactive urinary bladder with symptoms of urge incontinence, urgency, and frequency*

TABLETS

Adults. 5 mg daily; if tolerated well, increased to 10 mg daily.

DOSAGE ADJUSTMENT For patients with severe renal impairment or moderate hepatic impairment or patients taking ketoconazole or other potent CYP3A4 inhibitors, dosage limited to 5 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	3–8 hr	Unknown

Mechanism of Action

Antagonizes the effect of acetylcholine on muscarinic receptors in detrusor muscle, decreasing the muscle spasms that cause inappropriate bladder emptying. This action increases bladder capacity and volume, which relieves the sensation of urgency and frequency and enhances bladder control.

Contraindications

Gastric retention, hypersensitivity to solife-

nacin or its components, uncontrolled angle-closure glaucoma, urine retention

Interactions

DRUGS

ketoconazole, other potent CYP3A4

inhibitors: Possibly decreased metabolism of solifenacin and increased risk of adverse effects

Adverse Reactions

CNS: Confusion, depression, dizziness, fatigue, hallucinations, headache

CV: Hypertension, prolonged QT interval, peripheral edema, torsades de pointes

EENT: Blurred vision, dry eyes or mouth, pharyngitis

GI: Abdominal pain, constipation, indigestion, nausea, vomiting

GU: UTI, urinary retention

RESP: Cough

RESP: Pruritus, rash, urticaria

Other: Angioedema, influenza

Nursing Considerations

- Use cautiously in patients with ulcerative colitis, intestinal atony, or myasthenia gravis because solifenacin may decrease GI motility; in patients with significant bladder outflow obstruction because solifenacin may cause urine retention; in patients with hepatic impairment because solifenacin is metabolized in the liver; and in patients with renal impairment because solifenacin excretion may be impaired.
- Monitor elderly patients, especially those age 75 and over, for adverse reactions because they're at increased risk for solifenacin-induced adverse reactions.

PATIENT TEACHING

- Instruct patient to take solifenacin with a full glass of water and to swallow the tablet whole.
- Caution patient to avoid exertion in a warm or hot environment because sweating may be delayed, which could increase body temperature and increase risk of heatstroke.
- Advise patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Inform patient that alcohol may cause drowsiness, and urge patient to limit or avoid alcoholic beverages while taking solifenacin.

somatropin

Accretropin, Genotropin, Humatrope, Norditropin, Nutropin, Nutropin AQ, Omnitrope, Saizen, Serostim, Tev-Tropin

Class and Category

Chemical class: Recombinant DNA product

Therapeutic class: Growth hormone

Pregnancy category: B (Serostim) or C (Genotropin, Humatrope, Norditropin, Nutropin, Nutropin AQ, Saizen)

Indications and Dosages

➤ *To treat growth failure caused by growth hormone deficiency*

SUBCUTANEOUS INJECTION (NUTROPIN, NUTROPIN AQ)

Adults. 0.3 mg (0.9 international units)/kg/wk.

SUBCUTANEOUS INJECTION (SAIZEN)

Adults. *Initial:* 0.005 mg/kg daily, increased after 4 wk by no more than 0.01 mg/kg daily, as needed.

I.M. OR SUBCUTANEOUS INJECTION (HUMATROPE, NUTROPIN, SAIZEN)

Children. 0.18 to 0.3 mg (0.54 to 0.9 international units)/kg/wk, divided into equal doses given daily or every other day over 6 to 7 days.

SUBCUTANEOUS INJECTION (NORDITROPIN)

Adults. *Initial:* 0.004 mg/kg daily, increased after 6 wk by no more than 0.016 mg/kg daily, as needed.

SUBCUTANEOUS INJECTION (GENOTROPIN, NORDITROPIN)

Children. 0.16 to 0.24 mg (0.48 to 0.72 international units)/kg/wk, divided into equal doses given daily over 6 to 7 days.

SUBCUTANEOUS INJECTION (TEV-TROPIN)

Children. Up to 0.1 mg/kg three times/wk.

SUBCUTANEOUS INJECTION (OMNITROPE)

Adults. *Initial:* 0.04 mg/kg/wk divided into 7 daily doses and increased at 4- to 8-wk intervals, as needed. *Maximum:* 0.08 mg/kg/wk. Or, 0.15 to 0.30 mg/day.

Children. 0.16 to 0.24 mg/kg/wk divided into 6 to 7 daily doses.

SUBCUTANEOUS INJECTION (ACCETROPIN)

Children. 0.18 to 0.3 mg/kg/wk divided into 6 to 7 daily doses.

↗ *To treat growth failure caused by chronic renal insufficiency*

SUBCUTANEOUS INJECTION (NUTROPIN, NUTROPIN AQ)

Children. Up to 0.35 mg (1.05 international units)/kg/wk, divided into equal doses given daily.

↗ *To treat growth failure caused by Turner's syndrome*

SUBCUTANEOUS INJECTION (NUTROPIN, NUTROPIN AQ)

Adults and children. Up to 0.375 mg (1.125 international units)/kg/wk, divided into equal doses given daily or every other day over 7 days.

SUBCUTANEOUS INJECTION (NORDITROPIN)

Adults and children. Up to 0.067 mg/kg/day.

SUBCUTANEOUS INJECTION (ACCRETROPIN)

Children. 0.36 mg/kg/wk divided into 6 to 7 daily doses.

↗ *To treat short stature or growth failure in children with short stature homeobox-containing gene (SHOX) deficiency whose epiphyses are not closed*

SUBCUTANEOUS INJECTION (HUMATROPE)

Children. 0.35 mg/kg weekly divided into equal daily doses.

↗ *To provide long-term treatment of growth failure in children born small for gestational age and no catch-up growth by age 2*

SUBCUTANEOUS INJECTION (GENOTROPIN)

Children. 0.48 mg/kg/wk, divided into equal doses and administered daily over 6 to 7 days.

SUBCUTANEOUS INJECTION (HUMATROPE)

Children. Up to 0.47 mg/kg/wk, divided into equal doses and administered daily over 6 to 7 days.

SUBCUTANEOUS INJECTION (NORDITROPIN)

Children. Up to 0.067 mg/kg/day.

↗ *To treat growth factor failure due to Prader-Willi syndrome*

SUBCUTANEOUS INJECTION (GENOTROPIN)

Children. 0.24 mg/kg/wk.

↗ *To treat AIDS-related cachexia or weight loss*

SUBCUTANEOUS INJECTION (SEROSTIM)

Adults weighing more than 55 kg (121 lb). 6 mg at bedtime.

Adults weighing 45 to 55 kg (99 to 121 lb). 5 mg at bedtime.

Adults weighing 35 to 45 kg (77 to 99 lb). 4 mg at bedtime.

Adults weighing less than 35 kg. 0.1 mg/kg at bedtime.

DOSAGE ADJUSTMENT For patients at increased risk for adverse effects related to Serostim, 0.1 mg/kg every other day. For elderly patients, regardless of type of somatropin prescribed, lower starting dose and smaller dosage titration recommended.

Route	Onset	Peak	Duration
I.M., SubQ	Unknown	Unknown	12–48 hr

Mechanism of Action

Increases production of somatomedins (or insulin-like growth factor) in the liver and other tissues, which mediates somatropin's anabolic and growth-promoting effects. The drug binds to specific receptors throughout the body, stimulating amino acid transport; DNA, RNA, and protein synthesis; cell proliferation; and growth of bone and soft tissue.

Somatropin also decreases insulin cell receptor sensitivity, thereby increasing blood glucose level; stimulates triglyceride hydrolysis in adipose tissue and hepatic glucose output; and aids bone growth by promoting a positive calcium balance and retention of sodium and potassium.

Contraindications

Active neoplasia; active proliferative or severe nonproliferative diabetic retinopathy; acute critical illness due to complications following open-heart surgery, abdominal surgery, or multiple trauma; acute respiratory failure; cancer; closed epiphyses; hypersensitivity to somatropin, its components, or benzyl alcohol; Prader-Willi syndrome coupled with severe obesity, history of upper airway obstruction or sleep apnea, or severe respiratory impairment

Interactions

DRUGS

anabolic steroids, androgens, estrogens, thyroid hormones: Possibly accelerated epiphyseal closure
anticonvulsants, corticosteroids, cyclosporine, sex steroids: Possibly altered clearance of these drugs, increasing risk of adverse effects
corticosteroids, corticotropin: Inhibited growth response to somatropin; decreased

response of corticosteroids or corticotropin *oral estrogens*: Decreased somatropin effectiveness

Adverse Reactions

CNS: Depression, dizziness, fatigue, headache, hypoesthesia, insomnia, intracranial hypertension or tumor, paresthesia, weakness

CV: Chest pain, edema, hypertriglyceridemia

EENT: Otitis, papilledema, rhinitis, sinusitis, tonsillitis, vision changes, worsening of diabetic retinopathy

ENDO: Breast pain, edema, tenderness, or mass; gynecomastia; hyperglycemia; hypothyroidism

GI: Nausea, pancreatitis, vomiting

GU: UTI

HEME: Eosinophilia

MS: Arthralgia; back, bone, joint, or leg pain; carpal tunnel syndrome; myalgia; progression of existing scoliosis; slipped capital femoral epiphysis (children)

RESP: Upper respiratory tract infection

SKIN: Increased growth of nevi, rash

Other: Elevated serum alkaline phosphatase, inorganic phosphorus, and parathyroid hormone levels; flulike symptoms; injection site inflammation, lipoatrophy

Nursing Considerations

- Be aware that somatropin shouldn't be used in patients with malignancy and should be stopped if patient is diagnosed with malignancy. Cancer treatment must be completed with evidence of remission before somatropin can be started or restarted.
- Make sure patient with Prader-Willi syndrome has been evaluated for upper airway obstruction and sleep apnea before starting somatropin because of increased risk of respiratory arrest. Notify prescriber immediately and expect to stop drug if patient starts snoring, snoring increases, or other evidence of upper airway obstruction develops.
- Make sure patient has a funduscopic eye examination before starting and periodically throughout somatropin therapy to rule out papilledema.
- Use cautiously in elderly patients because they're more prone to adverse reactions to somatropin. Expect initial dosage to be

lower and dosage adjustment more gradual to minimize adverse effects.

- Reconstitute somatropin according to package directions. (Nutropin AQ and forms available in cartridges, such as Norditropin NordiFlex, don't require reconstitution.) In general, swirl vial gently rather than shaking it to dissolve contents.
- Don't reconstitute with diluent containing benzyl alcohol if drug will be given to neonate. Don't use diluent supplied for Humatrope for patients sensitive to Metacresol or glycerin; use sterile water for injection.
- Store Nutropin AQ vials and cartridges refrigerated in a dark place.
- Remember to rotate injection sites to avoid tissue atrophy at injection site.

WARNING Although uncommon, intracranial hypertension is possible. Monitor patient for such signs and symptoms as headache, nausea, papilledema, vision changes, and vomiting, especially during first 8 weeks of therapy. If intracranial hypertension occurs, notify prescriber, expect to discontinue drug, and provide supportive care, as needed.

- Because somatropin is a protein, monitor patient for local or systemic allergic reaction.
- Monitor patient's blood glucose level because somatropin may decrease insulin sensitivity, especially at higher doses.
- Monitor patient's thyroid function and obtain periodic test results, as ordered, because untreated hypothyroidism may interfere with somatropin, especially in children.
- Assess patient's skin regularly for changes that suggest skin malignancy.

PATIENT TEACHING

- Instruct diabetic patient who takes insulin to monitor blood glucose level frequently; somatropin may induce insulin resistance.
- Inform parents of a child with Turner's syndrome about increased risk of ear infections.
- Advise family or caregiver to observe patient for limping, which may indicate a slipped epiphysis.
- Teach patient or caregiver how to measure and administer drug at home using either pen device or vial, syringe, and needle.

sotalol hydrochloride

Betapace, Betapace AF, Sotacor (CAN)

Class and Category

Chemical class: Methanesulfonanilide

Therapeutic class: Class III antiarrhythmic

Pregnancy category: B

Indications and Dosages

↗ *To treat life-threatening ventricular arrhythmias*

TABLETS

Adults. *Initial:* 80 mg b.i.d. *Maintenance:* 160 to 320 mg daily in divided doses b.i.d. or t.i.d. *Maximum:* 640 mg daily.

DOSE ADJUSTMENT If creatinine clearance is 30 to 60 ml/min/1.73 m², dosage interval extended to every 24 hr; if creatinine clearance is less than 30 ml/min/1.73 m², dosage interval extended to every 36 to 48 hr, according to response; if creatinine clearance less than 10 ml/min/1.73 m², dosage adjusted as prescribed.

↗ *To maintain normal sinus rhythm in patients with highly symptomatic atrial fibrillation who are currently in sinus rhythm*

TABLETS

Adults. *Initial:* If creatinine clearance is 40 to 60 ml/min/1.73 m², give 80 mg daily; if creatinine clearance exceeds 60 ml/min/1.73 m², give 80 mg b.i.d. *Maintenance:* After at least 3 days (five or six doses given daily), if 80-mg dose is tolerated and QT interval less than 500 msec, dosage maintained and patient discharged. Or hospitalized patient monitored closely to determine maintenance dosage while increasing to 120 mg b.i.d. for 3 days (five or six doses if daily dosing). *Maximum:* 160 mg b.i.d. if creatinine clearance exceeds 60 ml/min/1.73 m².

DOSE ADJUSTMENT If 80-mg once or twice daily doesn't reduce frequency of atrial fibrillation relapses and is tolerated without excessive QT-interval prolongation (greater than 520 msec), dosage increased to 120 mg once or twice daily, depending on creatinine clearance. If 120-mg dose doesn't reduce frequency of early relapse and is tolerated using same criteria, dosage

increased to 160 mg once or twice daily, depending on creatinine clearance.

DOSE ADJUSTMENT If QT interval is 520 msec or more, dosage reduced until it returns to less than 520 msec. If QT interval exceeds 520 msec with lowest maintenance dosage of 80 mg, drug stopped. If renal function deteriorates, daily dose reduced by half and given daily.

Route	Onset	Peak	Duration
P.O.	Unknown	2–3 hr	Unknown

Mechanism of Action

Combines class II and class III antiarrhythmic activity to increase sinus cycle length. This beta blocker decreases AV nodal conduction and increases AV nodal refractoriness. Suppression of SA node automaticity and AV node conductivity decreases atrial and ventricular ectopy.

Contraindications

Asthma, atrial arrhythmias (if baseline QT interval exceeds 450 msec or creatinine clearance is less than 40 ml/min/1.73 m²), cardiogenic shock, congenital or acquired QT syndromes, COPD, heart failure (unless it results from tachyarrhythmia that's treatable by sotalol), hypersensitivity to sotalol or its components, second- or third-degree AV block without functioning pacemaker, sinus bradycardia

Interactions

DRUGS

allergen immunotherapy, allergenic extracts for skin testing: Increased risk of serious systemic adverse reaction or anaphylaxis
amiodarone: Additive depressant effect on conduction, negative inotropic effect
anesthetics (hydrocarbon inhalation): Increased risk of myocardial depression and hypotension
antacids: Altered sotalol effectiveness
astemizole, class I antiarrhythmics, phenothiazines, terfenadine, tricyclic antidepressants: Prolonged QT interval, life-threatening torsades de pointes
beta blockers (other): Additive beta blockade
beta₂-receptor stimulants: Decreased effectiveness of these drugs
calcium channel blockers, clonidine, diazoxide, guanabenz, reserpine and other anti-hypertensives: Additive antihypertensive

effect and, possibly, other beta-blocking effects

cimetidine: Possibly impaired sotalol clearance

glucagon: Possibly blunted hyperglycemic response

insulin, oral antidiabetic drugs: Impaired glucose control, increased risk of hyperglycemia

lidocaine: Decreased lidocaine clearance, increased risk of lidocaine toxicity

MAO inhibitors: Increased risk of significant hypertension

neuromuscular blockers: Possibly potentiated and prolonged neuromuscular blockade

phenothiazines: Increased blood levels of both drugs

propafenone: Increased blood level and half-life of sotalol

sympathomimetics, xanthines: Possibly mutual inhibition of therapeutic effects

Adverse Reactions

CNS: Anxiety, depression, dizziness, drowsiness, fatigue, insomnia, lethargy, nervousness, weakness

CV: AV conduction disorders, bradycardia, heart failure, hypotension, peripheral vascular insufficiency

EENT: Nasal congestion

ENDO: Hyperglycemia, hypoglycemia

GI: Abdominal pain, constipation, diarrhea, nausea, vomiting

GU: Sexual dysfunction

MS: Muscle weakness

RESP: Bronchospasm, dyspnea, wheezing

Nursing Considerations

- Expect to obtain baseline creatinine clearance and QT interval before starting sotalol.
- Monitor blood pressure, apical and radial pulses, fluid intake and output, daily weight, respiratory rate, and circulation in limbs before and during sotalol therapy.
- If prescriber is stopping amiodarone, be aware that sotalol shouldn't be started until QT interval has returned to baseline because of possible adverse cardiac effects.
- Be aware that stopping sotalol abruptly may cause life-threatening reactions.
- Monitor serum electrolyte levels because drug can increase risk of torsades de pointes in patients with electrolyte imbalances, especially hypokalemia or hypo-

magnesemia.

- Assess carefully if patient has diabetes mellitus or thyrotoxicosis because they may mask hypoglycemia and hyperthyroidism.

PATIENT TEACHING

- Advise patient to notify prescriber immediately if he has difficulty breathing.
- Urge patient to consult prescriber before taking OTC drugs, especially cold remedies, which may decrease sotalol's effectiveness.
- Urge patient to avoid hazardous activities until drug's CNS effects are known.

sparfloxacin

Zagam

Class and Category

Chemical class: Fluoroquinolone

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

- *To treat community-acquired pneumonia caused by Chlamydia pneumoniae, Haemophilus influenzae, H. parainfluenzae, Moraxella catarrhalis, Mycoplasma pneumoniae, or Streptococcus pneumoniae and acute bacterial exacerbations of chronic bronchitis caused by C. pneumoniae, Enterobacter cloacae, H. influenzae, H. parainfluenzae, Klebsiella pneumoniae, M. catarrhalis, Staphylococcus aureus, or S. pneumoniae*

TABLETS

Adults. 400 mg on day 1, followed by 200 mg/day for 10 days.

DOSE ADJUSTMENT For patients with creatinine clearance less than 50 ml/min/1.73 m², 400 mg on day 1 and then dosing interval extended to 200 mg every 48 hr for 9 days.

Mechanism of Action

Causes bacterial cells to die by inhibiting the enzyme DNA gyrase, which is responsible for unwinding and supercoiling bacterial DNA before it replicates.

Contraindications

History of photosensitivity, hypersensitivity

to quinolone derivatives, job or lifestyle that precludes compliance with measures to prevent phototoxicity, prolonged QTc interval or use of drugs that can prolong QTc interval

Interactions

DRUGS

aluminum-, calcium-, or magnesium-containing antacids; ferrous sulfate; magnesium-containing laxatives; sucralfate; zinc: Decreased bioavailability of sparfloxacin

amiodarone, astemizole, bepridil, cisapride, class IA antiarrhythmics (disopyramide, quinidine, procainamide), class III antiarrhythmics (ibutilide, sotalol), erythromycin, pentamidine, phenothiazines, terfenadine, tricyclic antidepressants, other drugs that can prolong QTc interval: Possibly prolonged QTc interval and torsades de pointes

Adverse Reactions

CNS: Asthenia, cerebral thrombosis, dizziness, drowsiness, headache, insomnia, lightheadedness, nervousness, seizures, somnolence

CV: Cardiopulmonary arrest, embolism, prolonged QTc interval, torsades de pointes, vasodilation

EENT: Laryngeal edema, taste perversion

GI: Abdominal pain, diarrhea, hepatic necrosis or failure, hepatitis, intestinal perforation, nausea, pseudomembranous colitis, vomiting

GU: Acute renal failure, vaginal candidiasis

HEME: Agranulocytosis, hemolytic anemia, pancytopenia, thrombocytopenia

MS: Rhabdomyolysis, tendinitis, tendon rupture

RESP: Interstitial pneumonia, pulmonary edema

SKIN: Photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Acidosis, anaphylaxis, angioedema, squamous cell carcinoma

Nursing Considerations

- Use sparfloxacin cautiously in patients with known or suspected CNS disorders because of risk of seizures. Institute seizure precautions according to facility policy.

- Monitor renal and liver function test results, as appropriate, during prolonged therapy.
- Measure QTc interval regularly because sparfloxacin has been found to increase QTc interval and risk of torsades de pointes.
- Severe diarrhea may indicate pseudomembranous colitis; give fluid, electrolyte, and protein replacement, as ordered.

PATIENT TEACHING

- Urge patient to avoid potentially hazardous activities until sparfloxacin's CNS effects are known.
- Advise patient to notify prescriber at once about aching or throbbing tendon pain.
- Instruct patient to wait 4 hours after taking sparfloxacin before taking antacids that contain aluminum, calcium, or magnesium; laxatives that contain magnesium; or vitamins that contain iron or zinc.
- Caution patient to avoid exposure to sunlight, bright natural light, and other sources of ultraviolet light during therapy and for 5 days afterward. Urge him to wear sunscreen and protective clothing when outdoors.
- Urge patient to notify prescriber at first sign of photosensitivity reaction (blistering, burning or swelling sensation, itching, rash, redness).

spectinomycin hydrochloride

Trobinic

Class and Category

Chemical class: Aminocyclitol, aminoglycoside derivative

Therapeutic class: Antibiotic

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat acute endocervical, rectal, and urethral gonorrhea caused by susceptible strains of Neisseria gonorrhoeae*

I.M. INJECTION

Adults and children weighing 45 kg (99 lb) or more. 2 g as a single dose, repeated as prescribed for adult if reinfection occurs or is strongly suspected. *Maximum:* 4 g for adults, 2 g for children.

Children weighing less than 45 kg (except infants). 40 mg/kg as a single dose.

Mechanism of Action

Binds to negatively charged sites on bacterial outer cell membrane, disrupting cell integrity, and binds to bacterial ribosomal subunits, inhibiting protein synthesis. Both actions lead to bacterial cell death.

Contraindications

Hypersensitivity to spectinomycin or its components

Adverse Reactions

CNS: Dizziness, insomnia

GI: Abdominal cramps, nausea, vomiting

Other: Injection site pain

Nursing Considerations

- To reconstitute spectinomycin, add 3.2 ml bacteriostatic water for injection (with benzyl alcohol) to each 2-g vial or 6.2 ml of diluent to each 4-g vial. Shake vial vigorously before withdrawing dose.
- Administer I.M. injection deep into large muscle mass, preferably upper outer quadrant of gluteal muscle.

PATIENT TEACHING

- Tell patient he'll be tested for syphilis at the start of treatment and 3 months later because spectinomycin treatment may mask or delay syphilis symptoms.
- Explain risk factors for sexually transmitted diseases, and teach correct condom use.
- Advise patient to encourage sexual partner to be tested for gonorrhea.
- Instruct patient to notify prescriber if signs and symptoms persist after a few days.

spironolactone

Aldactone, Novospiroton (CAN)

Class and Category

Chemical class: Aldosterone antagonist

Therapeutic class: Aldosterone antagonist, antihypertensive, diagnostic aid for primary hyperaldosteronism, diuretic

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat edema cause by heart failure, hepatic cirrhosis, or*

nephrotic syndrome

TABLETS

Adults. *Initial:* 25 to 200 mg daily in divided doses b.i.d. to q.i.d. for at least 5 days.

Maintenance: 75 to 400 mg daily in divided doses b.i.d. to q.i.d. *Maximum:* 400 mg daily.

Children. *Initial:* 1 to 3 mg/kg daily as a single dose or in divided doses b.i.d. to q.i.d. for at least 2 wk; adjusted, as needed, after 5 days. *Maximum:* 3 times initial dose.

↗ *To treat hypertension*

TABLETS

Adults. *Initial:* 50 to 100 mg daily as a single dose or in divided doses b.i.d. to q.i.d. for at least 2 wk; gradually adjusted every 2 wk, as needed, to control blood pressure, up to 200 mg daily. *Maximum:* 400 mg daily.

Children. *Initial:* 1 to 3 mg/kg daily as a single dose or in divided doses b.i.d. to q.i.d. for at least 2 wk; adjusted, as needed, after 5 days. *Maximum:* 3 times initial dose.

↗ *To aid in the diagnosis of primary hyperaldosteronism*

TABLETS

Adults. For long test, 400 mg daily in divided doses b.i.d. to q.i.d. for 3 to 4 wk; for short test, 400 mg daily in divided doses b.i.d. to q.i.d. for 4 days.

↗ *To treat primary hyperaldosteronism*

TABLETS

Adults. 100 to 400 mg daily in divided doses b.i.d. to q.i.d. before surgery. *Maximum:* 400 mg daily.

DOSAGE ADJUSTMENT Long-term maintenance dosage decreased for patients at risk for complications during surgery.

↗ *To substitute as therapy for diuretic-induced hypokalemia*

TABLETS

Adults. 25 to 100 mg daily as a single dose or in divided doses b.i.d. to q.i.d.

Maximum: 400 mg daily.

Route	Onset	Peak	Duration
P.O.*	Unknown	2–3 days	2–3 days

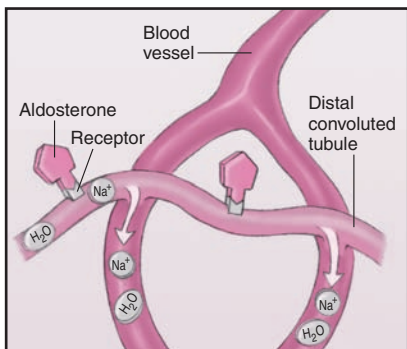

Contraindications

Acute renal insufficiency, anuria, hyperkalemia, hypersensitivity to spironolactone or its components

* For diuretic effect; others unknown.

Mechanism of Action

Normally, aldosterone attaches to receptors on the walls of distal convoluted tubule cells, causing sodium (Na^+) and water (H_2O) reabsorption in the blood, as shown at left. Spironolactone competes with aldosterone for these receptors,

thereby preventing sodium and water reabsorption and causing their excretion through the distal convoluted tubules, as shown below right. Increased urinary excretion of sodium and water reduces blood volume and blood pressure.

Interactions

DRUGS

ACE inhibitors, cyclosporine, other potassium-sparing diuretics, potassium-containing drugs, potassium supplements: Increased risk of hyperkalemia

digoxin: Possibly increased half-life of digoxin

exchange resins (sodium cycle), such as sodium polystyrene sulfonate: Increased risk of hypokalemia and fluid retention

heparin, oral anticoagulants: Decreased anticoagulant effect of these drugs

hypotension-producing drugs: Possibly potentiated antihypertensive or diuretic effect of spironolactone

lithium: Possibly lithium toxicity

NSAIDs, sympathomimetics: Decreased antihypertensive effect of spironolactone

FOODS

low-salt milk, salt substitutes: Increased risk of hyperkalemia

Adverse Reactions

CNS: Dizziness, encephalopathy, fatigue, headache

EENT: Increased intraocular pressure, nasal congestion, tinnitus, vision changes

ENDO: Gynecomastia

GI: Abdominal pain, anorexia, constipation, diarrhea, flatulence, nausea, vomiting

GU: Impotence

HEME: Aplastic anemia, neutropenia

RESP: Cough, dyspnea

MS: Arthralgia, back and leg pain, muscle weakness, myalgia

Other: Hyperkalemia

Nursing Considerations

- Be aware that for children or patients who have trouble swallowing, pharmacist may crush spironolactone tablets, mix with flavored syrup, and dispense as a suspension. It's stable 1 month when refrigerated.
- In diagnosing primary aldosteronism, test is considered positive if patient's serum potassium level rises when spironolactone is given and falls when it's discontinued.
- Expect to evaluate patient's serum potassium level 1 week after spironolactone therapy begins, after each dosage adjustment, monthly for the first 3 months, quarterly for 1 year, and then every 6 months thereafter or as ordered. Notify prescriber if level exceeds 5 mEq/L or patient's renal function deteriorates (serum creatinine level exceeding 4 mg/dl). If patient has severe heart failure, follow closely because hyperkalemia may be fatal in such patients.
- Evaluate spironolactone's effectiveness by assessing blood pressure and edema.

- Stop drug for several days, as prescribed, before patient undergoes adrenal vein catheterization to measure serum aldosterone level and plasma renin activity.

PATIENT TEACHING

- Instruct patient to take spironolactone with meals or milk.
- If patient can't swallow tablets, mention that pharmacist can crush and mix them with a flavored syrup as a suspension.
- Teach patient who takes spironolactone for hypertension how to measure his blood pressure. Urge him to monitor it regularly and report pressure greater than 140 mm Hg systolic or 90 mm Hg diastolic to prescriber.
- Caution patient that he may experience dizziness during spironolactone therapy if fluid balance is altered.

streptokinase

Kabikinase, Streptase

Class and Category

Chemical class: Purified beta-hemolytic

Streptococcus filtrate

Therapeutic class: Thrombolytic

Pregnancy category: C

Indications and Dosages

↗ *To lyse coronary artery thrombi*

I.V. INFUSION

Adults. 1,500,000 international units within 60 min of event.

INTRACORONARY INFUSION

Adults. 20,000-international unit bolus, followed by 2,000 international units/min for 60 min for total dose of 140,000 international units.

↗ *To lyse acute arterial thromboembolism or thrombosis, acute pulmonary embolism, or deep vein thrombosis*

I.V. INFUSION

Adults. 250,000-international unit bolus over 30 min, followed by 100,000 international units/hr for 24 to 72 hr.

↗ *To clear an occluded arteriovenous cannula*

I.V. INJECTION

Adults. 100,000 to 250,000 international units instilled slowly into each occluded lumen.

Mechanism of Action

Binds to fibrin in thrombus and converts trapped plasminogen to plasmin. Plasmin breaks down fibrin, fibrinogen, and other clotting factors, thereby dissolving the thrombus.

Route	Onset	Peak	Duration
I.V.	Immediate	20–120 min	4 hr

Incompatibilities

Don't mix streptokinase in the same syringe or give through the same I.V. line as other drugs.

Contraindications

Active internal bleeding, AV malformation or aneurysm, bleeding diathesis, history of stroke or intracranial or intraspinal surgery within the previous 2 months, hypersensitivity to streptokinase or its components, intracranial cancer, severe uncontrolled hypertension

Interactions

DRUGS

anticoagulants, enoxaparin, heparin, NSAIDs, platelet aggregation inhibitors:

Increased risk of bleeding

antifibrinolytics: Antagonized effects of both drugs

antihypertensives: Increased risk of severe hypotension, especially when streptokinase is administered rapidly to treat coronary artery occlusion

cefamandole, cefoperazone, cefotetan, pllicamycin, valproic acid: Possibly hypoprothrombinemia and increased risk of severe hemorrhage

corticosteroids, ethacrynic acid, salicylates: Possibly GI ulceration or bleeding

Adverse Reactions

CNS: Chills, fever

CV: Arrhythmias, hypotension

HEME: Unusual bleeding or bruising

Nursing Considerations

- Obtain hematocrit, platelet count, APTT, PT, and INR, as ordered, before giving streptokinase.
- To prevent foaming, don't shake drug during reconstitution.
- Check frequently for bleeding at I.V. site

and for blood in urine and stool. Perform neurologic assessment to detect intracranial bleeding.

- If serious spontaneous bleeding (not controlled by local pressure) occurs, stop streptokinase infusion immediately and notify prescriber.
- Monitor heart rate and rhythm by continuous ECG, as ordered.
- Treat fever with acetaminophen, as prescribed, rather than aspirin to reduce the risk of bleeding.

PATIENT TEACHING

- Explain to patient that he'll be on bed rest during streptokinase therapy.
- Inform patient that minor bleeding may occur at arterial puncture or surgical sites. Reassure him that appropriate care measures will be taken if bleeding occurs.
- Advise patient to wear or carry medical alert identification stating that he takes streptokinase.
- Inform patient that if he experiences chest pain within 12 months of therapy, he should notify health care providers that he has received streptokinase because repeated administration within 12 months may be ineffective.

streptomycin sulfate

Class and Category

Chemical class: Aminoglycoside

Therapeutic class: Antibiotic

Pregnancy category: D

Indications and Dosages

↗ *To treat gram-negative bacillary bacteremia, meningial infections, pneumonia, systemic infections, and UTI caused by susceptible strains of Aerobacter aerogenes, Brucella, Calymmatobacterium granulomatis, Enterococcus faecalis, Escherichia coli, Haemophilus ducreyi, H. influenzae, Klebsiella pneumoniae, and Proteus*

I.M. INJECTION

Adults. 1 to 2 g daily in divided doses every 6 to 12 hr. *Maximum:* 2 g daily.

Children. 20 to 40 mg/kg daily in divided doses every 6 to 12 hr.

↗ *As adjunct to treat endocarditis caused by Streptococcus viridans or E. faecalis*

I.M. INJECTION

Adults. 1 g b.i.d. for 1 wk (*S. viridans*) or 2 wk (*E. faecalis*) with a penicillin. Then, 500 mg b.i.d. for 1 wk (*S. viridans*) or 4 wk (*E. faecalis*).

↗ *As adjunct to treat tuberculosis caused by Mycobacterium tuberculosis*

I.M. INJECTION

Adults. 1 g daily with other antibiotics; dosage reduced to 1 g 2 or 3 times/wk, as appropriate and prescribed. *Maximum:* 2 g daily.

Children. 20 mg/kg daily with other antibiotics. *Maximum:* 1 g daily.

DOSAGE ADJUSTMENT For elderly patients, dosage decreased to 500 to 750 mg daily in combination with other antibiotics.

↗ *To treat plague caused by Yersinia pestis*

I.M. INJECTION

Adults. 2 g daily in 2 equally divided doses for at least 10 days.

Children. 30 mg/kg daily in divided doses b.i.d. or t.i.d. for 10 days.

↗ *To treat tularemia caused by Francisella tularensis*

I.M. INJECTION

Adults. 1 to 2 g daily in divided doses for 7 to 14 days.

DOSAGE ADJUSTMENT If creatinine clearance is 50 to 80 ml/min/1.73 m², dosage reduced to 7.5 mg/kg I.M. every 24 hr; if 10 to 49 ml/min/1.73 m², 7.5 mg/kg I.M. every 24 to 72 hr; if less than 10 ml/min/1.73 m², 7.5 mg/kg I.M. every 72 to 96 hr.

Mechanism of Action

Binds to negatively charged sites on the bacteria's outer cell membrane, disrupting cell integrity. Streptomycin also binds to bacterial ribosomal subunits and inhibits protein synthesis. Both actions lead to bacterial cell death.

Incompatibilities

Don't mix streptomycin in same solution or administer through same I.V. line as other antibiotics.

Contraindications

Hypersensitivity to streptomycin or other aminoglycosides

Interactions

DRUGS

antimyasthenics: Possibly decreased effect of antimyasthenics on skeletal muscle

beta-lactam antibiotics: Inactivation of streptomycin
capreomycin, other aminoglycosides: Increased potential for ototoxicity, nephrotoxicity, and neuromuscular blockade
indomethacin (I.V.): Decreased renal clearance of streptomycin when given to premature neonates, possibly leading to aminoglycoside toxicity
methoxyflurane, polymyxins (parenteral): Increased risk of nephrotoxicity and neuromuscular blockade
nephrotoxic and ototoxic drugs: Increased risk of nephrotoxicity and ototoxicity
neuromuscular blockers: Increased neuromuscular blockade

Adverse Reactions

CNS: Clumsiness, dizziness, neurotoxicity, paresthesia, peripheral neuropathy, seizures, unsteadiness, vertigo

EENT: Hearing loss, sensation of fullness in ears, tinnitus, vision loss

GI: Anorexia, nausea, thirst, vomiting

GU: Decreased or increased urine output, nephrotoxicity

MS: Muscle twitching

SKIN: Erythema, pruritus, rash, urticaria

Nursing Considerations

- Use streptomycin cautiously in patients with renal impairment. In severely uremic patients, single dose can produce high blood level of drug for several days; cumulative effects may produce ototoxicity.
- Expect prescriber to order baseline renal function studies and to assess cranial nerve VIII function (responsible for hearing) at start of streptomycin therapy to allow for later comparisons.
- Monitor serum peak and trough levels, as ordered, to ensure adequate but not toxic drug level.
- Be aware that streptomycin should be given only by I.M. injection.
- To reconstitute streptomycin, add between 4.2 and 4.5 ml of sodium chloride for injection or sterile water for injection to each 1-g vial to provide a concentration of 200 mg/ml, or add between 3.2 and 3.5 ml of diluent to each 5-g vial to provide a concentration of 250 mg/ml. Alternatively, add 6.5 ml of diluent to each 5-g vial to provide a concentration of 500 mg/ml.
- Don't give more than 500 mg/ml.

- Rotate injection sites to prevent sterile abscess formation.

PATIENT TEACHING

- Advise patient to refrigerate streptomycin solution at 36° to 46° F (2° to 8° C).
- Inform patient that treatment for tuberculosis lasts at least 1 year.
- Urge patient to notify prescriber if he has fullness or ringing in ears, hearing loss, or vertigo.

sucralfate

Apo-sucralfate (CAN), Carafate, Sulcrate (CAN), Sulcrate Suspension Plus (CAN)

Class and Category

Chemical class: Disulfated disaccharide, aluminum salt

Therapeutic class: Antilucer

Pregnancy category: B

Indications and Dosages

↗ *To prevent duodenal ulcer*

TABLETS

Adults and adolescents. 1 g b.i.d.

↗ *To treat active duodenal ulcer*

ORAL SUSPENSION

Adults and adolescents. 1 g q.i.d. 1 hr before meals and at bedtime for 4 to 8 wk, possibly less. Or, 2 g b.i.d. on empty stomach on waking and at bedtime for 4 to 8 wk, possibly less.

TABLETS

Adults and adolescents. 1 g q.i.d. 1 hr before meals and at bedtime for 4 to 8 wk, possibly less.

Mechanism of Action

May react with hydrochloric acid in the stomach to form a complex that buffers acid. The complex adheres electrostatically to proteins on the ulcer's surface and creates a protective barrier at the ulcer site. Sucralfate also inhibits back-diffusion of hydrogen ions and adsorbs pepsin and bile acids, actions that promote healing of an existing duodenal ulcer and prevent ulcer formation.

Interactions

DRUGS

aluminum-containing drugs (such as ant-

acids, antidiarrheals, buffered aspirin with aluminum, and vaginal douches): Possibly aluminum toxicity in patients with renal failure

antacids: Possibly interference with binding of sucralfate to GI mucosa

cimetidine, ciprofloxacin, digoxin, norfloxacin, ofloxacin, phenytoin, ranitidine, tetracycline, theophylline: Decreased bioavailability of these drugs

Adverse Reactions

CNS: Dizziness, drowsiness, light-headedness

EENT: Dry mouth

GI: Constipation, diarrhea, indigestion, nausea, vomiting

MS: Back pain

SKIN: Pruritus, rash, urticaria

Nursing Considerations

- Use sucralfate cautiously in patients with chronic renal failure because of increased risk of aluminum toxicity.
- Administer drug to patient when he has an empty stomach.

PATIENT TEACHING

- Instruct patient to take sucralfate on an empty stomach at least 1 hour before meals and at bedtime.
- Advise patient not to take antacids within 30 minutes of sucralfate.
- Caution patient to check with prescriber before taking another drug within 2 hours of sucralfate.

sulfadiazine

Class and Category

Chemical class: Sulfonamide

Therapeutic class: Antibiotic, antiprotozoal

Pregnancy category: C

Indications and Dosages

↗ *To treat asymptomatic carriers of meningitis*

TABLETS

Adults and adolescents. 1 g every 12 hr for 2 days.

Children ages 1 to 12. 500 mg every 12 hr for 2 days.

Children ages 2 to 12 months. 500 mg daily for 2 days.

↗ *To prevent recurrent rheumatic fever*

TABLETS

Adults and adolescents. 500 mg daily (for patients weighing less than 30 kg [66 lb]) to 1 g daily (for patients weighing 30 kg or more).

↗ *To treat inclusive nocardiosis*

TABLETS

Adults and adolescents. 4 to 8 g daily for at least 6 wk.

↗ *As adjunct to treat toxoplasmosis in patients with AIDS*

TABLETS

Adults and adolescents. 1 to 2 g every 6 hr, with 50 to 100 mg daily of pyrimethamine and 10 to 25 mg daily of leucovorin.

Children age 2 months and over. 50 mg/kg b.i.d. for 12 mo, together with 2 mg/kg daily of pyrimethamine for 2 days, then 1 mg/kg/day of pyrimethamine for 2 to 6 mo, then 1 mg/kg daily of pyrimethamine 3 times/wk for remainder of 12 mo; in addition, 5 mg of leucovorin given 3 times/wk for 12 mo. *Maximum:* 6 g daily.

↗ *To treat toxoplasmosis in pregnant women after week 16 of gestation*

TABLETS

Adults. 1 g every 6 hr, together with 25 mg daily of pyrimethamine and 5 to 15 mg daily of leucovorin.

Mechanism of Action

Inhibits para-aminobenzoic acid, a bacterial enzyme responsible for synthesizing folic acid, which susceptible bacteria require for growth. By inactivating bacteria, sulfadiazine prevents or alleviates infection.

Contraindications

Breastfeeding; hypersensitivity to sulfadiazine, its components, or other chemically related drugs, such as sulfonamides; pregnancy at term

Interactions

DRUGS

bone marrow depressants: Increased risk of leukopenic or thrombocytopenic effects

cyclosporine: Decreased blood cyclosporine level, increased risk of nephrotoxicity

estrogen-containing oral contraceptives: Increased risk of breakthrough bleeding and pregnancy

hemolytics: Increased risk of adverse effects

hepatotoxic drugs: Increased risk of hepatotoxicity

*hydantoin*s, oral anticoagulants, oral antidiabetic drugs: Increased or prolonged effects of these drugs, possibly toxicity

indomethacin, probenecid, salicylates: Increased blood level of free sulfadiazine caused by displacement from plasma protein-binding sites

methotrexate: Increased risk of leukopenic or thrombocytopenic effects of methotrexate

phenylbutazone, sulfipyrazone: Increased blood sulfadiazine level

uricosuric drugs: Potentiated uricosuric action

Adverse Reactions

CNS: Dizziness, fatigue, fever, headache, lethargy, weakness

EENT: Pharyngitis

GI: Anorexia, diarrhea, dysphagia, nausea, vomiting

GU: Crystalluria

HEME: Agranulocytosis, aplastic anemia, hemolytic anemia, leukopenia, thrombocytopenia, unusual bleeding or bruising

MS: Arthralgia, myalgia

SKIN: Blisters, erythema, jaundice, pallor, photosensitivity, pruritus, rash

Other: Drug-induced fever

Nursing Considerations

- Use sulfadiazine cautiously in patients with blood dyscrasias or megaloblastic anemia from folate deficiency because drug may cause blood dyscrasias; in those with G6PD deficiency because hemolysis may occur; in those with hepatic or renal impairment because of increased risk of toxicity; and in those with porphyria because drug may precipitate an acute attack.
- Obtain blood sample for CBC and body tissue or fluid specimen for culture and sensitivity tests, as ordered, before giving drug. Expect first dose to be given before results are available.

WARNING Monitor patient for drug-induced fever, which may develop 7 to 10 days after starting sulfadiazine therapy. Signs and symptoms may include abdominal pain, anorexia, ataxia, depression, diarrhea, headache, insomnia, nausea, peripheral neuropathy, tinnitus, and vomiting.

- Monitor fluid intake and output during therapy. Altered fluid balance may increase

risk of crystalluria.

- Frequently monitor blood glucose level, and assess for signs and symptoms of hypoglycemia in patients who take an oral antidiabetic drug. Be prepared to respond if hypoglycemia develops.

PATIENT TEACHING

- Instruct patient to take sulfadiazine exactly as prescribed and to complete the full course even if he feels better.
- Advise patient to take drug with a full glass of water and to drink plenty of fluids during therapy.
- Urge patient to notify prescriber if urine turns reddish brown; this may indicate crystalluria.
- Inform patient about possible dizziness, and urge him to avoid potentially hazardous activities until drug's CNS effects are known.
- Advise patient to avoid prolonged exposure to sunlight and to wear sunscreen and protective clothing when outdoors.
- Urge patient who takes oral contraceptives to use an additional method of birth control during therapy.
- Advise patient who takes an oral antidiabetic drug to check his blood glucose level frequently because of the increased risk of hypoglycemia during therapy.

sulfamethizole

Thiosulfil Forte

Class and Category

Chemical class: Sulfonamide

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

↗ *To treat cystitis and other UTIs caused by Enterobacter species, Escherichia coli, Klebsiella species, Proteus mirabilis, P. vulgaris, or Staphylococcus aureus*

TABLETS

Adults. 0.5 to 1 g every 6 to 8 hr.

Children age 2 months and over. 7.5 to 11.25 mg/kg every 6 hr.

DOSAGE ADJUSTMENT Dosage usually reduced for patients with impaired renal function.

Mechanism of Action

Inhibits para-aminobenzoic acid, a bacterial enzyme responsible for synthesizing folic acid, which susceptible bacteria require for growth. By inactivating bacteria, sulfamethizole prevents or alleviates infection.

Contraindications

Breastfeeding; hypersensitivity to sulfamethizole, its components, or other chemically related drugs, such as sulfonamides; pregnancy at term

Interactions

DRUGS

bone marrow depressants: Increased risk of leukopenic or thrombocytopenic effects

cyclosporine: Decreased blood cyclosporine level, increased risk of nephrotoxicity

estrogen-containing oral contraceptives: Increased risk of breakthrough bleeding and pregnancy

hemolytics: Increased risk of adverse effects

hepatotoxic drugs: Increased risk of hepatotoxicity

hydantoin, oral anticoagulants, oral antidiabetic drugs: Increased or prolonged effects of these drugs, possibly toxicity

indomethacin, probenecid, salicylates:

Increased blood level of free sulfamethizole caused by displacement from plasma protein-binding sites

methotrexate: Increased risk of leukopenic or thrombocytopenic effects of methotrexate

phenylbutazone, sulfapyrazone: Increased blood sulfamethizole level

uricosuric drugs: Potentiated uricosuric action

Adverse Reactions

CNS: Dizziness, fatigue, fever, headache, lethargy, weakness

EENT: Pharyngitis

GI: Anorexia, diarrhea, dysphagia, nausea, vomiting

GU: Crystalluria

HEME: Agranulocytosis, aplastic anemia, hemolytic anemia, leukopenia, thrombocytopenia, unusual bleeding or bruising

MS: Arthralgia, myalgia

SKIN: Blisters, erythema, jaundice, pallor, photosensitivity, pruritus, rash

Other: Drug-induced fever

Nursing Considerations

- Use sulfamethizole cautiously in patients with blood dyscrasias or megaloblastic anemia from folate deficiency because drug may cause blood dyscrasias; in those with G6PD deficiency because hemolysis may occur; in those with hepatic or renal impairment because of increased risk of toxicity; and in those with porphyria because drug may precipitate an acute attack.
- Obtain blood sample for CBC and body tissue or fluid specimen for culture and sensitivity tests, as ordered, before giving drug. Expect first dose to be given before results are available.

WARNING Monitor patient for drug-induced fever, which may develop 7 to 10 days after sulfamethizole starts. Signs and symptoms include abdominal pain, anorexia, ataxia, depression, diarrhea, headache, insomnia, nausea, peripheral neuropathy, tinnitus, and vomiting.

- Monitor fluid intake and output during therapy. Altered fluid balance may increase risk of crystalluria.
- Frequently monitor blood glucose level and assess for signs and symptoms of hypoglycemia in patients who take an oral antidiabetic drug. Be prepared to respond if hypoglycemia develops.

PATIENT TEACHING

- Instruct patient to take sulfamethizole exactly as prescribed and to complete the full course even if he feels better.
- Advise patient to take drug with a full glass of water and to drink plenty of fluids during therapy.
- Urge patient to notify prescriber if urine turns reddish brown; this may indicate crystalluria.
- Inform patient about possible dizziness, and urge him to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to avoid prolonged exposure to sunlight and to wear sunscreen and protective clothing when outdoors.
- Urge patient who takes oral contraceptives to use an additional method of birth control during therapy.
- Advise patient who takes an oral antidiabetic drug to check his blood glucose level frequently because of the increased risk of hypoglycemia during therapy.

sulfamethoxazole

Apo-Sulfamethoxazole (CAN),
Gantanol, Urobak

Class and Category

Chemical class: Sulfonamide

Therapeutic class: Antibiotic, antiprotozoal

Pregnancy category: C

Indications and Dosages

➤ *To treat chlamydial conjunctivitis; malaria (as adjunct to quinine sulfate and pyrimethamine); toxoplasmosis (as adjunct to pyrimethamine); and UTI, including pyelonephritis and cystitis, caused by susceptible organisms*

TABLETS

Adults. *Initial:* 2 g, followed by 1 g every 8 to 12 hr.

Children age 2 months and over. *Initial:* 50 to 60 mg/kg, then 25 to 30 mg/kg every 12 hr. *Maximum:* 2 g for initial dose, 75 mg/kg daily for subsequent doses.

DOSE ADJUSTMENT Dosage reduction usually needed for patients with impaired renal function.

➤ *To treat uncomplicated urethritis, cervicitis, and proctitis caused by Chlamydia trachomatis*

TABLETS

Adults. 1 g every 12 hr for 10 days.

DOSE ADJUSTMENT For patients with creatinine clearance of 10 to 30 ml/min/1.73 m², recommended dose reduced by 50% or dosing interval extended; for creatinine clearance of less than 10 ml/min/1.73 m², recommended dose reduced by 75% or dosing interval extended, as prescribed.

Mechanism of Action

Inhibits para-aminobenzoic acid, a bacterial enzyme responsible for synthesizing folic acid, which susceptible bacteria require for growth. By inactivating bacteria, sulfamethoxazole prevents or alleviates infection.

Contraindications

Breastfeeding; hypersensitivity to sulfamethoxazole, its components, or other chemically related drugs, such as sulfonamides; pregnancy at term

Interactions

DRUGS

bone marrow depressants: Increased risk of leukopenic or thrombocytopenic effects
cyclosporine: Decreased blood cyclosporine level, increased risk of nephrotoxicity
estrogen-containing oral contraceptives: Increased risk of breakthrough bleeding and pregnancy
hemolytics: Increased risk of adverse effects
hepatotoxic drugs: Increased risk of hepatotoxicity
hydantoin, oral anticoagulants, oral antidiabetic drugs: Increased or prolonged effects of these drugs, possibly toxicity
indomethacin, probenecid, salicylates: Increased blood level of free sulfamethoxazole caused by displacement from plasma protein-binding sites
methotrexate: Increased risk of leukopenic or thrombocytopenic effects of methotrexate
phenylbutazone, sulfapyrazone: Increased blood sulfamethoxazole level
uricosuric drugs: Potentiated uricosuric action

Adverse Reactions

CNS: Dizziness, fatigue, fever, headache, lethargy, weakness
EENT: Pharyngitis
GI: Anorexia, diarrhea, dysphagia, nausea, vomiting
GU: Crystalluria
HEME: Agranulocytosis, aplastic anemia, hemolytic anemia, leukopenia, thrombocytopenia, unusual bleeding or bruising
MS: Arthralgia, myalgia
SKIN: Blisters, erythema, jaundice, pallor, photosensitivity, pruritus, rash
Other: Drug-induced fever

Nursing Considerations

- Use sulfamethoxazole cautiously in patients with blood dyscrasias or megaloblastic anemia from folate deficiency because drug may cause blood dyscrasias; in those with G6PD deficiency because hemolysis may occur; in those with hepatic or renal impairment because of increased risk of toxicity; and in those with porphyria because drug may precipitate an acute attack.
- Obtain blood sample for CBC and body tissue or fluid specimen for culture and

sensitivity tests, as ordered, before giving drug. Expect first dose to be given before results are available.

WARNING Monitor patient for drug-induced fever, which may develop 7 to 10 days after sulfamethoxazole starts. Signs and symptoms include abdominal pain, anorexia, ataxia, depression, diarrhea, headache, insomnia, nausea, peripheral neuropathy, tinnitus, and vomiting.

- Monitor fluid intake and output during therapy. Altered fluid balance may increase risk of crystalluria.
- Frequently monitor blood glucose level and assess for signs and symptoms of hypoglycemia in patients who take an oral antidiabetic drug. Be prepared to respond if hypoglycemia develops.

PATIENT TEACHING

- Instruct patient to take sulfamethoxazole exactly as prescribed and to complete the full course even if he feels better.
- Advise patient to take drug with a full glass of water and to drink plenty of fluids during therapy.
- Urge patient to notify prescriber if urine turns reddish brown; this may indicate crystalluria.
- Inform patient about possible dizziness, and urge him to avoid potentially hazardous activities until drug's CNS effects are known.
- Advise patient to avoid prolonged exposure to sunlight and to wear sunscreen and protective clothing when outdoors.
- Urge patient who takes oral contraceptives to use an additional method of birth control during therapy.
- Advise patient who takes an oral antidiabetic drug to check his blood glucose level frequently because of increased risk of hypoglycemia during therapy.

sulfasalazine

Alti-Sulfasalazine (CAN), Azulfidine, Azulfidine EN-Tabs, PMS-Sulfasalazine (CAN), PMS-Sulfasalazine E.C. (CAN), Salazopyrin EN-Tabs (CAN), S.A.S.-500 (CAN), S.A.S. Enteric-500 (CAN)

Class and Category

Chemical class: Salicylate, sulfonamide

Therapeutic class: Anti-inflammatory, anti-rheumatic, immunomodulator
Pregnancy category: B

Indications and Dosages

➤ *To treat inflammatory bowel diseases, such as ulcerative colitis, and to maintain or prolong remission*

DELAYED-RELEASE TABLETS, TABLETS

Adults and adolescents. *Initial:* 500 to 1,000 mg every 6 to 8 hr. Or 500 mg every 6 to 12 hr to decrease adverse GI reactions. *Maintenance:* 500 mg every 6 hr.

Children over age 6. *Initial:* 6.7 to 10 mg/kg every 4 hr, 10 to 15 mg/kg every 6 hr, or 13.3 to 20 mg/kg every 8 hr. *Maintenance:* 7.5 mg/kg every 6 hr.

➤ *To treat rheumatoid arthritis*

DELAYED-RELEASE TABLETS, TABLETS

Adults. *Initial:* 500 to 1,000 mg daily during wk 1, increased by 500 mg daily every wk, as needed, up to 2,000 mg daily in divided doses. If no response after 12 wk, increased to 3,000 mg daily. *Maintenance:* 1,000 mg every 12 hr. *Maximum:* 3,000 mg daily.

➤ *To treat juvenile rheumatoid arthritis in patients who have not responded to salicylates or other NSAIDs*

DELAYED-RELEASE TABLETS

Children ages 6 to 16. 30 to 50 mg/kg daily in divided doses b.i.d. *Maximum:* 2 g daily.

Mechanism of Action

As a prodrug of sulfapyridine and 5-aminosalicylic acid (mesalamine), delivers more sulfapyridine and mesalamine to the colon than either metabolite could provide alone. Sulfapyridine provides antibacterial action along the intestinal wall; mesalamine inhibits cyclooxygenase, thereby decreasing the production of arachidonic acid metabolites and reducing colonic inflammation.

Contraindications

Hypersensitivity to salicylates, sulfasalazine, sulfonamides, chemically related drugs, or their components; intestinal or urinary obstruction; porphyria

Interactions

DRUGS

bone marrow depressants: Increased leukopenic and thrombocytopenic effects of both drugs

digoxin: Possibly inhibited absorption and

decreased blood level of digoxin
folic acid (vitamin B₉): Decreased folic acid absorption

hepatotoxic drugs: Increased risk of hepatotoxicity

*hydantoin*s, *oral anticoagulants*, *oral antidiabetic drugs*: Increased, prolonged, or toxic effects of these drugs

methotrexate, *phenylbutazone*, *sulfipyrazone*: Possibly potentiated effects of these drugs

Adverse Reactions

CNS: Ataxia, chills, depression, fatigue, fever, Guillain-Barré syndrome, headache, insomnia, meningitis, peripheral neuropathy, seizures, vertigo, weakness

CV: Pericarditis, vasculitis

EENT: Hearing loss, orange-yellow tears, pharyngitis, tinnitus

GI: Abdominal pain, anorexia, cirrhosis, diarrhea, elevated liver enzymes, hepatitis, hepatotoxicity, indigestion, jaundice, nausea, pancreatitis, ulcerative colitis exacerbation, vomiting

GU: Crystalluria, decreased ejaculatory volume, male infertility, nephritis, nephrotic syndrome, orange-yellow urine, toxic nephrosis

HEME: Agranulocytosis, aplastic anemia, Heinz body or hemolytic anemia, leukopenia, neutropenia, thrombocytopenia, unusual bleeding or bruising

MS: Arthralgia, rhabdomyolysis

RESP: Cyanosis, idiopathic pulmonary fibrosis, lymphocytic interstitial pneumonitis, pleuritis

SKIN: Alopecia, drug rash with eosinophilia and systemic symptoms (DRESS), erythema multiforme, exfoliative dermatitis, epidermal necrolysis, photosensitivity, pruritus, purpura, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

OTHER: Anaphylaxis, lupus erythematosus-like syndrome, serum sickness syndrome

Nursing Considerations

- Monitor CBC, liver function test results, and BUN and serum creatinine levels before and periodically during prolonged sulfasalazine therapy.
- Be aware that sulfasalazine doses over 4 g or a blood level over 50 mcg/ml increases the risk of adverse and toxic reactions.
- Monitor fluid intake and output and urine

color, pH, and consistency. Acidic urine may require alkalization to prevent crystalluria.

PATIENT TEACHING

- Instruct patient to take sulfasalazine with meals, milk, or an antacid to decrease GI distress, and to swallow tablets whole.
- Advise patient to prevent crystalluria by taking drug with a full glass of water and drinking at least 64 oz of fluid per day.
- Instruct patient and family to administer drug around the clock.
- Inform patient that symptom relief may take 2 to 5 days for ulcerative colitis and 4 to 12 weeks for rheumatoid arthritis.
- Alert patient that drug may turn urine and skin orange-yellow.
- Advise contact lens wearer to consider wearing glasses during therapy because drug can permanently stain contact lenses yellow.
- Instruct patient to avoid prolonged sun exposure and to wear protective clothing and sunscreen when outdoors.
- Advise patient to brush with a soft-bristled toothbrush and to use dental floss and toothpicks gently because leukopenic and thrombocytopenic drug effects increase risk of infection and gingival bleeding.
- Urge patient to return for laboratory tests and follow-up visits to monitor drug's effect.
- Instruct patient to report sore throat, fever, paleness, skin discoloration, or jaundice. These may be signs of serious adverse effects. Explain that prescriber may order tests to determine their cause and that drug may be discontinued until test results are known.

sulfipyrazone

Anturane, Apo-Sulfipyrazone (CAN), Novopyrazone (CAN)

Class and Category

Chemical class: Pyrazalone derivative

Therapeutic class: Antigout, uricosuric

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat chronic or intermittent gouty arthritis*

CAPSULES , TABLETS

Adults. *Initial:* 100 to 200 mg b.i.d., increased by 200 mg daily every 2 to 4 days, if needed. *Maintenance:* 100 to 200 mg b.i.d. *Maximum:* 400 mg b.i.d. during wk 1; then 200 to 400 mg b.i.d. until serum urate level is controlled.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	4–10 hr

Mechanism of Action

Inhibits renal tubular reabsorption of uric acid, thereby increasing uric acid excretion and decreasing serum urate level. Decreased serum urate level prevents urate deposition, tophus formation, and chronic joint changes. It also helps resolve existing urate deposits and eventually reduces the number of gouty arthritis attacks.

Contraindications

Active peptic ulcer disease, blood dyscrasias, hypersensitivity to sulfipyrazone or its components, symptoms of GI inflammation or ulceration

Interactions**DRUGS**

acetaminophen: Increased risk of hepatotoxicity, decreased acetaminophen effects

aminosalicylate sodium: Increased blood level and prolonged duration of this drug, possibly leading to toxicity

antineoplastics: Increased risk of uric acid nephropathy

bismuth subsalicylate and other salicylates: Decreased sulfipyrazone effects

cefamandole, cefoperazone, cefotetan, moxalactam, plicamycin, valproic acid: Possibly hypoprothrombinemia, increased risk of severe hemorrhage

diazoxide, mecamlamine, pyrazinamide: Possibly increased serum uric acid level

hydantoin: Increased blood hydantoin level, possibly leading to hydantoin toxicity

niacin: Possibly decreased uricosuric effect of sulfipyrazone

nitrofurantoin: Decreased nitrofurantoin effectiveness, possibly nitrofurantoin toxicity

NSAIDs, oral anticoagulants, platelet aggregation inhibitors, thrombolytics: Increased risk of bleeding

oral antidiabetic drugs: Increased risk of hypoglycemia

probenecid: Increased sulfipyrazone effects

theophylline: Possibly decreased blood theophylline level

verapamil: Increased clearance and decreased bioavailability of verapamil

ACTIVITIES

alcohol use: Possibly increased serum uric acid level

Adverse Reactions

CNS: Dizziness

EENT: Tinnitus

GI: Abdominal pain, epigastric discomfort, GI bleeding, indigestion, nausea, vomiting

GU: Dysuria, flank pain, hematuria, renal calculi, renal colic, renal failure

HEME: Agranulocytosis, anemia, aplastic anemia, leukopenia, thrombocytopenia

MS: Arthralgia, gouty arthritis (acute attack)

RESP: Bronchospasm, dyspnea, wheezing

SKIN: Erythema, rash

Nursing Considerations

- Expect to start with full maintenance dose, as ordered, for patient being switched to sulfipyrazone from another uricosuric.
- Monitor serum uric acid level periodically, as ordered, to evaluate drug effectiveness.
- Assess for signs of acute gouty arthritis, especially during first few months of sulfipyrazone therapy.

PATIENT TEACHING

- Instruct patient to take sulfipyrazone with food, milk, or an antacid to prevent GI distress.
- Stress the importance of taking drug every day, even when feeling better, to prevent acute gouty arthritis attacks.
- Inform patient that acute gouty arthritis may worsen during initial therapy but should improve as treatment continues. Explain that he may not experience drug's full therapeutic effect for 6 months.
- If an acute gouty arthritis attack occurs, advise patient to seek additional treatment but to continue taking sulfipyrazone, as prescribed, to help prevent exacerbation.
- Advise patient to drink at least 80 oz of fluids per day to decrease the risk of renal calculus formation.
- Instruct patient to consult prescriber before taking OTC products that contain

aspirin or acetaminophen.

- Advise patient to avoid alcohol while taking sulfipyrazone.
- Encourage patient to return for ordered follow-up laboratory tests to check for blood dyscrasias.

sulfisoxazole

Apo-Sulfisoxazole (CAN), Gantrisin, Novo-Soxazole (CAN), Sulfizole (CAN)

sulfisoxazole acetyl

Gantrisin

Class and Category

Chemical class: Sulfonamide

Therapeutic class: Antibiotic, antiprotozoal

Pharmacology category: C

Indications and Dosages

↗ *To treat nocardiosis; plague; malaria (as adjunct to quinine sulfate and pyrimethamine); and UTI, including pyelonephritis and cystitis, caused by susceptible organisms*

ORAL SUSPENSION, ORAL SYRUP, TABLETS

Adults and adolescents. *Initial:* 2 to 4 g daily in divided doses. *Maintenance:* 4 to 8 g daily in divided doses every 4 to 6 hr.

Maximum: 8 g daily.

Children over age 2 months. *Initial:* 75 mg/kg, followed by 120 to 150 mg/kg daily in divided doses every 4 to 6 hr. *Maximum:* 6 g daily.

↗ *To treat uncomplicated cystitis in women*

ORAL SUSPENSION, ORAL SYRUP, TABLETS

Adults. 2 g as a single dose.

↗ *To treat acute or recurrent otitis media in combination with erythromycin in penicillin-allergic patients*

ORAL SUSPENSION, ORAL SYRUP, TABLETS

Children. 150 mg of sulfisoxazole/kg daily and 50 mg of erythromycin/kg daily in divided doses q.i.d.

↗ *To treat lymphogranuloma venereum*

ORAL SUSPENSION, ORAL SYRUP, TABLETS

Adults. 500 mg every 6 hr for 21 days.

↗ *To treat uncomplicated urethritis, cervicitis, or proctitis caused by Chlamydia trachomatis*

ORAL SUSPENSION, ORAL SYRUP, TABLETS

Adults. 500 mg every 6 hr.

DOSAGE ADJUSTMENT For patients with renal impairment, dosing interval changed to every 8 to 24 hr, as prescribed.

Mechanism of Action

Inhibits para-aminobenzoic acid, a bacterial enzyme responsible for synthesizing folic acid, which susceptible bacteria require for growth. By inactivating bacteria, sulfisoxazole prevents or alleviates infection.

Contraindications

Breast-feeding; hypersensitivity to sulfisoxazole, other chemically related drugs, such as sulfonamides, or their components; pregnancy at term

Interactions

DRUGS

bone marrow depressants, methotrexate:

Increased risk of leukopenia or thrombocytopenia

cyclosporine: Increased risk of nephrotoxicity
diuretics: Increased incidence of thrombocytopenic purpura

hemolytics (such as doxapram and methyl-dopa): Increased risk of toxic reaction

hepatotoxic drugs (such as amiodarone):

Increased risk of hepatotoxicity

hydantoin, oral anticoagulants, oral antidiabetic drugs: Increased or prolonged effects of these drugs, possibly toxicity

indomethacin, probenecid, salicylates:

Increased blood sulfisoxazole level

oral contraceptives: Increased risk of breakthrough bleeding with long-term sulfisoxazole use

phenylbutazone, sulfipyrazone: Risk of increased blood sulfisoxazole level

thiopental: Increased anesthetic effect of thiopental

tolbutamide: Prolonged half-life of tolbutamide

uricosurics: Potentiated uricosuric action

Adverse Reactions

CNS: Dizziness, fatigue, fever, headache, lethargy, weakness

EENT: Pharyngitis

GI: Anorexia, diarrhea, dysphagia, nausea, vomiting

GU: Crystalluria

HEME: Agranulocytosis, aplastic anemia, hemolytic anemia, leukopenia, thrombocytopenia, unusual bleeding or bruising

MS: Arthralgia, myalgia

SKIN: Blisters, erythema, jaundice, pallor, photosensitivity, pruritus, rash

Other: Drug-induced fever

Nursing Considerations

- Use sulfisoxazole cautiously in patients with blood dyscrasias or megaloblastic anemia from folate deficiency because drug may cause blood dyscrasias; in those with G6PD deficiency because hemolysis may occur; in those with hepatic or renal impairment because of increased risk of toxicity; and in those with porphyria because drug may precipitate acute attack.
- Obtain blood sample for CBC and tissue or fluid specimen for culture and sensitivity testing, as ordered, before beginning sulfisoxazole therapy. Expect to give first dose before results are available.

WARNING Expect prescriber to discontinue sulfisoxazole if patient exhibits signs of blood dyscrasias, including fever, jaundice, maculopapular or other rash, pallor, pharyngitis, or purpura.

- Monitor CBC often, as appropriate, during treatment for signs of adverse reactions.
- Closely monitor patients with AIDS, who are at increased risk for adverse reactions.

WARNING Monitor patient for drug-induced fever, which may develop 7 to 10 days after sulfisoxazole starts. Signs and symptoms include abdominal pain, anorexia, ataxia, depression, diarrhea, headache, insomnia, nausea, peripheral neuropathy, tinnitus, and vomiting.

- Monitor fluid intake and output. Unless contraindicated, provide sufficient fluids to maintain a daily urine output of at least 1,200 mL.
- For otitis media caused by *Haemophilus influenzae*, expect to give drug with erythromycin, as prescribed.
- Frequently monitor blood glucose level and assess for signs of hypoglycemia in patients who take oral antidiabetic drugs.

PATIENT TEACHING

- Instruct patient to take sulfisoxazole exactly as prescribed and to complete the full course of therapy even if he feels better.
- Advise patient to take drug with a full glass of water.
- Inform patient that tablet may be chewed or crushed and mixed with liquid to ease swallowing.

- Advise patient to shake oral suspension well before use and to measure oral suspension or syrup dose with calibrated device to ensure accuracy.
- Inform patient that oral suspension or syrup form of drug may be stored at room temperature.
- Advise patient to drink 2 to 3 L of fluid daily to maintain hydration, unless contraindicated.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient who takes an oral antidiabetic to check her blood glucose level often because of the risk of hypoglycemia.
- Advise patient to avoid prolonged exposure to sunlight and to use sunscreen and wear protective clothing when outdoors.

sulindac

Apo-Sulin (CAN), Clinoril, Novo-Sundac (CAN)

Class and Category

Chemical class: Pyrroleacetic acid derivative

Therapeutic class: Antigout, anti-inflammatory, antirheumatic

Pregnancy category: Not rated

Indications and Dosages

↗ *To decrease pain and inflammation in ankylosing spondylitis, acute attacks of gout or pseudogout, bursitis, moderately painful arthralgia, osteoarthritis, rheumatoid arthritis, and tendinitis*

TABLETS

Adults and adolescents over age 14. *Initial:* 150 to 200 mg b.i.d., adjusted based on patient's response. *Maximum:* 200 mg b.i.d.

↗ *To relieve symptoms of acute gouty arthritis, acute subacromial bursitis, and supraspinatus tendinitis*

TABLETS

Adults and adolescents over age 14. 200 mg b.i.d. for 7 to 14 days; decreased to lowest effective dosage after satisfactory response occurs.

DOSAGE ADJUSTMENT For elderly patients, dosage reduced to 50% of usual adult dosage, if needed.

Mechanism of Action

May block the activity of cyclooxygenase,

an enzyme needed to synthesize prostaglandins, which mediate the inflammatory response and cause local vasodilation, swelling, and pain. By blocking cyclooxygenase and inhibiting prostaglandins, this NSAID reduces inflammatory symptoms and pain.

Route	Onset	Peak	Duration
P.O.	In 1 wk*	2–3 wk*	Unknown

Contraindications

Angioedema, asthma, bronchospasm, nasal polyps, rhinitis, or urticaria induced by aspirin, iodides, or other NSAIDs

Interactions

DRUGS

acetaminophen, cyclosporine, gold compounds, nephrotoxic drugs: Increased risk of adverse renal effects

antacids: Decreased blood level and effects of sulindac

antihypertensives: Risk of decreased antihypertensive effect

aspirin, salicylates: Decreased sulindac effects, increased risk of GI hemorrhage

bone marrow depressants: Increased risk of leukopenia and thrombocytopenia

cefamandole, cefoperazone, cefotetan, colchicine, oral anticoagulants, plicamycin, thrombolytics, valproic acid: Increased risk of bleeding

cimetidine, ranitidine: Increased bioavailability of both drugs

digoxin: Increased blood digoxin level and risk of digitalis toxicity

dimethyl sulfoxide (DMSO): Decreased sulindac effectiveness, possibly peripheral neuropathy with topical application of DMSO

diuretics: Possibly decreased loop diuretic effects and increased thiazide diuretic effects

glucocorticoids, other NSAIDs, potassium supplements: Increased risk of adverse GI effects

*hydantoin*s: Increased blood hydantoin level and risk of phenytoin toxicity

insulin, oral antidiabetic drugs: Increased risk of hypoglycemia

lithium: Possibly increased blood level and toxic effects of lithium

methotrexate: Decreased methotrexate excretion, possibly leading to toxicity

platelet aggregation inhibitors: Increased risk of bleeding, additive effects of these drugs

probenecid: Increased blood level and adverse and toxic effects of sulindac

ACTIVITIES

alcohol use: Increased risk of adverse GI effects, including GI bleeding

Adverse Reactions

CNS: Aseptic meningitis, cerebral hemorrhage, chills, drowsiness, fever, headache, ischemic stroke, malaise, nervousness, transient ischemic attack

CV: Deep vein thrombosis, edema, heart failure, hypertension, MI, palpitations, peripheral edema, vasculitis

ENT: Tinnitus

ENDO: Hypoglycemia

GI: Abdominal cramps or pain, anorexia, constipation, diarrhea, esophageal irritation, flatulence, gastritis, gastrointestinal bleeding or ulceration, hepatic failure, hepatitis, hepatotoxicity, indigestion, jaundice, liver failure, nausea, perforation of stomach or intestines, vomiting

GU: Acute renal failure, decreased urine output, interstitial nephritis, nephrotic syndrome, polyuria, proteinuria

HEME: Agranulocytosis, aplastic anemia, leukopenia, pancytopenia

RESP: Bronchial spasm, dyspnea, pulmonary edema, wheezing

SKIN: Diaphoresis, erythema multiforme, exfoliative dermatitis, maculopapular rash, pruritus, purpura, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, facial edema, hypersensitivity syndrome

Nursing Considerations

- Use sulindac with extreme caution in patients with a history of ulcer disease or GI bleeding because NSAIDs such as sulindac increase risk of GI bleeding and ulceration. Expect to use sulindac for the shortest time possible in these patients.
- Be aware that serious GI tract ulceration, bleeding, and perforation may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, with-

* For antirheumatic effects; unknown for anti-gout or anti-inflammatory effects.

hold drug and notify prescriber at once.

- Use sulindac cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

WARNING Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

- If patient has systemic lupus erythematosus and mixed connective tissue disease, monitor him closely because sulindac increases the risk of aseptic meningitis.

WARNING If patient has bone marrow suppression or is receiving antineoplastic drug therapy, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of sulindac may mask signs and symptoms, such as fever and pain.

- Especially if patient is elderly or taking sulindac long-term, watch for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver function test results because, in rare cases, elevated levels may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure.
- Watch BUN and serum creatinine levels in elderly patients; those with heart failure, impaired renal function, or hepatic dysfunction; and those taking diuretics or ACE inhibitors; because drug may cause renal failure.
- Monitor CBC for decreased hemoglobin and hematocrit because drug may worsen anemia.
- Assess patient's skin routinely for rash or other signs of hypersensitivity reaction because sulindac and other NSAIDs may cause serious skin reactions without warning, even in patients with no history of NSAID hypersensitivity. Stop drug at first sign of reaction, and notify prescriber.

WARNING Monitor patient for adventitious breath sounds and dyspnea; sulindac may cause fluid retention, which may precipitate heart failure in susceptible patients.

- Expect patient to undergo audiometric

examinations before and periodically during prolonged therapy, as ordered.

- Monitor patient for evidence of hypersensitivity syndrome, which could become life-threatening. Report multiple occurring and multi-organ adverse reactions to prescriber and expect drug to be discontinued. Be prepared to provide emergency supportive care, as ordered.

PATIENT TEACHING

- Instruct patient to take sulindac exactly as prescribed. Explain that higher doses don't increase effectiveness and may increase risk of adverse reactions.
- Advise patient to crush tablet and mix with food, if needed, to aid in swallowing.
- Instruct patient to take drug with or immediately after meals to decrease GI distress, to take with a full glass of water, and to remain upright for 20 to 30 minutes after administration to prevent drug from lodging in esophagus and causing esophageal irritation.
- Urge patient to notify prescriber immediately of chills, fever, rash, or sweating, which may indicate hypersensitivity.
- Advise patient to consult prescriber before using acetaminophen, alcohol, aspirin, other NSAIDs, or any OTC drugs during sulindac therapy.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Explain the need for periodic physical examinations and laboratory tests during prolonged therapy to monitor drug effectiveness.
- Inform patient that sulindac may increase the risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, weakness, and slurring of speech.
- Tell patient that sulindac also may increase the risk of serious adverse GI reactions; stress the need to seek immediate medical attention for such signs and symptoms as epigastric or abdominal pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.
- Alert patient to the possibility of rare but serious hypersensitivity reactions. Urge him to seek immediate medical attention for rash, blisters, itching, fever, or other indications of hypersensitivity.

sumatriptan succinate

Imitrex

Class and Category

Chemical class: Serotonin 5-HT₁-receptor agonist

Therapeutic class: Antimigraine

Pregnancy category: C

Indications and Dosages

➤ *To relieve acute migraine attacks, with or without aura, or cluster headaches*

TABLETS

Adults. 25 to 100 mg as a single dose as soon as possible after onset of symptoms, repeated every 2 hr, as needed and prescribed. *Maximum:* 300 mg daily.

DOSE ADJUSTMENT For patients with hepatic dysfunction, 50 mg is maximum single dose.

SUBCUTANEOUS INJECTION

Adults. *Initial:* 6 mg, repeated after 1 or 2 hr, if needed. *Maximum:* 2 (6-mg) injections/24 hr. If migraine symptoms return after initial subcutaneous injection, 50 mg P.O. every 2 hr up to 200 mg daily.

NASAL SPRAY

Adults. 1 or 2 sprays (5 or 10 mg) into one nostril as a single dose or 1 spray (20 mg) into one nostril as a single dose. One additional dose may be taken if another attack occurs after at least 2 hr. *Maximum:* 40 mg daily.

Route	Onset	Peak	Duration
P.O.	In 30 min	2–4 hr	Up to 24 hr
SubQ	In 10 min	1–2 hr	Up to 24 hr
Nasal	In 15 min	Unknown	Up to 24 hr

Mechanism of Action

May stimulate 5-HT₁ receptors, causing selective vasoconstriction of inflamed and dilated cranial blood vessels in carotid circulation, thus decreasing carotid arterial blood flow and relieving acute migraines.

Contraindications

Basilar or hemiplegic migraine, cardiovascular disease, concurrent use of ergotamine-containing drugs, hypersensitivity to

sumatriptan or its components, ischemic heart disease, Prinzmetal's angina, use within 14 days of MAO inhibitor therapy, use within 24 hours of another serotonin 5-HT₁ receptor agonist

Interactions

DRUGS

antidepressants, lithium: Increased risk of serious adverse effects

ergotamine-containing drugs: Possibly additive or prolonged vasoconstrictive effects

fluoxetine, fluvoxamine, paroxetine, sertraline: Possibly incoordination, hyperreflexia, and weakness

MAO inhibitors: Risk of decreased sumatriptan clearance, increased risk of serious adverse effects

Adverse Reactions

CNS: Anxiety, atypical sensations, dizziness, drowsiness, fatigue, fever, headache, malaise, sedation, seizures, vertigo, weakness

CV: Arrhythmias; chest heaviness, pain, pressure, or tightness; coronary artery vasospasm; ECG changes; hypertension; hypotension; palpitations

EENT: Abnormal vision; nasal burning (P.O., subcutaneous); jaw or mouth discomfort; nasal irritation (nasal); nose or throat discomfort; photophobia (P.O., subcutaneous); taste perversion (nasal); tongue numbness or soreness

GI: Abdominal discomfort, dysphagia

MS: Jaw discomfort, muscle cramps, myalgia, neck pain or stiffness

SKIN: Dermatitis, diaphoresis, erythema, flushing, pallor, photosensitivity (P.O., subcutaneous), pruritus, rash, urticaria

Other: Injection site burning, pain, and redness

Nursing Considerations

- Be aware that sumatriptan shouldn't be given to elderly patients because they're more likely to have decreased hepatic function, coronary artery disease (CAD), and more pronounced blood pressure increases.
- Assess patient for chest pain, and monitor blood pressure in patients with CAD before and for at least 1 hour after sumatriptan administration.

- Don't give sumatriptan within 24 hours of another 5-HT₁-receptor agonist, such as naratriptan, rizatriptan, or zolmitriptan.
- After nasal administration, rinse tip of bottle with hot water (don't suction water into bottle) and dry with a clean tissue. Replace cap after cleaning.
- Inspect injection solution for particles and discoloration before administering. Discard solution if you detect these changes.
- Be aware that drug shouldn't be administered I.V. because this may precipitate coronary artery vasospasm.
- Assess patients with risk factors for CAD for arrhythmias, chest pain, and other signs of heart disease.
- For patients with seizure disorder, institute seizure precautions according to facility policy because sumatriptan may lower seizure threshold.

PATIENT TEACHING

- Advise patient to use sumatriptan as soon as possible after the onset of migraine symptoms.
- Urge patient to contact prescriber and avoid taking sumatriptan if headache symptoms aren't typical.
- Remind patient not to exceed prescribed daily dosage.
- Advise patient to swallow tablets whole and drink fluids to disguise unpleasant taste.
- Show patient suitable sites for subcutaneous injection, and teach him how to load, administer, and discard autoinjector. Or, explain how to administer drug using needle-free drug delivery system, Sumavel DosePro. (Snap off plastic tip, flip back lever into active position, and press end of device to the skin of abdomen or thigh.)
- Instruct patient to administer no more than two subcutaneous doses in 24 hours and not to take a second dose if first dose doesn't provide significant relief.
- Inform patient that he may experience burning, pain, and redness for 10 to 30 minutes after subcutaneous injection. Suggest that he apply ice to relieve pain and redness.
- Teach patient how to use nasal form correctly.
- To avoid cross-contamination, advise patient not to use the same nasal container

for more than one person.

- Encourage patient to lie down in a dark, quiet room after taking drug to help relieve migraine.
- Instruct patient to seek emergency care for chest, jaw, or neck tightness after drug use because drug may cause coronary artery vasospasm; subsequent doses may require ECG monitoring.
- Urge patient to report palpitations or rash to prescriber.
- Advise patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Alert patient with seizure disorder that drug may lower seizure threshold.
- Encourage yearly ophthalmologic examinations for patients who require prolonged drug therapy.

T

tacrine hydrochloride (tetrahydroaminoacridine, THA)

Cognex

Class and Category

Chemical class: Monoamine acridine

Therapeutic class: Dementia treatment

Pregnancy category: C

Indications and Dosages

➤ *To treat mild to moderate Alzheimer's-type dementia*

CAPSULES

Adults. *Initial:* 10 mg q.i.d. for 4 wk, increased to 20 mg q.i.d. and adjusted every

4 wk as prescribed. *Maximum:* 160 mg daily in 4 divided doses.

Contraindications

Hypersensitivity to tacrine, other acridine derivatives, or their components; jaundice from previous tacrine use; serum bilirubin level that exceeds 3 mg/dl

Interactions

DRUGS

anticholinergics: Decreased effects of both drugs
cholinergics, other cholinesterase inhibitors: Increased effects of these drugs and tacrine, possibly leading to toxicity
cimetidine: Increased blood tacrine level, possibly leading to toxicity
neuromuscular blockers: Prolonged or exaggerated muscle relaxation
NSAIDs: Increased gastric acid secretion, possibly GI irritation and bleeding
theophylline: Increased blood theophylline level, possibly leading to toxicity

FOODS

Mechanism of Action

Tacrine may relieve dementia in patients with Alzheimer's disease by increasing the acetylcholine level in the CNS. In Alzheimer's disease, some cholinergic neurons lose their ability to function, which decreases the acetylcholine level. The remaining functioning cholinergic neurons release acetylcholine, but it's enzymatically broken down by cholinesterases into acetic acid and choline, as shown below left. Without acetyl-

choline to activate muscarinic (M) and nicotinic (N) receptors on postsynaptic cell membranes, nerve transmission and excitability decrease.

Tacrine binds with and inhibits cholinesterases, making more intact acetylcholine available in cholinergic synapses, as shown below right. This prolongs and enhances acetylcholine's effects, which increases nerve transmission and reduces symptoms of dementia.

all foods: Reduced tacrine bioavailability

ACTIVITIES

smoking: Possibly decreased tacrine effectiveness

Adverse Reactions

CNS: Agitation, anxiety, asthenia, ataxia, confusion, depression, dizziness, fatigue, hallucinations, headache, hostility, insomnia, seizures, somnolence, syncope, tremor

CV: Arrhythmias, chest pain, conduction disturbances, hypertension, hypotension, palpitations, peripheral edema, sick sinus syndrome

EENT: Rhinitis

GI: Abdominal pain, anorexia, constipation, diarrhea, elevated liver function test results, flatulence, indigestion, nausea, vomiting

GU: Bladder obstruction, urinary frequency and incontinence, UTI

MS: Back pain, muscle stiffness, myalgia

RESP: Asthma, cough, upper respiratory tract infection, wheezing

SKIN: Flushing, jaundice, purpura, rash

Other: Weight loss

Nursing Considerations

- In patients with asthma, monitor for wheezing and increased mucus production because tacrine may increase bronchoconstriction and bronchial secretions.
- Expect to monitor hepatic enzyme levels (specifically ALT), as ordered, every other week from at least week 4 to week 16 of tacrine therapy.
- If patient has elevated serum ALT level, monitor her for signs and symptoms of hepatitis, such as jaundice and right-upper-quadrant pain. ALT level should return to normal 4 to 6 weeks after therapy stops.
- Once ALT level returns to normal, expect to begin tacrine therapy again (starting at 10 mg q.i.d.) as prescribed, and check patient's hepatic enzyme levels weekly for 16 weeks, monthly for 2 months, and then every 3 months thereafter, as ordered.
- Monitor patient for bradyarrhythmias, conduction disturbances, and sick sinus syndrome because tacrine may have a vagotonic effect on the heart rate.

WARNING Be aware that tacrine's cholinergic effects may exacerbate seizures or parkinsonian symptoms.

- Monitor patient's urine output and assess

for abdominal distention and abnormal bowel sounds because drug's cholinergic effects may exacerbate conditions involving urinary tract or GI obstruction or ileus.

- Be aware that patients with peptic ulcer disease and those receiving NSAIDs are at increased risk for developing diarrhea, nausea, and vomiting because tacrine increases gastric acid secretion.
- Assess patient for increased signs and symptoms because drug becomes less effective as Alzheimer's disease progresses and the number of intact cholinergic neurons declines.

PATIENT TEACHING

- Instruct patient to take tacrine on an empty stomach, and advise caregiver to make sure that the patient swallows the drug.
- If patient experiences GI distress, suggest taking drug with meals. Mention that drug's effects may be delayed.
- Urge patient to seek assistance when walking and changing position until drug's effects are known. Instruct her to avoid potentially hazardous activities during this period.
- Advise patient not to smoke because it decreases drug's effectiveness.
- Caution patient not to stop taking drug abruptly. Doing so may impair cognitive ability.
- Inform caregiver that tacrine will become less effective as Alzheimer's disease progresses.
- Urge caregiver to make sure patient returns regularly for follow-up visits and laboratory tests to monitor drug effectiveness.

tacrolimus

Prograf

Class and Category

Chemical class: Macrolide

Therapeutic class: Immunosuppressant

Pregnancy category: C

Indications and Dosages

↗ *To prevent organ rejection in patients undergoing allogeneic liver, kidney, or heart transplantation*

CAPSULES**Adults having kidney transplantation.**

0.2 mg/kg/day given in two equally divided doses every 12 hr beginning only after renal function has recovered (serum creatinine level of 4 mg/dl or less).

DOSE ADJUSTMENT Black patients may need higher doses after kidney transplantation.

Adults having liver transplantation.

0.10 to 0.15 mg/kg/day given in two equally divided doses every 12 hr. Administer 6 hr after transplantation.

Adults having heart transplantation.

0.075 mg/kg/day given in two equally divided doses every 12 hr. Administer 6 hr after transplantation.

Children having liver transplantation.

0.15 to 0.20 mg/kg/day given in two equally divided doses every 12 hr. Administer 6 hr after transplantation.

I.V. INFUSION

Adults having kidney or liver transplantation. 0.03 to 0.05 mg/kg/day as a continuous infusion beginning no sooner than 6 hr after transplantation.

Adults having heart transplantation.

0.0187 to 0.025 mg/kg/day as a continuous infusion beginning no sooner than 6 hr after transplantation.

Children having liver transplantation.

0.03 to 0.05 mg/kg/day as a continuous infusion beginning no sooner than 6 hr after transplantation.

DOSE ADJUSTMENT Therapy delayed up to 48 hours or longer in patients with post-operative oliguria. For patients with hepatic or renal impairment, dosage kept at lower end of range with possible need for further reduction.

Mechanism of Action

Inhibits T-lymphocyte activation, possibly by binding to an intracellular protein, FKBP-12. This binding results in formation of a complex of tacrolimus-FKBP-12, calcium, calmodulin, and calcineurin, which inhibits phosphatase activity of calcineurin. This inhibition may prevent dephosphorylation and translocation of nuclear factor of activated T-cells, a nuclear component thought to initiate gene transcription for the formation of lymphokines. The result is inhibition of T-lymphocyte activation,

which produces immunosuppression.

Incompatibilities

Don't store diluted drug in PVC containers because of increased instability of tacrolimus and possible extraction of phthalates. Don't mix or co-infuse tacrolimus with solutions of pH 9 or greater, such as with acyclovir or ganciclovir, because of chemical instability of tacrolimus in alkaline media.

Contraindications

Breast-feeding, hypersensitivity to tacrolimus or its components, hypersensitivity to polyoxyl 60 hydrogenated castor oil (par-enteral form), ocular exposure, within 24 hours of cyclosporine therapy

Interactions**DRUGS**

aminoglycosides, amphotericin B, cisplatin, cyclosporine, other nephrotoxic drugs: Increased risk of renal impairment
bromocriptine, chloramphenicol, cimetidine, cisapride, clarithromycin, clotrimazole, cyclosporine, danazol, diltiazem, erythromycin, ethinyl estradiol, fluconazole, ganciclovir, itraconazole, ketoconazole, lansoprazole, magnesium-aluminum-hydroxide, metoclopramide, methylprednisolone, nefazodone, nicardipine, nifedipine, nelfinavir, omeprazole, protease inhibitors, ritonavir, troleandomycin, verapamil, voriconazole: Possibly increased blood tacrolimus level
carbamazepine, caspofungin, phenobarbital, phenytoin, rifabutin, rifampin, sirolimus, St. John's wort: Possibly decreased blood tacrolimus level
mycophenolic acid: Possibly increased plasma mycophenolic acid level
phenytoin: Possibly increased blood phenytoin level
sirolimus: Increased risk of wound healing complications, renal dysfunction, and insulin-dependent post-transplant diabetes mellitus
vaccines (live or killed): Possibly suppressed immune response and increased adverse effects of vaccine
FOODS
grapefruit juice: Possibly increased blood tacrolimus trough levels in liver transplant patients
high-fat foods: Decreased absorption of

oral tacrolimus

Adverse Reactions

CNS: Asthenia, fever, dizziness, headache, hemiparesis, insomnia, jittery feeling, leukoencephalopathy, mental changes, mutism, neurotoxicity, paresthesia, posterior reversible encephalopathy syndrome, progressive multifocal leukoencephalopathy, seizures, speech disorder, stroke, syncope, tremor

CV: Atrial and ventricular arrhythmias, cardiac arrest, chest pain, hypercholesterolemia, hyperlipemia, hypertension, hypertriglyceridemia, myocardial hypertrophy or ischemia, MI, pericardial effusion, peripheral edema, QT-interval prolongation, torsades de pointes, venous thrombosis

EENT: Blindness, cortical blindness, deafness, hearing loss, photophobia

ENDO: Cushingoid features, diabetes mellitus, hot flashes, hyperglycemia

GI: Abdominal pain, anorexia, ascites, bile duct stenosis, colitis, constipation, diarrhea, dyspepsia, enterocolitis, gastric ulcer, gastroenteritis, gastroesophageal reflux disease, hepatic impairment or toxicity, impaired gastric emptying, nausea, pancreatitis, venoocclusive liver disease, vomiting

GU: Acute renal failure, BK virus nephropathy, elevated creatinine and BUN levels, hemorrhagic cystitis, hemolytic-uremic syndrome, micturition abnormality, nephrotoxicity, oliguria, renal impairment, UTI

HEME: Anemia, decreased platelet count, disseminated intravascular coagulation, leukocytosis, neutropenia, pancytopenia, thrombocytopenia

MS: Arthralgia, back pain

RESP: Acute respiratory distress syndrome, atelectasis, bronchitis, cough increase, dyspnea, interstitial lung disease, lung infiltration, pleural effusion, respiratory distress or failure

SKIN: Flushing, malignancy, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, cytomegalovirus infection, hyperkalemia, hypokalemia, hypomagnesemia, hypophosphatemia, impaired wound healing, lymphoproliferative or malignant disorders, multi-organ failure, opportunistic infections (including activa-

tion of latent viral infections), primary graft dysfunction, weight loss

Nursing Considerations

- Don't start tacrolimus therapy within 24 hours of cyclosporine, and vice versa. If tacrolimus or cyclosporine blood levels are elevated beyond 24 hours of either drug being discontinued, the other drug should not be started until elevation is resolved.
- Be aware that I.V. tacrolimus therapy should only be given if patient can't tolerate oral tacrolimus. Patient should be switched to oral therapy as soon as possible.
- Expect to give drug with adrenal corticosteroid therapy.
- Dilute intravenous drug with normal saline solution or 5% dextrose to 0.004 to 0.02 mg/ml following manufacturer guidelines. Once diluted, drug should be stored in glass or polyethylene containers (not PVC, because of decreased stability and possible extraction of phthalates). Discard after 24 hours if not used.
- When converting patient from parenteral to oral therapy after heart transplantation, expect to give oral form 8 to 12 hours after infusion is discontinued.
- Be aware that children having liver transplantation usually need higher doses of tacrolimus than adults.

WARNING Closely monitor patient for anaphylaxis at least during first 30 minutes of I.V. administration. Make sure emergency equipment and drugs, such as aqueous solution of epinephrine and oxygen, are immediately available.

- Monitor patient's blood tacrolimus trough levels regularly, as ordered. Higher trough levels increase risk of toxicity.
- Monitor blood pressure, especially in patients with history of hypertension, because drug can worsen this condition.
- Monitor results of liver and renal function tests, as ordered, to detect signs of decreased function.
- Tacrolimus may increase serum cholesterol, lipid, and triglyceride levels.
- Monitor patient's blood glucose level closely because tacrolimus may cause post-transplant diabetes mellitus with the need for insulin therapy, especially in black and Hispanic patients.

- Monitor patient's serum potassium level, as ordered, because drug can alter it.
- Watch for evidence of neurotoxicity, especially in patients receiving high doses of drug. Evidence of encephalopathy includes headache, impaired consciousness, loss of motor function, psychiatric disturbance, seizures, and tremors.

PATIENT TEACHING

- Advise patient to take oral doses 12 hours apart at same time each day.
- Instruct patient to take capsules on an empty stomach.
- Tell patient to avoid consuming grapefruit juice while taking tadalafil.
- Advise patient not to stop taking drug without consulting prescriber.
- Instruct patient not to receive virus vaccines during therapy. Urge him to avoid people who have received such vaccines or to wear a protective mask when he's around them.
- Caution patient to avoid having contact with people who have infections during therapy because tadalafil causes immunosuppression.
- Stress importance of having repeated laboratory tests while taking tadalafil, and urge compliance.
- Inform patient that tadalafil therapy may result in insulin-dependent diabetes. Tell him to report frequent urination or an increase in thirst, hunger, or fatigue.
- Instruct patient to limit exposure to direct sunlight and to wear protective clothing and use sunscreen when exposure can't be avoided.

tadalafil

Adcirca, Cialis

Class and Category

Chemical class: Phosphodiesterase inhibitor

Therapeutic class: Anti-impotence

Pregnancy category: B

Indications and Dosages

↗ *To treat erectile dysfunction*

TABLETS

Adults. *Initial:* 10 mg daily taken 1 hr before sexual activity; dosage decreased to 5 mg or increased to 20 mg, as prescribed,

based on clinical response. *Maximum:* 20 mg daily. Or, 2.5 mg once daily, increased to 5 mg once daily, if needed.

DOSAGE ADJUSTMENT For patients taking potent CYP3A4 inhibitors such as itraconazole, ketoconazole, or ritonavir, dosage shouldn't exceed 10 mg every 72 hr. For patients with moderate to severe renal insufficiency who take drug on an as-needed basis, dosage shouldn't exceed 5 mg daily. For patients with mild to moderate hepatic impairment who take drug on an as-needed basis, dosage shouldn't exceed 10 mg daily. For patients who take drug once daily, no dosage adjustment is needed with mild to moderate hepatic or renal impairment; once daily dosing not recommended for use with severe hepatic or renal impairment.

↗ *To treat pulmonary arterial hypertension in order to improve exercise ability in patients classified as group 1 by the World Health Organization*

TABLETS (ADCIRCA)

Adults. 40 mg once daily.

DOSAGE ADJUSTMENT For patients with mild to moderate hepatic or renal impairment or who have already taken ritonavir for at least 1 week, initial dosage of 20 mg once daily and then increased as tolerated. For patient already taking tadalafil and being prescribed ritonavir, tadalafil temporarily discontinued for at least 24 hours before ritonavir starts. Then, after at least 1 week of ritonavir, tadalafil restarted at 20 mg once daily and then increased to 40 mg once daily, as tolerated.

Route	Onset	Peak	Duration
P.O.	Unknown	30 min– 6 hr	Unknown

Mechanism of Action

Enhances the effect of nitric oxide released in the penis during sexual stimulation. Nitric oxide activates the enzyme guanylate cyclase, which causes increased levels of cGMP in the corpus cavernosum. This leads to increased blood flow to the penis, thus producing an erection.

Contraindications

Continuous or intermittent nitrate therapy, hypersensitivity to tadalafil or its compo-

nents, retinitis pigmentosa

Interactions

DRUGS

carbamazepine, phenytoin, phenobarbital:

Possibly decreased tadalafil effects

doxazosin, tamsulosin and other alpha blockers: Increased risk of symptomatic hypotension

erythromycin, itraconazole, ketoconazole,

ritonavir: Prolonged tadalafil effects

nitrates: Profound hypotension

protease inhibitors (other than ritonavir):

Possibly prolonged tadalafil effects

rifampin: Decreased tadalafil effects

FOODS

grapefruit juice: Possibly prolonged tadalafil effects

ACTIVITIES

alcohol use: Potentiated blood pressure lowering effects

Adverse Reactions

CNS: Asthenia, dizziness, fatigue, headache, hypesthesia, insomnia, migraine, paresthesia, seizures, somnolence, stroke, syncope, transient global amnesia, vertigo

CV: Angina pectoris, chest pain, hypotension, hypertension, MI, postural hypotension, palpitations, sudden cardiac death, tachycardia

EENT: Blurred vision, changes in color vision, conjunctivitis, dry mouth, epistaxis, eyelid swelling, eye pain, hearing loss, increased lacrimation, nasal congestion, nasopharyngitis, nonarteritic anterior ischemic optic neuropathy, pharyngitis, retinal artery or vein occlusion, visual field defects

GI: Abnormal liver function studies, diarrhea, dysphagia, dyspepsia, esophagitis, gastroesophageal reflux, gastritis, increased gamma-glutamyl transpeptidase levels, nausea, upper abdominal pain, vomiting

GU: Priapism, spontaneous penile erection, UTI

MS: Arthralgia, back or neck pain, extremity pain, myalgia

RESP: Bronchitis, cough, dyspnea, upper respiratory tract infection

SKIN: Diaphoresis, exfoliative dermatitis, flushing, pruritus, rash, Stevens-Johnson syndrome, urticaria

Other: Facial edema, flulike symptoms, hypersensitivity reactions

Nursing Considerations

- Know that patients with hereditary degenerative retinal disorders, including retinitis pigmentosa, should not receive tadalafil because of the risk of serious ophthalmic adverse reactions.
- Patients with severe hepatic or renal impairment should not receive tadalafil because its effects in these patients are unknown.
- Use tadalafil cautiously in patients with left ventricular outflow obstruction, such as aortic stenosis and idiopathic hypertrophic subaortic stenosis, and those with severely impaired autonomic control of blood pressure because these conditions increase sensitivity to vasodilators such as tadalafil.
- Use tadalafil cautiously in patients with conditions that may predispose them to priapism, such as sickle cell anemia, multiple myeloma, leukemia, or penile deformities (such as angulation, cavernosal fibrosis, or Peyronie's disease).
- Monitor blood pressure and heart rate and rhythm before and during therapy.

PATIENT TEACHING

- Explain that, when used as needed to treat erectile dysfunction, tadalafil should be taken 1 hour before sexual activity to provide the most effective results. Alternatively, if the patient chooses to take a smaller dose of tadalafil daily, encourage him to take it at about the same time every day regardless of the timing of sexual activity.

WARNING Tell patient not to take tadalafil if he takes any form of organic nitrate, either continuously or intermittently, because profound hypotension and death could result. Tell him to seek immediate medical attention if he has a sudden loss of vision or hearing.

- If patient takes tadalafil to treat erectile dysfunction, advise him to obtain sexual counseling to help enhance the drug's effects.
- To avoid possible penile damage and permanent loss of erectile function, urge patient to notify prescriber immediately if erection is painful or lasts longer than 4 hours.
- Advise patient to limit alcohol consumption while taking tadalafil.

tamoxifen citrate

Apo-Tamox (CAN), **Gen-Tamoxifen** (CAN), **Nolvadex**, **Novo-Tamoxifen** (CAN), **Tamofen** (CAN), **Tamone** (CAN)

Class and Category

Chemical class: Triphenylethylene derivative
Therapeutic class: Nonsteroidal antiestrogen agent, partial estrogen agonist
Pregnancy category: D

Indications and Dosages

➤ *To treat metastatic breast cancer in men and women; to treat node-negative breast cancer in women, or node-positive breast cancer in postmenopausal women, after total or segmental mastectomy, axillary dissection, and breast irradiation*

TABLETS

Adults. 20 to 40 mg daily. Dosages greater than 20 mg administered b.i.d.

➤ *To reduce the risk of invasive breast cancer in women with ductal carcinoma in situ (DCIS) after surgery and radiation, to reduce the risk of breast cancer in women at high risk*

TABLETS

Adults. 20 mg daily for 5 yr.

Mechanism of Action

May block the effects of estrogen on breast tissue by competing with estrogen for estrogen-receptor binding sites. Estrogen may stimulate the growth of cancer cells.

Contraindications

Hypersensitivity to tamoxifen or its components; women at high risk for breast cancer and women with ductal carcinoma in situ and a history of deep vein thrombosis or pulmonary embolus or who need coumarin-type anticoagulant therapy; use with anastrozole therapy

Interactions

DRUGS

bromocriptine: Possibly increased blood tamoxifen level

estrogens: Possibly altered therapeutic effect of tamoxifen

warfarin and other coumarin-type anticoagulants: Increased anticoagulant effect of these drugs

Adverse Reactions

CNS: Confusion, depression, dizziness, fatigue, headache, light-headedness, somnolence, stroke, weakness

CV: Edema, hyperlipidemia, thrombosis

EENT: Keratopathy, ocular toxicity (including cataracts), optic neuritis, retinopathy

GI: Elevated liver function test results, hepatotoxicity, nausea, vomiting

GU: Endometrial cancer, endometrial hyperplasia, endometrial polyps, genital itching, menstrual irregularities, ovarian cysts, uterine malignancies, vaginal discharge (females); impotence, decreased libido (males)

HEME: Anemia, leukopenia, thrombocytopenia

MS: Transient bone or tumor pain

RESP: Pulmonary embolism

SKIN: Bullous pemphigoid, dry skin, erythema multiforme, rash, Stevens-Johnson syndrome, thinning hair

Other: Angioedema, hot flashes, hypercalcemia, weight gain

Nursing Considerations

WARNING Make sure that patient has been informed about serious or potentially life-threatening adverse effects associated with tamoxifen before therapy begins. Be aware that women with ductal carcinoma in situ and those at high risk for breast cancer are more likely to develop uterine cancer, stroke, or pulmonary emboli than others receiving tamoxifen.

- If patient is premenopausal, begin drug therapy in the middle of menstruation; if patient's menstrual cycles are irregular, verify that she has had a negative pregnancy test before therapy starts.
- Expect patient to undergo an ophthalmic examination before and periodically during tamoxifen therapy. Also expect to monitor patient for adverse ocular reactions, such as cataracts.
- Assess patient for signs and symptoms of thromboembolic events, such as shortness of breath, leg pain, and change in mental status.
- Periodically monitor patient's platelet and WBC counts, cholesterol and triglyceride levels, and liver function test results, as ordered.
- Monitor blood calcium level and assess

patient for signs and symptoms of hypercalcemia, such as nausea, vomiting, and thirst; tamoxifen may cause hypercalcemia in breast cancer patients with bone metastasis within a few weeks of starting treatment.

- Store tamoxifen in a closed, light-resistant container at room temperature.

PATIENT TEACHING

- Advise patient to swallow tamoxifen tablet whole with water.
- Instruct premenopausal patient to use a nonhormonal form of contraception, such as a condom or diaphragm, during tamoxifen therapy. Emphasize that she shouldn't become pregnant while taking drug and for 2 months afterward. Advise her to notify prescriber at once if she becomes pregnant during therapy.
- Inform patient of the most common side effects—hot flashes, vaginal discharge, and irregular menses.
- Urge patient to immediately notify prescriber if she notices a rash, itching, difficulty breathing, or facial swelling because they may signify a hypersensitivity reaction.
- Advise patient to notify prescriber if she experiences leg pain or calf swelling during tamoxifen therapy because they may indicate a blood clot.
- Instruct patient to report signs of hepatotoxicity, such as tiredness, nausea, yellow skin, and flulike symptoms.
- Advise patient to have regular gynecologic examinations and to notify prescriber about abnormal symptoms, including abdominal or pelvic pain, new breast lumps, and unusual vaginal discharge or bleeding.
- Urge patients who take tamoxifen for prophylaxis to have regular mammograms because tamoxifen doesn't prevent all cancers.
- Stress the importance of taking tamoxifen regularly. Urge patient to consult prescriber if adverse reactions, such as nausea and vomiting, are interfering with dosage schedule. These symptoms may be a sign of hypercalcemia.
- Inform women who wish to breast-feed that tamoxifen may appear in breast milk and cause serious adverse effects in the infant.

tamsulosin hydrochloride

Flomax

Class and Category

Chemical class: Sulfamoylphenethylamine derivative

Therapeutic class: Benign prostatic hyperplasia (BPH) treatment

Pregnancy category: B

Indications and Dosages

↗ *To treat BPH*

CAPSULES

Adults. *Initial:* 0.4 mg daily 30 min p.c. for 2 to 4 wk, increased to 0.8 mg daily if no response to initial dosage. *Maximum:* 0.8 mg daily.

Mechanism of Action

Blocks alpha₁-adrenergic receptors in the prostate. This action inhibits smooth-muscle contraction in the prostate, prostatic capsule, prostatic urethra, and bladder neck, which improves the rate of urine flow and reduces symptoms of BPH.

Contraindications

Hypersensitivity to tamsulosin, quinazolines, or their components

Interactions

DRUGS

alpha blockers: Additive effects of both drugs

cimetidine: Risk of decreased tamsulosin clearance

CYP2D6 inhibitors (such as fluoxetine, paroxetine, terbinafine), CYP3A4 inhibitors (such as erythromycin, ketoconazole):

Possibly increased plasma tamsulosin level
phosphodiesterase-5 inhibitors: Increased risk of hypotension

Adverse Reactions

CNS: Asthenia, dizziness, drowsiness, headache, insomnia, syncope, vertigo

CV: Chest pain, orthostatic hypotension

EENT: Amblyopia, diplopia, intraoperative floppy iris syndrome, pharyngitis, rhinitis

GI: Diarrhea, nausea

GU: Decreased libido, ejaculation disorders, priapism

MS: Back pain

RESP: Respiratory impairment

SKIN: Pruritus, rash, urticaria

Other: Angioedema

Nursing Considerations

- Be aware that prostate cancer should be ruled out before tamsulosin therapy begins.
- Give drug about 30 minutes after the same meal each day.
- If patient takes drug on an empty stomach, monitor his blood pressure because of the increased risk of orthostatic hypotension.
- If patient doesn't take drug for several days, resume therapy at 0.4 mg/dose, as prescribed.

PATIENT TEACHING

- Instruct patient not to open, crush, or chew tamsulosin capsules and to take drug about 30 minutes after the same meal each day.
- Instruct patient to notify prescriber if he misses several days of therapy, and caution him against restarting drug at previous dosage.
- Advise patient to avoid potentially hazardous activities until drug's CNS effects are known. Mention the need for caution if dosage is increased.
- Advise patient to change position slowly, especially after initial dose and each dosage increase, to minimize effects of orthostatic hypotension.

tapentadol

Nucynta

Class, Category, and Schedule

Chemical class: Mu-opioid agonist

Therapeutic class: Centrally acting synthetic analgesic

Pregnancy category: C

Controlled substance schedule: II

Indications and Dosages

↗ *To relieve moderate to severe acute pain*

TABLETS

Adults. 50 mg to 100 mg repeated every 4 to 6 hr, as needed. *Maximum:* 700 mg on first day; 600 mg daily thereafter

DOSAJE ADJUSTMENT On first day of therapy, second dose may be given as soon as

1 hour after first dose, if needed. For patients with moderate hepatic impairment (Child-Pugh Class B), dosage should not exceed 50 mg for each episode, and intervals between doses should be at least 8 hours.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	4 hr

Mechanism of Action

Binds with and activates opioid receptors (mainly mu receptors) in brain and spinal cord and inhibits norepinephrine reuptake to produce analgesia.

Contraindications

Acute or severe bronchial asthma, hypercapnia or significant respiratory depression not monitored or without available resuscitation equipment, hypersensitivity to tapentadol or its components, paralytic ileus, within 14 days of MAO inhibitor therapy

Interactions

DRUGS

CNS depressants: Increased risk of CNS depression

MAO inhibitors: Possibly hyperpyretic episodes, hypertensive crisis, serotonin syndrome, and severe seizures

serotonergics: Increased risk of potentially fatal serotonin syndrome

ACTIVITIES

alcohol use: Increased risk of CNS depression

Adverse Reactions

CNS: Abnormal dreams, anxiety, confusion, dizziness, fatigue, headache, insomnia, lethargy, seizure, serotonin syndrome, somnolence, syncope, tremor

CV: Hypotension

EENT: Dry mouth, nasopharyngitis

ENDO: Hot flash

GI: Constipation, dyspepsia, nausea, vomiting

GU: Anorexia, UTI

MS: Arthralgia

RESP: Respiratory depression, upper respiratory infection

SKIN: Diaphoresis, pruritis, rash, urticaria

Other: Hypersensitivity reactions, physical or psychological dependence, withdrawal

Nursing Considerations

- Be aware that tapentadol isn't recommended for patients with severe renal impairment (creatinine clearance less than 30 ml/min/1.73 m²) or severe hepatic dysfunction (Child-Pugh Class C).
 - Use tapentadol cautiously in patients with hypoxia, hypercapnia, or decreased respiratory reserve such as may occur in asthma, COPD, cor pulmonale, severe obesity, sleep apnea syndrome, myxedema, kyphoscoliosis, CNS depression, or coma. Also use cautiously in patients with head injury or conditions in which increased intracranial pressure may occur because drug may obscure the signs and symptoms. Also use cautiously in patients with mild to moderate renal or hepatic dysfunction and in patients with biliary tract disease, including acute pancreatitis, because drug may cause spasm of the sphincter of Oddi.
 - Expect to begin tapentadol therapy at lower doses in elderly patients because of age-related decreased renal and hepatic function.
 - Monitor patient's respiratory rate, depth, and effort during tapentadol therapy because drug may cause respiratory depression, especially in elderly or debilitated patients and in those who have conditions accompanied by hypoxia, hypercapnia, or upper airway obstruction. If respiratory rate drops below 10 breaths per minute, notify prescriber, expect drug to be discontinued, and provide needed supportive care, which may include an opioid antagonist such as naloxone, as ordered.
 - Monitor patient for evidence of physical and psychological dependence.
- WARNING** Watch patient closely for evidence of serotonin syndrome, which can be life-threatening. Report mental status changes (agitation, hallucinations, coma), autonomic instability (tachycardia, labile blood pressure, hyperthermia), neuromuscular abnormalities (hyperreflexia, incoordination) or GI disturbances (nausea, vomiting or diarrhea).
- Don't stop tapentadol abruptly if used on a regular basis because withdrawal symptoms may occur.
 - Be aware that tapentadol shouldn't be used during or just before labor and delivery.

PATIENT TEACHING

- Instruct patient to take tapentadol exactly as prescribed and not to adjust dose or frequency without consulting prescriber.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Caution patient to avoid alcohol or other CNS depressants while taking tapentadol.
- Advise patient who has been taking tapentadol regularly not to stop taking it abruptly but rather to taper drug use gradually and based on prescriber instructions to reduce the risk of withdrawal symptoms.

telavancin

Vibativ

Class and Category

Chemical class: Lipoglycopeptide

Therapeutic class: Antibacterial

Pregnancy category: C

Indications and Dosages

↗ *To treat complicated skin and skin structure infections caused by gram-positive organisms (Staphylococcus aureus, Streptococcus pyogenes, Streptococcus agalactiae, Streptococcus anginosus group [includes S. anginosus, S. intermedius, and S. constellatus], or Enterococcus faecalis (vancomycin-susceptible isolates only)*

I.V. INFUSION

Adults. 10 mg/kg administered over 60 min every 24 hours for 7 to 14 days

DOSAGE ADJUSTMENT For patients with creatinine clearance of 30 to 50 ml/min/1.73 m², dosage reduced to 7.5 mg/kg every 24 hours. For patient with creatinine clearance of at least 10 but less than 30 ml/min/1.73 m², 10 mg/kg every 48 hours.

Route	Onset	Peak	Duration
I.V.	Unknown	1–2 hr	24 hr

Mechanism of Action

Inhibits cell wall synthesis and alters the permeability of bacterial membranes, causing cell wall lysis and cell death. Telavancin is a lipoglycopeptide antibacterial that's a synthetic derivative of vancomycin.

Incompatibilities

Don't mix telavancin with other drugs or IV solutions containing additives. If administration must be through the same IV line, flush the line with 5% dextrose injection, 0.9% sodium chloride injection, or lactated Ringer's injection before and after infusing telavancin.

Contraindications

Hypersensitivity to telavancin or its components

Interactions

DRUGS

ACE inhibitors, loop diuretics, NSAIDs:

Increased risk of nephrotoxicity
drugs known to prolong the QT interval, such as clarithromycin, disopyramide, erythromycin, quindine: Increased risk of prolonged QT interval

Adverse Reactions

CNS: Dizziness, rigors

CV: Prolonged QT interval

EENT: Taste disturbance

GI: Abdominal pain, anorexia, diarrhea, *Clostridium difficile*-associated diarrhea, nausea, vomiting

GU: Elevated creatinine level, foamy urine, nephrotoxicity such as renal failure, impairment, or insufficiency

SKIN: Pruritus, rash

Other: Infusion-related reactions such as erythema or pain

Nursing Considerations

- Know that telavancin isn't recommended for patients with congenital long-QT syndrome, uncompensated heart failure, or severe left ventricular hypertrophy or who currently have a prolonged QT interval because it may prolong the QT interval, causing life-threatening complications.
- Use cautiously in patients taking drugs known to prolong the QT interval because of increased the risk of a prolonged QT interval.
- Make sure woman of childbearing age has a negative pregnancy test result before starting telavancin because of risk of fetal harm.
- Obtain baseline serum creatinine level before telavancin therapy starts, and monitor it throughout therapy, as ordered, because drug may cause nephrotoxicity,

especially in patients with pre-existing renal disease, diabetes mellitus, congestive heart failure, or hypertension and in patients taking such nephrotoxic drugs as NSAIDs, ACE inhibitors, and loop diuretics. If renal function declines, notify prescriber and expect to discontinue telavancin.

- Dilute a 250-mg vial with 15 ml or a 750-mg vial with 45 ml of a diluent such as 5% dextrose injection, sterile water for injection, or 0.9% sodium chloride injection to obtain a solution of 15 mg/ml. When ready to administer drug, further dilute doses of 150 mg to 800 mg in 100 to 250 ml of 5% dextrose injection, 0.9% sodium chloride injection, or lactated Ringer's injection before infusion. Doses less than 150 mg or greater than 800 mg should be further diluted in a volume that yields a final concentration of 0.6 to 0.8 mg/ml.
- Infuse telavancin over 60 minutes because more rapid infusion may cause a reaction like red-man syndrome, which causes flushing of upper body, urticaria, pruritus, or rash. If present, stop or slow infusion to resolve.
- Use telavancin within 4 hours of the time it is reconstituted in the vial (including its transfer to an infusion bag for further dilution) if kept at room temperature and 72 hours if refrigerated. Discard if time limit exceeds these parameters.
- Monitor patient for diarrhea, which may range from mild to severe and may occur up to 2 months after antibiotic is discontinued. Report diarrhea and, if *C. difficile* is suspected, expect telavancin to be discontinued. Provide supportive care, such as fluid and electrolyte replacement, protein supplementation, antibiotic therapy to treat *C. difficile*, and possibly surgical intervention, as needed.
- Be aware that while telavancin doesn't interfere with coagulation, it does interfere with certain tests used to monitor coagulation, such as PT, INR, APTT, activated clotting time, and coagulation-based factor Xa tests. Collect blood samples for coagulation tests as close as possible to administration of next dose of telavancin to minimize interference.

PATIENT TEACHING

- Instruct women of childbearing age to use effective contraception during telavancin therapy.
- Caution patient that diarrhea may occur up to 2 months after antibiotic has been discontinued and to report any persistent or severe episodes to prescriber.
- Warn patient that drug may cause urine to be foamy and taste to be altered.
- Advise patient to alert all prescribers that he takes telavancin because some drugs may interact with it, causing serious adverse effects.

telithromycin

Ketek

Class and Category

Chemical class: Semisynthetic ketolide

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

➤ *To treat mild to moderate community-acquired pneumonia caused by Streptococcus pneumoniae, Haemophilus influenzae, Moraxella catarrhalis, Chlamydomydia pneumoniae, or Mycoplasma pneumoniae*

TABLETS

Adults. 800 mg daily P.O. for 7 to 10 days.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	Unknown

Mechanism of Action

Binds to domains II and V of the 50S ribosomal subunit in many aerobic, anaerobic, gram-positive, and gram-negative bacteria of the respiratory tract. Telithromycin may also inhibit the assembly of nascent ribosomal units. These actions inhibit RNA-dependent protein synthesis in bacterial cells, causing them to die.

Contraindications

Cisapride or pimozide therapy; history of hepatitis or jaundice associated with use of telithromycin or any macrolide antibiotic; hypersensitivity to telithromycin, macrolide antibiotics, or their components; myasthenia gravis

Interactions

DRUGS

atorvastatin, lovastatin, midazolam,

pimozide, simvastatin: Possibly increased blood levels of these drugs

cisapride, dofetilide, procainamide, quini-dine: Increased risk of prolonged QT interval

itraconazole, ketoconazole: Increased blood level of telithromycin

oral anticoagulants: Possibly potentiated effects of oral anticoagulants

rifampin: Decreased blood level of telithromycin

sotalol: Decreased sotalol absorption

theophylline: Increased risk of adverse GI reactions

Adverse Reactions

CNS: Dizziness, fatigue, headache, insomnia, somnolence, transient loss of consciousness, vertigo

CV: Atrial arrhythmias, prolonged QT interval, torsades de pointes

EENT: Blurred vision, difficulty focusing eyes, diplopia, dry mouth, glossitis, oral candidiasis, stomatitis

GI: Abdominal distention or pain, anorexia, constipation, diarrhea, elevated liver function test results, flatulence, fulminant hepatitis, gastroenteritis, gastritis, hepatic failure or necrosis, hepatitis, nausea, pseudomembranous colitis, taste perversion, vomiting

GU: Vaginal candidiasis, vaginitis, vaginosis (fungal)

HEME: Increased platelet count

MS: Exacerbated myasthenia gravis, muscle cramps

RESP: Acute respiratory failure

SKIN: Diaphoresis, rash

Other: Angioedema, anaphylaxis

Nursing Considerations

- Be aware that telithromycin therapy shouldn't be used in patients who have congenital prolonged QT interval or ongoing proarrhythmic conditions (such as uncorrected hypokalemia or hypomagnesemia, or serious bradycardia) or in those receiving concurrent therapy with class IA or class III antiarrhythmics because telithromycin increases the risk of QT-interval prolongation, which may lead to ventricular arrhythmias, including torsades de pointes.

- Before administering the first telithromycin dose, expect to obtain respiratory specimens for culture and sensitivity testing.
- Monitor patient closely for diarrhea, which may indicate pseudomembranous colitis. If it occurs, notify prescriber and expect to withhold drug and give fluids, electrolytes, protein, and an antibiotic effective against *Clostridium difficile*.

WARNING Monitor patient's liver studies for abnormalities, and assess patient for evidence of liver dysfunction, such as fatigue, malaise, anorexia, nausea, jaundice, acholic stools, and liver tenderness, because telithromycin may cause potentially life-threatening acute hepatic failure and severe liver damage.

PATIENT TEACHING

- Stress need to take drug for prescribed duration even if patient feels better before prescription is finished.
- Caution patient to avoid hazardous activities until drug's CNS and visual effects are known. Explain that telithromycin can cause trouble focusing eyes, especially for first 30 minutes after a dose.
- Instruct patient to notify prescriber if visual disturbances occur, and tell her to avoid quick changes in viewing near and distant objects.
- Tell patient to alert prescriber if she faints because drug may alter heart rhythm.
- Caution patient to notify prescriber immediately about fatigue, malaise, anorexia, nausea, abdominal tenderness, yellow skin, or changes in stool appearance.

telmisartan

Micardis

Class and Category

Chemical class: Nonpeptide angiotensin II antagonist

Therapeutic class: Antihypertensive

Pregnancy category: C (first trimester), D (later trimesters)

Indications and Dosages

↗ *To manage hypertension, alone or with other antihypertensives*

TABLETS

Adults. *Initial:* 40 mg daily. *Maintenance:* 20 to 80 mg daily. *Maximum:* 80 mg daily.
↗ *To reduce risk of MI, stroke, or death from cardiovascular causes in patients at high risk who are unable to take ACE inhibitors*

TABLETS

Adults age 55 and over. 80 mg once daily.

Route	Onset	Peak	Duration
P.O.	Unknown	In 4 wk	Unknown

Mechanism of Action

Blocks angiotensin II from binding to receptor sites in many tissues, including vascular smooth muscle and adrenal glands. This action inhibits the vasoconstrictive and aldosterone-secreting effects of angiotensin II, which reduces blood pressure.

Contraindications

Hypersensitivity to telmisartan or its components

Interactions

DRUGS

digoxin: Increased peak blood digoxin level and risk of digitalis toxicity

diuretics, other antihypertensives: Enhanced hypotensive effect

lithium: Increased serum lithium levels and toxicity

ramipril: Increased serum ramipril level; decreased telmisartan level

Adverse Reactions

CNS: Asthenia, dizziness, fatigue, headache, syncope, weakness

CV: Atrial fibrillation, bradycardia, chest pain, congestive heart failure, hypertension, hypotension, MI, orthostatic hypotension, peripheral edema

EENT: Pharyngitis, sinusitis

GI: Abdominal pain, diarrhea, elevated liver enzyme levels, indigestion, nausea, vomiting

GU: Acute renal failure, erectile dysfunction, renal dysfunction, UTI

HEME: Anemia, eosinophilia, thrombocytopenia

MS: Back pain, leg or muscle cramps, myalgia, tendon pain, tendinitis, tenosynovitis

RESP: ACE cough, upper respiratory tract infection

SKIN: Diaphoresis, erythema, urticaria

Other: Anaphylaxis, angioedema, elevated uric acid level, flulike symptoms, hyperkalemia, hypovolemia

Nursing Considerations

- Give telmisartan cautiously to patients with dehydration or hyponatremia.
- Expect prescriber to add a diuretic to regimen if patient's blood pressure isn't well controlled by telmisartan.
- Check patient's blood pressure regularly. Be prepared to treat symptomatic hypotension by placing patient in supine position and giving normal saline solution, as ordered.
- Monitor BUN and serum creatinine levels and urine output in patients with impaired renal function because they're at increased risk for oliguria, progressive azotemia, and possibly acute renal failure.
- Monitor liver function test results, as appropriate, and assess for evidence of drug toxicity in patients with severe hepatic disease because they're at increased risk for toxicity from increased drug accumulation.
- Avoid using telmisartan in pregnant women during second and third trimesters because drug can increase the risk of fetal harm.

PATIENT TEACHING

- Advise patient to avoid hazardous activities until telmisartan's CNS effects are known.
- Instruct patient to change position slowly to minimize effects of orthostatic hypotension.
- Urge patient to immediately notify prescriber about diarrhea, dizziness, severe nausea, or vomiting.
- Instruct patient to consult prescriber before taking any new drug.
- Advise patient to drink adequate amounts of fluid during hot weather and when exercising.
- Advise female patients of childbearing age to notify prescriber immediately about known or suspected pregnancy.

temazepam

Apo-Temazepam (CAN), Novo-Temazepam (CAN), Restoril

Class, Category, and Schedule

Chemical class: Benzodiazepine

Therapeutic class: Sedative-hypnotic

Pregnancy category: X

Controlled substance schedule: IV

Indications and Dosages

↗ *To provide short-term management of insomnia*

CAPSULES

Adults. 7.5 to 30 mg 30 min before at bedtime. *Maximum:* 30 mg daily.

DOSAGE ADJUSTMENT For elderly or debilitated patients, 7.5 mg 30 min before bedtime. *Maximum:* 15 mg daily.

Mechanism of Action

May potentiate the effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptor sites in limbic and cortical areas of the CNS. By binding to these receptor sites, temazepam increases GABA's inhibitory effects and blocks cortical and limbic arousal.

Contraindications

Hypersensitivity to temazepam, other benzodiazepines, or their components; pregnancy

Interactions

DRUGS

antihistamines (such as brompheniramine, carbinoxamine, chlorpheniramine, clemastine, cyproheptadine, diphenhydramine, tri-mepazine), anxiolytics, barbiturates, general anesthetics, opioid analgesics, phenothiazines, promethazine, sedative-hypnotics, tramadol, tricyclic antidepressants: Increased sedation or respiratory depression
clozapine: Risk of respiratory depression or arrest
digoxin: Increased risk of elevated blood digoxin level and digitalis toxicity
flumazenil: Increased risk of withdrawal symptoms
levodopa: Possibly decreased levodopa effects
oral contraceptives: Decreased response to temazepam
phenytoin: Possibly phenytoin toxicity
probenecid: Increased response to temazepam
zidovudine: Possibly zidovudine toxicity

ACTIVITIES

alcohol use: Increased CNS depression and risk of apnea

smoking: Increased temazepam clearance

Adverse Reactions

CNS: Aggressiveness, anxiety (in daytime), ataxia, complex behaviors (such as sleep driving), confusion, decreased concentration, depression, dizziness, drowsiness, euphoria, fatigue, headache, insomnia, nightmares, slurred speech, suicidal ideation, syncope, talkativeness, tremor, vertigo, wakefulness during last third of night

CV: Palpitations, tachycardia

EENT: Abnormal or blurred vision, increased salivation, throat tightness

GI: Abdominal pain, constipation, diarrhea, hepatic dysfunction, nausea, thirst, vomiting

GU: Decreased libido

HEME: Agranulocytosis, anemia, leukopenia, neutropenia, thrombocytopenia

MS: Muscle spasm or weakness

RESP: Dyspnea, increased bronchial secretions

SKIN: Diaphoresis, flushing, jaundice, pruritus, rash

Other: Anaphylaxis, angioedema, physical and psychological dependence

Nursing Considerations

- Use temazepam cautiously in patients with a history of depression or suicidal thoughts.

WARNING Monitor patient closely for evidence of hypersensitivity reaction, such as dyspnea, throat tightness, nausea, vomiting, and swelling. If present, discontinue temazepam immediately, notify prescriber, and provide supportive care.

- Watch patient closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times and could lead to suicidal ideation.

WARNING Monitor patient for evidence of physical and psychological dependence during therapy.

- Implement safety precautions, according to facility policy, especially in elderly patients, because they're more sensitive to drug's CNS effects.
- Assess patients with respiratory depression, severe COPD, or sleep apnea for signs of

ventilatory failure.

- Be aware that temazepam can aggravate acute intermittent porphyria, myasthenia gravis, and severe renal impairment.
- Be aware that temazepam may cause worsening psychosis or deterioration of cognition or coordination in patients with late-stage Parkinson's disease.
- Be aware that drug shouldn't be discontinued abruptly, even after only 1 to 2 weeks of therapy, because doing so may cause seizures or withdrawal symptoms, such as insomnia, irritability, and nervousness.

PATIENT TEACHING

- Instruct patient to take temazepam exactly as prescribed and not to stop or change dosage without consulting prescriber.
- Explain the risks associated with abrupt cessation, including abdominal cramps, acute sense of hearing, confusion, depression, nausea, numbness, perceptual disturbances, photophobia, sweating, tachycardia, tingling, trembling, and vomiting.
- Advise patient to avoid consuming alcohol because it increases drug's sedative effects and the risk of such abnormal behaviors as sleep driving.
- Caution patient about possible drowsiness. Advise her to avoid potentially hazardous activities until drug's CNS effects are known.
- Urge patient to notify prescriber immediately about excessive drowsiness, nausea, and known or suspected pregnancy.
- Instruct patient to stop taking temazepam and seek emergency care if she experiences difficulty breathing, throat tightness, nausea, vomiting, or abnormally swelling.
- Advise patient that drug may cause abnormal behaviors during sleep, such as driving a car, eating, talking on the phone, or having sex without any recall of the event. If family notices any such behavior or patient sees evidence of such behavior upon awakening, the prescriber should be notified.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.

tenecteplase

TNKase

Class and Category

Chemical class: Purified glycoprotein

Therapeutic class: Thrombolytic

Pregnancy category: C

Indications and Dosages

↗ *To reduce mortality associated with acute MI*

I.V. INJECTION

Adults. Single bolus administered over 5 sec in individualized dosage based on patient's weight, as follows: 30 mg (6 ml) for patients weighing less than 60 kg (132 lb); 35 mg (7 ml) for patients weighing 60 to 69 kg (132 to 152 lb); 40 mg (8 ml) for patients weighing 70 to 79 kg (154 to 174 lb); 45 mg (9 ml) for patients weighing 80 to 89 kg (176 to 196 lb); 50 mg (10 ml) for patients weighing 90 kg (198 lb) or more. *Maximum:* 50 mg total dose.

Mechanism of Action

Binds to fibrin and converts plasminogen to plasmin. Plasmin breaks down fibrin, fibrinogen, and other clotting factors, resulting in dissolution of a coronary artery thrombus.

Incompatibilities

Don't administer tenecteplase through an I.V. line containing dextrose because precipitation may occur.

Contraindications

Active internal bleeding, aneurysm, arteriovenous malformation, bleeding disorders, brain tumor, history of cerebrovascular accident, hypersensitivity to tenecteplase or its components, intracranial or intraspinal surgery or trauma within past 2 months, severe uncontrolled hypertension

Interactions

DRUGS

abciximab, aspirin, clopidogrel, dipyridamole, heparin, oral anticoagulants, ticlopidine: Possibly increased risk of bleeding

Adverse Reactions

CNS: Intracranial hemorrhage

EENT: Epistaxis, gingival bleeding, pharyngeal bleeding

GI: GI and retroperitoneal bleeding

GU: Genitourinary bleeding, prolonged or heavy menstrual bleeding

HEME: Hematoma

RESP: Hemoptysis

SKIN: Bleeding at puncture sites, surgical incision sites, or venous cutdown sites

Nursing Considerations

WARNING Reconstitute tenecteplase for injection immediately before use because drug contains no antibacterial preservatives. If reconstituted drug isn't used immediately, refrigerate vial at 36° to 46° F (2° to 8° C). Discard solution if not used within 8 hours.

- To reconstitute and administer drug, use supplied 10-ml syringe with dual cannula device. Withdraw 10 ml of supplied (preservative-free) sterile water for injection into syringe, and inject entire contents into vial containing tenecteplase dry powder, directing stream of diluent into powder. Gently swirl—don't shake—vial until contents are completely dissolved. If slight foaming occurs during reconstitution, allow drug to stand undisturbed for a few minutes to allow large bubbles to dissipate. Then withdraw prescribed dose of tenecteplase from reconstituted drug in vial, using supplied syringe. Make sure that reconstituted preparation is a colorless to pale yellow transparent solution. Discard any unused solution.
- Give drug as a single I.V. bolus over 5 seconds. Although supplied syringe is intended for use with needleless I.V. systems, be aware that it is also compatible with a conventional needle. Follow manufacturer's directions for use with each system. Flush any dextrose-containing I.V. lines with saline solution before and after administering tenecteplase.

WARNING Monitor patient for evidence of GI bleeding, including bloody or black, tarry stools; bloody or coffee-ground vomitus; and severe stomach pain. Notify prescriber immediately if any of these signs or symptoms develops.

- Assess tenecteplase injection site for signs and symptoms of hematoma, including deep, dark purple bruises under skin and itching, pain, redness, or swelling. Also monitor patient for superficial bleeding, delayed bleeding at puncture sites, and bleeding from surgical incisions.
- Assess for signs and symptoms of intracranial bleeding (such as decreased level of consciousness), retroperitoneal bleeding

(such as abdominal pain or swelling and back pain), genitourinary bleeding (such as hematuria), or respiratory tract bleeding (such as hemoptysis). Notify prescriber immediately if patient develops any of these signs or symptoms.

- If serious bleeding (not controllable by local pressure) occurs, expect to discontinue concomitant heparin or oral antiplatelet therapy immediately.
- If possible, avoid I.M. injections and nonessential handling of patient for first few hours after drug administration.
- If arterial puncture becomes necessary during first few hours after teneceplase administration, expect to use an upper extremity that's accessible to manual compression. Apply pressure for at least 30 minutes after procedure, use a pressure dressing, and frequently monitor puncture site for signs of bleeding.

PATIENT TEACHING

- Advise patient to immediately report any bleeding, including from nose or gums.
- Instruct patient to limit physical activity during teneceplase administration to reduce the risk of injury or bleeding.

terazosin hydrochloride

Hytrin

Class and Category

Chemical class: Quinazoline derivative

Therapeutic class: Antihypertensive, benign prostatic hyperplasia (BPH) treatment

Pregnancy category: C

Indications and Dosages

➤ *To manage hypertension*

CAPSULES

Adults. *Initial:* 1 mg at bedtime.

Maintenance: 1 to 5 mg daily as a single dose or in divided doses every 12 hr.

Maximum: 20 mg daily.

➤ *To treat symptomatic BPH*

CAPSULES

Adults. *Initial:* 1 mg at bedtime, increased in increments to 2 mg, 5 mg, and then 10 mg, as prescribed, based on symptom improvement and urine flow rate.

Maintenance: 5 to 10 mg daily as a single

dose or in divided doses every 12 hr.

Maximum: 20 mg daily.

Route	Onset	Peak	Duration
P.O.	15 min	2–3 hr	24 hr

Mechanism of Action

Blocks postsynaptic α_1 -adrenergic receptors in many tissues, including vascular smooth muscle, the bladder neck, and the prostate. This action promotes vasodilation, which reduces blood pressure and improves urine flow.

Contraindications

Hypersensitivity to terazosin, other quinazolines, or their components

Interactions

DRUGS

clonidine: Possibly decreased clonidine effects

diuretics, other antihypertensives: Additive hypotensive effect

dopamine: Risk of decreased terazosin effects and antagonized vasoconstrictive effect of dopamine (in high doses)

epinephrine: Risk of decreased terazosin effects, possibly severe hypotension and tachycardia

indomethacin, other NSAIDs: Altered terazosin effects related to sodium and fluid retention

methoxamine, phenylephrine: Decreased vasopressor effects, and shortened duration of action of these drugs

phosphodiesterase-5 inhibitors, verapamil: Additive blood pressure-lowering effects and symptomatic hypotension

sympathomimetics: Decreased terazosin effects

Adverse Reactions

CNS: Asthenia, dizziness, headache, lethargy, nervousness, paresthesia, somnolence, syncope, vertigo

CV: Chest pain, hypotension, orthostatic hypotension, palpitations, peripheral edema, sinus tachycardia

EENT: Blurred vision, dry mouth, intraoperative floppy iris syndrome, nasal congestion, sinusitis

GI: Constipation, diarrhea, nausea, vomiting

MS: Arthralgia, back pain

Other: Flulike symptoms, weight gain

Nursing Considerations

- Be aware that prostate cancer should be ruled out before giving terazosin for BPH.
- Expect prescriber to reduce terazosin dosage if a diuretic or another antihypertensive is added to patient's regimen.
- Monitor blood pressure 2 to 3 hours after initial dose because of possible first-dose hypotension and again after 24 hours to evaluate patient's response.
- If patient requires administration by feeding tube, place capsule in 60 ml of warm tap water. Stir until capsule shell dissolves and liquid contents are released into water (5 to 10 minutes).
- Be aware that elderly patients may have exaggerated hypotension and other adverse reactions.

PATIENT TEACHING

- Instruct patient to take terazosin at the same time each night.
- Explain possible first-dose hypotension. Advise patient to change position and rise slowly to prevent syncope early in therapy. Suggest sitting or lying down if dizziness or light-headedness occurs.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to notify prescriber if she misses several doses in a row; caution her against resuming therapy at previous dose.
- Inform patient that drug may take 2 to 6 weeks to improve urinary hesitancy.
- Advise patient to avoid alcohol use, prolonged standing, and excessive exercise or exposure to hot weather because these activities can worsen orthostatic hypotension.
- Stress the importance of regular follow-up visits with prescriber to evaluate patient's response to drug.

terbinafine hydrochloride

Lamisil

Class and Category

Chemical class: Allylamine derivative

Therapeutic class: Antifungal

Pregnancy category: B

Indications and Dosages

↗ *To treat onychomycosis of fingernails and toenails*

TABLETS

Adults and adolescents. 125 mg b.i.d. or 250 mg daily for 6 to 12 wk.

DOSAGE ADJUSTMENT For patients with stable chronic hepatic dysfunction or renal dysfunction (creatinine clearance less than 50 ml/min/1.73 m² or serum creatinine greater than 3.4 mg/dl), dosage reduced by 50%.

Mechanism of Action

Inhibits the conversion of squalene mono-oxygenase to squalene epoxidase, a key enzyme in fungal biosynthesis. The resulting squalene accumulation weakens cell membranes and creates a deficiency of ergosterol, the fungal membrane component necessary for normal fungal growth.

Contraindications

Hypersensitivity to terbinafine or its components

Interactions

DRUGS

beta blockers, MAO inhibitors (type B), selective serotonin reuptake inhibitors, tricyclic antidepressants: Possibly increased blood levels of these drugs

cimetidine, other hepatic enzyme inhibitors: Significantly decreased terbinafine clearance, possibly increased adverse reactions

hepatotoxic drugs: Increased risk of hepatotoxicity

rifampin: Increased clearance and decreased effectiveness of terbinafine

FOODS

caffeine: Decreased caffeine clearance

ACTIVITIES

alcohol use: Increased risk of severe hepatitis

Adverse Reactions

CNS: Headache

EENT: Taste perversion

GI: Abdominal pain, anorexia, diarrhea, elevated liver function test results, flatulence, hepatic failure, indigestion, nausea, vomiting

SKIN: Cutaneous lupus erythematosus,

pruritus, rash, urticaria

Other: Angioedema, systemic lupus erythematosus

Nursing Considerations

- Because terbutaline has been linked to serious adverse hepatic effects, expect to send nail specimens for laboratory testing to confirm onychomycosis before starting therapy.
- Be aware that drug shouldn't be given to patients with chronic or active hepatic disease or renal impairment.
- Monitor patient for hepatic failure (anorexia, dark urine, fatigue, jaundice, nausea, pale stools, right upper abdominal pain, and vomiting). Expect to stop drug and obtain liver function tests if these problems develop.

PATIENT TEACHING

- Instruct patient to space terbutaline doses evenly if taking drug more than once a day.
- Stress the need to complete the full course of terbutaline therapy to prevent relapse of infection.
- Discourage consumption of alcohol during therapy.
- Tell patient to contact prescriber if onychomycosis doesn't improve in a few weeks.

terbutaline sulfate

Brethaire, Brethine, Bricanyl, Bricanyl Turbuhaler (CAN)

Class and Category

Chemical class: Sympathomimetic amine

Therapeutic class: Bronchodilator

Pregnancy category: B

Indications and Dosages

➤ *To prevent or reverse bronchospasm from asthma, bronchitis, or emphysema*

TABLETS (BRETHINE, BRICANYL)

Adults and adolescents age 15 and over.

2.5 to 5 mg t.i.d. at 6-hr intervals while awake. *Maximum:* 15 mg daily.

Children ages 12 to 15. 2.5 mg t.i.d. at 6-hr intervals while awake. *Maximum:* 7.5 mg daily.

Children ages 6 to 11. 50 to 75 mcg/kg t.i.d. at 6-hr intervals while awake. *Maximum:*

150 mcg/kg/dose or 5 mg daily.

SUBCUTANEOUS INJECTION (BRICANYL)

Adults and children age 12 and over.

Initial: 0.25 mg, repeated in 15 to 30 min as prescribed. *Maximum:* 0.5 mg/4-hr period.

Children ages 6 to 12. 5 to 10 mcg (0.005 to 0.01 mg)/kg every 15 to 20 min, up to 3 doses. *Maximum:* 400 mcg (0.4 mg)/dose.

INHALATION AEROSOL (BRETHAIRE)

Adults and children. 2 inhalations (400 mcg) every 4 to 6 hr, as needed and as prescribed.

INHALATION AEROSOL (BRICANYL TURBUHALER)

Adults and children. 1 inhalation (500 mcg), repeated after 5 min, as needed and as prescribed. *Maximum:* 6 inhalations daily.

Route	Onset	Peak	Duration
P.O.	30–90 min	2–3 hr	4–8 hr
SubQ	15–30 min	30–60 min	1.5–4 hr
Inhalation	In 5 min	30–90 min	3–6 hr

Mechanism of Action

Stimulates beta₂-adrenergic receptors in the lungs, which is believed to increase production of cAMP. The increased cAMP level relaxes bronchial smooth muscles, thereby increasing bronchial airflow and relieving bronchospasm.

Contraindications

Hypersensitivity to terbutaline, other sympathomimetic amines, or their components

Interactions

DRUGS

antihypertensives, diuretics: Decreased antihypertensive effect

beta blockers: Mutual inhibition of therapeutic effects, increased risk of bronchospasm

CNS stimulants: Additive CNS stimulation, possibly resulting in adverse effects

digoxin: Increased risk of arrhythmias, possibly digitalis toxicity

halogenated anesthetics: Possibly ventricular arrhythmias

MAO inhibitors: Possibly potentiated action of terbutaline; headache, hyperpyrexia, hypertension, possible hypertensive crisis

maprotiline, tricyclic antidepressants:

Possibly potentiated action of terbutaline
nitrates: Decreased effectiveness of nitrates
ritodrine: Increased effects of either drug
 and potential for adverse effects
sympathomimetics: Increased CNS stimulation
 and risk of adverse cardiovascular effects,
 including prolonged QT interval
thyroid hormones: Increased effects of either
 drug, risk of coronary insufficiency in
 patients with coronary artery disease
xanthines (theophylline): Increased CNS
 stimulation and other additive toxic effects

FOODS

caffeine: Increased CNS stimulation and
 other additive toxic effects

Adverse Reactions

CNS: Anxiety, dizziness, drowsiness, headache,
 insomnia, light-headedness, nervousness,
 restlessness, tremor, weakness

CV: Chest pain, irregular heartbeat, palpitations,
 tachycardia

EENT: Dry mouth, taste perversion

ENDO: Hyperglycemia

GI: Heartburn, nausea, vomiting

MS: Muscle spasms

RESP: Dyspnea

SKIN: Diaphoresis, flushing, rash

Nursing Considerations

- Use terbutaline cautiously in patients with cardiovascular disease because drug can adversely affect cardiovascular function. Monitor patient's heart rate and rhythm and blood pressure, and assess for chest pain.
- For subcutaneous use, inject into lateral deltoid area.
- Assess patient's respiratory rate, depth, and quality; oxygen saturation; and activity tolerance at regular intervals because continuous use of beta₂-agonists for 12 months or longer accelerates the decline in pulmonary function.

PATIENT TEACHING

- Teach patient how to use terbutaline aerosol inhaler or give subcutaneous injection, as needed.
- Instruct patient not to increase dose or frequency without consulting prescriber.
- Urge patient to seek immediate medical attention if symptoms worsen.
- Inform patient that she may experience transient nervousness or tremors during terbutaline therapy.

teriparatide

Forteo

Class and Category

Chemical class: Recombinant human parathyroid hormone (PTH)

Therapeutic class: Bone growth and density regulator

Pregnancy category: C

Indications and Dosages

↗ *To treat osteoporosis in postmenopausal women and primary or hypogonadal osteoporosis in men at high risk for fracture; to treat men and women with glucocorticoid-induced osteoporosis at high risk for fracture*

SUBCUTANEOUS INJECTION

Adults. 20 mcg daily for up to 2 yr.

Route	Onset	Peak	Duration
SubQ	2 hr	4–6 hr	16–24 hr

Contraindications

Hypersensitivity to teriparatide or its components

Interactions

DRUGS

digitalis glycosides: Possibly increased risk of digitalis toxicity

Adverse Reactions

CNS: Asthenia, depression, dizziness, headache, insomnia, paresthesia, syncope, vertigo

CV: Angina pectoris, chest pain, hypertension, transient orthostatic hypotension

EENT: Pharyngitis, rhinitis, taste perversion, tooth disorder

ENDO: Transient hypoparathyroidism

GI: Constipation, diarrhea, indigestion, vomiting

MS: Arthralgia, muscle cramps or spasms in back or leg, neck pain

RESP: Cough, dyspnea, pneumonia

SKIN: Diaphoresis, pruritus, rash, urticaria

Other: Angioedema, generalized pain, injection site reactions (erythema, localized bruising, minor bleeding, pain, pruritus, swelling), transient hypercalcemia or hypocalcemia

Nursing Considerations

WARNING Be aware that teriparatide

Mechanism of Action

Teriparatide, which contains recombinant PTH, stimulates new bone growth and increases bone density. In a patient with osteoporosis, bone density and mass are diminished by an imbalance between bone destruction and formation.

Normally, osteoclasts break down and resorb bone, leaving behind a cavity in a section of bone. Then bone-building cells, called osteoblasts, line the walls of the cavity and stimulate new bone formation. PTH stimulates these actions by attaching to receptors on osteoclasts and osteoblasts, as shown below.

Teriparatide binds to cell-surface receptors on osteoblasts and preferentially stimulates osteoblastic over osteoclastic activity. Also, the drug increases the amount of circulating calcium available for bone formation by increasing the intestinal absorption of calcium and phosphate, thus enhancing the rate of calcium resorption from bone, increasing the reabsorption of calcium, and inhibiting the reabsorption of phosphate in the kidneys. These actions stimulate new bone formation and increase bone density to reduce osteoporotic bone changes.

shouldn't be used to treat patients at risk for osteosarcoma (such as those with Paget's disease or a metabolic bone disease other than osteoporosis), unexplained elevations of alkaline phosphatase, open epiphyses, or prior skeletal radiation or malignancy.

WARNING Be aware that patients with hypercalcemia shouldn't receive teriparatide because drug may worsen hypercalcemia.

- Use drug cautiously in patients with active or recent urolithiasis because drug could worsen this condition.
- Monitor patient closely for allergic reactions because teriparatide is a peptide agent.
- Monitor patient's blood calcium level, and notify prescriber of any elevation; in persistent hypercalcemia, the drug may need to be stopped.
- Monitor patient's blood pressure during the first several doses of drug therapy because of a risk of transient orthostatic hypotension. If this occurs, place patient in a reclining position and alert prescriber.

PATIENT TEACHING

- Teach patient how to administer teriparatide by subcutaneous injection and how to properly use the delivery pen device and dispose of needles. Advise her not to share pen device with others.
- Inform patient that each delivery pen can be used for up to 28 days after the first injection but then should be discarded even if it still contains solution.
- Instruct patient to store the delivery pen in the refrigerator and to recap it when not in use to protect it from damage and light.
- Tell patient that delivery pen may be used immediately after removal from refrigerator.

tor and should be put back in refrigerator as soon as the injection is given.

- Instruct patient to inject drug into thigh or abdominal wall and to rotate injection sites.
- Caution patient to administer drug in a room where she can immediately sit or lie down if light-headedness or palpitations occur. Advise her to notify prescriber if these symptoms persist or worsen.
- Instruct patient to notify prescriber of persistent symptoms of hypercalcemia, such as nausea, vomiting, constipation, lethargy, and muscle weakness.
- Caution patient about potential developing osteosarcoma.

tetracycline hydrochloride

Achromycin, Achromycin V, Apo-Tetra (CAN), Novo-Tetra (CAN), Nu-Tetra (CAN), Panmycin, Robitet, Sumycin, Tetracap, Tetracyl, Tetracyl 500

Class and Category

Chemical class: Chlortetracycline derivative

Therapeutic class: Antibiotic

Pregnancy category: D

Indications and Dosages

↗ *To treat actinomycosis caused by susceptible organisms*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults and adolescents. 250 to 500 mg every 6 hr or 500 to 1,000 mg every 12 hr. *Maximum:* 4 g daily.

Children age 8 and over. 6.25 to 12.5 mg/kg every 6 hr or 12.5 to 25 mg/kg every 12 hr.

↗ *To treat acne vulgaris*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults and adolescents. *Initial:* 500 to 2,000 mg daily in divided doses until improvement occurs (usually in 3 wk); then dosage reduced gradually. *Maintenance:* 125 to 1,000 mg daily. *Maximum:* 4 g daily.

↗ *To treat brucellosis caused by susceptible organisms*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults and adolescents. 500 mg every 6 hr for 3 wk, given with 1 g of streptomycin I.M. every 12 hr in week 1 and daily in week 2. *Maximum:* 4 g daily.

Children ages 8 to 12. 6.25 to 12.5 mg/kg every 6 hr, or 12.5 to 25 mg/kg every 12 hr.

↗ *To treat gonorrhea caused by Neisseria gonorrhoeae*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults and adolescents. 1,500 mg, then 500 mg every 6 hr for 5 days. *Maximum:* 4 g daily.

↗ *To treat syphilis caused by Treponema pallidum*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults and adolescents. 500 mg every 6 hr for 15 days (for early syphilis) or 30 days (for late syphilis). *Maximum:* 4 g daily.

Children ages 9 to 12. 6.25 to 12.5 mg/kg every 6 hr, or 12.5 to 25 mg/kg every 12 hr.

↗ *To treat uncomplicated endocervical, rectal, or urethral infections caused by Chlamydia trachomatis*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults and adolescents. 500 mg q.i.d. for at least 7 days. *Maximum:* 4 g daily.

DOSAGE ADJUSTMENT For patients with renal impairment, dosage possibly reduced because of extended half-life.

Mechanism of Action

Exerts a bacteriostatic effect against a wide variety of gram-positive and gram-negative organisms by passing through the bacterial lipid bilayer, where it binds reversibly to 30S ribosomal subunits. Bound tetracycline blocks the binding of aminoacyl transfer RNA to messenger RNA, thus inhibiting bacterial protein synthesis.

Contraindications

Hypersensitivity to tetracycline or its components

Interactions

DRUGS

aluminum-, calcium-, or magnesium-containing antacids; iron supplements (oral); magnesium-containing laxatives; magnesium salicylate; multivitamins (containing manganese or zinc salts); sodium bicarbonate: Possibly impaired absorption of oral tetracycline and formation of nonabsorbable complexes

cholestyramine, colestipol: Possibly impaired absorption of oral tetracycline

digoxin: Possibly increased digoxin level

methoxyflurane: Possibly nephrotoxicity
oral contraceptives (containing estrogen):

Possibly reduced contraceptive reliability and increased risk of breakthrough bleeding (with long-term tetracycline use)

penicillins: Possibly decreased bactericidal effect of penicillins

vitamin A: Possibly benign intracranial hypertension

FOODS

dairy products and other foods: Possibly impaired absorption of oral tetracycline

Adverse Reactions

CNS: Dizziness, light-headedness, unsteadiness

EENT: Darkened or discolored tongue, enamel hypoplasia, oral candidiasis, tooth discoloration (in children)

GI: Abdominal pain, diarrhea, hepatotoxicity, nausea, rectal candidiasis, vomiting

GU: Vaginal candidiasis

SKIN: Photosensitivity

Nursing Considerations

- Avoid giving tetracycline to children under age 8 because drug may cause permanent brown or yellow tooth discoloration and enamel hypoplasia.
- Be aware that tooth discoloration and enamel hypoplasia may occur in breast-feeding infants, along with inhibition of linear skeletal growth, oral and vaginal candidiasis, and photosensitivity.
- To reduce the risk of esophageal irritation or ulceration, avoid bedtime dosing of tetracycline for patient with esophageal obstruction or compression.
- Assess for photosensitivity, which can develop within a few minutes or up to several hours after exposure to sunlight or other ultraviolet (UV) light. Effects may last for 1 to 2 days after discontinuation of drug.
- Be aware that citric acid in tetracycline preparations may accelerate drug deterioration and that using outdated drug may cause Fanconi's syndrome, characterized by multiple defects in renal tubular function. Symptoms include acidosis, bicarbonate wasting, glycosuria, hypokalemia, osteomalacia, and phosphaturia.

PATIENT TEACHING

- Instruct patient to take oral tetracycline at least 1 hour before meals or 2 hours after meals because dairy products and some foods may interfere with absorption.

- Advise patient to take each dose with a full glass of water while in an upright position to avoid esophageal or GI irritation.
- Instruct patient taking oral suspension to shake container well before measuring dose and to use a calibrated measuring device.
- Advise patient to avoid taking other drugs, including OTC antacids and other preparations, within 3 hours of oral tetracycline.
- Urge patient to complete entire course of tetracycline therapy even if she feels better.
- Caution her to avoid direct sunlight or UV light and to wear sunscreen when outdoors.
- Advise women who use oral contraceptives containing estrogen to use another method of contraception while taking tetracycline because contraceptives may be less effective.
- Stress the need to discard outdated tetracycline because of the risk of toxic effects.
- Encourage patient to take safety precautions if she experiences dizziness or other adverse CNS reactions.

thalidomide

Thalomid

Class and Category

Chemical class: Glutamic-acid derivative

Therapeutic class: Anti-inflammatory, immuno-modulator

Pregnancy category: X

Indications and Dosages

↗ *To treat acute cutaneous erythema nodosum leprosum*

CAPSULES

Adults and adolescents. 100 to 400 mg daily at bedtime or at least 1 hr after the evening meal. *Usual*: 200 mg.

DOSE ADJUSTMENT For patients weighing less than 50 kg (110 lb), dosage started at 100 mg.

↗ *To prevent or suppress recurrence of cutaneous erythema nodosum leprosum*

CAPSULES

Adults and adolescents. Minimum dosage necessary to control reaction; dosage tapered every 3 to 6 mo in increments of 50 mg every 2 to 4 wk, as prescribed.

Mechanism of Action

Suppresses the production of tumor necrosis factor-alpha, which reduces neutrophils and CD4 T cells in erythema nodosum leprosum lesions, thus preventing or controlling symptoms.

Contraindications

Hypersensitivity to thalidomide or its components; men, regardless of history of vasectomy, who refuse to wear latex condom during intercourse with women of childbearing age; pregnancy; women of childbearing age who aren't using two reliable contraceptive methods or aren't abstaining from heterosexual intercourse

Interactions

DRUGS

antihistamines, anxiolytics, barbiturates, chlorpromazine, CNS depressants, hypnotics, opioid analgesics, reserpine, sedatives:

Increased CNS depression

chloramphenicol, cisplatin, dapsone, didanosine, ethambutol, ethionamide, hydralazine, isoniazid, lithium, metronidazole, nitrofurantoin, nitrous oxide, other drugs associated with peripheral neuropathy, phenytoin, stavudine, vincristine, zalcitabine: Increased risk of peripheral neuropathy

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Agitation, anxiety, asthenia, chills, confusion, depression, dizziness, drowsiness, fatigue, fever, headache, insomnia, lethargy, loss of consciousness, malaise, mood changes, nervousness, paresthesia, peripheral neuropathy, seizures, somnolence, status epilepticus, stupor, syncope, tremor, vertigo

CV: Arrhythmias, bradycardia, embolism, hyperlipidemia, hypertension, orthostatic hypotension, peripheral edema, tachycardia, thrombosis

EENT: Dry mouth, oral candidiasis, pharyngitis, rhinitis, sinusitis, tooth pain

ENDO: Hypothyroidism

GI: Abdominal pain, anorexia, constipation, diarrhea, elevated liver function test results, flatulence, hepatic dysfunction, increased appetite, intestinal perforation, nausea, vomiting

GU: Albuminuria, elevated creatinine level,

hematuria, impotence

HEME: Anemia, decreased platelets count, leukopenia, neutropenia, prolonged PT

MS: Arthralgia, back or bone pain, muscle weakness, myalgia, neck pain or rigidity

RESP: Cough, dyspnea, pleural effusion, pulmonary embolism

SKIN: Acne, dermatitis, diaphoresis, dryness, erythema multiforme, photosensitivity, pruritus, rash

Other: Facial edema, hypercalcemia, hyperkalemia, hypocalcemia, hypokalemia, hyponatremia, increased alkaline phosphatase level, lymphadenopathy, pain (generalized), tumor lysis syndrome, weight loss or gain

Nursing Considerations

- Be aware that all patients receiving thalidomide must complete an informed consent form and participate in a confidential monitoring registry. Thalidomide may be obtained only through physicians and pharmacies registered in the System for Thalidomide Education and Prescribing Safety (STEPS) Program, a comprehensive safety program designed to prevent fetal exposure to thalidomide. Thalidomide may be dispensed only in original packaging and in no more than a 28-day supply. Prescriptions older than 7 days may not be filled.
- Be aware that female patients of childbearing age must use two contraceptive methods during therapy. Pregnancy testing must be performed 24 hours before starting thalidomide, weekly during first month of therapy, then monthly thereafter in women with regular menstrual cycles or every 2 weeks in women with irregular menstrual cycles.

WARNING Be aware that thalidomide shouldn't be given to pregnant patient. A single dose may cause severe birth defects or fetal death.

- Assess patient's medication history for use of carbamazepine, griseofulvin, HIV-protease inhibitors, modafinil, penicillins, phenytoin, rifabutin, rifampin, and the herbal remedy St. John's wort. These products can decrease the effectiveness of hormonal contraceptives during thalidomide therapy.

WARNING Monitor patient closely for evi-

dence of a venous thromboembolic event (shortness of breath, chest pain, or arm or leg swelling). Notify prescriber immediately and expect to assist with diagnostic studies to confirm suspicions and provide treatment, as ordered.

- To minimize sedative effect, give thalidomide in divided doses t.i.d. or q.i.d., as prescribed, with larger dose in the evening.
- Assess for early signs of peripheral neuropathy (muscle cramps, numbness and tingling in toes and fingers, pain or superficial sensory loss in feet or hands) in patients receiving long-term thalidomide therapy. Early detection and drug discontinuation, as prescribed, prevents further damage and increases the chance for reversal.
- Expect to stop thalidomide if absolute neutrophil count is less than $750/\text{mm}^3$. Routine monitoring of WBC count is recommended every other week for first 3 months of treatment in HIV-positive and other immunosuppressed patients and monthly in immunocompetent patients.

PATIENT TEACHING

- Instruct patient to have thalidomide prescription filled promptly because prescriptions more than 7 days old may not be filled.
- Urge patient to take drug exactly as prescribed.
- Inform female patient that drug will harm a fetus, and stress the need to avoid pregnancy. Tell her that pregnancy tests will be done before and frequently during therapy.
- Instruct female patient to abstain from sexual intercourse or to use two reliable methods of birth control simultaneously, starting 4 weeks before drug therapy and continuing for up to 4 weeks after therapy has been completed. One contraceptive method must be highly effective, such as an intrauterine device, oral contraceptive, or tubal ligation; the other may be a cervical cap, diaphragm, or latex condom.

WARNING Inform male patient, even one who has had a vasectomy, that he must use barrier contraception (latex condom) when having sexual intercourse with a woman of childbearing age.

- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Suggest changing positions slowly to minimize effects of orthostatic hypotension.
- Instruct patient to immediately report signs of peripheral neuropathy, including numbness, pain, or tingling in feet and hands.
- Inform HIV-positive patient of the need for viral-load testing after first and third months of therapy and then every 3 months.
- Urge patient to avoid using alcohol and donating blood or sperm during therapy.

theophylline

Aerolate, Aerolate III, Aerolate Jr., Aerolate Sr., Apo-Theo LA (CAN), Asmalix, Elixophyllin, Lanophyllin, PMS Theophylline (CAN), Pulmophylline (CAN), Quibron-T Dividose, Quibron-T/SR Dividose, Respbid, Slo-Bid Gyrocaps, Slo-Phyllin, Theo-24, Theo-SR (CAN), Theobid Duracaps, Theochron, Theoclear, Theoclear LA, Theo-Dur, Theolair, Theolair-SR, Theovent Long-Acting, T-Phyl, Truxophyllin, Uni-Dur, Uniphyl

Class and Category

Chemical class: Xanthine derivative

Therapeutic class: Bronchodilator

Pregnancy category: C

Indications and Dosages

↗ *As loading dose to treat reversible airway obstruction in patients not currently receiving theophylline*

CAPSULES, ELIXIR, ORAL SOLUTION, SYRUP, TABLETS

Adults and children. 5 mg/kg as a single dose.

I.V. INFUSION

Adults and children. 5 mg/kg infused over 20 to 30 min.

↗ *As partial loading dose to treat reversible airway obstruction in patients currently receiving theophylline*

CAPSULES, ELIXIR, ORAL SOLUTION, SYRUP, TABLETS, I.V. INFUSION

Adults and children. Individualized dosage based on blood theophylline level, as pre-

scribed. Loading dose based on principle that 0.5 mg/kg of theophylline will produce a 1-mcg/ml increase in blood theophylline level.

↗ *To provide maintenance treatment of reversible airway obstruction associated with asthma or COPD*

CAPSULES, TABLETS

Adults and children weighing more than 45 kg (99 lb). *Initial:* 300 mg daily in equally divided doses every 6 to 8 hr; after 3 days, if tolerated, increased to 400 mg daily in divided doses every 6 to 8 hr; after 3 more days, if tolerated, increased to 600 mg daily in divided doses every 6 to 8 hr. Dosages above 600 mg daily are based on blood theophylline level and clinical response.

Children age 1 and over weighing 45 kg or less. *Initial:* 12 to 14 mg/kg daily up to maximum of 300 mg daily in equally divided doses every 4 to 6 hr; after 3 days, if tolerated, increased to 16 mg/kg up to maximum of 400 mg daily in equally divided doses every 4 to 6 hr; after 3 more days, if tolerated, 20 mg/kg daily up to maximum of 600 mg daily in equally divided doses every 4 to 6 hr. Dosages above 600 mg daily are based on blood theophylline level and clinical response.

ELIXIR

Adults. *Initial:* 300 mg daily in equally divided doses every 6 to 8 hr; after 3 days, if tolerated, increased to 400 mg daily in divided doses every 6 to 8 hr; after 3 more days, if tolerated, increased to 600 mg daily in divided doses every 6 to 8 hr. Dosages above 600 mg daily are based on blood theophylline level and clinical response.

E.R. CAPSULES OR TABLETS

Adults and children weighing 45 kg or more. *Initial:* 300 mg daily in equally divided doses every 8 to 12 hr; after 3 days, if tolerated, increased to 400 mg daily in divided doses every 8 to 12 hr; after 3 more days, if tolerated, increased to 600 mg daily in divided doses every 8 to 12 hr. Dosages above 600 mg daily are based on blood theophylline level and clinical response.

Children age 1 and over weighing less than 45 kg. *Initial:* 12 to 14 mg/kg daily up to maximum of 300 mg daily in equally divided doses every 8 to 12 hr; after 3 days, if tolerated, increased to 16 mg/kg up to maximum

of 400 mg daily in equally divided doses every 8 to 12 hr; after 3 more days, if tolerated, dosage increased to 20 mg/kg daily up to maximum of 600 mg daily in equally divided doses every 8 to 12 hr. Dosages above 600 mg daily are based on blood theophylline level and clinical response.

ORAL SOLUTION, SYRUP

Adults and children weighing more than 45 kg. *Initial:* 300 mg daily in equally divided doses every 6 to 8 hr; after 3 days, if tolerated, increased to 400 mg daily in divided doses every 6 to 8 hr; after 3 more days, if tolerated, increased to 600 mg daily in divided doses every 6 to 8 hr. Dosages above 600 mg daily are based on blood theophylline level and clinical response.

Children age 1 and over weighing 45 kg or less. *Initial:* 12 to 14 mg/kg daily up to maximum of 300 mg daily in equally divided doses every 4 to 6 hr; after 3 days, if tolerated, increased to 16 mg/kg up to a maximum of 400 mg daily in equally divided doses every 4 to 6 hr; after 3 more days, if tolerated, dosage increased to 20 mg/kg daily up to maximum of 600 mg daily in equally divided doses every 4 to 6 hr. Dosages above 600 mg daily are based on blood theophylline level and clinical response.

Full-term infants ages 26 to 52 weeks.

Dosage individualized in mg/kg daily, as prescribed, and administered in equally divided doses every 6 hr.

Full-term infants up to age 26 weeks.

Dosage individualized in mg/kg daily, as prescribed, and administered in equally divided doses every 8 hr.

Premature infants age 24 days and over.

1.5 mg/kg every 12 hr.

Premature infants under age 24 days.

1 mg/kg every 12 hr.

I.V. INFUSION

Adults and adolescents age 16 and over.

0.4 mg/kg/hr for nonsmokers, 0.7 mg/kg/hr for smokers.

DOSAGE ADJUSTMENT For elderly patients and adults with cardiac decompensation, cor pulmonale, or hepatic impairment, I.V. dosage reduced to 0.2 mg/kg/hr.

Children ages 9 to 16. 0.7 mg/kg/hr.

Children ages 1 to 9. 0.8 mg/kg/hr.

Full-term infants up to age 1. Dosage indi-

vidualized in mg/kg daily as prescribed.

Mechanism of Action

Inhibits phosphodiesterase enzymes, causing bronchodilation. Normally, these enzymes inactivate cAMP and cGMP, which are responsible for bronchial smooth-muscle relaxation. Theophylline also may cause calcium translocation, antagonize prostaglandins and adenosine receptors, stimulate catecholamines, and inhibit cGMP metabolism.

Incompatibilities

Don't mix parenteral theophylline solution with any additives. Don't infuse theophylline through same I.V. line as Hetastarch (Hespan), a colloidal plasma volume expander, which is incompatible with theophylline.

Contraindications

Hypersensitivity to theophylline or its components, peptic ulcer disease, uncontrolled seizure disorder

Interactions

DRUGS

adenosine: Decreased adenosine effectiveness

allopurinol, cimetidine, ciprofloxacin, clarithromycin, disulfiram, enoxacin, erythromycin, fluvoxamine, interferon alpha (human recombinant), methotrexate, mexiletine, pentoxifylline, propafenone, propranolol, tacrine, thiabendazole, ticlopidine, troleandomycin, verapamil: Increased blood theophylline level and risk of toxicity

aminoglutethimide, carbamazepine, isoproterenol (I.V.), moricizine, oral contraceptives (containing estrogen), phenobarbital, phenytoin, rifampin: Decreased blood theophylline level and possibly drug effectiveness

benzodiazepines: Possibly reversal of benzodiazepine sedation

beta blockers: Possibly decreased bronchodilator effect of theophylline

ephedrine: Increased adverse effects, including insomnia, nausea, and nervousness

halothane anesthetics: Increased risk of ventricular arrhythmias

ketamine: Lowered seizure threshold

lithium: Decreased lithium effectiveness

neuromuscular blockers: Possibly antagonized neuromuscular blockade

sucralfate: Decreased absorption of oral theophylline

FOODS

high-carbohydrate, low-protein diet: Possibly decreased theophylline elimination

low-carbohydrate, high-protein diet; daily intake of charbroiled beef: Possibly increased theophylline elimination

ACTIVITIES

alcohol use: Increased blood theophylline level and risk of toxicity

smoking: Increased drug clearance, decreased drug effectiveness

Adverse Reactions

CNS: Agitation, anxiety (I.V. form), behavioral changes, confusion, disorientation, headache, insomnia, nervousness, seizures, tremor

CV: Hypotension, tachycardia, ventricular arrhythmias

ENDO: Hyperglycemia

GI: Abdominal pain, diarrhea, heartburn, nausea, vomiting

GU: Increased urine output

Other: Hypercalcemia

Nursing Considerations

- Be aware that ideal body weight is used to calculate theophylline dosages because drug doesn't bind well in body fat.
- Be aware that E.R. capsules and tablets shouldn't be used for oral loading doses.
- Infuse theophylline loading dose, bolus, or intermittent infusion at a rate that doesn't exceed 25 mg/min.
- Administer continuous theophylline infusion with rate-controlled infusion device.
- Monitor blood theophylline level, as ordered, to gauge therapeutic level and detect toxicity.
- Frequently assess heart rate and rhythm because theophylline can exacerbate existing arrhythmias.
- Be especially alert for signs of toxicity in patient with acute pulmonary edema, hypothyroidism, influenza vaccination, prolonged fever, sepsis with multiple organ failure, shock, or viral pulmonary infection because of decreased drug clearance.
- Monitor blood theophylline level in patients with uncorrected acidemia because they have an increased risk of toxicity.

- Expect patient with cystic fibrosis or hyperthyroidism to have increased theophylline clearance and decreased drug effectiveness. Monitor blood theophylline level, as ordered.
- Suspect toxicity if patient experiences vomiting, and be prepared to obtain blood theophylline level.

PATIENT TEACHING

- Instruct patient to swallow theophylline tablets whole and not to chew or crush them, unless scored for breaking.
- Explain that patient may open capsules and mix contents with soft food but that she shouldn't chew or crush granules.
- Instruct patient to take drug with a full glass of water on an empty stomach (30 to 60 minutes before meals or 2 hours after meals). However, suggest that she take drug with food or antacids if GI distress occurs.
- Encourage patient to take drug at the same times every day.
- Advise patient to notify prescriber if she develops a fever, makes a significant dietary change, or starts or stops smoking or taking other drugs because these factors may alter blood theophylline level.
- Tell female patient to notify prescriber if she is or could be pregnant.

thiethylperazine maleate

Torecan

Class and Category*Chemical class:* Piperazine phenothiazine*Therapeutic class:* Antiemetic*Pregnancy category:* Not rated**Indications and Dosages**➤ *To treat nausea and vomiting***TABLETS, I.M. INJECTION, SUPPOSITORIES****Adults and adolescents.** 10 mg once daily to t.i.d. *Maximum:* 30 mg daily.

Route	Onset	Peak	Duration
P.O.	30–60 min	Unknown	4 hr

Mechanism of Action

Relieves nausea and vomiting by centrally

blocking dopamine receptors in the medullary chemoreceptor trigger zone.

Contraindications

Breast-feeding; coma; hypersensitivity to thiethylperazine, sulfites, tartrazine dye, or their components; jaundice; severe CNS depression

Interactions**DRUGS**

aluminum- or magnesium-containing antacids, antidiarrheals (adsorbent): Decreased absorption of thiethylperazine

anticonvulsants (including barbiturates): Lowered seizure threshold

antihistamines, tricyclic antidepressants: Additive CNS and GI effects, including ileus and severe constipation

antihypertensives: Enhanced hypotensive effect of both drugs

antimuscarinics (including antiparkinsonian drugs, MAO inhibitors, meperidine, and phenothiazines): Additive GI effects, including ileus and severe constipation

appetite suppressants: Decreased anorectic effect

barbiturates, benzodiazepines, CNS depressants, general anesthetics, opioid analgesics: Additive CNS effects

beta blockers: Increased blood levels of both drugs; additive hypotensive effects; possibly arrhythmias, irreversible retinopathy, and tardive dyskinesia

bromocriptine: Possibly decreased effectiveness of bromocriptine

hepatotoxic drugs: Increased risk of hepatotoxicity

levodopa: Decreased effectiveness of levodopa

lithium: Possibly acute encephalopathy

methoxsalen, porfimer: Possibly increased photosensitivity

metrizamide: Increased risk of seizures

ototoxic drugs: Possibly masked symptoms of ototoxicity (dizziness, tinnitus, and vertigo)

phenytoin: Increased risk of phenytoin toxicity

quinidine: Possibly adverse cardiac effects

riboflavin: Increased requirements for riboflavin

sympathomimetics: Reduced vasopressor response and duration of action of sympathomimetics

tramadol: Additive CNS effects, increased risk of seizures

ACTIVITIES

alcohol use: Additive CNS effects

Adverse Reactions

CNS: Confusion, dizziness, EEG abnormalities, extrapyramidal reactions (dystonia, pseudoparkinsonism), sedation

CV: ECG changes, hypotension, orthostatic hypotension, tachycardia

EENT: Blurred vision, dry mouth

ENDO: Gynecomastia

GI: Constipation, increased appetite

GU: Darkened urine, ejaculation disorders, menstrual irregularities, urine retention

HEME: Agranulocytosis, leukopenia (transient)

SKIN: Contact dermatitis, photosensitivity

Other: Weight gain

Nursing Considerations

- Avoid using thiethylperazine in patients with neurologic impairment because drug can disrupt central temperature regulation.
- Avoid inadvertent I.V. administration of thiethylperazine; injection is for I.M. administration only.
- Keep patient in recumbent position for 30 to 60 minutes after I.M. injection to minimize the risk of hypotension.
- Be aware that parenteral preparations contain sulfites and that tablets contain tartrazine dye.
- Moisten suppository with water or water-soluble lubricant before insertion. If suppository has softened excessively, chill for 30 minutes or run under cold water before removing wrapper.
- Avoid skin contact with drug to prevent contact dermatitis.
- Because thiethylperazine may cause reactions from anticholinergic effects and adrenergic blockade, assess for blurred vision, constipation, dry mouth, impotence, urine retention (from cholinergic activity) and priapism (from alpha-adrenergic blockade).
- During prolonged therapy, assess for visual disturbances because drug may cause corneal keratopathy and retinal discoloration (pigmentary retinopathy).

WARNING Be aware that thiethylperazine may cause neuroleptic malignant syndrome, a rare but extremely serious reac-

tion characterized by cardiovascular instability, decreased level of consciousness, extrapyramidal effects, and hyperpyrexia.

- Monitor CBC with differential, as ordered, because drug may worsen existing blood dyscrasias, such as agranulocytosis, neutropenia, and thrombocytopenia, in patients with bone marrow suppression. Be aware that drug may worsen angle-closure glaucoma, encephalopathy, organic or traumatic brain damage, or tardive dyskinesia.
- When possible, avoid combining thiethylperazine with CNS depressants because these drugs may potentiate thiethylperazine's effects.
- Monitor patient with cardiac disease for exaggerated cardiovascular reactions.
- Implement seizure precautions and monitor for seizures in patients with known seizure disorder because drug may lower seizure threshold.
- Implement safety precautions, according to facility policy, for elderly patients. They may be especially sensitive to drug's sedative and extrapyramidal effects.
- Be prepared to discontinue drug 48 hours before myelography and to resume drug 24 to 48 hours afterward to minimize the risk of seizures.
- Be aware that photosensitivity may turn patient's skin yellow-brown, gray, or purple because of hyperpigmentation.
- Be aware that drug shouldn't be given to pregnant patient because it may cause jaundice and extrapyramidal symptoms in her neonate.

PATIENT TEACHING

- Instruct patient to stay recumbent for 1 hour after taking thiethylperazine to minimize effects of orthostatic hypotension.
- Advise patient to notify prescriber immediately about adverse CNS reactions, decreased urine output, or vision changes.
- Urge patient to avoid alcohol use and potentially hazardous activities during therapy.
- Encourage patient to avoid excessive sun exposure and to use sunscreen when she's outdoors.
- Advise patient on long-term therapy to have periodic eye examinations to detect possible eye disorders.

thiopental sodium

Pentothal

Class, Category, and Schedule

Chemical class: Barbiturate

Therapeutic class: Anticonvulsant, sedative-hypnotic

Pregnancy category: C

Controlled substance: Schedule III

Indications and Dosages

➤ *To control seizures from anesthesia or other causes*

I.V. INJECTION

Adults. *Initial:* 75 to 125 mg (3 to 5 ml of 2.5% solution) as soon as possible after onset of seizure. *Maximum:* 250 mg given over 10 min.

➤ *To facilitate narcoanalysis*

I.V. INFUSION OR INJECTION

Adults. Dosage individualized based on patient's age, condition, sex, and weight; injected at 100 mg/min (4 ml/min of 2.5% solution) with patient counting backwards from 100. Expect to discontinue injection once patient becomes confused with her counting but is still awake. Or, use 0.2% concentration in D₅W for injection and infuse at 50 ml/min.

➤ *To treat cerebral hypertension*

I.V. INFUSION OR INJECTION

Adults. 1.5 to 3.5 mg/kg, repeated as needed, to reduce elevated intracranial pressure (ICP).

Route	Onset	Peak	Duration
I.V.	10–40 sec	Unknown	10–30 min

Mechanism of Action

Depresses the CNS and may inhibit ascending transmission of impulses in the reticular formation. Thiopental may enhance or mimic inhibitory action of gamma-aminobutyric acid, thereby causing anticonvulsant effect and producing sedation and hypnosis. Thiopental may reduce ICP by increasing cerebral vascular resistance, which decreases cerebral blood flow and volume.

Incompatibilities

Don't mix thiopental with acidic I.V. drugs or solutions, succinylcholine, or tubocurarine.

Contraindications

History of porphyria; hypersensitivity to thiopental, its components, or other barbiturates

Interactions

DRUGS

clonidine, CNS depressants, guanabenz, magnesium sulfate, methyl dopa, metyrosine, pargyline, rauwolfia alkaloids: Additive CNS depressant effects
diazoxide, diuretics, guanadrel, guanethidine, mecamylamine, trimethaphan: Possibly additive hypotensive effect
ketamine: Increased risk of hypotension or respiratory depression; possibly countered hypnotic effect of thiopental
phenothiazines: Possibly increased CNS depression or excitation, increased hypotensive effect

ACTIVITIES

alcohol use: Additive CNS depressant effects

Adverse Reactions

CNS: Agitation, anxiety, seizures

CV: Bradycardia, hypotension, shock, tachycardia, thrombophlebitis

GI: Hiccups

RESP: Apnea, bronchospasm, cough, laryngospasm, respiratory depression, wheezing

SKIN: Hives, itching, rash, redness

Other: Angioedema

Nursing Considerations

- Before administering thiopental, expect to premedicate patient with an anticholinergic, such as atropine or glycopyrrolate, to minimize secretions.
- Be prepared to administer a test dose of 25 to 75 mg (1 to 3 ml of 2.5% solution) to determine tolerance or sensitivity. Expect to observe patient for at least 1 minute after administering test dose.
- Dilute drug with a compatible I.V. solution before administering, such as D₅W for injection, normal saline solution for injection, or sterile water for injection. Be aware that sterile water for injection shouldn't be used to prepare 0.2% or 0.4% solution because it would result in a hypotonic solution and cause hemolysis.
- To prepare 0.2% solution, dilute 1 g of thiopental with 500 ml of compatible diluent to produce a final concentration of 2 mg/ml.

- To prepare 0.4% solution, dilute 1 g thio-pental with 250 ml compatible diluent or 2 g thio-pental with 500 ml compatible diluent to produce a final concentration of 4 mg/ml.
- To prepare 2.5% solution, dilute 1 g of thio-pental with 40 ml of compatible dilu-ent or 5 g of thio-pental with 200 ml of compatible diluent to produce a final con-centration of 25 mg/ml.
- Inspect solution for particles before administration. Use solution within 24 hours of reconstitution, and discard unused portion after 24 hours.
- Monitor patient's blood and tissue oxy-genation and vital signs during I.V. administration. Keep emergency equip-ment and drugs nearby in case respiratory depression occurs.
- If patient has a history of CV disease or hypotension, monitor her for CV depres-sant effects, such as bradycardia, hypoten-sion, or shock.
- In patient with a history of seizures, insti-tute seizure precautions according to facil-ity protocol.
- Monitor respiratory rate, rhythm, and quality for signs of respiratory depression in debilitated patient or one with a history of respiratory disease.
- Monitor patient's neurologic status every hour, or as ordered, in patient with increased ICP.

PATIENT TEACHING

- Explain the need for frequent hemody-namic monitoring.
- Advise patient to use caution when driv-ing or performing tasks that require alert-ness for at least 24 hours after receiving thio-pental.
- Instruct patient not to consume alcohol or other CNS depressants for at least 24 hours after thio-pental administration (unless prescribed) because they increase the effects of thio-pental.
- Instruct patient to report persistent drowsiness, rash, severe dizziness, or skin lesions to prescriber.

thioridazine

Mellaril (CAN), Mellaril-S, Novo-Ridazine (CAN)

thioridazine hydrochloride

Apo-Thioridazine (CAN), Mellaril, Mellaril Concentrate, Novo-Ridazine (CAN), PMS Thioridazine

Class and Category

Chemical class: Piperidine phenothiazine

Therapeutic class: Antipsychotic drug

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat schizophrenia in patients un-responsive to other antipsychotic drugs*

ORAL SOLUTION, ORAL SUSPENSION, TABLETS

Adults and adolescents. *Initial:* 50 to 100 mg t.i.d., gradually increased, as needed and tolerated. *Maintenance:* 200 to 800 mg daily in two to four divided doses.

Maximum: 800 mg daily.

Children ages 2 to 12. *Initial:* 0.5 mg/kg daily in divided doses, gradually increased, as needed and tolerated. *Maximum:* 3 mg/kg daily.

Route	Onset	Peak	Duration
P.O.	Up to several wk	6 wk–6 mo	Unknown

Mechanism of Action

Depresses areas of the brain that control activity and aggression, including the cere-bral cortex, hypothalamus, and limbic sys-tem by blocking postsynaptic dopamine₂ (D₂) receptors. Drug may relieve anxiety by indirectly reducing arousal and increasing filtration of internal stimuli to the brain stem reticular activating system.

Contraindications

Coma; concurrent use of drugs that inhibit the metabolism of thioridazine, such as flu-oxetine, fluvoxamine, paroxetine, pindolol, and propranolol; concurrent use of drugs that prolong the QT interval; concurrent use of high doses of a CNS depressant; his-tory of arrhythmias; hypersensitivity to thioridazine, other phenothiazines, or their components; prolonged QT interval; reduced cytochrome P450 2D6 activity; severe CNS depression; severe hypertensive or hypertensive cardiac disease

Interactions**DRUGS**

amantadine, antihistamines, antimuscarinics, clozapine, cyclobenzaprine, diphenoxylate, disopyramide, maprotilene: Additive anticholinergic effects

amiodarone, bepridil, cisapride, disopyramide, erythromycin, flecainide, grepafloxacin, ibutilide, pimozide, probucol, procainamide, quinidine, sotalol, sparfloxacin, tocainide: Possibly prolonged QT interval

amphetamine, chlorpromazine, dextroamphetamine: Possibly decreased effects of these drugs and thioridazine

antacids, antidiarrheals (adsorbent), kaolin, rifabutin, rifampin, rifapentine: Reduced bioavailability of thioridazine

anxiolytics, benzodiazepines, clonidine, dronabinol, guanabenz, guanfacine, opioid analgesics, phenothiazines, sedative-hypnotics: Possibly increased CNS effects or hypotension

barbiturates, fosphenytoin, phenytoin, valproic acid: Increased CNS depression, lowered seizure threshold

bromocriptine: Possibly decreased effectiveness of bromocriptine

carbamazepine: Possibly decreased blood thioridazine level

charcoal: Reduced thioridazine absorption

dopamine, droperidol, haloperidol, metoclopramide, metyrosine: Possibly increased adverse CNS effects

ephedrine, epinephrine, norepinephrine, phenylephrine: Possibly severe hypotension, MI, or tachycardia

fluoxetine, fluvoxamine, other cytochrome P450 2D6 inhibitors, paroxetine, pindolol: Inhibited metabolism of thioridazine, leading to elevated blood thioridazine level

general anesthetics: Possibly potentiated CNS depression

guanadrel, guanethidine, methyl dopa: Inhibited hypotensive effect of these drugs

levodopa, pergolide, pramipexole, ropinirole: Possibly inhibited antiparkinsonian response

lithium (high doses): Risk of encephalopathic syndrome (characterized by confusion, elevated liver function test results and fasting blood glucose level, extrapyramidal symptoms, fever, lethargy, leukocytosis, and weakness)

MAO inhibitors: Possibly exaggerated

extrapyramidal reactions

methoxsalen, oral contraceptives, porfimer, sulfonamides, sulfonylureas, tetracyclines, thiazide diuretics, vitamin A analogues: Possibly increased photosensitivity

propranolol: Increased blood propranolol and thioridazine levels, increased CNS effects, hypotension

tramadol: Increased blood tramadol level, possibly increased risk of seizures

trazodone: Possibly additive hypotension

ACTIVITIES

alcohol use: Additive CNS effects

Adverse Reactions

CNS: Akathisia, altered temperature regulation, depression, dizziness, drowsiness, extrapyramidal reactions (dystonia, laryngospasm, motor restlessness, pseudoparkinsonism), headache, insomnia

CV: ECG changes, hypertension, hypotension, prolonged QT interval, torsades de pointes, ventricular tachycardia

EENT: Blurred vision, change in color perception, dry mouth, impaired night vision, mydriasis, photophobia

ENDO: Breast engorgement, galactorrhea

GI: Constipation, ileus, nausea

GU: Amenorrhea, decreased libido, ejaculation disorders, impotence, menstrual irregularities, priapism, urine retention

HEME: Agranulocytosis, anemia, aplastic anemia, eosinophilia, leukocytosis, leukopenia, pancytopenia, thrombocytopenia

SKIN: Hyperpigmentation, jaundice, photosensitivity

Other: Weight gain

Nursing Considerations

WARNING Expect to give thioridazine only if patient has failed to respond to therapy with at least two other antipsychotic drugs because thioridazine may prolong the QT interval and has been associated with torsades de pointes and sudden death.

WARNING Thioridazine shouldn't be used to treat elderly patients with dementia-related psychosis because drug increases the risk of death in these patients.

- Obtain baseline and serial ECG tracings and serum potassium levels, as ordered. Notify prescriber if QT interval is greater than 500 msec or if potassium level is abnormal, and expect to discontinue drug immediately.

- Frequently monitor blood pressure and assess for chest pain in patients with heart disease because thioridazine has caused hypotension and has precipitated angina on occasion. Also monitor urine output in patients with benign prostatic hyperplasia because drug can worsen urine retention.
- Be aware that high doses and large dosage changes in patient with a seizure disorder may lower seizure threshold. Institute seizure precautions, as appropriate, according to facility policy.
- Administer drug with food, milk, or a full glass of water to minimize GI distress.
- Measure oral suspension using calibrated measuring device. Dilute with 60 to 120 ml of fruit juice, distilled water, or acidified tap water immediately before administration.
- Don't give thioridazine oral suspension with carbamazepine oral suspension; a rubbery orange precipitate may form in stool.
- To prevent contact dermatitis, don't let oral solution come in contact with skin.
- Administer antacid or adsorbent antidiarrheal at least 1 hour before or 2 hours after thioridazine.

WARNING Be aware that thioridazine can cause neuroleptic malignant syndrome—most commonly in male patients. Signs and symptoms include altered level of consciousness, altered mental status, autonomic instability (diaphoresis, hypotension or hypertension, sinus tachycardia), hyperthermia, and severe extrapyramidal dysfunction. Acute renal failure, increased serum creatine phosphokinase level, and leukocytosis also have occurred. Notify prescriber immediately if such symptoms develop, and be prepared to discontinue therapy.

- Be aware that drug shouldn't be discontinued abruptly. Sudden withdrawal of thioridazine may produce transient dizziness, nausea, tremor, and vomiting.
- Assess for eye pain because drug's anticholinergic effects can worsen angle-closure glaucoma.
- Promptly investigate and report blurred vision, defective color perception, or impaired night vision because of the risk of pigmentary retinopathy.
- Expect prescriber to discontinue thiorida-

zine and order CBC if patient experiences signs of infection. Also expect drug therapy to be stopped 48 hours before myelography and resumed 24 to 48 hours afterward.

- Monitor patient for signs and symptoms of tardive dyskinesia—such as uncontrollable movements of the arms, face, or legs—even after treatment stops. Notify prescriber if they develop.

PATIENT TEACHING

- Instruct patient to take thioridazine exactly as prescribed and not to stop taking drug without consulting prescriber because of the risk of withdrawal symptoms.
- Instruct patient to notify prescriber immediately if she develops unusual symptoms, such as dizziness, palpitations, and syncope, because they may indicate the presence of torsades de pointes.
- Advise patient not to take drug within 2 hours of an antacid.
- Caution patient to avoid alcohol use, which increases thioridazine's sedative effects, and to avoid hazardous activities if drowsiness occurs.
- Urge patient to notify prescriber immediately if she experiences blurred vision, defective color perception, difficulty with nighttime vision, excessive drowsiness, nausea, sore throat, or other signs of infection. Thioridazine treatment may be discontinued.
- Advise female patient to use effective contraception while taking drug because its fetal effects are unknown. Instruct her to inform prescriber immediately of known or suspected pregnancy.
- Because drug may alter temperature regulation, encourage patient to avoid exposure to extreme temperatures during therapy.
- Advise patient to wear protective dark glasses to minimize the effects of adverse vision reactions.
- If patient requires long-term therapy, explain the risk of tardive dyskinesia, and urge her to notify prescriber immediately if she develops uncontrollable movements of her arms, face, or legs.
- Instruct patient to tell other prescribers that she's taking thioridazine before she takes any new drug.

thiothixene

Navane

thiothixene hydrochloride

Navane, Thiothixene HCl Intensol

Class and Category

Chemical class: Thioxanthene derivative

Therapeutic class: Antipsychotic

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat psychotic disorders, such as acute psychosis, psychotic depression, and schizophrenia*

CAPSULES (THIOTHIXENE), ORAL SOLUTION (THIOTHIXENE HYDROCHLORIDE)

Adults and children age 12 and over.

Initial: 2 mg t.i.d. (for mild conditions) or 5 mg b.i.d. (for more severe conditions), increased every wk, as needed. *Usual:* 10 to 40 mg daily in divided doses. *Maximum:* 60 mg daily (for severe conditions).

DOSE ADJUSTMENT For elderly patients, lowest effective dosage used for maintenance therapy; maximum dosage limited to 30 mg/ day. For some patients, one daily dose possibly used for maintenance therapy.

I.M. INJECTION (THIOTHIXENE HYDROCHLORIDE)

Adults. *Initial:* 4 mg b.i.d. to q.i.d. *Optimal:* 4 mg every 6 to 12 hr. *Usual:* 16 to 20 mg daily in divided doses. *Maximum:* 30 mg daily.

Mechanism of Action

Increases dopamine turnover by blocking postsynaptic dopamine receptors in the mesolimbic system. Eventually, dopamine neurotransmission decreases, resulting in antipsychotic effects.

Contraindications

Blood dyscrasias, coma, hypersensitivity to thiothixene or its components, Parkinson's disease, severe CNS depression, shock, use of quinidine

Interactions

DRUGS

amphetamines: Decreased effectiveness of either drug

antacids, antidiarrheals (adsorbent): Possibly

reduced bioavailability of thiothixene
antihistamines, tricyclic antidepressants: Additive anticholinergic effects, causing severe constipation, ileus, or increased intraocular pressure
bromocriptine: Possibly increased serum prolactin level and decreased effectiveness of bromocriptine
carbamazepine: Possibly decreased blood thiothixene level

dopamine: Decreased vasoconstrictive effect of dopamine (in high doses)

ephedrine, phenylephrine: Possibly reduced vasopressor response

epinephrine: Possibly epinephrine reversal, leading to severe hypotension, tachycardia, and possibly MI

erythromycin: Increased adverse effects of thiothixene

general anesthetics, opioid analgesics, tramadol: Additive CNS effects, increased risk of seizures

guanadrel, guanethidine: Possibly decreased antihypertensive effect of these drugs

hypotensive drugs: Possibly excessive hypotension

levodopa: Possibly reduced effectiveness of levodopa

lithium: Possibly encephalopathic syndrome (with a blood level that exceeds 12 mEq/L)

MAO inhibitors: Possibly exaggerated extrapyramidal reactions

metaraminol, methoxamine, norepinephrine: Possibly reduced vasopressor response

pergolide: Possibly reduced effectiveness of pergolide

propranolol: Possibly seizures and increased hypotension

quinidine: Additive orthostatic hypotension, possibly prolonged QT interval

ACTIVITIES

alcohol use: Additive CNS effects, increased risk of seizures

smoking: Possibly decreased blood thiothixene level

Adverse Reactions

CNS: Agitation, akathisia, drowsiness, dystonia, fatigue, insomnia, light-headedness, neuroleptic malignant syndrome, paradoxical exacerbation of psychotic disorder, restlessness, seizures, syncope, tardive dyskinesia, weakness

CV: ECG changes, edema, hypotension,

peripheral edema, tachycardia

EENT: Blurred vision, dry mouth, increased salivation, miosis, mydriasis, nasal congestion, retinopathy

ENDO: Breast engorgement, galactorrhea, hyperglycemia, hypoglycemia

GI: Anorexia, constipation, diarrhea, elevated liver function test results, ileus, increased appetite, nausea, vomiting

GU: Amenorrhea, glycosuria, impotence, priapism

HEME: Agranulocytosis, anemia, eosinophilia, hemolytic anemia, leukocytosis, leukopenia, neutropenia, pancytopenia, thrombocytopenia

SKIN: Contact dermatitis, decreased sweating, photosensitivity, pruritus, rash

Other: Hyperuricemia, weight gain

Nursing Considerations

WARNING Thiothixene shouldn't be used to treat elderly patients with dementia-related psychosis because drug increases the risk of death in these patients.

- Administer thiothixene capsules with food or milk if needed to minimize GI distress.
- Don't give drug within 1 hr of an antacid.
- Dilute oral solution with 60 to 120 ml of fruit or tomato juice, milk, soup, water, or a carbonated beverage. Measure dose and administer using a calibrated measuring device. Avoid spilling solution on skin because drug may cause contact dermatitis.
- Avoid inadvertent I.V. delivery of thiothixene. It's intended for I.M. use.
- Be aware that I.M. administration usually is reserved for acute, severe agitation or for patients who can't take oral preparations.
- Maintain patient in recumbent position for 30 minutes after I.M. injection to minimize orthostatic hypotension.
- Assess patient for early signs of potentially irreversible tardive dyskinesia, a syndrome of involuntary rhythmic movements of the face, jaw, mouth, or tongue.

WARNING Be aware that drug can precipitate neuroleptic malignant syndrome, a serious condition characterized by altered mental status, arrhythmias, diaphoresis, hyperpyrexia, muscle rigidity, and tachycardia, especially in patients with hyperthyroidism or thyrotoxicosis. Symptoms

may be severe enough to cause life-threatening respiratory depression.

- Monitor patient's serum calcium level because hypocalcemia may lead to dystonic reactions.
- Keep in mind that hypotension from thiothixene may precipitate angina in patients with known cardiac disease.

WARNING Be aware that drug-induced adverse CNS reactions may mimic or suppress neurologic evidence of CNS disorders, such as brain tumor, encephalitis, encephalopathy, meningitis, Reye's syndrome, and tetanus.

- Monitor for extrapyramidal symptoms—particularly dystonias—in children with acute illnesses, including CNS infections, dehydration, gastroenteritis, measles, or varicella-zoster infections.
- Monitor patient's CBC, as ordered, because serious adverse hematologic reactions may occur, such as agranulocytosis, leukopenia, and neutropenia. More frequent monitoring during first few months of thiothixene therapy is recommended for patients with a history of drug-induced leukopenia or neutropenia or who have had a significantly low WBC count in the past. If abnormalities occur during therapy, monitor patient for fever or other signs of infection, notify prescriber, and expect drug to be discontinued if abnormalities are severe.
- Implement seizure precautions in patients with a history of seizures or EEG abnormalities because thiothixene can lower the seizure threshold.
- Assess patient for eye pain because thiothixene's anticholinergic effects may worsen angle-closure glaucoma. Assess patient with benign prostatic hyperplasia for urine retention.

PATIENT TEACHING

- Fully inform patient facing long-term thiothixene therapy about risk of developing tardive dyskinesia.
- Advise patient to avoid exposure to sunlight or ultraviolet light, and to apply sunscreen when outdoors.
- Urge patient to avoid smoking or to begin a smoking cessation program while taking thiothixene.
- Encourage patient to avoid extreme temperature changes during drug therapy to

prevent hyperthermia or hypothermia caused by decreased sweating.

- Instruct patient to immediately report sore throat or other signs of infection.

thyroid USP

Armour Thyroid, Thyrar, Thyroid Strong, Westhroid

Class and Category

Chemical class: Porcine thyroid gland hormone

Therapeutic class: Thyroid hormone replacement

Pregnancy category: A

Indications and Dosages

↗ *To treat hypothyroidism without myxedema*

TABLETS

Adults and children. *Initial:* 60 mg daily, increased by 30 mg daily every mo p.r.n.

Maintenance: 60 to 120 mg daily.

↗ *To treat hypothyroidism or myxedema in patients with cardiovascular disease*

TABLETS

Adults. *Initial:* 15 mg daily; daily dosage doubled every 2 wk, as indicated to achieve desired response, up to 180 mg daily.

Maintenance: 60 to 180 mg daily.

↗ *To treat congenital hypothyroidism (cretinism) or severe hypothyroidism in children and infants*

TABLETS

Children and infants. *Initial:* 15 mg daily; daily dosage doubled every 2 wk, as indicated to achieve desired response, up to 180 mg daily. If desired response isn't achieved, dosage further increased by 30 to 60 mg daily. *Maintenance:* Individualized.

Mechanism of Action

Stimulates growth and maturation of tissues, increases energy expenditure, and affects all enzyme actions through several mechanisms. Thyroid hormone:

- regulates cell differentiation and proliferation
- aids in myelination of nerves and development of axonal and dendritic processes in the nervous system
- enhances protein and carbohydrate metabolism by promoting metabolic

processes that increase gluconeogenesis and protein synthesis and facilitate the mobilization of glycogen stores.

Contraindications

Acute MI not associated with hypothyroidism, hypersensitivity to thyroid USP or its components, obesity treatment, untreated thyrotoxicosis

Interactions

DRUGS

barbiturates, carbamazepine, phenytoin, rifampin: Possibly increased catabolism of thyroid hormone

cholestyramine, colestipol: Decreased effectiveness of thyroid hormone

corticosteroids: Decreased metabolism of corticosteroids

estrogens: Possibly increased circulating concentrations of thyroxine-binding globulin, decreased effectiveness of thyroid hormone

insulin, oral antidiabetic drugs: Possibly altered blood glucose control

ketamine: Risk of marked hypertension and tachycardia

oral anticoagulants: Altered anticoagulant effect

sympathomimetics: Increased adverse cardiovascular effects

tricyclic antidepressants: Increased therapeutic and toxic effects of both drugs

FOODS

all foods: Possibly altered absorption of thyroid hormone

Adverse Reactions

CNS: Headache, insomnia, nervousness, tremor

CV: Angina; arrhythmias, including atrial fibrillation and sinus tachycardia; palpitations

ENDO: Hyperthyroidism

GI: Diarrhea, vomiting

GU: Menstrual irregularities

SKIN: Alopecia, diaphoresis

Other: Heat intolerance, weight loss

Nursing Considerations

- Avoid giving oral thyroid hormone with food because it may alter drug absorption.
- Don't give thyroid hormone within 5 hours of cholestyramine or colestipol. Giving them together can reduce hormone absorption.

WARNING Be aware that thyroid hormone therapy can unmask or worsen adrenal insufficiency, precipitate adrenal crisis in patients with uncontrolled adrenal insufficiency, and increase the risk of arrhythmias in patients with coronary artery disease.

- Monitor blood glucose level often because thyroid hormone therapy can unmask or exacerbate symptoms of other endocrine disorders and also may alter antidiabetic drug dosage requirements in patients with diabetes mellitus. Be aware that withdrawal of thyroid hormone can precipitate a hypoglycemic response in susceptible patients.

PATIENT TEACHING

- Tell patient to take thyroid hormone on an empty stomach at the same time each day.
- Advise her to inform prescriber immediately and seek medical attention if she experiences chest pain, nervousness, or sweating.
- Instruct patient who uses cholestyramine or colestipol not to take these drugs within 5 hours of thyroid dose.
- Inform patient that full effects may not be evident for 1 to 3 weeks.
- Instruct patient with diabetes mellitus to monitor blood glucose level frequently.

thyrotropin (thyroid-stimulating hormone, TSH)

Thyotropar

thyrotropin alfa

Thyrogen

Class and Category

Chemical class: Recombinant glycoprotein of human TSH

Therapeutic class: Diagnostic aid

Pregnancy category: C

Indications and Dosages

➤ *To provide diagnostic follow-up of patients with well-differentiated thyroid carcinoma*

I.M. INJECTION (THYROTROPIN ALFA)

Adults and adolescents age 16 and over.

0.9 mg every 24 hr for 2 doses or every

72 hr for 3 doses. Scanning or serum thyroglobulin testing performed 72 hr after last injection.

➤ *To provide differential diagnosis of subclinical hypothyroidism or low thyroid reserve*

I.M. OR SUBCUTANEOUS INJECTION

(THYROTROPIN)

Adults and adolescents age 16 and over.

10 international units daily for 1 to 3 days, followed by radioactive iodine study 24 hr after last injection. No response indicates thyroid failure; substantial response indicates pituitary failure.

➤ *To determine thyroid status in patients receiving thyroid hormone, to differentiate between primary and secondary hypothyroidism*

I.M. OR SUBCUTANEOUS INJECTION

(THYROTROPIN)

Adults and adolescents age 16 and over.

10 international units daily for 1 to 3 days.

➤ *To aid in diagnosing thyroid carcinoma remnant after surgery*

I.M. OR SUBCUTANEOUS INJECTION

(THYROTROPIN)

Adults and adolescents age 16 and over.

10 international units daily for 3 to 7 days.

➤ *As adjunct for radioiodine ablation of thyroid tissue remnants in patients who have undergone a near-total or total thyroidectomy for well-differentiated thyroid cancer and who have no evidence of metastatic thyroid cancer*

I.M. INJECTION (THYROTROPIN ALPHA)

Adults. 0.9 mg, followed by a second

0.9 mg 24 hours later, followed by radioiodine administration 24 hours later.

Mechanism of Action

Stimulates production of thyroglobulin by active thyroid tissue and enhances uptake of iodine, synthesis of thyroid precursor hormones (monoiodotyrosine, diiodotyrosine, and levothyroxine), and release of triiodothyronine (T_3) and thyroxine (T_4) from the thyroid gland into systemic circulation. Thyrotropin also binds with thyroid cancer tissue and stimulates iodine uptake in radioactive iodine imaging to detect cancer cells in euthyroid patients after near-total or total thyroidectomy.

Contraindications

Coronary thrombosis, hypersensitivity to

thyrotropin or its components, uncorrected adrenal insufficiency

Adverse Reactions

CNS: Asthenia, fever, headache, pares-
thesia

ENDO: Hyperthyroidism

GI: Nausea, vomiting

RESP: Respiratory distress

SKIN: Rash, urticaria

Other: Flulike symptoms; sudden, rapid, painful enlargement of locally recurring papillary carcinoma

Nursing Considerations

WARNING Be aware that thyrotropin can unmask or worsen adrenal insufficiency, precipitate adrenal crisis in patients with uncontrolled adrenal insufficiency, and increase the risk of arrhythmias in patients with coronary artery disease.

- Reconstitute thyrotropin solution with manufacturer-provided diluent, which contains no preservatives.
- Administer I.M. thyrotropin injections to the buttocks.

WARNING Avoid inadvertent I.V. or intradermal injection of thyrotropin. I.V. administration may result in severe reactions, including diaphoresis, hypotension, nausea, tachycardia, and vomiting. Intradermal injection may damage tissue at injection site.

- Monitor patient closely, especially during first 24 hours after drug administration, because patients have died (rarely) during this time.
- Check for chest pain and increased heart rate, especially in patients with cardiac or coronary artery disease, including angina, hypertension, and recent acute MI, and in patients with residual thyroid tissue. Drug may increase serum thyroid hormone level.

PATIENT TEACHING

- Advise patient to continue taking prescribed thyroid hormone replacement while receiving injections of thyrotropin alfa unless otherwise directed by prescriber.
- If patient is scheduled for radioactive iodine test, tell her to follow a low-iodine diet.
- Inform patient that testing may take 5 to 12 days to complete.

tiagabine hydrochloride

Gabitril

Class and Category

Chemical class: Nipecotic acid derivative

Therapeutic class: Anticonvulsant

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat partial seizures*

TABLETS

Adults. *Initial:* 4 mg daily; increased by 4 mg/wk up to 16 mg daily, then dosage increased by 4 to 8 mg every wk until desired response occurs. *Usual:* 32 to 56 mg daily. *Maximum:* 56 mg daily in 2 to 4 divided doses.

Children ages 12 to 18. *Initial:* 4 mg daily for 1 wk, then increased by 4 to 8 mg/wk until desired response occurs. *Maximum:* 32 mg daily in 2 to 4 divided doses.

DOSAGE ADJUSTMENT For patients with impaired hepatic function, dosage individualized and reduced, or interval extended if needed, because of reduced drug clearance.

Mechanism of Action

Appears to inhibit neuronal and glial uptake of gamma-aminobutyric acid (GABA), the major inhibitory neurotransmitter in the CNS. Tiagabine makes more GABA available in the CNS to open chloride channels in postsynaptic membranes, thereby leading to membrane hyperpolarization and preventing transmission of nerve impulses.

Contraindications

Hypersensitivity to tiagabine or its components

Interactions

DRUGS

benzodiazepines, CNS depressants: Possibly additive CNS depression

carbamazepine, phenobarbital, phenytoin: Possibly decreased tiagabine effectiveness

ACTIVITIES

alcohol use: Possibly additive CNS depression

Adverse Reactions

CNS: Amnesia, anxiety, asthenia, ataxia, confusion, depression, dizziness, drowsi-

ness, EEG abnormalities, hostility, impaired cognition, insomnia, light-headedness, paresthesia, seizures, status epilepticus, suicidal ideation, tremor, weakness

EENT: Pharyngitis, stomatitis

GI: Abdominal pain, diarrhea, increased appetite, nausea, vomiting

GU: UTI

MS: Dysarthria

SKIN: Ecchymosis, rash

Nursing Considerations

- Give tiagabine with food.

WARNING Expect to taper dosage gradually, as prescribed, because stopping drug abruptly may increase seizure frequency.

- Take seizure precautions because tiagabine has caused seizures and status epilepticus in patients with no history of seizures.
- Watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and report concerns at once.

PATIENT TEACHING

- Instruct patient to take drug with food.
- Advise patient to avoid hazardous activities until drug's CNS effects are known. Also urge her to avoid alcohol use.
- If patient takes a CNS depressant, explain that drug may increase depressant effect.
- Instruct patient not to stop taking tiagabine abruptly. Explain that prescriber usually tapers dosage over 4 weeks to reduce the risk of withdrawal seizures.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report concerns immediately.
- Encourage woman who becomes pregnant while taking tiagabine to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting information about the safety of antiepileptic drugs during pregnancy.

ticarcillin disodium

Ticar

Class and Category

Chemical class: Penicillin

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat moderate to severe infections, such as bacteremia, diabetic foot ulcers, empyema, intra-abdominal infections, lower respiratory tract infections (including pneumonia), lung abscess, peritonitis, pulmonary infections due to complications of cystic fibrosis (including bronchiectasis and pneumonia), septicemia, and skin and soft-tissue infections (including cellulitis) caused by susceptible organisms*

I.V. INFUSION

Adults and children. 200 to 300 mg/kg daily in divided doses every 4 to 6 hr. *Usual:* 3 g every 4 hr or 4 g every 6 hr.

➤ *To treat uncomplicated UTI*

I.V. INFUSION, I.M. INJECTION

Adults and children weighing 40 kg (88 lb) or more. 1 g every 6 hr.

Children over age 1 month and weighing less than 40 kg. 50 to 100 mg/kg daily in divided doses every 6 to 8 hr.

➤ *To treat complicated UTI*

I.V. INFUSION

Adults and children. 150 to 200 mg/kg in equally divided doses every 4 to 6 hr. *Usual:* 3 g every 6 hr.

DOSAGE ADJUSTMENT For patients with creatinine clearance of 30 to 60 ml/min/1.73 m², 2 g I.V. every 4 hr; with creatinine clearance of 10 to 30 ml/min/1.73 m², 2 g I.V. every 8 hr; with creatinine clearance of less than 10 ml/min/1.73 m², 2 g I.V. every 12 hr or 1 g I.M. every 6 hr.

Mechanism of Action

Inhibits bacterial cell wall synthesis by binding to specific penicillin-binding proteins inside the bacterial cell wall. Ultimately, this leads to cell wall lysis and death.

Incompatibilities

Don't administer ticarcillin through the same I.V. line as amikacin, gentamicin, or tobramycin. Don't give within 1 hr of aminoglycosides.

Contraindications

Hypersensitivity to ticarcillin, penicillins, or their components

Interactions

DRUGS

aminoglycosides: Additive or synergistic

activity against some bacteria, possibly mutual inactivation

anticoagulants: Possibly interference with platelet aggregation, prolonged PT

methotrexate: Prolonged blood methotrexate level, increased risk of methotrexate toxicity

probenecid: Prolonged blood ticarcillin level

Adverse Reactions

CV: Thrombophlebitis, vasculitis

GI: Elevated liver function test results, nausea, pseudomembranous colitis, vomiting

GU: Proteinuria

HEME: Anemia, eosinophilia, hemorrhage, leukopenia, neutropenia, prolonged bleeding time, thrombocytopenia

SKIN: Erythema nodosum, exfoliative dermatitis, pruritus, rash, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, hypernatremia, hypokalemia, injection site pain, superinfection

Nursing Considerations

- Obtain body fluid or tissue samples for culture and sensitivity testing, as ordered. Review test results, if possible, before giving first dose of ticarcillin.
- Don't inject more than 2 g of drug at any one I.M. injection site.
- Reconstitute each gram of ticarcillin with 4 ml of compatible diluent. Further dilute reconstituted I.V. solution to 10 to 100 mg/ml with compatible I.V. solution. To minimize vein irritation, don't exceed concentration of 100 mg/ml. Concentrations of 50 mg/ml or greater are preferred. Infuse appropriate I.V. dose over 30 to 120 minutes.
- Check for local injection site reaction, including thrombophlebitis, during therapy.
- Be aware that ticarcillin may worsen symptoms in patients with a history of GI disease or colitis.
- For patients with renal impairment, take seizure precautions, according to facility policy, because of increased risk of seizures.
- Monitor patient closely for diarrhea, which may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold ticarcillin and treat

with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

- Also look for signs of superinfection, such as oral candidiasis and rash in breast-feeding infant.
- Monitor serum electrolyte levels for hypernatremia due to drug's high sodium content and for hypokalemia due to increased urinary potassium loss.

WARNING Monitor patient's platelet count, PT, and APTT because ticarcillin may increase bleeding time and, in rare cases, may induce thrombocytopenia.

PATIENT TEACHING

- Stress need to take full course of ticarcillin exactly as prescribed, even if feeling better.
- Urge patient to report past allergies to penicillins and to notify prescriber at once about adverse reactions, including fever.
- Advise patient to decrease sodium intake to reduce the risk of electrolyte imbalance.
- Instruct patient to report diarrhea that's severe or prolonged. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.

ticlopidine hydrochloride

Ticlid

Class and Category

Chemical class: Thienopyridine derivative

Therapeutic class: Antithrombotic, platelet aggregation inhibitor

Pregnancy category: B

Indications and Dosages

↗ *To reduce the risk of initial thrombotic stroke in patients who have experienced transient ischemic attack, to reduce the risk of recurrent stroke in patients who have previously experienced thrombotic stroke*

TABLETS

Adults. 250 mg b.i.d.

↗ *As adjunct to reduce the risk of subacute stent thrombosis after successful coronary stent implantation*

TABLETS

Adults. 250 mg b.i.d with antiplatelet doses

Mechanism of Action

Normally, platelets don't adhere to blood vessel walls. However, when a thrombotic stroke or other disorder damages blood vessel walls, platelets are activated and adhere within seconds. Once activated, platelets release adenosine diphosphate (ADP). This causes fibrinogen to bind to glycoprotein IIb/IIIa (GP IIb/IIIa) receptors on the surface of activated platelets and connect with other activated

platelets. Then a thrombus forms.

Ticlopidine inhibits the release of ADP from activated platelets, which prevents fibrinogen from binding to GP IIb/IIIa receptors on the surface of activated platelets, as shown below. This action prevents platelets from aggregating to form a thrombus, which prevents thrombosis of an implanted stent or recurrence of stroke.

of aspirin for up to 30 days after successful stent implantation.

Route	Onset	Peak	Duration
P.O.	2–4 days	8–11 days	1–2 wk

Contraindications

Coagulopathy, GI bleeding, hematologic disorders related to hematopoiesis (including history of thrombotic thrombocytopenic purpura, neutropenia, and thrombocytopenia), hemophilia, hypersensitivity to ticlopidine or its components, intracranial bleeding, retinal bleeding, severe hepatic disease

Interactions

DRUGS

aluminum- and magnesium-containing antacids: Possibly decreased peak blood ticlopidine level

antineoplastics, antithymocyte globulin, heparin, NSAIDs, oral anticoagulants, platelet aggregation inhibitors, salicylates, strontium-89 chloride, thrombolytics:

Increased risk of bleeding

cimetidine: Reduced clearance of ticlopi-

dine, increased risk of adverse reactions
cyclosporine, digoxin: Decreased blood level and possibly reduced effects of these drugs
porfimer: Decreased effectiveness of porfimer photodynamic therapy
xanthines (aminophylline, oxytriphylline, theophylline): Decreased theophylline clearance, increased risk of toxicity

Adverse Reactions

CNS: Dizziness

CV: Hypercholesterolemia, vasculitis

EENT: Tinnitus

GI: Abdominal pain, anorexia, diarrhea, elevated liver function test results, flatulence, indigestion, nausea, vomiting

HEME: Agranulocytosis, aplastic anemia, hemolysis, hemolytic anemia, neutropenia, pancytopenia, thrombocytopenia, thrombotic thrombocytopenia, thrombotic thrombocytopenic purpura

SKIN: Pruritus, purpura, rash

Other: Hyponatremia, serum sicknesslike reaction

Nursing Considerations

- Give ticlopidine with food to maximize GI

- absorption and minimize any GI distress.
- Avoid I.M. injections of other drugs because excessive bleeding, bruising, or hematoma may occur.
- During first 3 months of therapy, monitor CBC every 2 weeks, as ordered (more frequently in patients with depressed neutrophil count).
- Be aware that ticlopidine therapy typically is used for patients with stroke or an increased risk of stroke who can't tolerate aspirin because of the risk of neutropenia or agranulocytosis.

WARNING Be aware that ticlopidine therapy irreversibly affects platelet aggregation. Expect prescriber to discontinue drug 10 to 14 days before surgical procedures to prevent uncontrolled bleeding.

- Monitor serum cholesterol level during first month of ticlopidine therapy for expected increase. Hypercholesterolemia may persist for duration of treatment.

PATIENT TEACHING

- Urge patient to take ticlopidine with food.
- Inform patient that she may be at increased risk for infection because drug may decrease WBC or platelet count, especially in first 3 months of therapy.
- Advise patient to notify prescriber immediately if she has chills, fever, or sore throat.
- Urge patient to keep scheduled appointments for blood tests to detect abnormalities.
- Instruct patient to apply prolonged pressure to injured areas because bleeding may take longer than usual to stop. Urge her to immediately report to prescriber any unusual bleeding or bruising.

tigecycline

Tygacil

Class and Category

Chemical class: Glycylcycline

Therapeutic class: Antibiotic

Pregnancy category: D

Indications and Dosages

↗ To treat complicated skin and skin structure infections caused by *Escherichia coli*, *Enterococcus faecalis* (vancomycin-susceptible isolates only),

Staphylococcus aureus (methicillin-susceptible and -resistant isolates), *Streptococcus agalactiae*, *Streptococcus anginosus group* (includes *S. anginosus*, *S. intermedius*, and *S. constellatus*), *Streptococcus pyogenes*, and *Bacteroides fragilis*; to treat complicated intra-abdominal infections caused by *Citrobacter freundii*, *Enterobacter cloacae*, *E. coli*, *Klebsiella oxytoca*, *Klebsiella pneumoniae*, *Enterococcus faecalis* (vancomycin-susceptible isolates only), *S. aureus* (methicillin-susceptible isolates only), *S. anginosus group*, *B. fragilis*, *Bacteroides thetaiotaomicron*, *Bacteroides uniformis*, *Bacteroides vulgatus*, *Clostridium perfringens*, and *Peptostreptococcus micros*; to treat community-acquired bacterial pneumonia caused by *Streptococcus pneumoniae* (penicillin-susceptible isolates), including cases with concurrent bacteremia, *Haemophilus influenzae* (beta-lactamase negative isolates), and *Legionella pneumophila*

I.V. INFUSION

Adults. *Initial:* 100 mg infused over 30 to 60 min followed by 50 mg infused over 30 to 60 min every 12 hr for 5 to 14 days for complicated skin and skin structure infections and intra-abdominal infections (7 to 14 days for community-acquired bacterial pneumonia).

DOSAGE ADJUSTMENT For patients with severe hepatic impairment, initial dosage of 100 mg should be followed by a reduced maintenance dosage of 25 mg every 12 hr.

Mechanism of Action

Inhibits protein translation in bacteria by binding to the 30S ribosomal subunit, which prevents binding of amino-acyl tRNA molecules to the ribosome complex, thus interfering with protein synthesis. Through this bacteriostatic action, bacteria are weakened.

Incompatibilities

Don't give amphotericin B, chlorpromazine, methylprednisolone, or voriconazole simultaneously through the same Y-site.

Contraindications

Hypersensitivity to tigecycline or its components

Adverse Reactions

CNS: Asthenia, chills, dizziness, fever, headache, insomnia, somnolence

CV: Bradycardia, hypertension, hypotension, peripheral edema, phlebitis, septic shock, tachycardia, thrombophlebitis, vasodilation

EENT: Dry mouth, taste perversion

ENDO: Hyperglycemia, hypoglycemia

GI: Abdominal pain, acute pancreatitis, anorexia, constipation, diarrhea, dyspepsia, elevated liver enzyme levels, hepatic dysfunction or failure, jaundice, nausea, pancreatitis, pseudomembranous colitis, vomiting

GU: Elevated BUN and creatinine levels, vaginal candidiasis

HEME: Anemia, increased PT, leukocytosis, thrombocytopenia

MS: Back pain

RESP: Increased cough, dyspnea

SKIN: Diaphoresis, photosensitivity, pruritus, rash

Other: Anaphylaxis, hypersensitivity reaction, hypocalcemia; hypokalemia; hyponatremia; hypoproteinemia; injection site reaction, such as edema, phlebitis, inflammation, and pain

Nursing Considerations

- Obtain body tissue and fluid samples for culture and sensitivity tests as ordered before giving first dose of tigecycline. Expect to begin drug therapy before test results are known.
- Avoid giving tigecycline to children under age 8 because drug may cause permanent brown or yellow tooth discoloration and enamel hypoplasia.
- Use tigecycline cautiously in patients hypersensitive to tetracycline antibiotics because glycylicycline antibiotics are structurally similar to tetracyclines.
- Also use cautiously in patients with complicated intra-abdominal infections secondary to intestinal perforation because of the risk of septic shock.
- Determine whether female patients could be pregnant before starting tigecycline therapy because the drug may cause harm to fetus.
- Reconstitute each vial of tigecycline with 5.3 ml of 0.9% sodium chloride injection or 5% dextrose injection to achieve a con-

centration of 10 mg/ml. Note that the color will be yellow to orange. If it's not, the solution should be discarded.

Immediately withdraw reconstituted solution from the vial and add to a 100-ml I.V. bag for infusion. Drug may be stored in the I.V. bag at room temperature for up to 6 hours or refrigerated up to 24 hours before use.

- If the patient's I.V. line is used to infuse other drugs, flush the line with either 0.9% sodium chloride injection or 5% dextrose injection before and after tigecycline infusion.
- Infuse tigecycline over 30 to 60 minutes.
- Monitor patient closely for diarrhea, which may indicate pseudomembranous colitis, which is known to occur with many antibiotics. If diarrhea occurs during tigecycline therapy, notify prescriber and expect to withhold drug. Expect to treat pseudomembranous colitis, if confirmed, with fluids, electrolytes, protein, and an antibiotic effective against *Clostridium difficile*.
- Monitor patient for adverse reactions, keeping in mind the similarity between tigecycline and tetracycline.
- Assess patient for superinfection, such as vaginal candidiasis, that may result from overgrowth of nonsusceptible organisms, including fungi. If signs of infection are present, notify prescriber and provide supportive care, as prescribed.
- Monitor patient's liver function closely. If enzyme levels become elevated, notify prescriber because dosage may need to be decreased or drug discontinued.
- Be aware that adverse reactions may continue after therapy stops.

PATIENT TEACHING

- Instruct patient to report adverse reactions, especially hypersensitivity reactions, such as a rash or itching, as well as diarrhea.
- Tell patient to report discomfort at the infusion site because the site may need to be changed.
- Urge patient to report diarrhea that's severe or prolonged. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.

tiludronate disodium

(contains 200 mg of tiludronic acid per tablet)

Skelid

Class and Category

Chemical class: Aminobiphosphonate

Therapeutic class: Bone resorption inhibitor

Pregnancy category: C

Indications and Dosages

➤ *To treat Paget's disease in patients with serum alkaline phosphatase levels at least twice the upper limit of normal, who are symptomatic or at risk for future complications of the disease*

TABLETS

Adults. *Initial:* 400 mg of tiludronic acid daily 2 hr before or after meals for 3 mo. *Maximum:* 400 mg of tiludronic acid daily.

Mechanism of Action

Reduces the activity of cells that cause bone loss and increases bone mass. Tiludronate may act by inhibiting osteoclast activity on newly formed bone resorption surfaces. This activity reduces the number of sites at which bone is remodeled. When bone formation exceeds bone resorption at these remodeling sites, bone mass increases. Tiludronate may also inhibit bone destruction by binding to hydroxyapatite crystals, which give bone its rigidity.

Contraindications

Creatinine clearance less than 30 ml/min/1.73 m², esophageal abnormalities that delay esophageal emptying, hypersensitivity to tiludronate or its components

Interactions

DRUGS

aluminum- or magnesium-containing antacids, mineral supplements (such as calcium, iron), salicylates, salicylate-containing compounds: Decreased absorption of tiludronate

indomethacin: Possibly increased bioavailability of tiludronate

FOODS

all foods and beverages (except plain water): Decreased absorption of tiludronate

Adverse Reactions

CNS: Dizziness, headache

CV: Chest pain, edema

EENT: Cataracts, conjunctivitis, glaucoma, pharyngitis, rhinitis

GI: Diarrhea, esophageal irritation and ulceration, flatulence, indigestion, nausea, vomiting

MS: Arthralgia, back pain, myalgia, osteonecrosis of jaw

RESP: Cough, upper respiratory tract infection

SKIN: Rash

Other: Flulike symptoms

Nursing Considerations

- Be prepared to monitor serum calcium levels before, during, and after tiludronate therapy because drug may exacerbate such conditions as hyperparathyroidism, hypocalcemia, and vitamin D deficiency. Ensure adequate dietary intake of calcium and vitamin D during and after treatment. If hypocalcemia occurs, expect to administer a calcium supplement, as prescribed.

WARNING Be aware that tiludronate may irritate upper GI mucosa, causing such adverse reactions as esophageal ulcer. To help minimize these reactions, have patient take drug with full glass of plain water and remain upright for at least 30 minutes.

PATIENT TEACHING

- Instruct patient to take drug with 6 to 8 oz of plain water on an empty stomach (at least 2 hours before or after beverages, food, other drugs, or mineral supplements, including mineral water) because food and beverages may severely reduce drug's effect. Also, advise her to remain upright for at least 30 minutes after taking drug.
- Advise patient not to chew or suck on tablet to reduce the risk of esophageal irritation.
- Instruct patient to notify prescriber immediately if she develops signs or symptoms of esophageal irritation, such as trouble swallowing or worsening heartburn; these may indicate a serious esophageal disorder.
- Caution patient not to take salicylate-containing drugs, such as aspirin, during tiludronate therapy.

timolol maleate

Apo-Timol (CAN), Blocadren, Novo-Timol (CAN)

Class and Category

Chemical class: Beta blocker

Therapeutic class: Antihypertensive, MI prophylactic, vascular headache prophylactic

Pregnancy category: C

Indications and Dosages

↗ *To manage hypertension*

TABLETS

Adults. *Initial:* 10 mg b.i.d., increased every wk as prescribed. *Maintenance:* 20 to 40 mg daily in divided doses. *Maximum:* 60 mg daily.

↗ *To provide long-term prophylaxis after MI*

TABLETS

Adults. 10 mg b.i.d., beginning 1 to 4 wk after MI and continuing for at least 2 yr.

↗ *To prevent migraine headache*

TABLETS

Adults. *Initial:* 10 mg b.i.d. *Maintenance:* 20 mg daily in divided doses. *Maximum:* 30 mg daily; discontinued after 8 wk, as prescribed, if maximum dose is ineffective.

Route	Onset	Peak	Duration
P.O.	30 min	1–2 hr	4–8 hr

Mechanism of Action

Selectively blocks α_1 and β_2 receptors in vascular smooth muscle and β_1 receptors in the heart. This reduces peripheral vascular resistance and blood pressure and relieves migraine headaches. Timolol's potent beta blockade prevents the reflex tachycardia that typically occurs with most alpha blockers, and decreases cardiac excitability, cardiac output, and myocardial oxygen demand, thus preventing MI.

Contraindications

Acute bronchospasm; asthma; cardiogenic shock; children; COPD (severe); heart failure; hypersensitivity to timolol, other beta blockers, or their components; second- or third-degree AV block; severe sinus bradycardia

Interactions

DRUGS

allergen immunotherapy, allergenic extracts for skin testing: Increased risk of serious systemic adverse reactions or anaphylaxis

amiodarone: Additive depressant effect on cardiac conduction, negative inotropic effect

anesthetics (hydrocarbon inhalation):

Increased risk of myocardial depression and hypotension

beta blockers: Additive beta blockade effects

calcium channel blockers, clonidine, diazoxide, guanabenz, reserpine, other hypotension-producing drugs: Additive hypotensive effect and, possibly, other beta blockade effects

cimetidine: Possibly interference with timolol clearance

estrogens: Decreased antihypertensive effect of timolol

fentanyl, fentanyl derivatives: Possibly increased risk of initial bradycardia after induction doses of fentanyl or derivative (with long-term timolol use)

glucagon: Possibly blunted hyperglycemic response

insulin, oral antidiabetic drugs: Possibly masking of tachycardia in response to hypoglycemia, impaired glucose control

lidocaine: Decreased lidocaine clearance, increased risk of lidocaine toxicity

MAO inhibitors: Increased risk of significant hypertension

neuromuscular blockers: Possibly potentiated and prolonged action of these drugs

NSAIDs: Possibly decreased hypotensive effect

phenothiazines: Increased blood levels of both drugs

phenytoin (parenteral): Additive cardiac depressant effect

sympathomimetics, xanthines: Possibly mutual inhibition of therapeutic effects

Adverse Reactions

CNS: Asthenia, decreased concentration, depression, dizziness, fatigue, fever, hallucinations, headache, insomnia, nervousness, nightmares, paresthesia, stroke, syncope, vertigo

CV: Angina, arrhythmias, bradycardia, cardiac arrest, chest pain, edema, palpitations, Raynaud's phenomenon, vasodilation

EENT: Diplopia, dry eyes, eye irritation,

ptosis, tinnitus, vision changes

ENDO: Hyperglycemia, hypoglycemia

GI: Abdominal pain, diarrhea, hepatomegaly, indigestion, nausea, vomiting

GU: Decreased libido, impotence

MS: Arthralgia, decreased tolerance to exercise, extremity pain, muscle weakness

RESP: Bronchospasm, cough, crackles, dyspnea

SKIN: Alopecia, diaphoresis, hyperpigmentation, pruritus, purpura, rash

Other: Anaphylaxis, weight loss

Nursing Considerations

WARNING Be aware that timolol may mask evidence of acute hypoglycemia in diabetic patient. It also may mask certain signs of hyperthyroidism, such as tachycardia.

- Be aware that timolol may prolong hypoglycemia by interfering with glycogenolysis or may promote hyperglycemia by decreasing tissue sensitivity to insulin.
- Monitor blood pressure and cardiac output, as appropriate, for patient with a history of systolic heart failure or left ventricular dysfunction because timolol's negative inotropic effect can depress cardiac output.

WARNING Timolol shouldn't be discontinued abruptly because this may produce MI, myocardial ischemia, severe hypertension, or ventricular arrhythmias, particularly in patient with known cardiovascular disease.

- Expect varied drug effectiveness in elderly patients; they may be less sensitive to drug's antihypertensive effect or more sensitive because of reduced drug clearance.
- Monitor for impaired circulation in elderly patients with age-related peripheral vascular disease or patients with Raynaud's phenomenon. Such patients may experience exacerbated symptoms from increased alpha stimulation. Elderly patients also are at increased risk for beta blocker–induced hypothermia.
- If timolol worsens skin condition, such as psoriasis, notify prescriber.

PATIENT TEACHING

- Instruct patient taking timolol to inform prescriber of chest pain, fainting, light-headedness, or shortness of breath, which may indicate the need for dosage change.

- Caution patient not to stop taking drug abruptly. Timolol dosage must be tapered gradually under prescriber's supervision.
- Instruct patient with diabetes to monitor blood glucose level often during therapy.
- Warn patient with psoriasis about possible flare-ups of skin condition.

tinidazole

Tindamax

Class and Category

Chemical class: Synthetic nitroimidazole

Therapeutic class: Antiprotozoal

Pregnancy category: C

Indications and Dosages

↗ *To treat trichomoniasis caused by Trichomonas vaginalis*

TABLETS

Adults. 2 g one time with food.

↗ *To treat giardiasis caused by Giardia duodenalis (G. lamblia)*

TABLETS

Adults. 2 g one time with food.

Children age 4 and over. 50 mg/kg (up to 2 g) one time with food.

↗ *To treat intestinal amebiasis caused by Entamoeba histolytica*

TABLETS

Adults. 2 g daily for 3 days with food.

Children age 4 and over. 50 mg/kg (up to 2 g) daily for 3 days with food.

↗ *To treat amebic liver abscess caused by Entamoeba histolytica*

TABLETS

Adults. 2 g daily for 3 to 5 days with food.

Children age 4 and over. 50 mg/kg (up to 2 g) daily for 3 to 5 days with food.

DOSAGE ADJUSTMENT For patients receiving hemodialysis, an additional dose equivalent to one-half the dose prescribed should be given after the dialysis treatment on the days dialysis is performed.

Mechanism of Action

Undergoes intracellular chemical reduction during anaerobic metabolism. After tinidazole is reduced, it damages DNA's helical structure and breaks its strands, which inhibits bacterial nucleic acid synthesis and causes cell death.

Contraindications

Breast-feeding, hypersensitivity to tinidazole or its components, treatment of trichomoniasis during first trimester of pregnancy

Interactions

DRUGS

cholestyramine: Possibly decreased bioavailability of tinidazole

cimetidine, ketoconazole: Possibly delayed elimination and increased blood level of tinidazole

cyclosporine, tacrolimus: Possibly increased serum cyclosporine and tacrolimus levels

disulfiram: Possibly combined toxicity, resulting in confusion and psychosis
flurouracil: Possibly decreased flurouracil clearance

lithium: Possibly increased serum lithium levels

oral anticoagulants: Possibly increased anticoagulant effect

oxytetracycline: Possibly diminished effect of tinidazole

phenobarbital, phenytoin, rifampin: Possibly increased metabolism and decreased blood level of tinidazole

ACTIVITIES

alcohol use: Possibly disulfiram-like effects

Adverse Reactions

CNS: Ataxia, dizziness, coma, confusion, depression, drowsiness, fatigue, fever, headache, insomnia, malaise, peripheral neuropathy, seizures, vertigo, weakness

CV: Palpitations

EENT: Dry mouth, excessive salivation, furry tongue, metallic or bitter taste, oral candidiasis, pharyngitis, stomatitis, tongue discoloration

GI: Abdominal cramps, anorexia, constipation, diarrhea, epigastric discomfort, flatulence, hepatic abnormalities, indigestion, nausea, thirst, vomiting

GU: Darkened urine, dysuria, increased vaginal discharge, menorrhagia, UTI, vaginal candidiasis or odor, vulvo-vaginal discomfort

HEME: Reversible thrombocytopenia, transient leukopenia or neutropenia

MS: Arthralgia, arthritis, myalgia, pelvic pain

RESP: Bronchospasm, dyspnea, upper respiratory tract infection

SKIN: Diaphoresis, erythema multiforme, flushing, pruritus, rash, Stevens-Johnson syndrome, urticaria

Other: Angioedema

Nursing Considerations

- Use tinidazole cautiously in patients with CNS disease or blood dyscrasias because tinidazole's adverse effects may worsen these disorders. Also use cautiously in patients with hepatic impairment because a chemically related drug has reduced elimination.
- Take seizure precautions. If a seizure or other abnormal neurologic symptoms occur, notify prescriber and expect to stop drug.
- Treat a patient diagnosed with trichomoniasis and her sexual partner with the same dose of tinidazole and at the same time, as ordered, because trichomoniasis is a sexually transmitted disease.
- Monitor patient's total WBC count and differential if retreatment with tinidazole is needed because adverse hematologic reactions may occur with repeated use.

PATIENT TEACHING

- Tell patient to take tinidazole with food to minimize gastric discomfort.
- Instruct patient unable to swallow tablets to crush tinidazole and mix in artificial cherry syrup and then take with food.
- Advise patient to avoid alcohol while taking tinidazole and for 3 days afterward because alcohol can cause intense flushing.
- Tell patient to alert prescriber before taking tinidazole if she thinks or knows she is pregnant because tinidazole crosses the placental barrier during the first trimester and its effects on the fetus are unknown.
- Instruct breast-feeding patient not to breast-feed during therapy and for 3 days after taking last dose.

tinzaparin sodium

Innohep

Class and Category

Chemical class: Low-molecular-weight heparin

Therapeutic class: Anticoagulant, anti-thrombotic

Pregnancy category: B

Indications and Dosages

↗ *As adjunct to treat pulmonary thromboembolism and acute symptomatic deep vein thrombosis*

SUBCUTANEOUS INJECTION

Adults. 175 anti-Xa international units/kg daily for at least 6 days. *Maximum:* 18,000 to 21,000 anti-Xa international units daily.

Route	Onset	Peak	Duration
SubQ	2–3 hr	4–6 hr	24 hr

Mechanism of Action

Potentiates the action of antithrombin III, a coagulation inhibitor. By binding with antithrombin III, tinzaparin rapidly binds with and inactivates clotting factors (primarily fibrin and factor Xa). Without thrombin, fibrinogen can't convert to fibrin and clots can't form.

Contraindications

Active major bleeding; heparin-induced thrombocytopenia (current or past); hypersensitivity to tinzaparin or its components, other low-molecular-weight heparins, sulfites, benzyl alcohol, or pork products

Interactions

DRUGS

alteplase, anistreplase, aspirin, dextran, dipyridamole, NSAIDs, oral anticoagulants, streptokinase, sulfapyrazone, urokinase:

Possibly increased risk of bleeding and risk of spinal or epidural hematomas

Adverse Reactions

CNS: Confusion, dizziness, epidural or spinal hematoma, headache, insomnia, intracranial hemorrhage, paralysis

CV: Angina, hypertension, hypotension, tachycardia

EENT: Epistaxis, gingival bleeding, pharyngeal bleeding

GI: Constipation, elevated liver function test results, GI and retroperitoneal bleeding, hematemesis, nausea, vomiting

GU: Hematuria, genitourinary bleeding, prolonged or heavy menstrual bleeding, UTI

HEME: Anemia, thrombocytopenia, unusual bruising

MS: Back pain

RESP: Dyspnea, hemoptysis, pulmonary embolism

SKIN: Bleeding at puncture sites, surgical incision sites, or venous cutdown sites; rash
Other: Injection site hematoma, including itching, pain, redness, and swelling

Nursing Considerations

- Use tinzaparin with extreme caution in patients who are elderly and have renal insufficiency because drug may increase the risk of death.
- Expect warfarin therapy to begin within 1 to 3 days of tinzaparin use.
- Monitor patient's INR. Expect therapy to continue until INR reaches 2.0 for 2 consecutive days.

WARNING Monitor patient for evidence of GI bleeding, including bloody or black, tarry stools; bloody or coffee-ground vomitus; and severe stomach pain. Notify prescriber immediately if patient develops any of these signs or symptoms.

- Assess tinzaparin injection site for signs and symptoms of hematoma, including deep, dark purple bruises under skin and itching, pain, redness, or swelling.
- Assess patient for evidence of intracranial bleeding (such as decreased level of consciousness), retroperitoneal bleeding (such as abdominal pain or swelling and back pain), genitourinary bleeding (such as hematuria), or respiratory tract bleeding (such as hemoptysis). Notify prescriber immediately about any of these signs or symptoms.
- If serious bleeding (not controllable by local pressure) occurs, expect to discontinue any concomitant warfarin or antiplatelet drugs immediately.
- Expect to treat bleeding by administering 1 mg of protamine sulfate 1% solution I.V. per 100 anti-Xa international units of tinzaparin, as prescribed.
- If possible, avoid giving I.M. injections to patient receiving tinzaparin. If arterial puncture becomes necessary during tinzaparin therapy, expect to apply pressure after procedure and to monitor puncture site frequently for signs of bleeding.
- Monitor patient's laboratory tests for elevated liver enzyme levels. If significant elevations persist or worsen, notify prescriber immediately.

WARNING Monitor patient receiving tinzaparin and epidural or spinal anesthesia or

when a spinal puncture is performed because spinal hematomas can occur, causing long-term or permanent paralysis. Watch for evidence of neurologic impairment, such as changes in sensory or motor function. If present, notify prescriber immediately because urgent care is needed to minimize effects of hematoma. Use of indwelling epidural catheters, concurrent use of other drugs that affect hemostasis, a history of traumatic or repeated epidural or spinal punctures, or a history of spinal deformity or spinal surgery increases the risk of spinal or epidural hematomas in patients receiving tinzaparin.

PATIENT TEACHING

- Advise patient who is receiving tinzaparin to immediately report any bleeding, including from nose or gums.
- Instruct patient to limit physical activity during tinzaparin administration to reduce the risk of injury or bleeding.
- Urge female patient to notify prescriber if she is or could be pregnant.

tiopronin

Thiola

Class and Category

Chemical class: Thiol compound

Therapeutic class: Antiurolithic

Pregnancy category: C

Indications and Dosages

➤ *To prevent the formation of urinary cystine calculi*

TABLETS

Adults. 800 mg daily in 3 divided doses.

Children over age 9. 15 mg/kg in 3 divided doses.

DOSE ADJUSTMENT For patients with a history of hypersensitivity to penicillamine, therapy initiated at a reduced dosage; later dosage adjusted as prescribed, according to urine cystine level.

Route	Onset	Peak	Duration
P.O.	Rapid	Unknown	8–10 hr

Mechanism of Action

Inhibits the formation of urinary cystine calculi by undergoing thiol-disulfide

exchange with cystine (cystine-cystine disulfide) to form a water-soluble compound, tiopronin-cystine disulfide.

Contraindications

History of agranulocytosis, aplastic anemia, or thrombocytopenia; hypersensitivity to tiopronin or its components

Interactions

DRUGS

bone marrow depressants: Increased risk of adverse hematologic effects

hepatotoxic drugs: Increased risk of hepatotoxic effects

nephrotoxic drugs: Increased risk of nephrotoxic effects

Adverse Reactions

CNS: Chills, fever

CV: Peripheral edema

EENT: Laryngeal edema, stomatitis

GU: Hematuria, proteinuria

HEME: Anemia, eosinophilia, leukopenia, thrombocytopenia

MS: Arthralgia

SKIN: Ecchymosis, jaundice, pruritus, rash, urticaria

Nursing Considerations

- Watch for drug fever, which may occur during first month of tiopronin therapy.
- Be aware that drug may be stopped temporarily, then restarted at lower dose.
- Expect to monitor urine cystine level so dosage can be adjusted to keep cystine level below 250 g/ml.

PATIENT TEACHING

- Instruct patient to take tiopronin on an empty stomach, 1 hour before or 2 hours after meals, for faster drug absorption.
- Advise patient to drink at least 3 L of fluid daily to maintain a urine output of at least 2 L daily during therapy.
- Urge patient to maintain a diet low in methionine, which is an essential amino acid found in eggs, cheese, fish, and milk.

tiotropium bromide

Spiriva HandiHaler

Class and Category

Chemical class: Nonane bromide monohydrate

Therapeutic class: Anticholinergic, bronchodilator

Pregnancy category: C

Indications and Dosages

➤ *To prevent bronchospasm associated with COPD, including chronic bronchitis and emphysema; to reduce COPD exacerbations*

AEROSOL CAPSULES

Adults. 18 mcg (1 capsule) with 2 inhalations once daily using HandiHaler inhalation device

Mechanism of Action

Prevents acetylcholine from attaching to muscarinic receptors on membranes of smooth-muscle cells. By blocking acetylcholine's effects in the bronchi and bronchioles, tiotropium relaxes smooth muscles and causes bronchodilation.

Contraindications

Hypersensitivity to atropine or its derivatives, including ipratropium, tiotropium, or their components

Interactions

DRUGS

anticholinergics: Possibly increased anticholinergic effects

Adverse Reactions

CNS: Depression, difficulty speaking, dizziness, paresthesia, stroke

CV: Angina, atrial fibrillation, chest pain, hypercholesterolemia, palpitations, peripheral edema, supraventricular tachycardia, tachycardia

EENT: Application site irritation (glossitis, mouth ulceration, pharyngolaryngeal pain), blurred vision, cataract, dry mouth, epistaxis, eye pain, glaucoma, hoarseness, laryngitis, oral candidiasis, pharyngitis, rhinitis, sinusitis, stomatitis, throat irritation, visual halos

ENDO: Hyperglycemia

GI: Abdominal pain, constipation, dysphagia, gastroesophageal reflux, indigestion, intestinal obstruction, ileus, vomiting

GU: Urinary difficulty, urine retention, UTI

MS: Arthritis, leg or skeletal pain, myalgia

RESP: Cough, paradoxical bronchospasm, upper respiratory tract infection

SKIN: Pruritus, rash, urticaria

Other: Allergic reaction, angioedema, candidiasis, flulike symptoms, infection

Nursing Considerations

- Use tiotropium cautiously in patients with angle-closure glaucoma, benign prostatic hyperplasia, or bladder neck obstruction.

WARNING Monitor patient closely after giving first dose of tiotropium for immediate hypersensitivity reactions, including angioedema and paradoxical bronchospasm. If reaction occurs, notify prescriber and expect to stop tiotropium and provide supportive care. Because atropine is of a similar structure, monitor patients hypersensitive to atropine closely when giving tiotropium because of potential for similar hypersensitivity reactions. Also use tiotropium cautiously in patients who have severe hypersensitivity to milk proteins.

- Monitor patient's renal function, as ordered, especially in patients with moderate to severe renal impairment, because tiotropium is excreted mainly by the kidneys.
- Monitor patient's pulmonary function, as ordered, to evaluate the effectiveness of tiotropium.

PATIENT TEACHING

- Caution patient not to use tiotropium to treat acute bronchospasm.
- Instruct patient on the proper use of the HandiHaler inhalation device. Tell patient to place the capsule into the center chamber of the inhalation device and then to press and release the button on the side of the inhalation device to pierce the capsule. Then have the patient exhale completely, close her lips around the mouthpiece, inhale slowly and deeply, and hold her breath for as long as is comfortable.
- Alert patient that the HandiHaler device should not be used for taking any other drug and that tiotropium must be taken only using the device and never swallowed.
- Tell patient not to expose capsules to air until ready for use. To remove a capsule from the blister pack, tell patient to open the foil only as far as the stop line to avoid exposing the rest of the capsules in the blister pack to air. Instruct patient to discard capsules if they are inadvertently exposed to air and won't be used immediately.
- Advise patient to keep powder out of her

eyes because it may irritate them or blur her vision.

- Instruct patient to rinse her mouth after each treatment to help minimize throat dryness and irritation.
- Advise patient to tell prescriber about decreased response to tiotropium as well as difficulty urinating, eye pain, palpitations, and vision changes.

tirofiban hydrochloride

Aggrastat

Class and Category

Chemical class: Tyrosine derivative

Therapeutic class: Platelet aggregation inhibitor

Pregnancy category: B

Indications and Dosages

➔ *To treat acute coronary syndrome*

I.V. INFUSION

Adults. 0.4 mcg/kg/min for 30 min, followed by 0.1 mcg/kg/min.

DOSAGE ADJUSTMENT For patients with creatinine clearance of less than 30 ml/min/1.73 m², infusion rate reduced by one-half.

Route	Onset	Peak	Duration
I.V.	Immediate	30 min	4–8 hr

Mechanism of Action

Binds to glycoprotein IIb/IIIa receptor sites on the surface of activated platelets.

Circulating fibrinogen can bind to these receptor sites and link platelets together, forming a clot that eventually blocks a coronary artery. By binding to receptor sites, tirofiban prevents the normal binding of fibrinogen and other factors and inhibits platelet aggregation.

Incompatibilities

Don't infuse tirofiban in same I.V. line with any drug other than atropine sulfate, dobutamine, dopamine, epinephrine hydrochloride, furosemide, heparin, lidocaine, midazolam hydrochloride, morphine sulfate, nitroglycerin, potassium chloride, propranolol hydrochloride, or famotidine (Pepcid injection).

Contraindications

Acute pericarditis; arteriovenous malformation; coagulopathy; stroke that occurred within previous 30 days or a history of hemorrhagic stroke; GI or GU bleeding; hemophilia; history of thrombocytopenia after tirofiban use; hypersensitivity to tirofiban or its components; intracranial aneurysm or mass, intracranial bleeding, retinal bleeding, aortic dissection, or any evidence of active abnormal bleeding within previous 30 days; major surgery or trauma within previous 6 weeks; severe uncontrolled hypertension (systolic blood pressure above 180 mm Hg, diastolic blood pressure above 110 mm Hg)

Interactions

DRUGS

antineoplastics, antithymocyte globulin, NSAIDs, oral anticoagulants, platelet aggregation inhibitors, strontium-89 chloride, thrombolytics: Increased risk of bleeding

levothyroxine, omeprazole: Increased rate of tirofiban clearance

porfimer: Decreased effectiveness of porfimer photodynamic therapy

salicylates: Increased risk of bleeding, possibly hypoprothrombinemia

Adverse Reactions

CNS: Chills, dizziness, fever, headache, intracranial hemorrhage

CV: Edema, hemopericardium, peripheral edema, sinus bradycardia

GI: Hematemesis, nausea, retroperitoneal bleeding, vomiting

GU: Hematuria, pelvic pain

HEME: Severe thrombocytopenia with chills, fever, and possibly fatal bleeding complications

RESP: Pulmonary hemorrhage

SKIN: Diaphoresis, rash, urticaria

Other: Allergic reaction, anaphylaxis, infusion site bleeding

Nursing Considerations

WARNING Dilute 50-ml vial of tirofiban before use; don't dilute 500-ml container because it holds premixed solution ready for I.V. infusion. Don't use solution unless it's clear and the seal is intact.

- If prescribed, give tirofiban with heparin for 48 to 108 hours. Expect to continue infusion throughout angiography and for

12 to 24 hours after angioplasty or atherectomy.

WARNING If patient is also receiving a heparin infusion, expect to monitor APTT before treatment, 6 hours after heparin infusion starts, and regularly thereafter. Expect to adjust heparin dosage to maintain APTT at about two times the control. Notify prescriber immediately if patient develops an abnormally high APTT. Also, assess patient for signs and symptoms of abnormal bleeding and report them to prescriber immediately because potentially life-threatening bleeding may occur.

- After cardiac catheterization or percutaneous transluminal coronary angioplasty, keep patient on bed rest with head of bed elevated. Ensure hemostasis of percutaneous site for at least 4 hours before discharge. Minimize invasive procedures, including epidural procedures, to reduce the risk of bleeding.
- Monitor patient's platelet count, hemoglobin level, and hematocrit, as ordered. Expect to discontinue tirofiban if patient's platelet count is less than 90,000/mm³. Expect to give a platelet transfusion, as prescribed, if platelet count falls below 50,000/mm³.

PATIENT TEACHING

- Advise patient to immediately report any bleeding, bruising, headache, pain, or swelling during I.V. infusion of tirofiban.

tizanidine hydrochloride

Zanaflex

Class and Category

Chemical class: Imidazoline

Therapeutic class: Antispasmodic

Pregnancy category: C

Indications and Dosages

➤ *To manage acute and intermittent increases of muscle tone with spasticity*

TABLETS

Adults. 4 mg every 6 to 8 hr, p.r.n., increased gradually by 2 to 4 mg/dose, as needed and as prescribed. *Maximum:* 36 mg daily or 3 doses daily.

Mechanism of Action

Reduces spasticity by decreasing the release of excitatory amino acids. This alpha₂-adrenergic agonist's action increases presynaptic inhibition of spinal motor neurons, with the greatest effects on polysynaptic pathways.

Route	Onset	Peak	Duration
P.O.	Unknown	1–2 hr	3–6 hr

Contraindications

Hypersensitivity to tizanidine or its components, use with ciprofloxacin or fluvoxamine

Interactions

DRUGS

acetaminophen: Delayed peak effects of acetaminophen

alpha₂-adrenergic agonists: Possibly significant hypotension

antihypertensives: Additive hypotensive effects

CYP1A2 inhibitors (such as acyclovir, amiodarone, cimetidine, famotidine, mexiletine, propafenone, ticlopidine, verapamil, zileuton), fluoroquinolones (including ciprofloxacin, fluvoxamine): Possibly increased plasma tizanidine level; increased risk of hypotension and sedation

oral contraceptives: Decreased tizanidine clearance

rofecoxib: Possibly increased adverse reactions

ACTIVITIES

alcohol use: Increased adverse effects of tizanidine, additive CNS depression

Adverse Reactions

CNS: Anxiety, delusions, drowsiness, dyskenesia, fatigue, fever, hallucinations, slurred speech

CV: Orthostatic hypotension

EENT: Dry mouth, pharyngitis, rhinitis

GI: Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, elevated liver function test results, hepatic failure, hepatomegaly, nausea, vomiting

GU: Urinary frequency, UTI

MS: Back pain, muscle weakness, myasthenia

SKIN: Diaphoresis, jaundice, rash, ulceration

Nursing Considerations

- Be aware that extreme caution is required if tizanidine is prescribed for a patient with hepatic impairment because the drug is extensively metabolized in the liver.
- Monitor hepatic and renal function for first 6 months and periodically thereafter.
- Expect prolonged drug use to inhibit saliva.
- Be aware that tizanidine should be stopped slowly to prevent withdrawal and rebound hypertension, tachycardia, and hypertonia.

PATIENT TEACHING

- Caution patient not to stop taking tizanidine suddenly to prevent adverse effects.
- Advise patient to change positions slowly to minimize effects of orthostatic hypotension.
- Urge patient to avoid alcohol during drug therapy because of its additive CNS effects.
- Tell patient to notify prescriber or a dentist if dry mouth lasts longer than 2 weeks.
- Instruct patient to inform all prescribers and pharmacists about any drug he starts or stops taking.

tobramycin sulfate

Tobi

Class and Category

Chemical class: Aminoglycoside

Therapeutic class: Antibiotic

Pregnancy category: D

Indications and Dosages

➤ *To treat bacteremia; bone and joint, gynecologic, intra-abdominal, lower respiratory tract, skin and soft-tissue, and urinary tract infections; endocarditis; meningitis; neonatal sepsis; pyelonephritis; and septicemia caused by susceptible strains of Acinetobacter species, Aeromonas species, Citrobacter species, Enterobacter species, Escherichia coli, Haemophilus influenzae (beta lactamase-negative and -positive), Klebsiella species, Morganella morganii, Proteus mirabilis, Proteus vulgaris, Providencia rettgeri, Pseudomonas aeruginosa, Salmonella species, Serratia species, Shigella species, Staph-*

lococcus aureus, and Staphylococcus epidermidis; to treat febrile neutropenia

I.V. INFUSION, I.M. INJECTION

Adults. 3 to 6 mg/kg daily in divided doses every 8 to 12 hr.

Children over age 5. 2 to 2.5 mg/kg every 8 hr.

Children under age 5. 2.5 mg/kg every 8 to 16 hr.

Neonates over age 7 days weighing more than 2 kg (4.4 lb). 2.5 mg/kg every 8 hr.

Neonates over age 7 days weighing 1.2 to 2 kg (2.6 to 4.4 lb). 2.5 mg/kg every 8 to 12 hr.

Neonates age 7 days and under weighing 2 kg or more. 2.5 mg/kg every 12 hr.

Neonates age 7 days and under weighing 1.2 to 2 kg. 2.5 mg/kg every 12 to 18 hr.

Preterm neonates weighing 1 to 1.2 kg (2.2 to 2.6 lb). 2.5 mg/kg every 18 to 24 hr.

Preterm neonates weighing less than 1 kg. 3.5 mg/kg every 24 hr.

➤ *To treat pulmonary infection caused by P. aeruginosa in patients with cystic fibrosis*

I.V. INFUSION

Adults and children. 2.5 to 3.3 mg/kg every 8 hr; dosage adjusted to achieve peak blood drug level of 8 to 12 mcg/ml and trough blood drug level below 2 mcg/ml.

INHALATION

Adults and children over age 6. 1 ampule (300 mg) b.i.d. in alternating periods of 28 days on and 28 days off.

➤ *To treat meningitis caused by susceptible organisms*

INTRATHECAL INJECTION

Adults. 4 to 8 mg daily with parenteral therapy.

Children. 1 to 2 mg daily with parenteral therapy.

➤ *To treat systemic infection*

INTRAPERITONEAL INFUSION

Adults and children. 1.5 to 2 mg/kg.

➤ *To treat dialysis-associated peritonitis in patients with end-stage renal disease*

INTRAPERITONEAL INFUSION

Adults and children. 4 to 8 mg/L in each dialysate exchange bag, increased, as prescribed, to 6 to 8 mg/L in documented *Pseudomonas* infection or to 20 mg/L administered in one exchange bag daily.

DOSAGE ADJUSTMENT For patients with renal impairment, dosage possibly reduced.

Mechanism of Action

Inhibits bacterial protein synthesis by binding irreversibly to one of two aminoglycoside-binding sites on the 30S ribosomal subunit, resulting in bacteriostatic effects. Bactericidal effects may stem from tobramycin's ability to accumulate within cells so that the intracellular drug level exceeds the extracellular level.

Incompatibilities

Don't mix tobramycin in same solution with parenteral aminoglycosides or beta-lactam antibiotics because mutual inactivation may result. Don't dilute or mix inhalation solution in nebulizer with dornase alfa.

Contraindications

Concurrent cidofovir therapy; hypersensitivity to tobramycin, aminoglycosides, sodium bisulfite, or their components

Interactions

DRUGS

acyclovir, aminoglycosides, amphotericin B, carboplatin, cisplatin, NSAIDs, vancomycin: Additive nephrotoxicity
carbenicillin, ticarcillin: Possibly inactivation of tobramycin
dimenhydrinate: Possibly masking of symptoms of ototoxicity
ethacrynic acid, furosemide: Additive ototoxicity
general anesthetics, neuromuscular blockers: Possibly increased neuromuscular blockade

Adverse Reactions

CNS: Confusion, dizziness, headache, lethargy, neurotoxicity, vertigo

EENT: Hearing loss, tinnitus

GI: *Clostridium difficile*-associated diarrhea, diarrhea, elevated liver function test results, nausea, vomiting

GU: Elevated BUN and serum creatinine levels, nephrotoxicity, oliguria, proteinuria, renal failure

HEME: Anemia, leukocytosis, leukopenia, neutropenia, thrombocytopenia

SKIN: Exfoliative dermatitis, pruritus, rash, urticaria

Other: Hypocalcemia, hypokalemia, hypomagnesemia, hyponatremia, injection site pain

Nursing Considerations

- Obtain fluid and tissue samples for culture

and sensitivity testing before and during tobramycin therapy, as ordered. Review results, if available, before therapy starts.

- After reconstituting with 30 ml of sterile or bacteriostatic water for injection, dilute further with normal saline solution or D₅W.
- Give each I.V. dose over 20 to 60 minutes.

WARNING Don't infuse tobramycin over less than 20 minutes to avoid neuromuscular blockade and excessive peak drug level.

- Don't expose ampules for inhalation solution to intense light. Refrigerate them at 36° to 46° F (2° to 8° C).
- Because drug can cause bilateral and irreversible hearing loss, assess for early signs of cochlear and vestibular ototoxicity, including high-frequency hearing loss and vertigo.
- Monitor serum calcium, magnesium, potassium, and sodium levels to detect electrolyte imbalances.

WARNING Be alert for allergic reactions, including anaphylaxis, because some forms of drug contain sodium bisulfite.

- Stop tobramycin therapy 7 days before starting cidofovir therapy, as prescribed.
- Watch for signs of nephrotoxicity, such as elevated BUN and serum creatinine levels.
- Expect dehydration to increase the risk of nephrotoxicity.

WARNING Monitor patient with myasthenia gravis or parkinsonism for increased muscle weakness because of tobramycin's potential curare-like effect.

- Monitor patient closely for diarrhea, which may indicate pseudomembranous colitis caused by *C. difficile*. If diarrhea occurs, notify prescriber, expect to withhold tobramycin, and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

PATIENT TEACHING

- For inhaled tobramycin, instruct patient to inhale over 10 to 15 minutes, using a handheld nebulizer with a compressor.
- Teach patient how to use nebulizer while sitting or standing upright and to breathe normally through its mouthpiece. Nose clips may help patient breathe through her mouth.
- Instruct patient to disinfect her nebulizer every other treatment day by boiling the

nebulizer parts (except tubing) for a full 10 minutes and then drying the parts on a clean, lint-free cloth.

- Urge patient to immediately report high-frequency hearing loss and vertigo.
- Instruct female patient to notify prescriber immediately about known or suspected pregnancy because drug poses danger to fetus.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools may occur 2 or more months after antibiotic therapy and may be serious, requiring prompt treatment.

tocainide hydrochloride

Tonocard

Class and Category

Chemical class: Lidocaine analogue

Therapeutic class: Class IB antiarrhythmic

Pregnancy category: C

Indications and Dosages

↗ *To treat life-threatening, sustained ventricular tachycardia*

TABLETS

Adults. *Initial:* 400 mg every 8 hr.

Maintenance: 1.2 to 1.8 g daily in divided doses every 8 hr.

DOSE ADJUSTMENT Dosage possibly reduced by 25% if creatinine clearance is 10 to 30 ml/min/1.73 m² and by 50% if creatinine clearance is less than 10 ml/min/1.73 m².

Route	Onset	Peak	Duration
P.O.	Unknown	0.5–2 hr	8 hr

Mechanism of Action

Combines with fast sodium channels in myocardial cell membranes, which inhibits sodium influx into cells and decreases ventricular depolarization, automaticity, and excitability during diastole.

Contraindications

Hypersensitivity to tocainide or its components, second- or third-degree AV block without ventricular pacemaker

Interactions

DRUGS

- antiarrhythmics:* Possibly additive cardiac effects, additive toxicity
- beta blockers:* Increased cardiac index, left ventricular pressures, and pulmonary artery wedge pressures
- cimetidine:* Possibly decreased blood tocainide level
- rifampin:* Accelerated hepatic metabolism of tocainide, reduced tocainide effectiveness

Adverse Reactions

CNS: Agitation, anxiety, ataxia, coma, confusion, depression, dizziness, fatigue, hallucinations, headache, mood changes, nervousness, paresthesia, psychosis, seizures, sleep disturbance, syncope, tremor, vertigo

CV: AV conduction disorders, bradycardia, chest pain, heart failure, hypertension, hypotension, palpitations, prolonged QT interval, PVCs, tachycardia, ventricular fibrillation

EENT: Blurred vision, vision changes

GI: Anorexia, diarrhea, nausea, vomiting

HEME: Agranulocytosis, anemia, aplastic anemia, bone marrow depression, hemolysis, leukopenia, neutropenia, thrombocytopenia

RESP: Pulmonary edema, fibrosis, and hypersensitivity (pneumonitis); respiratory arrest

SKIN: Diaphoresis, exfoliative dermatitis, pruritus, rash, skin lesions, urticaria

Nursing Considerations

- Monitor CBC with differential weekly during first 3 months of tocainide treatment and routinely thereafter to detect blood dyscrasias. Although rare, agranulocytosis, anemia, aplastic anemia, bone marrow depression, hemolysis, leukopenia, neutropenia, or thrombocytopenia may be fatal. Expect findings to normalize about 1 month after therapy stops.
- Maintain continuous cardiac monitoring or obtain periodic ECG tracings, as ordered, to assess drug effectiveness.
- Watch for tremor, a possible sign of maximum dosing.
- Assess patient for additive adverse cardiac effects, especially if tocainide is used with another antiarrhythmic.
- Be aware that tocainide is secreted in breast milk and has the potential to cause

serious adverse reactions in breast-feeding infants.

PATIENT TEACHING

- Inform patient that electrophysiologic studies may be performed before tocainide therapy starts.
- Tell patient to notify prescriber about tremor because dosage may need adjustment.
- Explain that chest X-rays may be needed if adverse pulmonary reactions occur.
- Inform patient that ambulatory monitoring may be needed to verify antiarrhythmic response.
- Stress the importance of keeping all scheduled appointments for follow-up blood tests.

tocilizumab

Actemra

Class and Category

Chemical class: Recombinant human anti-human interleukin 6 (IL-6) monoclonal antibody

Therapeutic class: Biologic disease-modifying antirheumatic drug (DMARD)

Pregnancy category: C

Indications and Dosages

↗ *To treat moderate to severe active rheumatoid arthritis in patients who have had an inadequate response to one or more tumor necrosis factor antagonist therapies*

I.V. INFUSION

Adults. 4 mg/kg given over 60 minutes every 4 wk, increased, as needed, to 8 mg/kg given over 60 minutes every 4 wk.

Maximum: 800 mg per infusion.

DOSAGE ADJUSTMENT Dosage reduced from 8 mg/kg to 4 mg/kg for management of dose-related laboratory changes, including elevated liver enzymes (AST or ALT 1 to 3 times the upper limit of normal), neutropenia (absolute neutrophil count approaching 1,000/mm³), or thrombocytopenia (platelet count approaching 100,000/mm³).

Mechanism of Action

Binds to interleukin 6 (IL-6) receptors to interrupt signaling through them. IL-6 is a proinflammatory cytokine produced by

various cells, such as T- and B-cells, lymphocytes, monocytes, and fibroblasts. It also is produced by synovial and endothelial cells, leading to local production of IL-6 in joints affected by inflammatory processes such as rheumatoid arthritis. Binding of IL-6 receptors prevents inflammation-related signals from being relayed, which reduces inflammatory response and relieves signs and symptoms of rheumatoid arthritis.

Incompatibilities

Don't mix tocilizumab with other drugs.

Contraindications

Hypersensitivity to tocilizumab or its components, absolute neutrophil count below 2,000/mm³, platelet count below 100,000/mm³, ALT or AST above 1.5 times upper limit of normal

Interactions

DRUGS

anti-CD20 monoclonal antibodies, IL-1R antagonists, selective co-stimulation modulators, TNF antagonists: Increased risk of immunosuppression and infection
atorvastatin; cytochrome P-450 substrates with a narrow therapeutic index such as cyclosporine, theophylline, warfarin; CYP3A4 substrates such as lovastatin, oral contraceptives, simvastatin; omeprazole: Possibly decreased plasma levels of these drugs with decreased effectiveness
live vaccines: Increased risk of adverse vaccine effects

Adverse Reactions

CNS: Dizziness, headache

CV: Elevated lipid levels, hypertension

EENT: Nasopharyngitis, oral ulceration

GI: Diverticulitis, elevated liver enzymes, gastritis, gastroenteritis, perforation, upper abdominal pain

GU: UTI

HEME: Neutropenia, thrombocytopenia

MS: Bacterial arthritis

RESP: Bronchitis, pneumonia, upper respiratory tract infection

SKIN: Cellulitis, pruritus, rash, urticaria

Other: Anaphylaxis, anti-tocilizumab antibodies, herpes zoster, malignancies, opportunistic infections including activation of latent infections, sepsis, tuberculosis with pulmonary or extrapulmonary disease

Nursing Considerations

- Tocilizumab may be used as monotherapy to treat rheumatoid arthritis or together with methotrexate or other nonbiological DMARDs.
 - Tocilizumab isn't recommended for patients with active liver disease or impairment because drug may adversely affect liver function.
 - Make sure patient has a tuberculin skin test before therapy starts. If skin test is positive, tuberculosis treatment will need to be started before tocilizumab therapy can begin. Even patients who have tested negative for tuberculosis may develop tuberculosis during therapy. Monitor patient for persistent cough, wasting or weight loss, and low-grade fever and report such findings to prescriber.
- WARNING** If patient has evidence of an active infection when drug is prescribed, therapy shouldn't start until infection has been treated. Monitor all patients for infections, including invasive fungal infections such as aspergillosis, candidiasis, or pneumocystis; or bacterial, mycobacterial, protozoal, or viral opportunistic infections during and after therapy, especially patients who are taking immunosuppressants. If a serious infection develops, expect prescriber to interrupt drug therapy until infection is controlled.
- Obtain a baseline of patient's absolute neutrophil count, platelet count, and liver enzymes before starting tocilizumab therapy, as ordered. Therapy shouldn't begin if patient's absolute neutrophil count is below $2,000/\text{mm}^3$, platelet count below $100,000/\text{mm}^3$ or ALT or AST level is above 1.5 times the upper limit of normal. Monitor these values, as ordered, every 4 to 8 weeks and report abnormalities. Dosage adjustment may be required or drug may need to be discontinued.
 - Use tocilizumab cautiously in patients with recurrent infection or increased risk of infection, patients who live in regions where tuberculosis and histoplasmosis are endemic, and patients with a history of CNS demyelinating disorders because they may occur, although rarely, during tocilizumab therapy.
 - When preparing to give tocilizumab, begin by withdrawing from a 100-ml infusion

bag or bottle containing 0.9% sodium chloride injection a volume equal to the volume of tocilizumab solution in the patient's dose. Slowly add drug from each vial into infusion bag or bottle and gently invert bag to mix while avoiding foaming. Discard any unused drug left in vials. Once fully diluted, solution may be stored in the refrigerator or at room temperature for up to 24 hours.

- Give tocilizumab with an infusion set, and never as I.V. push or bolus. Don't infuse concurrently with other drugs in same I.V. line.

WARNING Stop tocilizumab immediately and notify prescriber if patient has an allergic reaction. Provide supportive care, as needed.

PATIENT TEACHING

- Review the signs and symptoms of an allergic reaction (rash, swollen face, difficulty breathing), and tell patient to seek emergency care immediately if these occur.
- Inform patient that infections, including activation of latent infections such as tuberculosis, may occur during tocilizumab therapy. Instruct him to report unusual, persistent, or severe signs and symptoms to prescriber.
- Instruct patient to immediately contact a healthcare provider about severe, persistent abdominal pain because it could reflect GI perforation.
- Advise patient to avoid people with infections and to have all prescribed laboratory tests performed.
- Inform patient that risk of developing a malignancy is higher in patients taking tocilizumab but is still rare. Emphasize importance of follow-up visits and reporting any unusual or sudden signs or symptoms.
- Caution against receiving live-virus vaccines while taking tocilizumab.
- Advise patient to inform all health care providers about tocilizumab use and to inform prescriber about any OTC medications being taken, including herbal remedies and vitamin and mineral supplements.
- Urge woman who becomes pregnant while receiving tocilizumab to contact prescriber and to join the pregnancy registry by call-

ing 1-877-311-8972 so exposure to tocilizumab can be monitored.

tolazamide

Tolinase

Class and Category

Chemical class: First-generation sulfonylurea

Therapeutic class: Antidiabetic

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat type 2 diabetes mellitus that's uncontrolled by diet and exercise*

TABLETS

Adults. *Initial:* 100 mg daily with breakfast if fasting blood glucose level is less than 200 mg/dl; 250 mg daily if fasting blood glucose level is more than 200 mg/dl. Dose adjusted every wk by 100 to 250 mg, if needed. Doses greater than 500 mg daily are divided and given every 12 hr. *Maximum:* 1,000 mg daily.

DOSAGE ADJUSTMENT If patient takes more than 40 units daily of insulin, initial dosage increased to 250 mg daily and insulin dosage decreased by 50%.

Route	Onset	Peak	Duration
P.O.	Unknown	3–4 hr	10–20 hr

Mechanism of Action

Stimulates insulin release from beta cells in the pancreas. Tolazamide also increases peripheral tissue sensitivity to insulin either by enhancing insulin binding to cellular receptors or by increasing the number of insulin receptors.

Contraindications

Diabetic coma; diabetic ketoacidosis; hypersensitivity to tolazamide, sulfonylureas, or their components; pregnancy; sole therapy for type 1 diabetes mellitus

Interactions

DRUGS

ACE inhibitors, anabolic steroids, androgens, azole antifungals, bromocriptine, chloramphenicol, clofibrate, disopyramide, guanethidine, H₂-receptor antagonists, insulin, magnesium salts, MAO inhibitors, methyl dopa,

octreotide, oxyphenbutazone, phenylbutazone, probenecid, quinidine, salicylates, sulfonamides, tetracycline, theophylline, tricyclic antidepressants, urinary acidifiers: Increased risk of hypoglycemia

asparaginase, calcium channel blockers, cholestyramine, clonidine, corticosteroids, danazol, diazoxide, estrogen, glucagon, hydantoins, isoniazid, lithium, morphine, nicotinic acid, oral contraceptives, phenothiazines, rifabutin, rifampin, sympathomimetics, thiazide diuretics, thyroid drugs, urinary alkalisers: Increased risk of hyperglycemia
beta blockers: Possibly hyperglycemia or masking of signs and symptoms of hypoglycemia

digoxin: Increased risk of digitalis toxicity
pentamidine: Initial hypoglycemia and then hyperglycemia if beta cell damage occurs

ACTIVITIES

alcohol use: Altered blood glucose control (usually hypoglycemia), possibly disulfiram-like reaction

Adverse Reactions

CNS: Dizziness, fatigue, headache, malaise, paresthesia, vertigo

ENDO: Hypoglycemia

GI: Anorexia, cholestasis, heartburn, nausea, vomiting

HEME: Agranulocytosis, aplastic anemia, hemolysis, hemolytic anemia, leukopenia, thrombocytopenia

MS: Muscle weakness

SKIN: Erythema, photosensitivity, pruritus, rash, urticaria

Nursing Considerations

- When switching an insulin-treated patient with type 2 diabetes, expect to start tolazamide at 100 mg daily if patient takes less than 20 units daily of insulin, or 250 mg daily if patient takes 20 to 40 units daily of insulin.
- Anticipate that patient receiving tolazamide may need temporary insulin treatment during periods of physiologic stress, such as fever, surgery, systemic infection, and trauma.
- For patient over age 65, expect to start tolazamide at 100 mg daily.
- Assess elderly patients for signs of hypoglycemia because they're more susceptible to drug's hypoglycemic effect. Anticipate that hypoglycemia may be more difficult

to detect.

- Assess patient with thyroid disease for altered blood glucose control because thyroid hormone increases GI absorption of glucose.
- Expect prescriber to stop tolazamide 2 weeks before pregnant patient delivers her neonate to minimize the risk of prolonged hypoglycemia in neonate.

PATIENT TEACHING

- Advise patient to avoid alcohol while taking tolazamide.
- Teach patient and family members how to monitor blood glucose level and how to recognize signs of hypoglycemia and hyperglycemia.
- Instruct patient to treat mild hypoglycemia with fruit juice or other simple sugars.

tolbutamide

Apo-Tolbutamide (CAN), Novo-Butamide (CAN), Orinase

Class and Category

Chemical class: First-generation sulfonylurea

Therapeutic class: Antidiabetic

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat type 2 diabetes mellitus that's uncontrolled by diet and exercise*

TABLETS

Adults. *Initial:* 1 to 2 g daily in divided doses b.i.d. or t.i.d. *Maintenance:* 0.25 to 2 g daily. *Maximum:* 3 g daily.

Route	Onset	Peak	Duration
P.O.	Unknown	3–4 hr	6–12 hr

Mechanism of Action

Stimulates insulin release from beta cells in the pancreas. Tolbutamide also increases peripheral tissue sensitivity to insulin either by enhancing insulin binding to cellular receptors or by increasing the number of insulin receptors.

Contraindications

Diabetes complicated by pregnancy; diabetic coma; diabetic ketoacidosis; hypersensitivity to tolbutamide, sulfonylureas, or their

components; sole therapy for type 1 diabetes mellitus

Interactions

DRUGS

ACE inhibitors, anabolic steroids, androgens,azole antifungals, bromocriptine, chloramphenicol, clofibrate, disopyramide, guanethidine, H₂-receptor antagonists, insulin, magnesium salts, MAO inhibitors, methyl dopa, octreotide, oxyphenbutazone, phenylbutazone, probenecid, quinidine, salicylates, sulfonamides, tetracycline, theophylline, tricyclic antidepressants, urinary acidifiers: Increased risk of hypoglycemia

asparaginase, calcium channel blockers, cholestyramine, clonidine, corticosteroids, danazol, diazoxide, estrogen, glucagon, hydantoins, isoniazid, lithium, morphine, nicotinic acid, oral contraceptives, phenothiazines, rifabutin, rifampin, sympathomimetics, thiazide diuretics, thyroid drugs, urinary alkalisers: Increased risk of hyperglycemia
beta blockers: Possibly hyperglycemia or masking of signs and symptoms of hypoglycemia

digoxin: Increased risk of digitalis toxicity
pentamidine: Initial hypoglycemia and then hyperglycemia if beta cell damage occurs

ACTIVITIES

alcohol use: Altered blood glucose control (usually hypoglycemia), possibly disulfiram-like reaction

Adverse Reactions

CNS: Dizziness, fatigue, headache, malaise, paresthesia, vertigo

ENDO: Hypoglycemia

GI: Anorexia, cholestasis, heartburn, nausea, vomiting

HEME: Agranulocytosis, aplastic anemia, hemolysis, hemolytic anemia, leukopenia, thrombocytopenia

MS: Muscle weakness

SKIN: Erythema, photosensitivity, pruritus, rash, urticaria

Nursing Considerations

- If patient takes 20 units or less of insulin daily, expect a possible transfer from insulin to tolbutamide. If patient takes more than 20 units of insulin daily, expect to reduce insulin dosage as tolbutamide therapy starts.
- Anticipate that patient receiving tolbuta-

amide may need temporary insulin treatment during periods of physiologic stress, such as fever, surgery, systemic infection, or trauma.

- Assess elderly patients for signs of hypoglycemia because they're more susceptible to drug's hypoglycemic effect. Anticipate that hypoglycemia may be more difficult to detect.
- Assess patient with thyroid disease for altered blood glucose control because thyroid hormone increases GI absorption of glucose.
- Expect prescriber to stop tolbutamide 2 weeks before pregnant patient delivers her neonate to minimize the risk of prolonged hypoglycemia in neonate.

PATIENT TEACHING

- Advise patient to avoid alcohol while taking tolbutamide.
- Teach patient and family members how to monitor blood glucose level and recognize signs of hypoglycemia and hyperglycemia.
- Instruct patient to treat mild hypoglycemia with fruit juice or other simple sugars.

tolcapone

Tasmar

Class and Category

Chemical class: Nitrobenzophenone

Therapeutic class: Antidyskinetic

Pregnancy category: C

Indications and Dosages

➤ *As adjunct (with levodopa and carbidopa) to treat Parkinson's disease*

TABLETS

Adults. *Initial:* 100 mg t.i.d. *Maximum:* 200 mg t.i.d.

Mechanism of Action

Prolongs plasma half-life of levodopa by inhibiting catechol-*O*-methyltransferase (COMT), an enzyme responsible for metabolizing catecholamines—including dopa, dopamine, epinephrine, norepinephrine, and their hydroxylated metabolites. COMT inhibition decreases the metabolizing enzyme for levodopa, which yields a more sustained plasma levodopa level, making more available for diffusion into

the CNS to be converted to dopamine.

Contraindications

Confusion, hyperpyrexia, or rhabdomyolysis with previous use of tolcapone; hepatic dysfunction; hypersensitivity to tolcapone or its components

Interactions

DRUGS

desipramine: Possibly increased frequency of adverse effects

levodopa: Increased levodopa bioavailability, with increased risk of orthostatic hypotension and syncope

MAO inhibitors: Possibly inhibited catecholamine metabolism

Adverse Reactions

CNS: Confusion, dizziness, drowsiness, dyskinesia, fatigue, fever, hallucinations, headache, lethargy, loss of balance

CV: Chest pain, orthostatic hypotension

EENT: Dry mouth

GI: Abdominal pain, acute fulminant liver failure, anorexia, cholestasis, constipation, diarrhea, elevated liver function test results, vomiting

GU: Bright yellow urine, hematuria

MS: Muscle cramps, rhabdomyolysis

RESP: Dyspnea, upper respiratory tract infection

SKIN: Diaphoresis, jaundice

Other: Intense urges to perform certain activities (such as gambling and sex)

Nursing Considerations

- Ensure that patient has had the risks of tolcapone therapy explained fully to him and has signed the acknowledgement form before starting therapy.
- Use cautiously in patient with severe dyskinnesia or dystonia because drug is known to cause rhabdomyolysis.
- Monitor liver function test results, as ordered, during tolcapone therapy to detect hepatic impairment. Expect to discontinue drug if patient's liver enzymes exceed twice the upper limit of normal or if patient has any signs or symptoms of liver dysfunction, such as persistent nausea, fatigue, lethargy, anorexia, jaundice, dark urine, pruritus, or right upper quadrant tenderness.
- Assess patient for hallucinations, especially in patient over age 75.

- Anticipate that drug may precipitate or exaggerate preexisting dyskinesia.
- Expect tolcapone to be discontinued if no improvement occurs after 3 weeks of drug therapy.
- Assess patient for skin changes regularly because risk of melanoma is higher in patients with Parkinson's disease. It isn't clear whether risk results from disease or drugs used to treat it.

PATIENT TEACHING

- Inform patient that urine may turn bright yellow during tolcapone therapy.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to notify prescriber immediately about darkened urine, decreased appetite, fatigue, jaundice, lethargy, and right-sided abdominal pain.
- Caution patient not to stop taking drug abruptly. Explain that prescriber will supervise tapering of drug dosage.
- Urge patient to have regular follow-up appointments and laboratory tests.
- Urge patient to have regular skin examinations by a dermatologist or other qualified health professional.
- Advise patient to notify prescriber about intense urges (as for gambling or sex) because dosage may need to be reduced or drug discontinued.

tolmetin

Novo-Tolmetin (CAN), Tolectin DS, Tolectin 200, Tolectin 400 (CAN), Tolectin 600

Class and Category

Chemical class: Pyrroleacetic acid derivative
Therapeutic class: Anti-inflammatory
Pregnancy category: C (first trimester), Not rated (later trimesters)

Indications and Dosages

➤ *To relieve moderate pain from rheumatoid arthritis and osteoarthritis*

CAPSULES, TABLETS

Adults. *Initial:* 400 mg t.i.d. *Maintenance:* 600 to 1,800 mg daily in divided doses t.i.d. or q.i.d. *Maximum:* 2,000 mg daily for rheumatoid arthritis, 1,600 mg daily for osteoarthritis.

➤ *To treat juvenile rheumatoid arthritis*

CAPSULES, TABLETS

Children over age 2. *Initial:* 20 mg/kg daily in divided doses t.i.d. or q.i.d. *Maintenance:* 15 to 30 mg/kg daily in divided doses. *Maximum:* 30 mg/kg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	1–2 wk	Unknown

Mechanism of Action

Blocks cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate the inflammatory response and cause local vasodilation, swelling, and pain. Prostaglandins also promote pain transmission from the periphery to the spinal cord. By blocking cyclooxygenase and inhibiting prostaglandins, tolmetin reduces inflammatory symptoms and relieves pain.

Contraindications

Angioedema, asthma, bronchospasm, nasal polyps, rhinitis, or urticaria caused by aspirin, iodides, or other NSAIDs

Interactions

DRUGS

ACE inhibitors, beta blockers: Decreased effectiveness of these drugs, possibly reduced renal function
alendronate, corticosteroids, other NSAIDs, salicylates: Possibly adverse GI effects
anticoagulants, platelet aggregation inhibitors, thrombolytics: Additive inhibition of platelet aggregation; prolonged bleeding time
antineoplastics, antithymocyte globulin, strontium-89 chloride: Increased risk of bleeding
cidofovir: Possibly nephrotoxicity
cyclosporine: Potentiated cyclosporine nephrotoxicity
digoxin: Increased blood digoxin level
lithium: Possibly lithium toxicity
methotrexate: Increased or prolonged blood methotrexate level

ACTIVITIES

alcohol use: Increased risk of adverse GI effects

Adverse Reactions

CNS: Aseptic meningitis, cerebral hemorrhage, ischemic stroke, depression, dizziness, drowsiness, fatigue, headache, tran-

sient ischemic attack, weakness

CV: Chest pain, deep vein thrombosis, edema, hypertension, MI, peripheral edema

EENT: Tinnitus

ENDO: Hypoglycemia

GI: Abdominal pain; constipation; diarrhea; elevated liver function test results; flatulence; gastritis; GI bleeding, perforation, or ulceration; hepatitis; indigestion; jaundice; liver failure; nausea; peptic ulcer disease; vomiting

GU: Acute renal failure, dysuria, elevated BUN level, hematuria, interstitial nephritis, nephrotic syndrome, nephrotoxicity, proteinuria, UTI

HEME: Agranulocytosis, aplastic anemia, hemolytic anemia, leukopenia, pancytopenia, prolonged bleeding time

SKIN: Erythema multiforme, exfoliative dermatitis, maculopapular rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, weight gain or loss

Nursing Considerations

- Give tolmetin with food or milk to reduce adverse GI reactions.
- Assess patient for improvement within 7 days and progressive improvement over several successive weeks.
- Use tolmetin with extreme caution in patients with a history of ulcer disease or GI bleeding because NSAIDs such as tolmetin increase the risk of GI bleeding and ulceration. Expect to use tolmetin for the shortest time possible in these patients.
- Be aware that serious GI tract ulceration, bleeding, and perforation may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, withhold drug and notify prescriber at once.
- Use tolmetin cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

WARNING Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

WARNING If patient has bone marrow suppression or is receiving antineoplastic drug therapy, monitor laboratory results (including WBC count), and watch for

evidence of infection because anti-inflammatory and antipyretic actions of tolmetin may mask signs and symptoms, such as fever and pain.

- Especially if patient is elderly or taking tolmetin long-term, watch for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver function test results because, rarely, elevated levels may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure.
- Monitor BUN and serum creatinine levels in patients with heart failure, impaired renal function, or hepatic dysfunction; those taking diuretics or ACE inhibitors; and elderly patients because drug may cause renal failure.
- Monitor CBC for decreased hemoglobin and hematocrit because drug may worsen anemia.
- Assess patient's skin routinely for rash or other signs of hypersensitivity reaction because tolmetin and other NSAIDs may cause serious skin reactions without warning, even in patients with no history of NSAID hypersensitivity. Stop drug at first sign of reaction, and notify prescriber.
- Assess invasive sites or wounds for bleeding and bruising from drug's effects on platelets.

PATIENT TEACHING

- Tell patient to take drug with food or milk.
- Urge patient to limit sodium intake because drug may cause fluid retention.
- Tell patient to avoid alcohol during therapy.
- Teach patient how to perform proper oral hygiene, and advise her to have needed dental work done before tolmetin therapy starts because of the increased risk of bleeding.
- Explain that tolmetin may increase the risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, weakness, and slurring of speech.
- Tell patient that tolmetin also may

increase the risk of serious adverse GI reactions; stress the need to seek immediate medical attention for such signs and symptoms as epigastric or abdominal pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.

- Alert patient to the possibility of rare but serious skin reactions. Urge her to seek immediate medical attention for rash, blisters, itching, fever, or other indications of hypersensitivity.

tolterodine tartrate

Detrol, Detrol LA

Class and Category

Chemical class: Prodrug of 5-hydroxymethyltolterodine

Therapeutic class: Antispasmodic

Pregnancy category: C

Indications and Dosages

↗ *To treat overactive bladder*

TABLETS

Adults. 2 mg b.i.d. Reduced to 1 mg b.i.d. based on patient response and tolerance.

DOSAGE ADJUSTMENT Dosage reduced to 1 mg b.i.d. for patients with significant hepatic or renal dysfunction and for patients who are also receiving cytochrome P-450 3A4 inhibitors, such as clarithromycin, erythromycin, and the antifungals itraconazole, ketoconazole, and miconazole.

E.R. TABLETS

Adults. 4 mg daily. Reduced to 2 mg daily based on individual response and tolerance.

Mechanism of Action

Exerts antimuscarinic (atropine-like) and potent direct antispasmodic (papaverine-like) actions on smooth muscle in the bladder, which decreases detrusor muscle contractions. This helps reduce urinary frequency and urgency as well as urge-related incontinence.

Contraindications

Gastric retention, hypersensitivity to tolterodine tartrate or its components, uncontrolled angle-closure glaucoma, urine retention

Interactions

DRUGS

clarithromycin, erythromycin, itraconazole, ketoconazole, miconazole: Possibly increased blood tolterodine level

class IA antiarrhythmics (such as quinidine, procainamide) or class III antiarrhythmics (such as amiodarone, sotalol): Possibly increased risk of prolonged QT interval
fluoxetine: Possibly decreased tolterodine metabolism

Adverse Reactions

CNS: Confusion, disorientation, dizziness, drowsiness, fatigue, hallucinations, headache, memory impairment, somnolence, worsening of dementia

CV: Chest pain, edema, hypertension, palpitations, QT interval prolongation, tachycardia

EENT: Abnormal vision, blurred vision, dry eyes, dry mouth

GI: Abdominal pain, constipation, diarrhea, flatulence, indigestion, nausea

GU: Dysuria, urine retention, UTI

Other: Anaphylaxis, angioedema, flulike symptoms

Nursing Considerations

- Use cautiously in patients with decreased GI motility, myasthenia gravis, or narrow-angle glaucoma because tolterodine could make these conditions worse.

WARNING Monitor patients with a history of bladder outflow obstruction for decreased urine output or bladder distention because tolterodine poses a risk of urine retention.

- Monitor patients with a history of GI obstructive disorders, such as pyloric stenosis, for abdominal distention or bloating because of increased risk of gastric retention.
- Be aware that drug's antimuscarinic effects may produce blurred vision, dizziness, and drowsiness. If these occur, institute fall precautions according to facility policy.

PATIENT TEACHING

- Instruct patient taking tolterodine to immediately report to prescriber difficulty urinating or infrequent urination.
- Advise patient not to drive or perform activities that require high alertness until drug's CNS and vision effects are known. Instruct her to notify prescriber if dizzi-

ness or blurred vision persists.

- Encourage patient to use sugarless candy, gum, or ice to relieve dry mouth. Advise her to notify prescriber or dentist if dry mouth persists or worsens over 2 weeks.

tolvaptan

Samsca

Class and Category

Chemical class: Non-peptide vasopressin receptor antagonist

Therapeutic class: Antihyponatremic

Pregnancy category: C

Indications and Dosages

➤ *To treat significant hypervolemic and euvolemic hyponatremia (serum sodium level less than 125 mEq/L or symptomatic but less-marked hyponatremia that has resisted correction with fluid restriction), including patients with heart failure, cirrhosis, or syndrome of inappropriate antidiuretic hormone (SIADH)*

TABLETS

Adults. *Initial:* 15 mg once daily, increased after at least 24 hours to 30 mg once daily. *Maximum:* 60 mg once daily.

Mechanism of Action

Raises serum sodium levels by increasing urine output and decreasing urine osmolality. Tolvaptan does this by preventing attachment of vasopressin to vasopressin V2 receptors on cell membranes in the nephron's collecting duct. Without vasopressin activity, urinary water excretion increases.

Contraindications

Acute need to raise serum sodium urgently; anuria; concomitant use of strong CYP3A inhibitors such as clarithromycin, ketoconazole, indinavir, itraconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin; hypovolemic hyponatremia; hypersensitivity to tolvaptan or its components; inability of patient to sense or respond appropriately to thirst

Interactions

DRUGS

ACE inhibitors, angiotensin receptor blockers,

potassium sparing diuretics, potassium supplements: Increased risk of hyperkalemia
CYP3A inducers such as barbiturates, carbamazepine, phenytoin, rifabutin, rifampin, rifapentin, St. John's wort: Decreased serum tolvaptan level and decreased effectiveness
CYP3A inhibitors such as aprepitant, clarithromycin, diltiazem, erythromycin, fluconazole, ketoconazole, indinavir, itraconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, verapamil; P-gp inhibitors such as cyclosporine: Increased serum tolvaptan level and risk of adverse reactions
digoxin: Increased digoxin level

FOODS

grapefruit juice: Increased serum tolvaptan level

Adverse Reactions

CNS: Asthenia, CVA, fever, thirst

CV: Deep vein thrombosis, intracardiac thrombus, ventricular fibrillation

EENT: Dry mouth

ENDO: Diabetic ketoacidosis, hyperglycemia

GI: Anorexia, constipation, gastrointestinal bleeding, ischemic colitis, nausea

GU: Nocturia, polyuria, urethral or vaginal hemorrhage

HEME: Disseminated intravascular coagulation, prolonged prothrombin time

MS: Rhabdomyolysis

RESP: Pulmonary embolism, respiratory failure

Other: Dehydration, hyperkalemia, hyponatremia, hypovolemia

Nursing Considerations

- Use cautiously in patients with cirrhosis because of increased risk of GI bleeding.

WARNING Give tolvaptan, initially or if reintroduced, in a hospital setting because too-rapid correction of hyponatremia (more than 12 mEq/L in 24 hour) causes osmotic demyelination (affective changes, coma, dysarthria, dysphagia, lethargy, mutism, spastic quadriparesis, seizures, death). If present, notify prescriber immediately and expect to stop tolvaptan and give hypotonic fluids.

- Monitor fluid and electrolyte balance regularly, especially when starting tolvaptan and adjusting dosage, as ordered.
- Don't restrict fluids during first 24 hours of therapy because doing so may increase

the risk of overly-rapid correct of serum sodium, hypovolemia, and dehydration.

- Use of hypertonic saline isn't recommended during tolvaptan therapy because effects are unknown.

PATIENT TEACHING

- Instruct patient to consume fluids according to thirst during first 24 hours of therapy and not to try to limit fluid intake.
- When drug is discontinued, tell patient that he'll need to resume fluid restriction and will need continued monitoring of sodium level and fluid status.

topiramate

Topamax

Class and Category

Chemical class: Sulfamate-substituted monosaccharide

Therapeutic class: Anticonvulsant

Pregnancy category: C

Indications and Dosages

↗ *To treat partial-onset or primary generalized tonic-clonic seizures*

CAPSULES

Adults and children age 10 and over.

Initial: 25 mg b.i.d. in morning and evening. Increased by 50 mg daily every wk. *Maintenance:* 200 mg b.i.d. in morning and evening.

↗ *As adjunct to treat partial seizures and primary generalized tonic-clonic seizures*

CAPSULES, TABLETS

Adults and adolescents age 17 and over.

Initial: 25 to 50 mg daily in divided doses b.i.d. for 1 wk. Increased by 25 to 50 mg daily every wk. *Maintenance:* 200 to 400 mg daily in divided doses b.i.d. *Maximum:* 1,600 mg daily.

Children ages 2 to 16. *Initial:* 25 mg or less at bedtime for 1 wk. Increased every 1 to 2 wk by 1 to 3 mg/kg daily in divided doses every 12 hr, as prescribed. *Usual:* 5 to 9 mg/kg daily in divided doses every 12 hr.

↗ *As adjunct to treat seizures associated with Lennox-Gastaut syndrome*

CAPSULES, TABLETS

Children ages 2 to 16. 25 mg at bedtime for 1 wk. Increased every 1 to 2 wk by 1 to 3 mg/kg daily in divided doses every 12 hr,

as prescribed. *Usual:* 5 to 9 mg/kg daily in divided doses every 12 hr.

↗ *To prevent migraine headache*

CAPSULES, TABLETS

Adults. *Initial:* 25 mg daily in evening for 1 wk; then 25 mg b.i.d. for 1 wk; then 25 mg in morning and 50 mg in evening for 1 wk. *Maintenance:* 50 mg b.i.d.

DOSAGE ADJUSTMENT For patients with moderate to severe renal impairment, dosage possibly reduced by 50%.

Mechanism of Action

May block the spread of seizures by reducing the length and frequency of excitatory transmission. Topiramate increases the availability of the inhibitory neurotransmitter gamma-aminobutyric acid by blocking voltage-sensitive sodium channels. This action promotes the movement of chloride ions into neurons.

Contraindications

Hypersensitivity to topiramate or its components

Interactions

DRUGS

antihistamines, barbiturates, benzodiazepines, CNS depressants, opioid analgesics, skeletal muscle relaxants, tricyclic antidepressants: Additive CNS depression
carbamazepine: Decreased blood topiramate level

carbonic anhydrase inhibitors: Increased risk of renal calculus formation

digoxin: Possibly decreased blood digoxin level

ethinyl estradiol: Increased risk of breakthrough bleeding

oral contraceptives: Increased risk of breakthrough bleeding, decreased contraceptive efficacy

phenobarbital: Altered blood phenobarbital level

phenytoin: Decreased blood level of topiramate

probenecid: Possibly blocked renal tubular reabsorption of topiramate and decreased blood topiramate level

valproic acid: Decreased blood levels of both drugs, increased risk of hyperammonemia

ACTIVITIES

alcohol use: Additive CNS depression

Adverse Reactions

CNS: Agitation, anxiety, asthenia, ataxia, confusion, decreased concentration, depression, dizziness, encephalopathy, fatigue, fever, hallucinations, headache, hyperthermia, hypoesthesia, insomnia, irritability, memory loss, mood changes, nervousness, paresthesia, psychomotor slowing, psychosis, slurred speech, somnolence, suicidal ideation, syncope, tremor

CV: Cardiac arrest, chest pain, hot flashes, hypertension, hypotension, palpitations, vasodilation

EENT: Blurred vision, diplopia, dry mouth, gingivitis, hearing loss, maculopathy, nystagmus, periorbital pain, pharyngitis, rhinitis, secondary angle-closure glaucoma with acute myopia, sinusitis, taste perversion, tinnitus, tongue edema, vision changes

ENDO: Breast pain, hyperglycemia

GI: Abdominal pain, anorexia, constipation, diarrhea, flatulence, gastroenteritis, gastroesophageal reflux, hepatic failure, hepatitis, indigestion, nausea, pancreatitis, vomiting

GU: Cystitis, decreased libido, dysmenorrhea, dysuria, frequent urination, impotence, menstrual irregularities, renal calculi, renal tubular acidosis, UTI, vaginitis

HEME: Anemia, leukopenia

MS: Arthralgia, back pain, leg cramps or pain, muscle weakness

RESP: Bronchitis, cough, dyspnea, pulmonary embolism, upper respiratory tract infection

SKIN: Acne, alopecia, decreased sweating, erythema multiforme, pemphigus, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Dehydration, hyperammonemia, metabolic acidosis, weight gain or loss

Nursing Considerations

- Obtain baseline serum bicarbonate level before topiramate therapy and monitor periodically throughout therapy, as ordered.
- Use topiramate cautiously in patients with inborn errors of metabolism or impaired hepatic function, or who are taking valproic acid because they may be at higher risk for hyperammonemia with or without encephalopathy while taking topiramate.
- Give capsule with water and have patient swallow it whole. If needed, open capsules

and empty contents onto a spoonful of soft food. Discard unused portion.

- Never store food sprinkled with drug for use at a later time.

WARNING Anticipate an increase in seizures if therapy stops abruptly. Take seizure precautions, as appropriate. Expect drug to be withdrawn gradually if time permits.

- If patient reports ocular pain or decreased visual acuity, notify prescriber immediately; topiramate may cause increased intraocular pressure and secondary angle-closure glaucoma. Expect to stop drug immediately.
- If patient has a history of renal calculi, assess for signs of recurrence.

PATIENT TEACHING

- Instruct patient to swallow topiramate tablets whole.
- Urge patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Advise patient to watch for decreased sweating and significantly increased body temperature, especially during hot weather, and to notify prescriber immediately if they occur.
- Tell patient to maintain adequate fluid intake to minimize the risk of developing kidney stones.
- Advise female patient of possible breakthrough bleeding. If she takes an oral contraceptive, encourage her to use another form of contraception during therapy.
- Caution patient not to stop taking topiramate abruptly because seizures may occur. Instead, patient should expect drug to be withdrawn gradually if it needs to be discontinued.
- Instruct patient to seek immediate emergency care for blurred vision, other visual disturbances, or periorbital pain.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when topiramate therapy starts or dosage changes, and to report concerns at once to prescriber.
- Urge woman who becomes pregnant while taking topiramate to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting information about the safety of antiepileptic drugs during pregnancy.

torsemide

Demadex

Class and Category

Chemical class: Anilinopyridine sulfonylurea derivative

Therapeutic class: Antihypertensive, diuretic

Pregnancy category: B

Indications and Dosages

↗ *To treat edema in heart failure*

TABLETS, I.V. INJECTION

Adults. *Initial:* 10 to 20 mg daily, adjusted by doubling, as prescribed, to achieve desired effect. *Maximum:* 200 mg daily.

↗ *To treat edema in chronic renal failure*

TABLETS, I.V. INJECTION

Adults. *Initial:* 20 mg daily, adjusted by doubling, as prescribed, to achieve desired effect. *Maximum:* 200 mg daily.

↗ *To treat ascites, alone or with amiloride or spironolactone*

TABLETS, I.V. INJECTION

Adults. *Initial:* 5 to 10 mg daily. *Maximum:* 40 mg daily.

↗ *To manage hypertension*

TABLETS

Adults. *Initial:* 5 mg daily, increased to 10 mg daily after 4 to 6 wk, as prescribed, if response is inadequate. *Maximum:* 10 mg daily.

Route	Onset	Peak	Duration
P.O.	1 hr	1–2 hr	6–8 hr
I.V.	10 min	1 hr	6–8 hr

Mechanism of Action

Blocks active sodium and chloride reabsorption in the ascending loop of Henle by promoting rapid excretion of water, sodium, and chloride. Torsemide also increases the production of renal prostaglandins, increasing the plasma renin level and renal vasodilation. As a result, blood pressure falls, reducing preload and afterload.

Contraindications

Hypersensitivity to torsemide, sulfonamides, or their components

Interactions

DRUGS

ACE inhibitors, antihypertensives: Additive

hypotension

amiloride, spironolactone, triamterene:

Possibly counteracted torsemide-induced hypokalemia

amphotericin B: Increased risk of nephrotoxicity and severe, prolonged hypokalemia or hypomagnesemia

cisplatin: Increased risk of significant hypokalemia or hypomagnesemia, possibly permanent ototoxicity

cortisone, fluorocortisone, hydrocortisone:

Increased risk of sodium retention and hypokalemia

digoxin: Increased risk of arrhythmias and digitalis toxicity due to hypokalemia or hypomagnesemia

indomethacin: Possibly decreased diuretic and antihypertensive effects of torsemide and increased risk of renal failure

lithium: Possibly lithium toxicity

metolazone, thiazide diuretics: Increased risk of severe fluid and electrolyte loss

neuromuscular blockers: Possibly increased neuromuscular blockade due to hypokalemia

probenecid: Possibly decreased diuretic effect of torsemide

quinidine and other ototoxic drugs: Increased risk of ototoxicity

salicylates: Increased risk of salicylate toxicity

ACTIVITIES

alcohol use: Additive diuresis and, possibly, dehydration

Adverse Reactions

CNS: Dizziness, drowsiness, fatigue, headache, insomnia, lethargy, nervousness, restlessness, weakness

CV: Chest pain, ECG abnormalities, edema, hypotension, tachycardia

EENT: Dry mouth, hearing loss, ototoxicity, pharyngitis, rhinitis, tinnitus

GI: Constipation, diarrhea, indigestion, nausea, thirst, vomiting

GU: Azotemia (prerenal), oliguria, urinary frequency

MS: Muscle spasms, myalgia

RESP: Cough

Other: Hypochloremia, hypokalemia, hypomagnesemia, hyponatremia, hypovolemia

Nursing Considerations

- Inject I.V. torsemide slowly over 2 minutes. Flush I.V. line with normal saline solution before and afterward.

- Don't exceed 200 mg in a single I.V. dose of torsemide.
- Monitor patient's serum electrolyte levels and fluid intake and output to detect hypovolemia.

WARNING Expect torsemide-induced electrolyte imbalances, such as hypokalemia and hypomagnesemia, to increase the risk of toxicity and fatal arrhythmias in a patient who takes a digitalis glycoside. Hypokalemia also potentiates the neuromuscular blockade effects of nondepolarizing neuromuscular blockers.

PATIENT TEACHING

- Advise patient to change position slowly to minimize the effects of orthostatic hypotension.
- Instruct patient to notify prescriber at once about drowsiness, dry mouth, hearing changes, lethargy, muscle pain, nausea, restlessness, thirst, vomiting, or weakness.
- Advise diabetic patient to monitor her blood glucose level often because drug may raise it.

tramadol hydrochloride

Ultram, Ultram ER

Class and Category

Chemical class: Cyclohexanol

Therapeutic class: Analgesic

Pregnancy category: C

Indications and Dosages

➤ To relieve moderate to moderately severe pain

TABLETS

Adults and adolescents over age 16. 50 to 100 mg every 4 to 6 hr, p.r.n. *Maximum:* 400 mg daily.

DOSE ADJUSTMENT If patient has hepatic impairment, dosage reduced to 50 mg every 12 hr. If patient is age 75 or over, maximum dosage reduced to 300 mg daily. If creatinine clearance is 30 ml/min/1.73 m² or less, interval increased to every 12 hr and maximum dosage limited to 200 mg daily.

E.R. TABLETS

Adults. 100 mg once daily, increased in 100-mg increments once daily every 5 days, as needed. *Maximum:* 300 mg once daily.

Mechanism of Action

Binds with mu receptors and inhibits the reuptake of norepinephrine and serotonin, which may account for tramadol's analgesic effect.

Route	Onset	Peak	Duration
P.O.	1 hr	2–3 hr	7–14 hr

Contraindications

Alcohol intoxication; excessive use of central-acting analgesics, hypnotics, opioids, or other psychotropic drugs; hypersensitivity to tramadol or its components; use within 14 days of MAO inhibitor therapy

Interactions

DRUGS

alpha blockers, CYP2D6 and CYP3A4 inhibitors (amitriptyline, erythromycin, fluoxetine, paroxetine, quinidine), linezolid, lithium, MAO inhibitors, St. John's wort, selective serotonin and norepinephrine reuptake inhibitors, tricyclic antidepressants, triptans: Increased risk of serotonin syndrome
amiodarone, cimetidine, clomipramine, desipramine, fluphenazine, haloperidol, propa-fenone, quinidine, ritonavir, thioridazine: Decreased analgesia, increased adverse effects of tramadol
amitriptyline, amphetamines, antipsychotics, bupropion, cyclobenzaprine, dextroamphetamine, erythromycin, fluoxetine, ketoconazole, paroxetine, quinidine, MAO inhibitors, naloxone, tricyclic antidepressants: Increased risk of seizures

barbiturates, benzodiazepines, opioid analgesics, sedative-hypnotics, tranquilizers:

Additive CNS depression

carbamazepine: Increased tramadol metabolism

general anesthetics: Increased CNS and respiratory depression

phenothiazines, rifampin: Additive CNS depression, increased risk of seizures

warfarin: Possibly increased INR

ACTIVITIES

alcohol use: Additive CNS depression

Adverse Reactions

CNS: Agitation, anxiety, asthenia, depression, dizziness, emotional lability, euphoria, fatigue, fever, hallucinations, headache, hypertonia, hypoesthesia, insomnia, lethargy, nervousness, paresthesia, restlessness,

rigors, seizures, serotonin syndrome, somnolence, suicidal ideation, tremor, vertigo, weakness

CV: Chest pain, orthostatic hypotension, vasodilation

EENT: Blurred vision, dry mouth, nasal or sinus congestion, sore throat, vision changes

ENDO: Hot flashes

GI: Abdominal pain, anorexia, constipation, diarrhea, indigestion, nausea, vomiting

GU: Urinary frequency, urine retention

MS: Arthralgia; back, limb, or neck pain

RESP: Cough, dyspnea

SKIN: Diaphoresis, dermatitis, flushing, pruritus, rash

Other: Flulike illness, physical and psychological dependence

Nursing Considerations

- Be aware that tramadol shouldn't be given to patients with a history of anaphylactoid reactions to codeine or other opioids.

WARNING Monitor patient closely for evidence of serotonin syndrome, such as agitation, hallucinations, coma, tachycardia, labile blood pressure, hyperthermia, hyperreflexia, incoordination, nausea, vomiting, or diarrhea. Notify prescriber at once because serotonin syndrome may be life-threatening. Be prepared to discontinue drug and provide supportive care.

- Because tramadol may lead to physical and psychological dependence, assess patient for evidence of dependence or abuse. Avoid giving drug to patients with a history of dependence on other opioids.
- Avoid giving tramadol to patients with acute abdominal conditions because it may mask evidence and disrupt assessment of the abdomen.
- After patient receives first tramadol dose, watch for allergic reactions, including angioedema, bronchospasm, pruritus, Stevens-Johnson syndrome, toxic epidermal necrolysis, and urticaria. Also watch for signs and symptoms of anaphylaxis, such as dyspnea and hypotension.
- If patient has respiratory depression, assess respiratory status often, and expect to give a nonopioid analgesic—not tramadol.
- If patient develops respiratory depression, expect to give naloxone. Watch for seizures because naloxone may increase this risk. Take seizure precautions.
- Assess respiratory status often if patient

has increased intracranial pressure or head injury because of possible increased carbon dioxide retention and CSF pressure, either of which may cause respiratory depression. Also, be aware that tramadol may constrict pupils, obscuring evidence of intracranial complications.

WARNING Watch for seizures in patients with epilepsy, a history of seizures, or an increased risk of seizures, such as those with head injury, metabolic disorders, alcohol or drug withdrawal, or CNS infection.

- Expect to taper tramadol rather than stopping it abruptly to avoid such acute withdrawal symptoms as anxiety, diarrhea, insomnia, nausea, pain, panic attacks, paresthesias, piloerection, rigors, sweating, tremor, and upper respiratory symptoms.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

PATIENT TEACHING

- Urge patient to follow prescribed dose limits and dosing intervals to prevent respiratory depression and seizures.
- Instruct patient prescribed extended-release form to swallow tablet whole and not to chew, crush, or split tablet.
- Caution patient not to stop tramadol abruptly.
- Instruct patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to avoid alcohol while taking tramadol.
- Urge patient to notify prescriber about known, suspected, or intended pregnancy.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes and to report concerns at once to prescriber.
- Tell patient to notify prescriber immediately if he develops any sudden onset, unusual, persistent, or severe adverse reactions.

trandolapril

Mavik

Class and Category

Chemical class: ACE inhibitor (non-sulphydryl-containing)

Therapeutic class: Antihypertensive, vasodilator

Pregnancy category: C (first trimester), D (later trimesters)

Indications and Dosages

↗ *To manage hypertension*

TABLETS

Adults. *Initial:* 1 mg daily, increased every wk based on clinical response. Dosage may be given in two daily doses if antihypertensive effect diminishes before 24 hr. *Usual:* 2 to 4 mg daily. *Maximum:* 8 mg daily.

DOSAGE ADJUSTMENT Initial dosage increased to 2 mg daily for blacks with hypertension. Initial dosage reduced to 0.5 mg for patients also receiving a diuretic, those with a creatinine clearance of less than or equal to 30 ml/min/1.73 m², and those with cirrhosis.

↗ *To treat heart failure after MI*

TABLETS

Adults. *Initial:* 1 mg daily. *Usual:* 4 mg or more daily. *Maximum:* 8 mg daily.

Route	Onset	Peak	Duration
P.O.	2 hr	8 hr	24 hr

Mechanism of Action

Reduces blood pressure by inhibiting the conversion of angiotensin I to angiotensin II. Angiotensin II is a potent vasoconstrictor that stimulates the renal cortex to secrete aldosterone. Decreased release of aldosterone reduces sodium and water retention and increases their excretion, thereby reducing blood pressure. Trandolapril may also inhibit renal and vascular production of angiotensin II.

Contraindications

History of angioedema related to previous treatment with ACE inhibitor, hypersensitivity to trandolapril or its components

Interactions

DRUGS

allopurinol, bone marrow depressants (such as methotrexate), corticosteroids (systemic), cytostatic drugs, procainamide: Increased risk of potentially fatal neutropenia or agranulocytosis
antacids: Decreased blood trandolapril level
cyclosporine, potassium-containing drugs, potassium-sparing diuretics, potassium sup-

plements: Increased risk of hyperkalemia
diuretics, other antihypertensives: Increased hypotensive effects

lithium: Increased blood lithium level and risk of lithium toxicity

NSAIDs, sympathomimetics: Possibly reduced antihypertensive effects

sodium aurothiomalate: Increased risk of nitroid reactions such as facial flushing, nausea, vomiting, and hypotension

FOODS

high-potassium diet, low-sodium milk, potassium-containing salt substitutes: Increased risk of hyperkalemia

ACTIVITIES

alcohol use: Possibly increased hypotensive effect

Adverse Reactions

CNS: Dizziness, fatigue, fever, headache

CV: Hypotension, orthostatic hypotension

EENT: Loss of taste

GI: Diarrhea, nausea

GU: Decreased libido, impotence

MS: Myalgia

RESP: Cough, dyspnea, upper respiratory tract infection

SKIN: Pruritus, rash

Other: Angioedema

Nursing Considerations

WARNING Closely monitor blood pressure during first 2 weeks of therapy and whenever dosage is adjusted, especially in patients with heart failure, hyponatremia, or severe volume or sodium loss. If excessive hypotension occurs, notify prescriber immediately, place patient in supine position, and infuse I.V. normal saline solution, as prescribed.

WARNING Be alert for signs and symptoms of angioedema. If swelling of tongue, glottis, or larynx causes airway obstruction, notify prescriber and be prepared to discontinue drug and administer emergency measures, including subcutaneous epinephrine 1:1,000 (0.3 to 0.5 ml).

- Continue to monitor patient's blood pressure to assess drug's long-term effectiveness.

PATIENT TEACHING

- Instruct patient to notify prescriber immediately and stop taking trandolapril if she experiences swelling of face, eyes, lips, or tongue or has difficulty breathing.

- Explain that drug may cause dizziness and light-headedness, especially during first few days of therapy. Advise patient to avoid driving and other potentially hazardous activities until drug's CNS effects are known and to notify prescriber immediately if she faints.
- Inform female patient of childbearing age about risks of taking tranexamic acid during pregnancy, especially during second and third trimesters. Urge her to use effective contraceptive method and to notify prescriber immediately if she becomes or thinks she might be pregnant.
- Advise patient planning to undergo surgery or anesthesia to inform specialist that she's taking tranexamic acid.
- Instruct patient to consult prescriber before using potassium supplements or salt substitutes containing potassium.
- Inform patient about possible loss of taste, which may result in weight loss. Reassure her that loss of taste is usually reversed after 2 to 3 months.

tranexamic acid

Lysteda

Class and Category

Chemical class: Synthetic lysine amino acid derivative

Therapeutic class: Antifibrinolytic

Pregnancy category: B

Indications and Dosages

↗ *To treat cyclic heavy menstrual bleeding*

TABLETS

Adults. 1,300 mg three times daily for a maximum of 5 days during monthly menstruation

DOSE ADJUSTMENT For patient with a serum creatinine level above 1.4 mg/dl but equal to or less than 2.8 mg/dl, 1,300 mg two times a day for a maximum of 5 days during menstruation; for patient with a serum creatinine level above 2.8 mg/dl but equal to or less than 5.7 mg/dl, 1,300 mg once daily for a maximum of 5 days during menstruation; for patient with a serum creatinine level above 5.7 mg/dl, 650 mg once daily for a maximum of 5 days during menstruation.

Mechanism of Action

Displaces plasminogen from surface of fibrin by binding to high-affinity lysine site of plasminogen. This diminishes dissolution of hemostatic fibrin, which decreases bleeding.

Route	Onset	Peak	Duration
P.O.	Unknown	3 hr	Unknown

Contraindications

Active thromboembolic disease; history or intrinsic risk of thrombosis or thromboembolism, including retinal vein or artery occlusion; hypersensitivity to tranexamic acid or its components

Interactions

DRUGS

anti-inhibitor coagulant concentrates, factor IX complex concentrates, hormonal contraceptives: Increased thrombotic risk
tissue plasminogen activators: Possibly decreased effectiveness of both tranexamic acid and the tissue plasminogen activator
tretinoin (oral): Possibly exacerbation of the pro-coagulant effect of tretinoin

Adverse Reactions

CNS: Cerebral thrombosis, dizziness, fatigue, headache, migraine

CV: Deep vein thrombosis

EENT: Central retinal artery and vein obstruction, feeling of throat tightness, impaired color vision, liginous conjunctivitis, nasal and sinus congestion, sinusitis, visual abnormalities

GI: Abdominal pain, diarrhea, nausea, vomiting

GU: Acute renal cortical necrosis

HEME: Anemia

MS: Arthralgia, back pain, muscle cramps and spasms, myalgia

RESP: Dyspnea, pulmonary embolism, respiratory congestion,

SKIN: Allergic skin reactions, facial flushing

Other: Anaphylaxis, multiple allergies including seasonal

Nursing Considerations

- Tranexamic acid therapy isn't recommended for women who use hormonal contraceptives or who take factor IX complex concentrates or anti-inhibitor coagulant concentrates because of the increased

risk of thromboembolism.

- Use tranexamic acid cautiously in patients with acute promyelocytic leukemia taking oral tretinoin for remission induction because of possible exacerbation of the pro-coagulant effect of tretinoin.
- Cerebral edema and cerebral infarction may occur in women taking tranexamic acid if a subarachnoid hemorrhage occurs.

WARNING Monitor patient closely for allergic reactions to tranexamic acid such as dyspnea, a feeling of throat tightness, and facial flushing that may require emergency medical treatment.

PATIENT TEACHING

- Instruct patient to swallow tranexamic acid tablets whole, without chewing or breaking them. Therapy shouldn't exceed 5 days during menstruation.
- Tell patient to seek emergency care immediately if she has any signs of allergic reaction, especially dyspnea, a feeling of throat tightness, and facial flushing, and to stop taking drug.
- Advise patient to report any changes in vision or ocular discomfort.

tranylcypromine sulfate

Parnate

Class and Category

Chemical class: Nonhydrazine derivative

Therapeutic class: Antidepressant

Pregnancy category: Not rated

Indications and Dosages

↗ To treat major depressive episodes with out melancholia

TABLETS

Adults and adolescents over age 16. 30 mg/day in divided doses. After first 2 wk, increased by 10 mg every 1 to 2 wk, as prescribed. *Maintenance:* 10 to 40 mg daily. *Maximum:* 60 mg daily.

DOSE ADJUSTMENT For elderly patients, initial dosage possibly reduced to 2.5 to 5 mg daily and increased by 2.5 to 5 mg every 3 to 4 days, as prescribed; maximum dosage 45 mg daily. Alternative therapies should be carefully considered for patients over age 60.

Mechanism of Action

Reversibly binds to MAO, reducing its activity and resulting in increased levels of neurotransmitters, including dopamine, epinephrine, and norepinephrine. This regulation of CNS neurotransmitters helps ease depression.

Route	Onset	Peak	Duration
P.O.	7–10 days	4–8 wk	10 days

Contraindications

Cardiovascular disease; cerebrovascular disease; heart failure; hepatic disease; history of headaches; hypersensitivity to tranylcypromine or its components; hypertension; pheochromocytoma; severe renal impairment; use of anesthetics, antihypertensives, bupropion, buspirone, carbamazepine, CNS depressants, cyclobenzaprine, dextromethorphan, meperidine, other MAO inhibitors, selective serotonin-reuptake inhibitors, sympathomimetics, or tricyclic antidepressants

Interactions

DRUGS

amoxapine, bupropion, maprotiline, selective norepinephrine reuptake inhibitors, selective serotonin reuptake inhibitors, trazodone, tricyclic antidepressants: Increased risk of severe hypertensive crisis, increased anticholinergic effects

anticonvulsants: Additive CNS depression

antihistamines: Possibly prolonged anticholinergic and CNS depressant effects

antipsychotics: Additive anticholinergic, hypotensive, and sedative effects

beta blockers: Possibly worsened bradycardia
bromocriptine: Increased blood prolactin level and interference with bromocriptine effects

buspirone: Increased blood pressure
dextroamphetamine, isometheptene, local anesthetics, naphazoline, oxymetazoline, psychostimulants, sympathomimetics, tetrahydrozoline, xylometazoline: Increased risk of severe hypertensive reaction

dextromethorphan, tryptophan: Increased risk of serotonin syndrome
diuretics: Additive hypotensive effects

doxapram: Increased vasopressor effects
furazolidone, procarbazine, selegiline: Increased risk of severe hyperpyretic or

hypertensive crisis, seizures, or death
guanadrel, guanethidine: Increased risk of moderate to severe hypertension
insulin, oral antidiabetic drugs: Possibly prolonged hypoglycemic response
levodopa: Increased vasopressor effects, hypertension, adverse cardiovascular effects
meperidine: Increased risk of coma, diaphoresis, excitation, hypertension, rigidity, severe respiratory depression, shock, and, possibly, death
methylodopa: Increased risk of hallucinations
metrizamide, tramadol: Increased risk of seizures
succinylcholine: Possibly prolonged succinylcholine effects

FOODS

aged cheese; avocados; bananas; fava or broad beans; cured sausage (bologna, pepperoni, salami, and summer sausage) or other meat; overripe fruit; pickled fish, meats, or poultry; protein extract; smoked fish, meats, or poultry; soy sauce; yeast extract; and other foods high in pressor amines, such as tyramine: Increased risk of sudden, severe hypertension

caffeine-containing beverages and foods: Increased risk of severe hypertensive crisis and dangerous arrhythmias

ACTIVITIES

alcohol-containing products that also may contain tyramine, such as beer (including reduced-alcohol and alcohol-free beer), wine (red and white), sherry, hard liquor, liqueurs: Increased risk of hypertensive crisis

Adverse Reactions

CNS: Anxiety, chills, dizziness, drowsiness, fever, headache, insomnia, intracranial hemorrhage, paresthesia, restlessness, suicidal ideation, tremor, weakness

CV: Bradycardia, chest pain, edema, hypertensive crisis, orthostatic hypotension, palpitations, tachycardia

EENT: Blurred vision, dry mouth, mydriasis, photophobia, tinnitus

GI: Abdominal pain, anorexia, constipation, diarrhea, nausea, vomiting

GU: Ejaculation disorders, impotence, urine retention

HEME: Agranulocytosis, anemia, leukopenia, thrombocytopenia

MS: Muscle spasms, myoclonus, neck stiffness

SKIN: Clammy skin, diaphoresis

Nursing Considerations

- Monitor patient's blood pressure during tranylcypromine therapy to detect hypertensive crisis and to decrease the risk of orthostatic hypotension.

WARNING Notify prescriber immediately if patient has evidence of hypertensive crisis, such as chest pain, headache, neck stiffness, and palpitations. Expect to stop drug right away.

- Anticipate that therapeutic response may not occur for up to 4 weeks.
- Expect drug to aggravate symptoms of Parkinson's disease, including muscle spasms, myoclonic movement, and tremor.
- Keep dietary restrictions in place for at least 2 weeks after stopping tranylcypromine because of the slow recovery from drug's enzyme-inhibiting effects.
- Expect to stop tranylcypromine 10 days before elective surgery, as prescribed, to avoid hypotension.
- Be aware that abrupt cessation of drug can precipitate original symptoms.
- Check diabetic patient's blood glucose level often to detect loss of control.
- Anticipate that coadministration with a selective serotonin reuptake inhibitor may cause confusion, seizures, severe hypertension, and other, less severe symptoms.
- Monitor severely depressed patients, including children and teens, for suicidal tendencies. Take safety measures, and notify prescriber immediately.
- Assess patient for sudden insomnia. If it develops, notify prescriber and be prepared to administer drug early in the day.

PATIENT TEACHING

- Instruct patient to avoid foods that contain cheese and that are high in tyramine, such as anchovies, avocados, bananas, beer, canned figs, caviar, Chianti wine, chocolate, dried fruit, fava beans, liqueurs, meat tenderizers, overripe fruit, pickled herring, raspberries, sauerkraut, sherry, sour cream, soy sauce, yeast extract, and yogurt while taking tranylcypromine.
- Urge patient to continue dietary restrictions for at least 2 weeks after tranylcypromine therapy stops.
- Advise patient to notify prescriber at once about chest pain, dizziness, headache, nausea, neck stiffness, palpitations, rapid heart rate, sweating, and vomiting.

- Urge patient to avoid alcohol and excessive caffeine intake during therapy.
- Urge patient to change position slowly to minimize orthostatic hypotension.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Caution patient not to take any other prescribed or OTC drugs without consulting prescriber.
- Caution patient not to stop drug abruptly to avoid recurrence of original symptoms.
- Instruct female patient to use effective contraception during tranylcypromine therapy to prevent fetal abnormalities. Urge her to notify prescriber immediately about known or suspected pregnancy.

WARNING Urge parents to watch their child or adolescent closely for abnormal thinking or behavior or increased aggression or hostility. Stress importance of notifying prescriber about unusual changes.

trazodone hydrochloride

Trazon, Trialodine

Class and Category

Chemical class: Triazolopyridine derivative
Therapeutic class: Antidepressant, anxiolytic
Pregnancy category: C

Indications and Dosages

➤ *To treat major depression, with or without generalized anxiety*

TABLETS

Adults. *Initial:* 150 mg daily in divided doses, increased by 50 mg daily every 3 to 4 days, p.r.n., as prescribed. *Maximum:* 400 mg daily for outpatients, 600 mg daily for inpatients.

Children ages 6 to 18. *Initial:* 1.5 to 2 mg/kg daily in divided doses, increased every 3 to 4 days, p.r.n., as prescribed. *Maximum:* 6 mg/kg daily in divided doses.

Mechanism of Action

Blocks serotonin reuptake along the presynaptic neuronal membrane, causing an antidepressant effect. Trazodone exerts an alpha-adrenergic blocking action and produces modest histamine blockade, causing a sedative effect. It also inhibits the vasopres-

or response to norepinephrine, which reduces blood pressure.

Route	Onset	Peak	Duration
P.O.	1–2 wk	Unknown	Unknown

Contraindications

Hypersensitivity to trazodone or its components, recovery from acute MI

Interactions

DRUGS

anticonvulsants: Decreased seizure threshold
antihypertensives: Increased risk of excessive hypotension

anxiolytics, brompheniramine, carbinoxamine, chlorpheniramine, clemastine, dimenhydrinate, diphenhydramine, doxylamine, general anesthetics, methdilazine, opioid analgesics, phenothiazines, sedative-hypnotics, skeletal muscle relaxants: Increased CNS depression, increased risk of respiratory depression and hypotension
barbiturates: Decreased seizure threshold and barbiturate effects, increased drowsiness

bupirone, selective serotonin-reuptake inhibitors, tricyclic antidepressants: Possibly excessive serotonergic stimulation

carbamazepine: Decreased trazodone level
clonidine: Interference with clonidine's antihypertensive effect

digoxin: Possibly increased blood digoxin level and risk of digitalis toxicity
erythromycin, indinavir, itraconazole, ketoconazole, nefazodone, protease inhibitors, ritonavir: Possibly increased blood trazodone level with increased risk of adverse effects

MAO inhibitors: Increased serotonin effects
warfarin: Decreased anticoagulation response

ACTIVITIES

alcohol use: Increased CNS depression, risk of respiratory depression and hypotension

Adverse Reactions

CNS: Dizziness, drowsiness, fatigue, headache, light-headedness, nervousness, suicidal ideation, syncope, tremor

CV: Arrhythmias, hypotension, orthostatic hypotension, palpitations

EENT: Blurred vision, dry mouth

GI: Constipation, indigestion, nausea, vomiting

GU: Anorgasmia, ejaculation disorders, increased libido, priapism

SKIN: Pruritus, rash

Nursing Considerations

- Give trazodone shortly after the patient has a meal or light snack to reduce nausea.
- Give larger portion of daily dose at bedtime if drowsiness occurs.
- Because trazodone's mechanism of action is similar to that of selective serotonin reuptake inhibitors, expect high doses (6 to 8 mg/kg) to increase blood serotonin level and low doses (0.05 to 1 mg/kg) to decrease blood serotonin level.
- Expect most patients who respond to trazodone to do so by the end of the second week of therapy.
- Closely monitor depressed patients, including children and teens, for suicidal thoughts and tendencies. Notify prescriber if they occur, and take suicide precautions according to facility policy.
- Be aware that adverse CNS reactions usually improve after patient completes a few weeks of therapy.

WARNING Be aware that trazodone therapy may increase the risk of priapism.

PATIENT TEACHING

- Urge patient to avoid taking trazodone on an empty stomach because doing so may increase the risk of dizziness or lightheadedness.
- Caution patient to avoid potentially hazardous activities during therapy.
- Advise patient not to fast during trazodone therapy because of possible adverse CNS reactions.
- Instruct male patient to notify prescriber immediately about priapism.

WARNING Urge parents to watch their child or adolescent closely for abnormal thinking or behavior or increased aggression or hostility. Stress importance of notifying prescriber about unusual changes.

treprostinil sodium

Remodulin, Tyvaso

Class and Category

Chemical class: Prostaglandin, tricyclic benzidine analog

Therapeutic class: Vasodilator

Pregnancy category: B

Indications and Dosages

➤ *To treat pulmonary artery hypertension in patients who have New York Heart Association Class II to IV symptoms in order to diminish exercise-induced symptoms*

I.V. INFUSION, SUBCUTANEOUS INFUSION (REMODULIN)

Adults. *Initial:* 1.25 nanograms/kg/min.

Maintenance: Infusion rate increased in increments of no more than 1.25 nanograms/kg/min each wk for first 4 wk, and in increments of no more than 2.5 nanograms/kg/min each wk thereafter, as needed. *Maximum:* 40 nanograms/kg/min.

DOSAGE ADJUSTMENT If initial dosage isn't tolerated or if patient has mild to moderate hepatic insufficiency, decrease to 0.625 nanogram/kg/min (using ideal body weight).

ORAL INHALATION (TYVASO)

Adults. *Initial:* 18 mcg (3 breaths) four times daily, evenly spaced at 4 hr apart while awake. Increased in 1 to 2 wk to 36 mcg (6 breaths) four times daily, evenly spaced at 4 hr apart while awake. Then increased in another 1 to 2 wk to 54 mcg (9 breaths) four times daily evenly spaced 4 hr apart while awake, as tolerated.

Maintenance: 54 mcg (9 breaths) four times daily, evenly spaced at 4 hr apart while awake. *Maximum:* 54 mcg (9 breaths) four times daily, evenly spaced at 4 hr apart while awake.

DOSAGE ADJUSTMENT For patient unable to tolerate initial dose, dosage decreased to 6 mcg (1 breath) or 12 mcg (2 breaths) four times daily, evenly spaced at 4 hours apart while awake, and then increased to 18 mcg (3 breaths) four times daily, evenly spaced at 4 hr apart while awake when tolerated. Then increased gradually every 1 to 2 wk to achieve target range of 54 mcg or highest tolerated dose.

Mechanism of Action

Acts directly on pulmonary and systemic arterial vascular beds to produce vasodilation. Vasodilatory effects reduce right and left ventricular afterload and increase cardiac output and stroke volume. These effects improve symptoms of pulmonary

hypertension, such as dyspnea, and enable patients with pulmonary hypertension to walk farther with less discomfort.

Contraindications

Hypersensitivity to treprostinil, its components, or structurally related compounds

Interactions

DRUGS

anticoagulants: Increased risk of bleeding

antihypertensives, diuretics, other vasodilators: Increased risk of hypotension

cytochrome P-450 inhibitors such as gemfibrozil: Increased plasma treprostinil level and increased risk of adverse effects

cytochrome P-450 inducers such as rifampin: Decreased plasma treprostinil level and decreased effectiveness

Decreased plasma treprostinil level and decreased effectiveness

Adverse Reactions

CNS: Anxiety, dizziness, fatigue, headache, restlessness

CV: Chest pain, edema, hypotension, right ventricular heart failure, vasodilatation

EENT: Epistaxis, jaw pain, pharyngolaryngeal pain (inhalation form), throat irritation (inhalation form)

GI: Diarrhea, nausea, vomiting

HEME: Bleeding, thrombocytopenia

RESP: Cough (inhalation form), dyspnea, hemoptysis (inhalation form), wheezing (inhalation form)

MS: Bone or jaw pain

SKIN: Cellulitis, pallor, pruritus, rash

Other: Infusion site pain or reaction (erythema, hematoma, induration, pain, paresthesia, rash, swelling, thrombophlebitis)

Nursing Considerations

- Use treprostinil cautiously in patients with hepatic or renal impairment because of increased risk of adverse effects.
- Assess patient's ability to care for an I.V. or subcutaneous catheter and to use an infusion pump. Discuss findings with prescriber before starting treprostinil therapy.
- Be aware that drug shouldn't be diluted when given subcutaneously.
- When drug will be given I.V., dilute with sterile water for injection or normal saline solution according to instructions provided. Watch for blood-borne infections and sepsis in patients receiving drug through an indwelling central venous catheter, which increases the risk.

- Calculate infusion rate using the formula provided in the package insert, or refer to charts in package insert to find infusion delivery rate for prescribed dosage and administration route.

WARNING Don't abruptly stop treprostinil infusion or make sudden large reductions in dose because symptoms of pulmonary hypertension may worsen.

- When giving drug by inhalation, use only the Tyvaso inhalation system.
- Assess patient often for drug effectiveness and for adverse reactions. Know that the goal of dosage adjustments is to find a dose that will improve symptoms of pulmonary hypertension, such as dyspnea and fatigue, while minimizing adverse effects, such as headache, nausea, vomiting, restlessness, anxiety, and infusion site pain or reaction.
- Monitor patient's platelet count and assess patient often for bleeding because drug may increase risk of bleeding episodes.
- Be aware that patient must be discharged with a backup infusion pump. It should be adjustable to about 0.002 ml/hr and have alarms that indicate occlusion/no delivery, low battery, programming error, and motor malfunction. Also, the pump should have a delivery accuracy of 66% or better, be positive-pressure driven, and have a reservoir made of polyvinyl chloride, polypropylene, or glass. Make sure patient has additional I.V. or subcutaneous infusion sets to prevent potential interruptions in drug delivery. Likewise, patient prescribed drug via inhalation must be discharged with a backup inhalation system.

PATIENT TEACHING

- Explain to patient that treprostinil is infused continuously through an I.V. or subcutaneous catheter via an infusion pump.
- Teach patient to operate and maintain the I.V. or subcutaneous infusion pump and to recognize the drug's adverse effects.
- To reduce the risk of infection, caution patient to always use aseptic technique when preparing and giving drug.
- Tell patient that a vial of drug shouldn't be used beyond 14 days after opening (for I.V. or subcutaneous use) and that once the drug is placed in the pump's reservoir,

it shouldn't be used after 72 hours.

- Instruct patient to store treprostinil vials at room temperature (about 25° C [77° F]).
- Teach patient prescribed inhalation form of drug how to use the inhalation system and how to clean it after last treatment of the day. Advise patient always to have a backup device in case of malfunction. Make sure patient understands that no other drug should be mixed with treprostinil in medication cup before administration. Explain that each ampule contains enough drug for all 4 treatments for a day. Tell him to twist off the top of ampule before first treatment of the day and squeeze entire contents into medication cup. Dose is controlled by how many breaths he takes. In between treatments, inhalation device should be capped and stored in an upright position.
- Caution patient to avoid skin or eye contact with treprostinil solution. If it occurs, instruct patient to flush area immediately with water.
- Inform patient that drug will be needed for prolonged periods, possibly years. Stress the importance of not stopping drug abruptly or making sudden large reductions in dosage without consulting prescriber because symptoms could worsen.
- Make sure patient understands that treprostinil use doesn't preclude the subsequent use of an alternative I.V. prostacyclin therapy such as epoprostenol.
- Make sure patient has emergency contact information for problems or questions about giving treprostinil at home.

triamcinolone

Aristocort, Aristopak, Atolone, Kenacort, Nasacort AQ

triamcinolone acetonide

AllerNaze, Azmacort, Cenocort A-40, Cinonide-40, Kenaject-40, Kenalog-10, Kenalog-40, Ken-Jec-40, Nasacort, Nasacort HFA, Robalog, Tac-3, Triam-A, Triamonide, Tri-Kort, Trilog

triamcinolone diacetate

Acetocot, Amcort, Aristocort, Aristocort Forte, Articulose-LA, Cenocort Forte, Cinalone 40, Clinacort, Kenacort Diacetate, Tilone, Tramacort-D, Triam-Forte, Triamolone 40, Tristoject

triamcinolone hexacetonide

Aristospan

Class and Category

Chemical class: Synthetic glucocorticoid

Therapeutic class: Anti-inflammatory, immunosuppressant

Pregnancy category: C (nasal and oral inhalation), Not rated (oral and parenteral)

Indications and Dosages

➤ *To prevent bronchospasm or provide long-term corticosteroid treatment to control asthma*

ORAL INHALATION (TRIAMCINOLONE ACETONIDE)

Adults and children age 12 and over.

Initial: 2 metered sprays (200 mcg) t.i.d. or q.i.d. *Maintenance:* Individualized dosage given b.i.d. *Maximum:* 16 metered sprays daily in divided doses.

Children ages 6 to 11. 2 to 4 metered sprays (200 to 400 mcg) b.i.d. to q.i.d. *Maximum:* 12 metered sprays daily.

➤ *To treat acute rheumatic carditis, berylliosis, and Hodgkin's disease; as adjunct to treat fulminating or disseminated pulmonary tuberculosis (with appropriate antituberculosis therapy)*

SYRUP (TRIAMCINOLONE DIACETATE), TABLETS (TRIAMCINOLONE)

Adults and children age 12 and over.

Initial: 4 to 48 mg daily as a single dose or in divided doses. Some patients may require an initial dose of 60 mg.

Children under age 12. 0.42 to 1.7 mg/kg daily as a single dose or in divided doses.

I.M. INJECTION (TRIAMCINOLONE ACETONIDE)

Adults and children age 12 and over. 40 to 80 mg every 4 wk, as needed.

Children ages 6 to 11. 40 mg every 4 wk, as needed, or 30 to 200 mcg/kg every 1 to 7 days.

I.M. INJECTION (TRIAMCINOLONE DIACETATE)

Adults and children age 12 and over. 40 mg every wk, or 4 to 7 times the daily P.O. dose as a single injection every 4 days to every 4 wk.

Children ages 6 to 11. 40 mg/wk.

↗ *To relieve inflammation caused by acute gouty arthritis, acute nonspecific tenosynovitis, acute or subacute bursitis, epicondylitis, osteoarthritis, posttraumatic osteoarthritis, rheumatoid arthritis, and synovitis*

SYRUP (TRIAMCINOLONE DIACETATE)

Adults and children age 12 and over. 4 to 48 mg daily as a single dose or in divided doses, adjusted, as prescribed, to lowest effective dose based on clinical response.

TABLETS (TRIAMCINOLONE)

Adults and children age 12 and over. 8 to 16 mg daily in divided doses t.i.d. or q.i.d., adjusted, as prescribed, to lowest effective dose based on clinical response.

SYRUP (TRIAMCINOLONE DIACETATE), TABLETS (TRIAMCINOLONE)

Children ages 6 to 11. 0.42 to 1.7 mg/kg daily as a single dose or in divided doses, adjusted based on clinical response.

I.M. INJECTION (TRIAMCINOLONE ACETONIDE)

Adults and children age 12 and over. 40 to 80 mg every 4 wk.

Children ages 6 to 11. 40 mg every 4 wk.

I.M. INJECTION (TRIAMCINOLONE DIACETATE)

Adults and children age 6 and over. 40 mg every wk as single injection, repeated every 4 wk if needed.

INTRA-ARTICULAR OR INTRABURSAL INJECTION (TRIAMCINOLONE ACETONIDE)

Adults and children age 6 and over. 2.5 to 15 mg, as needed.

INTRA-ARTICULAR OR INTRASYNOVIAL INJECTION (TRIAMCINOLONE DIACETATE)

Adults. 5 to 40 mg, repeated as prescribed every 1 to 8 wk, as needed.

INTRA-ARTICULAR INJECTION (TRIAMCINOLONE HEXACETONIDE)

Adults. 2 to 20 mg, repeated as prescribed every 3 to 4 wk, as needed.

↗ *To treat primary (Addison's disease) or secondary adrenocortical insufficiency*

SYRUP (TRIAMCINOLONE DIACETATE)

Adults and children age 12 and over. 4 to 12 mg daily as a single dose or in divided doses.

SYRUP (TRIAMCINOLONE DIACETATE), TABLETS**(TRIAMCINOLONE)**

Children ages 6 to 11. 0.12 mg (base)/kg daily as a single dose or in divided doses.

↗ *To treat inflammatory dermatoses*

TABLETS (TRIAMCINOLONE)

Adults and children age 12 and over. 8 to 16 mg daily. *Usual:* 1 to 2 mg daily.

↗ *To treat disseminated lupus erythematosus*

TABLETS (TRIAMCINOLONE)

Adults and children age 12 and over. 20 to 30 mg daily. *Usual:* 3 to 30 mg daily.

↗ *To treat nephrotic syndrome*

TABLETS (TRIAMCINOLONE)

Adults and children age 12 and over. 16 to 20 mg daily.

↗ *To relieve symptoms of perennial and seasonal allergic rhinitis*

TABLETS (TRIAMCINOLONE)

Adults and children age 12 and over. 8 to 12 mg daily. *Usual:* 2 to 6 mg daily.

Children ages 6 to 11. 0.42 to 1.7 mg/kg daily as a single dose or in divided doses.

NASAL INHALATION (NASACORT)

Adults and children age 12 and over.

Initial: 220 mcg daily in 2 sprays (55 mcg each)/nostril. *Maintenance:* 110 mcg daily in 1 spray (55 mcg)/nostril. *Maximum:* 440 mcg (8 sprays daily).

NASAL INHALATION (NASACORT AQ)

Adults and children age 12 and over.

Initial: 110 mcg daily in 2 sprays (55 mcg each)/nostril. *Maintenance:* 55 mcg daily in 1 spray/ nostril. *Maximum:* 220 mcg or 4 sprays daily.

Children ages 6 to 11. 110 mcg daily in 1 spray (55 mcg each)/nostril. *Maximum:* 220 mcg or 4 sprays daily.

Children ages 2 to 5. 110 mcg daily in 1 spray (55 mcg)/nostril. *Maximum:* 100 mcg or 2 sprays daily.

NASAL INHALATION (NASACORT HFA)

Adults and children age 12 and over.

Initial: 220 mcg daily in 2 sprays (55 mcg each)/nostril. May be increased to 440 mcg daily in 4 sprays/nostril, as needed.

Children ages 6 to 11. 220 mcg daily in 2 sprays (55 mcg each)/nostril.

NASAL INHALATION (ALLERNAZE)

Adults and children age 12 and over.

Initial: 200 mcg daily in 2 sprays (50 mcg each)/nostril. *Maximum:* 400 mcg daily in 4 sprays (50 mcg each)/nostril or divided into 2 daily doses.

➤ To treat chronic idiopathic thrombocytopenic purpura

TABLETS (TRIAMCINOLONE)

Adults and children age 12 and over.

0.8 mg/kg daily.

Route	Onset	Peak	Duration
P.O. (tablets)	Unknown	1–2 hr	2.25 days
I.M.*	24–48 hr	Unknown	1–6 wk
I.M.†	Slow	Unknown	4 days–4 wk
Inhalation	12 hr	3–4 hr	Unknown
Intra-articular, intra-bursal*	Unknown	Unknown	Several wk
Intra-articular, intra-synovial†	Unknown	Unknown	1–8 wk

Mechanism of Action

Inhibits the release of prostaglandins and leukotrienes, thus reducing immediate and late-phase allergic responses in chronic asthma. Triamcinolone also:

- decreases peribronchial edema and mucus secretion by inhibiting the binding of allergens to immunoglobulin E antibodies on the surface of mast cells, thereby inactivating the release of chemotactic substances
- decreases inflammation by interfering with leukocyte adhesion to capillary walls
- inhibits the release of leukocytic acid hydrolases, preventing macrophage accumulation at the infection site
- inhibits histamine and kinin release, preventing the formation of scar tissue.

Incompatibilities

Don't mix triamcinolone hexacetonide with parenteral local anesthetics because precipitation can occur.

Contraindications

Acute status asthmaticus (inhalation form), hypersensitivity to triamcinolone or its components, live-virus vaccine therapy, systemic fungal infection

* Acetonide.

† Diacetate.

Interactions

DRUGS

amphotericin B, ethacrynic acid, furosemide, thiazide diuretics: Increased potassium-wasting effect, severe hypokalemia
aspirin: Increased blood salicylate level, increased risk of salicylate toxicity
barbiturates, carbamazepine, phenytoin, rifampin: Increased triamcinolone metabolism

cholinesterase inhibitors: Increased risk of severe muscle weakness in patients with myasthenia gravis

digitalis glycosides: Increased risk of arrhythmias and digitalis toxicity

estrogens: Increased triamcinolone effects
insulin, oral antidiabetic drugs: Increased blood glucose level

isoproterenol: Increased risk of cardiotoxicity
live-virus vaccines: Decreased antibody response, increased risk of neurologic complications

neuromuscular blockers: Increased risk of hypokalemia and enhanced neuromuscular blockade

NSAIDs: Increased risk of adverse GI effects
 toxoids: Decreased resistance to toxoids

Adverse Reactions

CNS: Dizziness, emotional lability, exacerbated psychosis, fatigue, headache, insomnia, restlessness, seizures, vertigo

CV: Edema, heart failure, hypertension

EENT: Altered sense of smell or taste, cataracts, dry mouth, epistaxis (nasal form), glaucoma, hoarseness, nasal congestion,

nasal irritation (inhalation form), nasal septal perforation (nasal form), oropharyngeal candidiasis, pharyngitis, posterior subcapsular cataracts, rhinorrhea, secondary ocular infection, sinusitis, sneezing

ENDO: Cushing's syndrome, diabetes mellitus, growth retardation (children)

GI: Abdominal pain, constipation, diarrhea, dyspepsia, esophageal ulceration, gastritis, nausea, vomiting

GU: Cystitis, renal disease, UTI, vaginitis

MS: Bone mineral density loss, bursitis, muscle wasting or weakness, myalgia, osteoporosis, tenosynovitis

RESP: Asthma, bronchitis, bronchospasm (inhalation form), chest congestion, dyspnea, increased cough

SKIN: Ecchymosis, petechiae (parenteral

form), photosensitivity, pruritus, rash, striae, urticaria

Other: Anaphylaxis; angioedema; facial edema; flu syndrome; herpes infection; impaired wound healing; injection site atrophy, induration, pain, soreness, and sterile abscess; weight gain

Nursing Considerations

- Be aware that high doses of corticosteroids such as trimcinolone aren't recommended for patients with cranial trauma who don't require a corticosteroid for another condition because of increased risk of death.
 - Triamcinolone should be administered with extreme caution, if at all, in patients who have active or quiescent tuberculosis infection of the respiratory tract, untreated fungal or bacterial infection, systemic viral or parasitic infection, or ocular herpes simplex because this drug can make these infections worse.
 - Give oral form of triamcinolone with meals to minimize GI distress.
 - Use calibrated device to measure liquid doses.
 - If necessary, crush tablets and mix with food or fluids.
 - Shake I.M. suspension thoroughly before drawing it into syringe.
 - Be aware that specialized training may be needed to administer parenteral triamcinolone.
 - Don't administer parenteral forms of triamcinolone I.V.
 - Be aware that triamcinolone may reactivate tuberculosis in patients who have a history of it.
 - Monitor patients, especially infants, closely for gasping syndrome because parenteral triamcinolone contains benzyl alcohol. Exposure to high doses may result in toxicity evidenced by life-threatening hypotension and metabolic acidosis.
- WARNING** Assess patient for signs and symptoms of adrenal insufficiency (fatigue, hypotension, lassitude, nausea, vomiting, and weakness) during times of stress, such as infection, surgery, or trauma. Notify prescriber immediately if you detect these signs and symptoms because adrenal insufficiency may be life-threatening.
- Be aware that, although rare, bone mineral

density loss and osteoporosis may occur, which may increase risk of fractures, especially in patients on prolonged triamcinolone therapy.

PATIENT TEACHING

- Caution patient not to adjust triamcinolone dosage without consulting prescriber.
- Teach patient how to administer nasal aerosols properly, using manufacturer's instructions, to avoid nasal irritation.
- Instruct patient to dispose of aerosol canister after 240 uses (100 uses for Nasacort HFA) because dosage may not be correct after that time.
- Teach patient how to use nasal spray, including how to prime spray pump bottle before use. Caution patient to not to get nasal spray in eyes. If this occurs, patient should rinse his eyes well with water.
- Inform patient that maximum benefit of triamcinolone therapy may not occur for up to 2 weeks.
- Advise patient to notify prescriber immediately if asthma fails to respond to inhaled drug because additional systemic therapy may be needed.
- Caution patient to avoid exposure to people who have chickenpox or measles throughout triamcinolone therapy and for 12 months afterward.
- Advise patient to have periodic eye examinations during long-term therapy because triamcinolone can cause glaucoma or ocular nerve damage.

triamterene

Dyrenium

Class and Category

Chemical class: Pteridine derivative

Therapeutic class: Diuretic

Pregnancy category: B

Indications and Dosages

➤ To treat edema in cirrhosis, heart failure, and nephrotic syndrome

CAPSULES

Adults. *Initial:* 25 to 100 mg daily.

Maximum: 300 mg daily.

Mechanism of Action

Inhibits sodium reabsorption in distal con-

voluted tubules and cortical collecting ducts, causing sodium and water loss and enhancing potassium retention.

Route	Onset	Peak	Duration
P.O.	2–4 hr	1 to several days	7–9 hr

Contraindications

Anuria, diabetic nephropathy or renal disease linked to renal insufficiency, hyperkalemia (potassium level of 5.5 mEq/L or more), hypersensitivity to triamterene or its components, severe hepatic dysfunction

Interactions

DRUGS

ACE inhibitors, amiloride, angiotensin-II receptor antagonists, cyclosporine, heparin, potassium-containing drugs, potassium salts, potassium supplements, spironolactone:

Increased risk of hyperkalemia

amantadine: Decreased amantadine clearance, possibly amantadine toxicity

antihypertensives: Increased antihypertensive effect

diuretics: Increased diuretic effect

folic acid: Possibly antagonized action of folic acid

indomethacin: Increased risk of renal impairment

lithium: Increased risk of lithium toxicity

NSAIDs: Decreased diuretic effect of triamterene, increased risk of hyperkalemia

oral antidiabetic drugs: Altered blood glucose control

Adverse Reactions

CNS: Dizziness, fatigue, headache, weakness

EENT: Dry mouth

ENDO: Hyperglycemia, hypoglycemia

GI: Diarrhea, nausea, vomiting

GU: Azotemia, elevated BUN and serum creatinine levels, renal calculi

SKIN: Jaundice, photosensitivity, rash

Nursing Considerations

- Be aware that triamterene shouldn't be given to patient with creatinine clearance below 10 ml/min/1.73 m² because this condition increases the risk of drug-induced hyperkalemia.
- Monitor serum potassium level during therapy, especially in patient with renal impairment or diabetes mellitus. Also

monitor patient's BUN and serum creatinine levels to assess renal function and prevent hyperkalemia.

- Monitor patient for irregular heartbeat, which is usually the first sign of hyperkalemia.
- If you suspect hyperkalemia, obtain an ECG tracing, as ordered. A widened QRS complex or an arrhythmia requires prompt additional therapy.
- Monitor laboratory test results and watch for signs of metabolic or respiratory acidosis, which may occur suddenly in patient with cardiac disease or uncontrolled diabetes mellitus.
- Monitor patient's serum uric acid and sodium levels, as ordered, because triamterene may reduce uric acid clearance and increase the risk of gout and hyperuricemia. This drug also may worsen pre-existing hyponatremia.
- Monitor CBC with differential because drug may increase the risk of megaloblastic anemia in patient with folic acid deficiency.

PATIENT TEACHING

- Advise patient to take triamterene with food or milk.
- Instruct patient to avoid exposure to excessive heat or sunlight to prevent dehydration and, possibly, photosensitivity.
- Explain to patient with a history of gout that drug may increase the risk of attack.
- Advise patient to notify prescriber about ineffective diuresis and unexplained weight gain during therapy.

triazolam

Alti-Triazolam (CAN), Apo-Triazo (CAN), Gen Triazolam (CAN), Halcion, Novo-Triolam (CAN)

Class, Category, and Schedule

Chemical class: Benzodiazepine

Therapeutic class: Sedative-hypnotic

Pregnancy category: X

Controlled substance schedule: IV

Indications and Dosages

↗ *To provide short-term management of insomnia*

TABLETS

Adults. 0.125 to 0.25 mg at bedtime.

Maximum: 0.5 mg daily (for patients with inadequate response to usual dose).

DOSE ADJUSTMENT For elderly or debilitated patients, initial dosage reduced to 0.125 mg at bedtime and maximum dosage limited to 0.25 mg daily.

Route	Onset	Peak	Duration
P.O.	15–30 min	Unknown	Unknown

Mechanism of Action

Potentiates effects of the inhibitory neurotransmitter gamma-aminobutyric acid, which increases inhibition of the ascending reticular activating system and produces varying levels of CNS depression, including sedation, hypnosis, skeletal muscle relaxation, anticonvulsant activity, and coma.

Contraindications

Hypersensitivity to triazolam or its components; itraconazole, ketoconazole, or nefazodone therapy; pregnancy

Interactions

DRUGS

anxiolytics, barbiturates, brompheniramine, carbinoxamine, cetirizine, chlorpheniramine, clemastine, cyproheptadine, dimenhydrinate, diphenhydramine, doxylamine, general anesthetics, methdilazine, opioid analgesics, sedative-hypnotics, phenothiazines, promethazine, tramadol, tricyclic antidepressants, trimepazine: Increased sedation, respiratory depression

cimetidine, diltiazem, disulfiram, erythromycin, probenecid, verapamil: Increased sedation

fluconazole: Increased blood triazolam level and effects

flumazenil: Increased risk of withdrawal symptoms

itraconazole, ketoconazole, nefazodone:

Delayed triazolam elimination

oral contraceptives: Increased blood triazolam level

FOODS

grapefruit juice: Increased blood triazolam level and sedation

ACTIVITIES

alcohol use: Increased sedation, respiratory depression

Adverse Reactions

CNS: Anxiety, ataxia, complex behaviors

(such as sleep driving), confusion, depression, dizziness, drowsiness, fatigue, headache, insomnia, nightmares, syncope, talkativeness, tremor, vertigo

EENT: Throat tightness

GI: Nausea, vomiting

RESP: Dyspnea

Other: Anaphylaxis, angioedema, physical and psychological dependence

Nursing Considerations

- Be aware that triazolam shouldn't be discontinued abruptly, even after only 1 to 2 weeks of therapy. Doing so can cause withdrawal symptoms, including abdominal cramps, confusion, depression, diaphoresis, hyperacusis, insomnia, irritability, nausea, nervousness, paresthesia, perceptual disturbances, photophobia, tachycardia, tremor, and vomiting.

WARNING Assess patient for signs of physical and psychological dependence, and notify prescriber if they occur.

- Monitor patient's respiratory rate and depth and ABG results, as appropriate, because drug may worsen ventilatory failure in patient with pulmonary disease, such as severe COPD, respiratory depression, or sleep apnea. Use drug cautiously in patients with acute intermittent porphyria, myasthenia gravis, and severe renal impairment because it may aggravate these conditions.

- Take safety precautions for elderly patients because triazolam may impair cognitive and motor function and increase the risk for falls.

- Use drug cautiously in patients with advanced Parkinson's disease because it may worsen cognition, coordination, and psychosis.

WARNING Monitor patient closely for hypersensitivity reactions such as dyspnea, throat tightness, nausea, vomiting, and swelling. If present, stop triazolam immediately, notify prescriber, and provide supportive care.

PATIENT TEACHING

- Instruct patient to take triazolam exactly as prescribed and not to stop taking it abruptly because of the risk of having withdrawal symptoms.
- Instruct patient to stop taking triazolam and seek emergency care if she has trouble

breathing, throat tightness, nausea, vomiting, or abnormal swelling.

- Advise patient that drug may cause abnormal behaviors during sleep, such as driving a car, eating, talking on the phone, or having sex without any recall of the event. If family notices any such behavior or patient sees evidence of such behavior upon awakening, the prescriber should be notified.
- Caution patient about possible drowsiness during therapy.
- Urge patient to avoid alcohol consumption because it increases drug's sedative effects and risk of abnormal behaviors, such as sleep driving.
- Advise patient to notify prescriber about excessive drowsiness, known or suspected pregnancy, and nausea.

trifluoperazine hydrochloride

Apo-Trifluoperazine (CAN),
PMS-Trifluoperazine (CAN)

Class and Category

Chemical class: Piperazine phenothiazine

Therapeutic class: Antianxiety, antipsychotic

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat psychotic disorders*

SYRUP, TABLETS

Adults and adolescents. *Initial:* 2 to 5 mg b.i.d., increased gradually, as needed.

Maintenance: 15 to 20 mg daily. *Maximum:* 40 mg daily.

Children age 6 and over. *Initial:* 1 mg daily or in divided doses b.i.d., increased gradually, as needed.

I.M. INJECTION

Adults and adolescents. 1 to 2 mg every 4 to 6 hr, as needed. *Maximum:* 10 mg daily.

Children age 6 and over. 1 mg daily or in divided doses b.i.d., as needed.

↗ *To relieve anxiety*

SYRUP, TABLETS, I.M. INJECTION

Adults and adolescents. *Initial:* 1 to 2 mg daily, increased gradually, as needed.

Maximum: 6 mg daily for 12 wk.

Mechanism of Action

Blocks postsynaptic dopamine receptors, increasing dopamine turnover and decreasing dopamine neurotransmission. This action may depress the areas of the brain that control activity and aggression, including the cerebral cortex, hypothalamus, and limbic system. Trifluoperazine may relieve anxiety by indirectly reducing arousal and increasing the filtering of internal stimuli to the reticular activating system.

Contraindications

Blood dyscrasias; bone marrow depression; cerebral arteriosclerosis; coma; coronary artery disease; hepatic dysfunction; hypersensitivity to trifluoperazine, other phenothiazines, or their components; myeloproliferative disorders; severe hypertension or hypotension; significant CNS depression; subcortical brain damage; use of high doses of CNS depressants

Interactions

DRUGS

adsorbent antidiarrheals, aluminum- and magnesium-containing antacids: Possibly inhibited absorption of oral trifluoperazine
amantadine, anticholinergics, antidyskinetics, antihistamines: Possibly intensified adverse anticholinergic effects, increased risk of trifluoperazine-induced hyperpyrexia
amphetamines: Decreased stimulant effect of amphetamines, decreased antipsychotic effect of trifluoperazine

anticonvulsants: Lowered seizure threshold
antithyroid drugs: Increased risk of agranulocytosis

apomorphine: Possibly decreased emetic response to apomorphine, additive CNS depression

appetite suppressants: Decreased effects of appetite suppressants

astemizole, cisapride, disopyramide, erythromycin, pimozide, probucol, procainamide, quinidine: Prolonged QT interval, increased risk of ventricular tachycardia

beta blockers: Increased blood levels of both drugs, possibly leading to additive hypotensive effect, arrhythmias, irreversible retinopathy, and tardive dyskinesia
bromocriptine: Impaired therapeutic effects of bromocriptine

CNS depressants: Additive CNS depression
ephedrine, metaraminol: Decreased vaso-

pressor response to ephedrine

epinephrine: Blocked alpha-adrenergic effects of epinephrine

extrapyramidal reaction-causing drugs (droperidol, haloperidol, metoclopramide, metyrosine, risperidone): Increased severity and frequency of extrapyramidal reactions
hepatotoxic drugs: Increased risk of hepatotoxicity

hypotension-producing drugs: Possibly severe hypotension with syncope

levodopa: Decreased antidyskinetic effect of levodopa

lithium: Reduced absorption of oral trifluoperazine, possibly encephalopathy and additive extrapyramidal effects

MAO inhibitors, maprotiline, tricyclic antidepressants: Possibly prolonged and intensified sedative and anticholinergic effects, increased blood level of antidepressants, impaired trifluoperazine metabolism, increased risk of neuroleptic malignant syndrome

mephenetermine: Decreased antipsychotic effect of trifluoperazine and vasopressor effect of mephenetermine

methoxamine, phenylephrine: Decreased vasopressor effect and shortened duration of action of these drugs

metrizamide: Increased risk of seizures
opioid analgesics: Increased risk of CNS and respiratory depression, orthostatic hypotension, severe constipation, and urine retention

ototoxic drugs: Possibly masking of some symptoms of ototoxicity, such as dizziness, tinnitus, and vertigo

phenytoin: Lowered seizure threshold; inhibited phenytoin metabolism, possibly leading to phenytoin toxicity

photosensitizing drugs: Possibly additive photosensitivity and intraocular photochemical damage to choroid, lens, or retina
thiazide diuretics: Possibly hyponatremia and water intoxication

ACTIVITIES

alcohol use: Increased CNS and respiratory depression, increased hypotensive effect

Adverse Reactions

CNS: Akathisia, altered temperature regulation, dizziness, drowsiness, extrapyramidal reactions (dystonia, pseudoparkinsonism, tardive dyskinesia)

CV: Hypotension, orthostatic hypotension, tachycardia

EENT: Blurred vision, dry mouth, nasal congestion, ocular changes (deposits of fine particles in cornea and lens), pigmentary retinopathy

ENDO: Galactorrhea, gynecomastia

GI: Constipation, epigastric pain, nausea, vomiting

GU: Ejaculation disorders, menstrual irregularities, urine retention

SKIN: Contact dermatitis, decreased sweating, photosensitivity, pruritus, rash

Other: Injection site irritation and sterile abscess, weight gain

Nursing Considerations

WARNING Trifluoperazine shouldn't be used to treat elderly patients with dementia-related psychosis because drug increases the risk of death in these patients

- Use trifluoperazine cautiously in patients with glaucoma because of drug's anticholinergic effect.
- Before administration, observe parenteral solution, which may turn slightly yellow without altering its potency. Don't use solution if discoloration is pronounced or precipitate is present.
- For I.M. administration, inject drug slowly and deep into upper outer quadrant of the buttocks. Keep patient in a supine position for 30 minutes after injection to minimize hypotensive effect.
- Rotate I.M. injection sites to avoid irritation and sterile abscesses.

WARNING Watch closely for tardive dyskinesia, which may continue after treatment stops. Signs include uncontrolled movements of arms, body, cheeks, jaw, legs, mouth, or tongue. Notify prescriber if such signs occur.

- Closely monitor elderly patients and severely ill or dehydrated children. They're at increased risk for certain adverse CNS reactions.
- To prevent contact dermatitis, avoid skin contact with oral or injection solution.

PATIENT TEACHING

- Instruct patient to take trifluoperazine exactly as prescribed and not to stop taking drug abruptly or without consulting prescriber.
- Advise patient to take drug with food or a

full glass of milk or water to minimize adverse GI reactions.

- Urge patient to consult prescriber before using other drugs because of possible interactions.
- Instruct patient to notify prescriber immediately if she experiences difficulty swallowing or speaking and her tongue protrudes from her mouth.
- Caution patient to avoid alcohol during therapy.
- Advise patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Instruct patient to change position slowly to minimize effects of orthostatic hypotension.
- Urge patient to avoid exposure to the sun and extreme heat because drug may cause photosensitivity and interfere with thermoregulation. Encourage her to wear sunscreen when outdoors.

triflupromazine

Vesprin

Class and Category

Chemical class: Phenothiazine

Therapeutic class: Antiemetic, antipsychotic

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat psychotic disorders*

I.M. INJECTION

Adults and adolescents. 60 mg, as needed.

Maximum: 150 mg daily.

Children age 30 months and over. 0.2 to 0.25 mg/kg, as needed. *Maximum:* 10 mg daily.

↗ *To treat nausea and vomiting*

I.V. INJECTION

Adults. 1 mg, p.r.n. *Maximum:* 3 mg daily.

I.M. INJECTION

Adults and adolescents. 5 to 15 mg every 4 hr. *Maximum:* 60 mg daily.

Children age 30 months and over. 0.2 to 0.25 mg/kg, p.r.n. *Maximum:* 10 mg daily.

Mechanism of Action

Blocks postsynaptic dopamine receptors, increasing dopamine turnover and decreasing dopamine neurotransmission. This action may depress the areas of the brain

that control activity and aggression, including the cerebral cortex, hypothalamus, and limbic system. Triflupromazine also prevents nausea and vomiting by inhibiting or blocking dopamine receptors in the medullary chemoreceptor trigger zone and, peripherally, by blocking the vagus nerve in the GI tract.

Contraindications

Blood dyscrasias, bone marrow depression, cerebral arteriosclerosis, coma or severe CNS depression, concurrent use of large amount of CNS depressants, coronary artery disease, hepatic dysfunction, hypersensitivity to phenothiazines, severe hypertension or hypotension, subcortical brain damage

Interactions

DRUGS

amantadine, anticholinergics, antidyskinetics,

antihistamines: Possibly intensified adverse anticholinergic effects and increased risk of triflupromazine-induced hyperpyrexia

amphetamines: Decreased stimulant effect of amphetamines, decreased antipsychotic effect of triflupromazine

anticonvulsants: Lowered seizure threshold

antithyroid drugs: Increased risk of agranulocytosis

apomorphine: Possibly decreased emetic response to apomorphine, additive CNS depression

appetite suppressants: Decreased anorectic effect of appetite suppressants

astemizole, cisapride, disopyramide, erythromycin, pimozide, probutol, procainamide, quinidine: Prolonged QT interval, increased risk of ventricular tachycardia

beta blockers: Increased blood levels of both drugs, possibly leading to additive hypotensive effect, arrhythmias, irreversible retinopathy, and tardive dyskinesia

bromocriptine: Impaired therapeutic effects of bromocriptine

CNS depressants: Additive CNS depressant effects

ephedrine: Decreased vasopressor response to ephedrine

epinephrine: Blocked alpha-adrenergic effects of epinephrine

extrapyramidal reaction-causing drugs (droperidol, haloperidol, metoclopramide, metyrosine, risperidone): Increased severity and

frequency of extrapyramidal reactions

hepatotoxic drugs: Increased risk of hepatotoxicity

hypotension-producing drugs: Possibly severe hypotension with syncope

levodopa: Decreased antidyskinetic effect of levodopa

lithium: Possibly encephalopathy and additive extrapyramidal effects

MAO inhibitors, maprotiline, tricyclic antidepressants: Increased CNS depression, impaired triflupromazine metabolism, increased risk of neuroleptic malignant syndrome

mephentermine: Possibly antagonized antipsychotic effect of triflupromazine and vasopressor effect of mephentermine

metaraminol: Decreased vasopressor effect of metaraminol

methoxamine, phenylephrine: Decreased vasopressor effect and shortened duration of action of these drugs

metrizamide: Increased risk of seizures
opioid analgesics: Increased risk of CNS and respiratory depression, orthostatic hypotension, severe constipation, and urine retention

ototoxic drugs: Possibly masking of symptoms of ototoxicity, such as dizziness, tinnitus, and vertigo

phenytoin: Lowered seizure threshold; inhibited phenytoin metabolism, possibly leading to phenytoin toxicity

photosensitizing drugs: Possibly additive photosensitivity and intraocular photochemical damage to choroid, lens, or retina

thiazide diuretics: Possibly hyponatremia and water intoxication

ACTIVITIES

alcohol use: Increased CNS and respiratory depression, increased hypotensive effect

Adverse Reactions

CNS: Akathisia, altered temperature regulation, dizziness, drowsiness, extrapyramidal reactions (dystonia, pseudoparkinsonism, tardive dyskinesia)

CV: Hypotension, orthostatic hypotension, tachycardia

EENT: Blurred vision, dry mouth, nasal congestion, ocular changes (deposits of fine particles in cornea and lens), pigmentary retinopathy

ENDO: Galactorrhea, gynecomastia

GI: Constipation, epigastric pain, nausea, vomiting

GU: Ejaculation disorders, menstrual irregularities, urine retention

SKIN: Decreased sweating, photosensitivity, pruritus, rash

Other: Injection site irritation and sterile abscess, weight gain

Nursing Considerations

- Use triflupromazine cautiously in patients with glaucoma because of drug's anticholinergic effects.
- Before administration, observe parenteral solution, which may turn slightly yellow without altering potency. Don't use solution if discoloration is pronounced or precipitate is present.
- Don't let solution come in contact with your skin because contact dermatitis may occur.
- For I.M. administration, slowly inject triflupromazine deep into upper outer quadrant of buttocks. Keep patient supine for 30 minutes afterward to minimize hypotensive effect.
- Rotate I.M. injection sites to avoid irritation and sterile abscesses.

WARNING Watch closely for tardive dyskinesia, which may continue after treatment stops. Signs include uncontrolled movements of arms, body, cheeks, jaw, legs, mouth, or tongue. Notify prescriber if such signs occur.

- Closely monitor elderly patients and severely ill or dehydrated children. They're at increased risk for certain adverse CNS reactions.

PATIENT TEACHING

- Instruct patient to change position slowly to minimize effects of orthostatic hypotension.
- Urge patient to avoid potentially hazardous activities until triflupromazine's CNS effects are known.
- Instruct patient to notify prescriber immediately if she experiences difficulty swallowing or speaking and her tongue protrudes from her mouth.
- Caution patient to avoid alcohol during therapy.
- Urge patient to avoid exposure to the sun and extreme heat because drug may cause photosensitivity and interfere with

thermoregulation. Encourage her to wear sunscreen when outdoors.

trihexyphenidyl hydrochloride

Apo-Trihex (CAN), Artane, PMS Trihexyphenidyl (CAN), Trihexane, Trihexy

Class and Category

Chemical class: Tertiary amine

Therapeutic class: Antidyskinetic

Pregnancy category: C

Indications and Dosages

↗ *To treat parkinsonism*

ELIXIR, TABLETS

Adults. *Initial:* 1 to 2 mg on day 1, divided into 3 equal doses and given with meals. Total daily dose increased by 2 mg every 3 to 5 days until desired response or maximum dose is reached. *Maximum:* 15 mg daily.

E.R. CAPSULES

Adults. 5 mg after breakfast; additional 5 mg 12 hr later, if needed. *Maximum:* 15 mg daily.

↗ *To treat drug-induced extrapyramidal symptoms*

TABLETS

Adults. 1 mg daily, increased to 5 to 15 mg/day, as prescribed, to control symptoms.

Route	Onset	Peak	Duration
P.O.	1 hr	Unknown	6–12 hr

Mechanism of Action

Blocks acetylcholine's action at cholinergic receptor sites, which restores normal dopamine and acetylcholine balance in the brain, relaxing muscle movement and decreasing drooling, rigidity, and tremor. Drug also may inhibit reuptake and storage of dopamine, prolonging its action.

Contraindications

Achalasia, bladder neck or prostatic obstruction, narrow-angle glaucoma, hypersensitivity to trihexyphenidyl or its components, megacolon, myasthenia gravis, pyloric or duodenal obstruction, stenosing peptic ulcer

Interactions

DRUGS

amantadine, anticholinergics, MAO inhibitors, tricyclic antidepressants: Increased anticholinergic effects

antidiarrheals (adsorbent): Possibly decreased therapeutic effects of trihexyphenidyl

chlorpromazine: Decreased blood chlorpromazine level

CNS depressants: Increased sedative effect

levodopa: Increased efficacy of levodopa

ACTIVITIES

alcohol use: Increased sedation

Adverse Reactions

CNS: Confusion, dizziness, drowsiness, nervousness

EENT: Blurred vision; dry eyes, mouth, nose, or throat; mydriasis

GI: Constipation, nausea, vomiting

GU: Dysuria, urine retention

SKIN: Decreased sweating

Nursing Considerations

- Use trihexyphenidyl cautiously in patients with cardiovascular, hepatic, or renal disorders. Patients with cardiovascular disorders, such as atherosclerosis, hypertension, and ischemic heart disease, are at risk for tachycardia and coronary ischemia from drug's positive chronotropic effects. Hepatic and renal dysfunction increase the risk of adverse reactions.
- Before therapy begins, assess patient's muscle rigidity and tremor to establish a baseline. During therapy, reassess patient to detect improvement in these signs and evaluate drug effectiveness.
- Obtain patient's intraocular pressure before and periodically during trihexyphenidyl therapy, as ordered, because drug can precipitate incipient glaucoma.

PATIENT TEACHING

- Instruct patient to take trihexyphenidyl after meals.
- Teach patient not to break or chew E.R. capsules.
- Instruct patient to use calibrated device to measure elixir.
- Advise patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Advise patient with dry eyes or increased contact lens awareness to use lubricating

drops or stop wearing contact lenses during drug therapy.

- Caution patient being treated for parkinsonism not to stop taking trihexyphenidyl suddenly because doing so may worsen symptoms.
- Advise patient to maintain adequate hydration and avoid exercising during hot weather because trihexyphenidyl increases the risk of heatstroke.

trimethobenzamide hydrochloride

Benzacot, Tebamide, Tigan, Tribenzagan, Trimazide

Class and Category

Chemical class: Ethanolamine derivative

Therapeutic class: Antiemetic

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat nausea and vomiting*

CAPSULES

Adults and adolescents. 250 mg every 6 to 8 hr, p.r.n.

Children weighing 15 to 45 kg (33 to 99 lb). 100 to 200 mg every 6 to 8 hr, p.r.n.

I.M. INJECTION

Adults and adolescents. 200 mg every 6 to 8 hr, p.r.n.

DOSE ADJUSTMENT For patient with renal impairment, dosage decreased or dose interval lengthened.

Mechanism of Action

Prevents or stops nausea and vomiting by blocking dopamine receptors and emetic impulses at the chemoreceptor trigger zone in the brain.

Contraindications

Children (I.M.); hypersensitivity to trimethobenzamide, benzocaine, or any of their components

Interactions

DRUGS

apomorphine: Decreased emetic response to apomorphine, increased CNS effects
barbiturates, belladonna alkaloids, phenothiazines: Increased risk of coma, extrapyramidal reactions, opisthotonos, and seizures

CNS depressants: Possibly enhanced effects of both drugs

ototoxic drugs: Possibly masked signs of ototoxicity

Adverse Reactions

CNS: Dizziness, drowsiness, headache

EENT: Blurred vision

GI: Diarrhea

MS: Muscle cramps

Other: Injection site burning, irritation, pain, redness, or swelling

Nursing Considerations

- Use trimethobenzamide cautiously in dehydrated patients and those with an electrolyte imbalance, encephalitis, encephalopathy, gastroenteritis, or high fever.
- Be aware that trimethobenzamide shouldn't be used in children who have viral illnesses because they're at increased risk for Reye's syndrome, characterized by abrupt onset of irrational behavior; lethargy; persistent, severe vomiting; progressive encephalopathy leading to coma, seizures, and possibly death.
- To minimize injection site irritation, inject trimethobenzamide deep into a large muscle mass using the Z-track technique, which blocks solution from escaping along the injection route.

PATIENT TEACHING

- Inform patient that drug may cause blurred vision, dizziness, and drowsiness. Advise her to avoid hazardous activities until drug's CNS effects are known.
- Inform patient's parents or caregivers that trimethobenzamide may cause Reye's syndrome, and urge them to notify prescriber immediately if they notice decreased level of consciousness, irrational behavior, lethargy, or severe vomiting.

trimethoprim

Proloprim, Trimpex

Class and Category

Chemical class: Dihydrofolic acid analogue

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

↗ *To treat UTI caused by Enterobacter*

species, Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis, or coagulase-negative staphylococci, including Staphylococcus saprophyticus

TABLETS

Adults and children age 12 and over.

100 mg every 12 hr or 200 mg daily for 10 days.

DOSAGE ADJUSTMENT For patients with creatinine clearance of 15 to 30 ml/min/1.73 m², dosage usually reduced by 50%.

Mechanism of Action

Inhibits formation of tetrahydrofolic acid, the metabolically active form of folic acid, in susceptible bacteria. This depletes folate, an essential component of bacterial development, thereby disrupting production of bacterial nucleic acid and protein.

Contraindications

Hypersensitivity to trimethoprim or its components, megaloblastic anemia from folate deficiency, severe renal impairment (creatinine clearance less than 15 ml/min/1.73 m²)

Interactions

DRUGS

bone marrow depressants: Increased risk of leukopenia, thrombocytopenia

cyclosporine: Increased risk of nephrotoxicity

dapsone: Increased blood levels and risk of adverse effects (especially methemoglobinemia) of both drugs

folate antagonists: Increased risk of megaloblastic anemia

phenytoin: Decreased phenytoin metabolism, increased risk of phenytoin toxicity

procainamide: Increased blood levels of procainamide and its metabolite, N-acetylprocainamide

rifampin: Increased elimination and decreased effectiveness of trimethoprim

warfarin: Increased anticoagulant activity of warfarin

Adverse Reactions

CNS: Fever, headache

EENT: Glossitis

GI: Abdominal pain, anorexia, diarrhea, elevated liver function test results, epigastric pain, nausea, vomiting

GU: Elevated BUN and serum creatinine levels

HEME: Leukopenia, megaloblastic anemia,

methemoglobinemia, neutropenia, thrombocytopenia

SKIN: Exfoliative dermatitis, pruritus, rash

Nursing Considerations

- Obtain urine specimen, as ordered, before trimethoprim therapy starts.
- Give drug on an empty stomach to enhance absorption.
- Evaluate patient's test values for folic acid deficiency and signs of bone marrow depression.
- Monitor serum potassium level and renal function studies, as ordered, in patients with decreased renal function because these patients are at increased risk for hyperkalemia and toxic reactions when receiving trimethoprim.

PATIENT TEACHING

- Instruct patient to complete entire course of trimethoprim therapy, as prescribed, even if she feels better beforehand.
- Advise patient to take drug with food or milk if GI distress occurs.
- Instruct patient to notify prescriber if she experiences rash, severe fatigue, sore throat, or unusual bleeding or bruising.

trimipramine maleate

Apo-Trimip (CAN), Novo-Tripriamine (CAN), Rhotrimine (CAN), Surmontil

Class and Category

Chemical class: Dibenzazepine derivative

Therapeutic class: Antidepressant

Pregnancy category: C

Indications and Dosages

➤ *To treat depression*

CAPSULES

Adults in inpatient settings. *Initial:* 100 mg daily in divided doses, increased gradually in a few days to 200 mg daily. *Maximum:* 300 mg daily in 2 to 3 wk.

Adolescents in inpatient settings. *Initial:* 50 mg daily in divided doses, increased as needed. *Maximum:* 100 mg daily.

Adults in outpatient settings. *Initial:* 75 mg/day in divided doses, increased gradually up to 150 mg daily, as needed.

Maintenance: 50 to 150 mg daily.

Maximum: 200 mg daily.

Adolescents in outpatient settings. *Initial:* 50 mg daily in divided doses, increased as needed. *Maximum:* 100 mg daily.

DOSAGE ADJUSTMENT For elderly patients, initial dosage reduced to 50 mg daily in divided doses, and maximum dosage limited to 100 mg daily.

Route	Onset	Peak	Duration
P.O.	2–3 wk	Unknown	Unknown

Mechanism of Action

Inhibits the reuptake of norepinephrine at presynaptic neurons, thus increasing its concentration in synapses. This action may elevate mood and relieve depression.

Contraindications

Hypersensitivity to trimipramine, other dibenzazepine tricyclic antidepressants, or their components; recovery period after an MI; use within 14 days of an MAO inhibitor or other tricyclic antidepressant

Interactions

DRUGS

amantadine, anticholinergics, antidyskinetics, antihistamines: Increased anticholinergic effects (confusion, hallucinations, nightmares)

anticonvulsants: Increased CNS depression, lowered seizure threshold (high trimipramine doses), decreased anticonvulsant effect

antithyroid drugs: Risk of agranulocytosis
barbiturates, carbamazepine: Decreased blood level and effects of trimipramine
bupropion, clozapine, cyclobenzaprine, haloperidol, loxapine, maprotiline, molindone, phenothiazines, thioxanthenes: Increased and prolonged sedative and anticholinergic effects of both drugs, increased risk of seizures

cimetidine: Decreased trimipramine metabolism, possibly leading to trimipramine toxicity

clonidine: Decreased hypotensive effect and increased CNS depressant effect of clonidine

CNS depressants: Increased hypotension and CNS and respiratory depression

disulfiram, ethchlorvynol: Transient delirium, risk of CNS depression (ethchlorvynol)

fluoxetine: Increased trimipramine level
guanadrel, guanethidine: Decreased hypotensive effect

MAO inhibitors: Increased risk of death, hyperpyrexia, hypertensive crisis, severe seizures

methylphenidate: Decreased methylphenidate effects, increased blood trimipramine level

metrizamide: Increased risk of seizures
naphazoline (ophthalmic), oxymetazoline (nasal or ophthalmic), phenylephrine (nasal or ophthalmic), xylometazoline (nasal):

Increased vasopressor effect of these drugs
oral anticoagulants: Increased anticoagulation

phenothiazines: Increased blood trimipramine level, decreased phenothiazine metabolism

pimozide, probucol: Increased risk of arrhythmias, possibly prolonged QT interval

sympathomimetics: Increased risk of arrhythmias, hyperpyrexia, severe hypertension

thyroid hormones: Increased therapeutic and toxic effects of both drugs

ACTIVITIES

alcohol use: Increased hypotension and CNS and respiratory depression

Adverse Reactions

CNS: Anxiety, ataxia, confusion, delirium, dizziness, drowsiness, excitement, extrapyramidal reactions, hallucinations, headache, insomnia, nervousness, nightmares, parkinsonism, seizures, stroke, suicidal ideation, tremor

CV: Arrhythmias, orthostatic hypotension

EENT: Blurred vision, dry mouth, increased intraocular pressure, taste perversion, tinnitus, tongue swelling

ENDO: Gynecomastia, syndrome of inappropriate ADH secretion

GI: Constipation, diarrhea, heartburn, ileus, increased appetite, nausea, vomiting

GU: Sexual dysfunction, testicular swelling, urine retention

HEME: Agranulocytosis, bone marrow depression

RESP: Wheezing

SKIN: Alopecia, diaphoresis, jaundice, photosensitivity, pruritus, rash, urticaria

Other: Facial edema, weight gain

Nursing Considerations

- Watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.
- Expect to gradually reduce trimipramine dosage, as prescribed, before electroconvulsive therapy.

PATIENT TEACHING

- Instruct patient to take the last dose early in the evening to avoid insomnia.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to change position slowly to minimize orthostatic hypotension.
- Urge patient to avoid alcohol during therapy.
- Advise patient to avoid exposure to excessive sunlight and to wear sunscreen when she's outdoors.
- Instruct patient to notify prescriber about the development of unusual bruising and signs of infection.
- Suggest that patient use sugarless gum or hard candy to relieve dry mouth.

WARNING Urge parents to watch their child or adolescent closely for abnormal behavior, increased aggression or hostility, or suicidal tendencies, especially when therapy starts or dosage is adjusted. Stress need to notify prescriber about changes.

tromethamine

Tham

Class and Category

Chemical class: Organic amine

Therapeutic class: Alkalinizer

Pregnancy category: C

Indications and Dosages

↗ *To treat metabolic acidosis associated with cardiac arrest*

I.V. INFUSION

Adults and children. 3.6 to 10.8 g (111 to 333 ml) of 0.3 M solution.

I.V. INJECTION

Adults and children. If chest is opened, 2 to 6 g injected directly into open ventricular cavity.

↗ *To treat metabolic acidosis during cardiac bypass surgery*

I.V. INFUSION

Adults and children. 9 ml (2.7 mEq or 0.32 g) of 0.3 M solution/kg as a single dose. *Usual:* 500 ml (150 mEq or 18 g) infused over 1 hr. *Maximum:* 500 mg/kg over 1 hr.

Mechanism of Action

Combines with hydrogen ions and their associated acid anions, including lactic, pyruvic, and carbonic acid, to form salts that are excreted in urine. Tromethamine exerts additional alkalinizing effects by acting as an osmotic diuretic, promoting the excretion of alkaline urine that contains increased amounts of carbon dioxide and electrolytes.

Contraindications

Anuria, chronic respiratory acidosis, hypersensitivity to tromethamine or its components, uremia

Interactions

DRUGS

amphetamines, quinidine, other pH-dependent drugs: Altered excretion of these drugs

Adverse Reactions

CNS: Fever

CV: Vasospasm

ENDO: Hypoglycemia

GI: Hepatic necrosis (hemorrhagic)

RESP: Respiratory depression

Other: Hypervolemia; infusion site infection, phlebitis, or venous thrombosis; metabolic alkalosis

Nursing Considerations

- Evaluate blood pH, blood glucose, and serum bicarbonate and electrolyte levels, and partial pressure of arterial carbon dioxide before, during, and after tromethamine therapy, as ordered.
- Be aware that, except in life-threatening situations, tromethamine therapy is limited to no more than 1 day because of the risk of alkalosis.

WARNING Be aware that exceeding the recommended dosage can cause alkalosis, respiratory depression, and reduced carbon dioxide level.

- Expect I.V. tromethamine administration to increase the risk of hypervolemia and pulmonary edema.

- Assess the infusion site often for infiltration, which may cause inflammation, necrosis, thrombosis, tissue sloughing, and vasospasm.
- Be aware that patients with renal failure have an increased risk of developing hyperkalemia. For such patients, be prepared to monitor ECG continuously and assess serum potassium level frequently.
- Monitor patient's blood glucose level often during and after therapy because rapid delivery can cause hypoglycemia for several hours.

PATIENT TEACHING

- Inform family members that patient's vital signs and laboratory test results will be measured frequently to monitor her progress.

trospium chloride

Sanctura, Sanctura XR

Class and Category

Chemical class: Quaternary ammonium compound

Therapeutic class: Bladder antispasmodic

Pregnancy category: C

Indications and Dosages

↗ *To treat overactive bladder with symptoms of urge urinary incontinence, urgency, and urinary frequency*

TABLETS

Adults. 20 mg b.i.d. 1 hour before meals or on empty stomach.

DOSAGE ADJUSTMENT For patients with severe renal insufficiency (creatinine clearance less than 30 ml/min/1.73 m²) and patients age 75 or over, dosage reduced to 20 mg daily at bedtime.

E.R. TABLETS

Adults. 60 mg daily in the morning, 1 hour before a meal or on empty stomach.

Route	Onset	Peak	Duration
P.O.	Unknown	5–6 hr	Unknown

Mechanism of Action

Antagonizes the effect of acetylcholine on muscarinic receptors in the bladder. Trospium's parasympatholytic action reduces the tonus of smooth muscle in the

bladder. These actions increase maximum cystometric bladder capacity and volume with the first detrusor contraction, which relieves the sensation of urgency and frequency and enhances bladder control.

Contraindications

Gastric retention, hypersensitivity to trospium or its components, uncontrolled angle-closure glaucoma, urine retention

Interactions**DRUGS**

anticholinergics: Increased frequency or severity of adverse effects; possibly reduced absorption of trospium

digoxin, metformin, morphine, pancuronium,

procainamide: Possibly increased plasma concentration of trospium, digoxin, metformin, morphine, pancuronium, procainamide

ACTIVITIES

alcohol use: Possibly increased drowsiness

Adverse Reactions

CNS: Dizziness, drowsiness, fatigue, headache, light-headedness

CV: Palpitations, tachycardia

EENT: Blurred vision; dry eyes, mouth, or throat

GI: Abdominal distention or pain, constipation, flatulence, indigestion, vomiting

GU: Urine retention

SKIN: Decreased sweating, dry skin, flushing, rash

Other: Angioedema

Nursing Considerations

- Use trospium cautiously in patients with ulcerative colitis, intestinal atony, or myasthenia gravis because drug may decrease GI motility; patients with significant bladder outflow obstruction because drug may cause urine retention; patients with hepatic impairment because drug's effects on the liver are unknown; and patients with renal impairment because drug excretion may be impaired.
- Monitor elderly patients carefully, especially those age 75 or over, for adverse reactions because elderly patients have an increased risk of trospium-induced adverse reactions.

PATIENT TEACHING

- Instruct patient to take trospium on an

empty stomach or at least 1 hour before eating because food delays its absorption.

- Caution patient to avoid performing activities in a warm or hot environment because sweating may be delayed, which could cause a sudden increase in body temperature and heatstroke.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Inform patient that alcohol may increase the risk of drowsiness; urge patient to limit or abstain from alcoholic beverages while taking trospium.

tubocurarine chloride

Class and Category

Chemical class: Isoquinoline derivative

Therapeutic class: Anticonvulsant

Pregnancy category: C

Mechanism of Action

Tubocurarine reduces the intensity of skeletal muscle contractions caused by electrically induced seizures. Normally, when a nerve impulse arrives at a somatic motor nerve terminal, it triggers acetylcholine (ACh) stored in synaptic vesicles to be released into the neuromuscular junction. The released ACh binds with nicotinic receptors embedded in the skeletal muscle motor endplate, as shown below left, triggering muscle cell depolarization and contraction.

Indications and Dosages

➤ *To manage muscle contractions of seizures associated with electroshock therapy*

I.V. INJECTION

Adults. 157 mcg/kg (0.157 mg/kg) over 30 to 90 sec, given just before electroshock therapy. Expect initial dose to be 3 mg less than calculated total dose.

➤ *To produce skeletal muscle paralysis during anesthesia*

I.V. OR I.M. INJECTION

Adults. *Initial:* 6 to 9 mg. *Maintenance:* 3 to 4.5 mg in 3 to 5 min. if needed. For prolonged procedures, 3-mg supplemental doses given.

Infants and children. 500 mcg/kg I.V.

Neonates. *Initial:* 250 to 500 mcg/kg I.V. *Maintenance:* One-fifth to one-sixth of initial dose if needed.

➤ *To facilitate endotracheal intubation and aid controlled respiration during mechanical ventilation*

I.V. INJECTION

Tubocurarine is a nondepolarizing neuromuscular blocker that acts as a competitive antagonist of ACh. By binding to the nicotinic receptors, as shown below right, it prevents transmission of the action potential at the neuromuscular junction, thereby sustaining skeletal muscle relaxation and eliminating the peripheral muscular manifestations of seizures. The drug has no effect on the CNS processes involved with seizures because it doesn't cross the blood-brain barrier.

Adults. *Initial:* 16.5 mcg/kg. *Maintenance:* Dosage individualized based on patient response.

↗ *To aid in the diagnosis of myasthenia gravis*

I.V. INJECTION

Adults. 4 to 33 mcg/kg. After 2 to 3 min, 1.5 mg of neostigmine is given I.V. to terminate the test.

- Keep emergency equipment and drugs readily available in case respiratory depression occurs.

PATIENT TEACHING

- Explain the need for frequent hemodynamic monitoring.

Route	Onset	Peak	Duration
I.V.	1 min	2–5 min	20–40 min

Incompatibilities

Don't mix tubocurarine with barbiturates, such as methohexital or thiopental, because a precipitate may form.

Contraindications

Hypersensitivity to tubocurarine or its components, patients in whom histamine release may be dangerous

Interactions

DRUGS

alfentanil, fentanyl, sufentanil: Prevented or reversed muscle rigidity from these drugs
aminoglycosides, anesthetics, capreomycin, citrate-anticoagulated blood, clindamycin, lidocaine (I.V.), lincomycin, polymyxins, procaine (I.V.), trimethaphan: Additive neuromuscular blocking effects

beta blockers, calcium salts: Prolonged and enhanced effects of tubocurarine

magnesium salts, procainamide, quinidine: Enhanced blockade effects

opioid analgesics: Additive histamine release effects, additive respiratory depressant effects, worsened bradycardia and hypotension

Adverse Reactions

CV: Arrhythmias, bradycardia, edema, hypotension, shock, tachycardia

RESP: Bronchospasm

SKIN: Erythema, flushing, itching, rash

Other: Anaphylaxis

Nursing Considerations

- If patient has a history of CV disease or is hypotensive, monitor her for further decrease in blood pressure.
- Monitor patient for bronchospasm and hypotension because tubocurarine may cause increased histamine release.

U V W

urea (carbamide)

Ureaphil

Class and Category

Chemical class: Carbonic acid diamide salt
Therapeutic class: Antiglaucoma, diuretic
Pregnancy category: C

Indications and Dosages

↗ *To reduce cerebral edema and intracranial pressure*

I.V. INFUSION

Adults and children age 2 and over. 500 mg to 1.5 g/kg as 30% solution in D₅W, D₁₀W, or 10% invert sugar solution infused over 30 min to 2 hr at 4 or 6 ml/min, according to manufacturer's instructions. *Maximum:* 2 g/kg daily.

Children under age 2. 100 mg to 1.5 g/kg as 30% solution in D₅W, D₁₀W, or 10% invert sugar solution infused over 30 min to 2 hr at 4 or 6 ml/min, according to manufacturer's instructions.

↗ *To treat malignant or secondary glaucoma*

I.V. INFUSION

Adults. 500 mg to 1.5 g/kg as 30% solution in D₅W, D₁₀W, or 10% invert sugar solution infused over 30 min to 2 hr at 4 or 6 ml/min, according to manufacturer's instructions. *Maximum:* 2 g/kg daily.

DOSAGE ADJUSTMENT Dosage reduced or drug withheld for patients with renal impairment if BUN level rises to 75 mg/dl or more or if diuresis fails to occur within 2 hr after administration.

Mechanism of Action

Elevates blood plasma osmolality, creating an osmotic effect that increases movement of water from the brain, CSF, and anterior portion of the eyes into interstitial fluid and plasma. This action reduces cerebral edema, intracranial pressure, CSF volume, and intraocular pressure. Large doses inhibit reabsorption of water and solutes in the renal tubules and induce diuresis by affect-

ing the osmotic pressure gradient of the glomerular filtrate.

Route	Onset	Peak	Duration
I.V.	10 min	1–2 hr	3–10 hr*

Contraindications

Active intracranial bleeding, hepatic failure, hypersensitivity to urea or its components, renal impairment, severe dehydration

Interactions

DRUGS

carbonic anhydrase inhibitors, other diuretics: Additive diuretic and intraocular pressure-reducing effects
lithium: Increased renal excretion of lithium

Adverse Reactions

CNS: Agitation, confusion, fever, headache, hyperthermia, nervousness, subarachnoid hemorrhage, subdural hematoma, syncope
CV: Tachycardia
EENT: Dry mouth, intraocular hemorrhage
GI: Nausea, thirst, vomiting
GU: Elevated BUN level
HEME: Hemolysis
SKIN: Blemishes, extravasation with tissue necrosis and sloughing
Other: Dehydration, hypokalemia, hyponatremia, infusion site phlebitis or thrombosis

Nursing Considerations

- For maximum reduction of intracranial or intraocular pressure, expect to give urea 60 minutes before ocular or intracranial surgery.
- Don't mix urea with invert sugar solution if patient has fructose intolerance from aldolase deficiency.
- Avoid infusing drug into leg veins to reduce risk of phlebitis and thrombosis.
- Discard unused portion of drug after 24 hours.
- Be aware that rapid administration may cause hemolysis, increased capillary bleeding, and, in patients with glaucoma, intraocular hemorrhage.
- Maintain adequate hydration to minimize adverse reactions. Assess for signs of dehydration, including dry mucous mem-

* For diuresis; 5 to 6 hr for reduced intraocular pressure.

branes and tenting.

- Monitor BUN and serum electrolyte levels as well as fluid intake and output during urea therapy because prolonged use can cause diuresis.

PATIENT TEACHING

- Instruct patient to notify prescriber immediately about difficulty breathing or shortness of breath because drug can cause transient increases in circulatory volume, leading to circulatory overload, worsening of heart failure, or pulmonary edema.
- Tell patient to expect increased urine output.
- Encourage patient to remain on bed rest during therapy.

urokinase

Abbokinase, Abbokinase Open-Cath

Class and Category

Chemical class: Renal enzymatic protein

Therapeutic class: Thrombolytic

Pregnancy category: B

Indications and Dosages

➤ *To treat acute coronary artery thrombosis*

INTRACORONARY INFUSION

Adults. 6,000 international units/min until artery is maximally opened (up to 2 hr may be required). *Usual:* 500,000 international units.

➤ *To treat acute pulmonary thromboembolism including massive events*

I.V. INFUSION

Adults. *Initial:* 4,400 international units/kg over 10 min, followed by 4,400 international units/kg/hr for 12 hr.

➤ *To clear I.V. catheter occlusion*

INSTALLATION

Adults and children. 5,000 international units/ml instilled into occluded line.

Route	Onset	Peak	Duration
I.V.	Unknown	20 min– 2 hr	4 hr
Intra- coronary	Unknown	Unknown	4 hr

Mechanism of Action

Indirectly promotes conversion of plasminogen to plasmin, an enzyme that breaks

down fibrin clots, fibrinogen, and other plasma proteins, including procoagulant factors V and VIII.

Incompatibilities

Don't administer I.V. urokinase through same I.V. line as other drugs or add other drugs to urokinase solution.

Contraindications

Arteriovenous malformation, bleeding disorder, hypersensitivity to urokinase or its components, internal bleeding, intracranial aneurysm, intracranial or intraspinal surgery during previous 2 months, intracranial tumor, recent cardiopulmonary resuscitation, recent trauma, severe uncontrolled hypertension (systolic blood pressure 200 mm Hg or higher, or diastolic blood pressure 110 mm Hg or higher), stroke during previous 2 months

Interactions

DRUGS

antifibrinolytics (aminocaproic acid, apro-tinin): Mutual antagonism

antihypertensives: Increased risk of severe hypotension

cefamandole, cefoperazone, cefotetan, plicamycin, valproic acid: Increased risk of hypoprothrombinemia and severe hemorrhage

corticosteroids, ethacrynic acid, salicylates (nonacetylated): Increased risk of GI ulceration and bleeding

enoxaparin, heparin, NSAIDs, oral anticoagulants, platelet-aggregation inhibitors:

Increased risk of hemorrhage

thiotepa: Increased therapeutic effects of thiotepa

Adverse Reactions

CNS: Chills, CVA, fever, headache

CV: Arrhythmias, including tachycardia; chest pain; cholesterol embolization; hypertension; hypotension

EENT: Orolingual edema

GI: Nausea, vomiting

HEME: Unusual bleeding

MS: Back pain, myalgia

RESP: Bronchospasm, dyspnea, hypoxemia, wheezing

SKIN: Cyanosis, ecchymosis, flushing, pruritus, rash, urticaria

Other: Anaphylaxis, infusion site reactions, metabolic acidosis

Nursing Considerations

- To prevent foaming, don't shake urokinase when reconstituting. Consult pharmacist about giving drug through 0.45-micron or smaller cellulose membrane filter.
- Assess baseline hematocrit, platelet count, thrombin time, APTT, PT, and INR as ordered.
- Monitor heart rate and rhythm by continuous ECG during therapy, especially during rapid lysis of coronary thrombi. Arrhythmias can occur with reperfusion.
- Monitor blood pressure for hypotension. If it occurs, notify prescriber and expect to reduce infusion rate.
- Check for bleeding at puncture sites and in urine and stool. Check for intracranial bleeding by performing frequent neurologic assessments.
- After arterial puncture, apply pressure for at least 30 minutes and then apply pressure dressing. Check often for bleeding during therapy.
- To prevent bleeding and associated complications, avoid venipunctures; use an external blood pressure cuff to measure blood pressure; give acetaminophen (not aspirin), as prescribed, for fever; and handle patient as little as possible.

WARNING If serious bleeding begins and can't be controlled with local pressure, stop infusion immediately and notify prescriber.

PATIENT TEACHING

- Instruct patient to remain on bed rest during urokinase therapy.
- Inform patient that minor bleeding may occur at wounds or puncture sites.

ursodiol (ursodeoxycholic acid)

Actigall, Urso Forte, URSO 250, Ursofalk (CAN)

Class and Category

Chemical class: Naturally occurring bile acid

Therapeutic class: Bile salt replenisher, cholelitholytic

Pregnancy category: B

Indications and Dosages

↗ To prevent gallstone formation in obese

patients during rapid weight loss

CAPSULES

Adults and adolescents. 300 mg b.i.d. Or, 8 to 10 mg/kg daily in divided doses b.i.d. or t.i.d.

↗ To dissolve gallstones

CAPSULES

Adults and adolescents. 8 to 10 mg/kg daily in divided doses b.i.d. or t.i.d.

↗ To treat primary biliary cirrhosis

TABLETS

Adults. 13 to 15 mg/kg daily in two to four divided doses.

Mechanism of Action

Suppresses hepatic synthesis, biliary secretion, and intestinal reabsorption of cholesterol. Prolonged use promotes dissolution of gallstones.

Contraindications

Acute cholangiitis; gallstone complications (such as biliary GI fistula; biliary obstruction; calcified, radiopaque, or radiotranslucent bile-pigment gallstones; cholecystitis; pancreatitis); hypersensitivity to ursodiol, other bile acids, or their components

Interactions

DRUGS

aluminum-containing antacids, cholestyramine, colestipol: Decreased absorption and therapeutic effects of ursodiol

clofibrate, estrogens, neomycin, oral contraceptives, progestins: Interference with ursodiol's therapeutic effects; increased risk of gallstone formation

FOODS

any foods: Increased dissolution of drug

Adverse Reactions

CNS: Anxiety, asthenia, depression, fatigue, headache, sleep disturbance

CV: Chest pain, hypertension, peripheral edema

ENDO: Hyperglycemia

EENT: Metallic taste, rhinitis, stomatitis

GI: Abdominal pain, cholecystitis, constipation, diarrhea, esophagitis, flatulence, indigestion, nausea, peptic ulcer, vomiting

GU: Elevated creatinine level

HEME: Leukopenia, thrombocytopenia

MS: Arthralgia, back pain, myalgia

RESP: Cough

SKIN: Alopecia, diaphoresis, dry skin, pruritus, rash, urticaria

Nursing Considerations

- Administer ursodiol with food to increase drug dissolution.
- Give aluminum-containing antacids, cholestyramine, and colestipol at least 1 hour before or 4 hours after ursodiol because they may decrease drug's effects.
- Expect drug to be discontinued if gallstones haven't partially dissolved after 12 months of therapy.
- If patient inadvertently takes too much ursodiol, diarrhea will most likely result and may warrant systemic treatment.

PATIENT TEACHING

- Tell patient to take ursodiol with meals.
- Urge patient to take aluminum-containing antacids at least 1 hour before or 4 hours after ursodiol to support absorption.
- Urge patient to notify prescriber immediately if evidence of acute cholecystitis develops, such as acute right-upper-quadrant abdominal pain.
- Inform patient that he may need to take ursodiol for a prolonged period before gallstones dissolve.
- Advise diabetic patient to monitor blood glucose levels during therapy because ursodiol may alter blood glucose control.

ustekinumab

Stelara

Class and Category

Chemical class: Human IgG1k monoclonal antibody

Therapeutic class: Antipsoriasisitic

Pregnancy category: B

Indications and Dosages

↗ *To treat moderate to severe plaque psoriasis in patients who are candidates for phototherapy or systemic therapy*

SUBCUTANEOUS INJECTION

Adults weighing 100 kg (220 lb) or less:

Initial: 45 mg followed by 45 mg 4 wk later and then 45 mg every 12 wk.

Adults weighing more than 100 kg

(220 lb): *Initial:* 90 mg followed by 90 mg 4 wk later and then 90 mg every 12 wk.

Mechanism of Action

Binds to p40 protein subunit used by interleukin (IL)-12 and IL-23 cytokines. These

specific cytokines are involved in inflammatory and immune responses, such as natural killer cell activation and CD4+ T-cell differentiation and activation. By disrupting signaling mediated by IL-12 and IL-23, signs and symptoms caused by inflammatory and immune responses in plaque psoriasis are diminished or relieved.

Route	Onset	Peak	Duration
SubQ	Unknown	7–13.5 days	Unknown

Contraindications

Hypersensitivity to ustekinumab or its components

Interactions

DRUGS

cytochrome P-450 substrates such as cyclosporine, theophylline, warfarin: Possibly altered effects or blood levels of these drugs when ustekinumab is started or stopped
live-virus vaccines: Increased risk of adverse vaccine effects

Adverse Reactions

CNS: Depression, dizziness, fatigue, headache, reversible leukoencephalopathy syndrome

ENDO: Nasopharyngitis, pharyngolaryngeal pain

GI: Diarrhea, diverticulitis, gastroenteritis

GU: UTI

MS: Back pain, myalgia, osteomyelitis

RESP: Pneumonia, upper respiratory tract infection

SKIN: Cellulitis, pruritus

Other: Anti-ustekinumab antibodies, injection site reactions (bruising, erythema, hemorrhage, induration, irritation, pain, pruritus, swelling), malignancies (breast; colon; head and neck; kidney; non-melanoma of skin, kidney, prostate, thyroid), serious infection including bacterial, fungal and viral infections and reactivation of latent infections

Nursing Considerations

- Make sure patient has a tuberculin skin test before therapy starts. If skin test is positive, treatment of latent tuberculosis should start before ustekinumab therapy starts. Also expect antituberculosis therapy to start if patient has a history of latent or active tuberculosis but adequate therapy

can't be confirmed or if patient has a negative test for latent tuberculosis but has risk factors for tuberculosis.

- Make sure patient is current with all immunizations before starting ustekinumab therapy because patient shouldn't receive live vaccines during treatment. BCG vaccines shouldn't be given for 1 year before or after ustekinumab therapy.

WARNING If patient has evidence of an active infection when drug is prescribed, therapy shouldn't start until infection has been treated. Monitor all patients for infection during therapy, especially those receiving immunosuppressants. If a serious infection, an opportunistic infection, or sepsis develops, expect prescriber to stop ustekinumab and start appropriate antimicrobial therapy.

- Patients with a history of cancer or who have genetic deficiencies in IL-12 or IL-23 should be thoroughly evaluated before ustekinumab therapy starts because various cancers have occurred in patients being treated with ustekinumab. Monitor patients throughout therapy for unusual, persistent, or severe signs and symptoms.
- Use ustekinumab cautiously in patients with recurrent infection or increased risk of infection and in patients who live in regions where tuberculosis and histoplasmosis are endemic.
- Give ustekinumab using a 27G, half-inch needle into upper arms, gluteal region, thighs, or any quadrant of abdomen. Rotate sites, and avoid areas that are tender, bruised, erythematous, or indurated.
- Note that needle cover on prefilled syringe contains a latex derivative and shouldn't be handled by persons with a latex allergy.
- Monitor patient for headache, seizures, vision disturbances, and confusion, which may signal reversible posterior leukoencephalopathy syndrome, a rare neurologic disorder that may occur with ustekinumab therapy. If present, notify prescriber, discontinue ustekinumab therapy, and provide appropriate treatment, as ordered.

PATIENT TEACHING

- Inform patient that treatment must be supervised by a health care professional.
- Inform patient that tuberculosis may occur during ustekinumab therapy. Instruct him to report persistent cough,

wasting or weight loss, and low-grade fever to prescriber.

- Teach patient to recognize and report evidence of infection; drug may need to be stopped. Advise patient to avoid people with infections and to have all prescribed laboratory tests performed.
- Inform patient that the risk of developing certain kinds of cancer is higher in patients taking ustekinumab. Emphasize importance of follow-up visits and reporting any unusual, persistent, or sudden-onset signs or symptoms.
- Caution against receiving live-virus vaccines while taking ustekinumab; doing so may adversely affect the immune system.
- Urge patient to inform all health care providers about ustekinumab use and to inform prescriber about all OTC medications being taken, including herbal remedies and vitamin and mineral supplements.

valproic acid

Alti-Valproic (CAN), Depakene, Depakote ER, Deproic (CAN), Dom-Proic (CAN), Med-Valproic (CAN), Novo-Valproic (CAN), Nu-Valproic (CAN), PMS-Valproic Acid (CAN), Stavzor

valproate sodium

Depacon

divalproex sodium

Depakote, Depakote Sprinkle, Epival (CAN)

Class and Category

Chemical class: Carboxylic acid derivative

Therapeutic class: Anticonvulsant

Pregnancy category: D

Indications and Dosages

➤ To treat simple or complex absence seizures, complex partial seizures, myoclonic seizures, and generalized tonic-clonic seizures as monotherapy

CAPSULES, DELAYED-RELEASE SPRINKLE CAPSULES, DELAYED-RELEASE TABLETS, SYRUP, I.V. INFUSION (VALPROIC ACID, VALPROATE SODIUM, DIVALPROEX SODIUM)

Adults and adolescents. *Initial:* 10 to 15 mg/kg/day in divided doses b.i.d. or

t.i.d., increased by 5 to 10 mg/kg daily every wk, as needed and as prescribed. *Maximum:* 60 mg/kg daily.

Children. *Initial:* 15 to 45 mg/kg daily in divided doses b.i.d. or t.i.d., increased by 5 to 10 mg/kg/day every wk, as needed and as prescribed.

↗ *As adjunct to treat simple or complex absence seizures, complex partial seizures, myoclonic seizures, and generalized tonic-clonic seizures*

CAPSULES, DELAYED-RELEASE SPRINKLE CAPSULES, DELAYED-RELEASE TABLETS, SYRUP, I.V. INFUSION (VALPROIC ACID, VALPROATE SODIUM, DIVALPROEX SODIUM)

Adults and adolescents. 10 to 30 mg/kg/day in divided doses, increased by 5 to 10 mg/kg/day every wk, as needed and as prescribed.

Children. 30 to 100 mg/kg daily in divided doses, as prescribed.

DOSE ADJUSTMENT For adults being converted from immediate-release divalproex tablets to delayed-release tablets, dosage increased to 8% to 20% more than total daily dose of immediate-release tablets and given once daily.

↗ *To treat acute manic phase of bipolar disorder*

DELAYED-RELEASE TABLETS (DIVALPROEX SODIUM), DELAYED-RELEASE CAPSULES (STAVZOR)

Adults. *Initial:* 750 mg daily in divided doses. *Maximum:* 60 mg/kg daily.

↗ *To prevent migraine headache*

TABLETS, TABLETS (DIVALPROEX SODIUM), DELAYED-RELEASE CAPSULES (STAVZOR)

Adults. 250 mg every 12 hr, increased p.r.n. *Maximum:* 1 g daily.

DELAYED-RELEASE TABLETS (DIVALPROEX SODIUM)

Adults. 500 mg daily, increased, as needed and prescribed, up to 1 g daily. *Maximum:* 1 g daily.

Mechanism of Action

May decrease seizure activity by blocking reuptake of gamma-aminobutyric acid (GABA), the most common inhibitory neurotransmitter in the brain. GABA suppresses the rapid firing of neurons by inhibiting voltage-sensitive sodium channels.

Contraindications

Hepatic dysfunction; hypersensitivity to valproic acid, valproate sodium, divalproex sodium, or their components; urea cycle disorders

Interactions

DRUGS

aspirin, heparin, NSAIDs, oral anticoagulants, thrombolytics: Increased inhibition of platelet aggregation and risk of bleeding
barbiturates, primidone: Increased blood levels of both drugs, additive CNS effects
carbamazepine: Possibly decreased valproic acid effectiveness

carbapenem antibiotics (ertapenem, imipenem, meropenem): Reduced serum valproic acid level, causing loss of seizure control
cholestyramine: Decreased bioavailability of valproic acid

clonazepam: Increased risk of absence seizures

CNS depressants: Increased CNS depression

diazepam: Inhibited diazepam metabolism

ethosuximide: Unpredictable blood ethosuximide level

felbamate: Impaired valproic acid metabolism and increased blood drug level

haloperidol, loxapine, MAO inhibitors,

maprotiline, phenothiazines, thioxanthenes,

tricyclic antidepressants: Increased CNS

depression, lowered seizure threshold

lamotrigine: Decreased lamotrigine clearance

mefloquine: Decreased blood levels of valproic acid, divalproex, and valproate sodium; increased risk of seizures

phenytoin: Increased risk of phenytoin toxicity, loss of seizure control

phenytoin: Increased risk of phenytoin toxicity, loss of seizure control

ACTIVITIES

alcohol use: Additive CNS depression

Adverse Reactions

CNS: Agitation, ataxia, confusion, depression, dizziness, drowsiness, euphoria, hallucinations, headache, hyperesthesia, hypothermia, lack of coordination, lethargy, loss of seizure control, paresthesia, psychosis, sedation, suicidal ideation, tremor, vertigo, weakness

EENT: Diplopia, nystagmus, pharyngitis, spots before eyes

ENDO: Galactorrhea, hyperglycemia

GI: Abdominal pain, anorexia, constipation, diarrhea, elevated liver function test results, hepatotoxicity, increased appetite, indigestion, nausea, pancreatitis, vomiting

GU: Menstrual irregularities

HEME: Eosinophilia, hematoma, leukopenia, prolonged bleeding time, thrombocytopenia

MS: Dysarthria

SKIN: Alopecia, diaphoresis, erythema multiforme, jaundice, petechiae, photosensitivity, pruritus, rash, Stevens-Johnson syndrome

Other: Facial edema, hyperammonemia, injection site pain, weight gain or loss

Nursing Considerations

- Give oral valproic acid or divalproex with food to minimize GI irritation, if needed.
- Administer drug at least 2 hours before or 6 hours after cholestyramine.
- Don't mix syrup with carbonated beverages; result may be an unpleasant-tasting mixture and irritate mouth and throat.
- Don't break or let patient chew delayed-release tablets.
- As needed, sprinkle contents of delayed-release sprinkle capsules on small amount of semisolid food just before administration. Instruct patient not to chew contents of delayed-release sprinkle capsules.
- For I.V. administration, dilute prescribed dose with at least 50 ml compatible diluent and infuse over 60 minutes.
- Patient should be switched from I.V. to P.O. form of valproic acid as soon as possible.
- Patient with hypoalbuminemia or another protein-binding deficiency is at increased risk for valproic acid toxicity.
- Watch for evidence of decreased hepatic function, including anorexia, facial edema, jaundice, lethargy, loss of seizure control, malaise, vomiting, and weakness.
- Monitor liver function test results, as ordered. Assess for signs and symptoms of hepatotoxicity during first 6 months of treatment, especially in children under age 2. Notify prescriber immediately if you suspect hepatotoxicity.
- Monitor platelet count, as ordered, for signs of thrombocytopenia, and notify prescriber if they appear.

WARNING Hyperammonemia may occur even if liver function test results are normal. Monitor ammonia levels, as ordered. If patient develops unexplained lethargy, vomiting, or changes in mental status with an increase in ammonia level; if asymptomatic ammonia elevations are detected and persist; or if patient develops hypothermia even without hyperammonemia, expect to discontinue valproic acid.

- Watch patient closely for suicidal tendencies, particularly when therapy starts and

dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.

- Monitor patient's drug level, as ordered, especially early in therapy and if patient takes other drugs because interactions can alter the blood level.
- Drug may alter urine ketone test and thyroid function tests.

PATIENT TEACHING

- Instruct patient to swallow capsules whole to prevent irritation to mouth and throat. However, delayed-release sprinkle capsules may be opened and contents mixed with food for easier swallowing. Instruct patient not to chew contents of delayed-release sprinkle capsules.
- Advise patient to avoid hazardous activities during therapy because drug may affect mental and motor performance.
- Urge patient to avoid alcohol during therapy.
- Urge woman to notify prescriber at once about suspected or known pregnancy.
- Advise patient to notify prescriber if tremor develops during therapy; it may be dose-related.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Encourage woman who becomes pregnant while taking valproic acid to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting information about the safety of antiepileptic drugs during pregnancy.

valsartan

Diovan

Class and Category

Chemical class: Nonpeptide tetrazole derivative

Therapeutic class: Antihypertensive

Pregnancy category: C (first trimester), D (later trimesters)

Indications and Dosages

➤ To manage hypertension, alone or with other antihypertensives

CAPSULES

Adults. *Initial:* 80 or 160 mg daily, increased as needed and prescribed.

Maximum: 320 mg/day.

Children ages 6 to 16. 1.3 mg/kg (up to 40 mg total) once daily, increased as needed and prescribed. *Maximum:* 2.7 mg/kg (up to 160 mg) daily.

➤ *To treat New York Heart Association (NYHA) class II to IV heart failure*

CAPSULES

Adults. *Initial:* 40 mg b.i.d., increased to 80 mg b.i.d. and then 160 mg b.i.d., as needed and prescribed. *Maximum:* 320 mg daily.

➤ *To reduce cardiovascular mortality in stable patients with left ventricular failure or dysfunction following an MI*

CAPSULES

Adults. *Initial:* 20 mg b.i.d. starting as early as 12 hr after MI, increased to 40 mg b.i.d. within 7 days, followed by subsequent adjustments to 160 mg b.i.d., as tolerated. *Maintenance:* 160 mg b.i.d.

DOSAGE ADJUSTMENT If patient develops symptomatic hypotension or renal dysfunction, dosage decreased.

Route	Onset	Peak	Duration
P.O.	2 hr	6 hr	24 hr

Mechanism of Action

Blocks the hormone angiotensin II from binding to receptor sites in vascular smooth muscle, adrenal glands, and other tissues. This action inhibits vasoconstrictive and aldosterone-secreting effects of angiotensin II, thereby reducing blood pressure.

Contraindications

Hypersensitivity to valsartan or its components

Interactions

DRUGS

antihypertensives, diuretics: Additive hypotensive effect

potassium salts, potassium-sparing diuretics: Possibly hyperkalemia

FOODS

potassium-containing salt substitutes: Possibly hyperkalemia

Adverse Reactions

CNS: Dizziness, fatigue, headache, insomnia

CV: Edema, hypotension, vasculitis

EENT: Pharyngitis, rhinitis, sinusitis

GI: Abdominal pain, diarrhea, elevated

liver enzymes, hepatitis, indigestion, nausea, vomiting

GU: Increased blood creatinine level

HEME: Thrombocytopenia

MS: Arthralgia, back pain, rhabdomyolysis

RESP: Cough, upper respiratory tract infection

SKIN: Alopecia, rash

Other: Angioedema, hyperkalemia, viral infection

Nursing Considerations

- Valsartan shouldn't be given to patients who have hypovolemia or are taking a diuretic because of increased risk of severe hypotension from volume depletion.
- Check patient's blood pressure often during therapy.
- Be aware that maximal blood pressure reduction typically occurs after 4 weeks.
- Monitor serum potassium level because drug may elevate potassium level by blocking aldosterone secretion.

PATIENT TEACHING

- Instruct patient to take valsartan exactly as prescribed at the same time each day to maintain therapeutic effect.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to avoid using potassium-containing salt substitutes without consulting prescriber.
- Instruct female patient of childbearing age to use reliable birth control during therapy and to notify prescriber at once about known or suspected pregnancy because valsartan will need to be discontinued.
- Urge patient to keep follow-up appointments to monitor progress.

vancomycin hydrochloride

Vancocin

Class and Category

Chemical class: Tricyclic glycopeptide derivative

Therapeutic class: Antibiotic

Pregnancy category: B (oral), C (parenteral)

Indications and Dosages

➤ *To treat pseudomembranous colitis*

caused by Clostridium difficile and enterocolitis caused by staphylococci

CAPSULES, ORAL SOLUTION

Adults and adolescents. 125 to 500 mg every 6 hr for 7 to 10 days. *Maximum:* 2 g daily.

Children. 10 mg/kg (up to 125 mg) every 6 hr for 7 to 10 days. *Maximum:* 2 g daily.

➤ *To treat bacterial endocarditis caused by methicillin-resistant Staphylococcus aureus*

I.V. INFUSION

Adults. 30 mg/kg daily in equally divided doses b.i.d. for 4 to 6 wk. *Maximum:* 2 g daily.

➤ *As adjunct to treat bacterial endocarditis caused by methicillin-resistant S. aureus in patients with prosthetic heart valve*

I.V. INFUSION

Adults. 30 mg/kg daily in equally divided doses b.i.d. to q.i.d. for 6 wk or longer in conjunction with rifampin and gentamicin. *Maximum:* 2 g daily.

➤ *To treat bacterial endocarditis caused by Streptococcus bovis or Streptococcus viridans*

I.V. INFUSION

Adults. 30 mg/kg daily in equally divided doses b.i.d. for 4 wk. *Maximum:* 2 g daily.

➤ *As adjunct to treat bacterial endocarditis caused by enterococci*

I.V. INFUSION

Adults. 30 mg/kg daily in equally divided doses b.i.d. for 4 to 6 wk in conjunction with gentamicin. *Maximum:* 2 g daily.

➤ *To treat bacterial septicemia, bone and joint infections, pneumonia, and skin and soft-tissue infections caused by staphylococcus, including methicillin-resistant strains, and life-threatening infections*

I.V. INFUSION

Adults and children age 12 and over. 500 mg every 6 hr or 1 g every 12 hr infused over at least 60 min. *Maximum:* 4 g daily.

Children ages 1 month to 12 years. 10 mg/kg every 6 hr or 20 mg/kg every 12 hr infused over at least 60 min.

Neonates ages 1 week to 1 month. *Initial:* 15 mg/kg followed by 10 mg/kg every 8 hr infused over at least 60 min.

Neonates under age 1 week. *Initial:* 15 mg/kg followed by 10 mg/kg every 12 hr infused over at least 60 min.

Mechanism of Action

Inhibits bacterial RNA and cell wall synthesis; alters permeability of bacterial membranes, causing cell wall lysis and cell death.

Incompatibilities

Don't give I.V. vancomycin through same I.V. line as other drugs. Don't add to albumin-containing solutions, alkaline solutions, aminophylline, amobarbital sodium, aztreonam, cefepime, ceftazidime, chloramphenicol sodium succinate, chlorothiazide sodium, dexamethasone sodium phosphate, foscarnet sodium, heparin sodium, methicillin sodium, penicillin G, pentobarbital sodium, phenobarbital sodium, piperacillin sodium and tazobactam sodium, secobarbital sodium, and sodium bicarbonate. Vancomycin may precipitate with heavy metals.

Contraindications

Hypersensitivity to vancomycin or its components, hypersensitivity to corn or corn products when vancomycin is given with dextrose solutions

Interactions

DRUGS

aminoglycosides (amikacin, gentamicin, tobramycin), amphotericin B, bacitracin (parenteral), bumetanide, capreomycin, carmustine, cidofovir, cisplatin, cyclosporine, ethacrynic acid, furosemide, paromomycin, pentamidine (parenteral), polymyxins, salicylates (parenteral), streptozocin: Additive nephrotoxicity or ototoxicity
antihistamines, buclizine, cyclizine, meclizine, phenothiazines, thioxanthenes, trimethobenzamide: Masked symptoms of ototoxicity
cholestyramine, colestipol: Decreased antibacterial activity of oral vancomycin
dexamethasone: Decreased penetration of vancomycin into CSF
nephrotoxic drugs: Increased risk of nephrotoxicity

Adverse Reactions

CNS: Chills, dizziness, vertigo

CV: Hypotension

EENT: Ototoxicity

GI: Nausea, pseudomembranous colitis

GU: Nephrotoxicity

HEME: Eosinophilia, neutropenia

RESP: Dyspnea, wheezing

SKIN: Exfoliative dermatitis; drug rash with

eosinophilia and systemic symptoms (DRESS); extravasation with pain, tenderness, thrombophlebitis, and tissue necrosis; pruritus; rash; toxic epidermal necrolysis; urticaria

Other: Anaphylaxis, drug-induced fever, injection site inflammation, superinfection

Nursing Considerations

- To reconstitute 500-mg vial of vancomycin for I.V. use, add 10 ml of sterile water for injection; further dilute with at least 100 ml of compatible I.V. solution. For 1-g vial of dry, sterile powder, add 20 ml of sterile water for injection; further dilute with at least 200 ml of compatible I.V. solution.

WARNING Infuse over at least 1 hour. Rapid delivery may cause hypotension or transient “red man syndrome,” characterized by chills; fainting; fever; flushing of face, neck, upper arms, and torso; hypotension; nausea; tachycardia; and vomiting.

- Monitor blood vancomycin levels, as ordered; therapeutic levels are 10 to 15 mcg/ml trough and 30 to 40 mcg/ml peak.
- Monitor serum vancomycin concentration in patients with renal impairment or colitis because significant increases in blood drug level have occurred in such patients taking multiple oral doses of vancomycin.
- If patient has an inflammatory intestinal disorder, assess him often for adverse reactions because vancomycin absorption may be increased in these conditions.
- Check CBC results and serum creatinine and BUN levels during therapy, especially if patient has renal impairment or takes an aminoglycoside.
- Observe I.V. infusion site for evidence of extravasation, including necrosis, pain, tenderness, and thrombophlebitis. If extravasation occurs, discontinue infusion immediately and notify prescriber.
- Assess hearing during therapy. Transient or permanent ototoxicity may occur if patient receives an excessive amount of drug, has an underlying hearing loss, or receives concurrent aminoglycosides.
- Monitor patient closely for diarrhea because it may indicate pseudomembranous colitis caused by *Clostridium difficile*, a risk with many antibiotics. If diarrhea occurs during therapy, notify prescriber and expect to withhold drug. If confirmed, treat with fluids, electrolytes, pro-

tein, and an antibiotic effective against *C. difficile*.

PATIENT TEACHING

- Instruct patient to use a calibrated measuring device to accurately measure doses of oral solution.
- Advise patient to notify prescriber if no improvement occurs after a few days.
- Instruct patient to complete full course of vancomycin, as prescribed.
- Instruct patient to notify prescriber if she develops severe or persistent diarrhea.
- Instruct patient to keep follow-up appointments during and after treatment.

vardenafil hydrochloride

Levitra

Class and Category

Chemical class: Phosphodiesterase type 5 inhibitor

Therapeutic class: Anti-impotence agent

Pregnancy category: B

Indications and Dosages

↗ **To treat erectile dysfunction**

TABLETS

Adults. 10 mg taken 1 hr before sexual activity; increased to 20 mg or decreased to 5 mg, as needed. *Maximum:* 20 mg and once-daily limit regardless of dosage.

DOSAGE ADJUSTMENT If patient takes ritonavir, vardenafil dosage shouldn't exceed 2.5 mg in 72 hr. If patient takes indinavir, saquinavir, atazanavir, clarithromycin, ketoconazole 400 mg daily, itraconazole 400 mg daily, or another potent CYP3A4 inhibitor, vardenafil dosage shouldn't exceed 2.5 mg in 24 hr. If patient takes ketoconazole 200 mg and itraconazole 200 mg daily, vardenafil dosage shouldn't exceed 5 mg in 24 hr.

Route	Onset	Peak	Duration
P.O.	30 min	30 min–2 hr	4–5 hr

Mechanism of Action

Enhances effect of nitric oxide (released in the penis by sexual stimulation) and inhibits phosphodiesterase type 5, which increases cGMP level, relaxes smooth muscle, and increases blood flow into the cor-

pus cavernosum, producing an erection.

Contraindications

Concurrent administration of alpha blockers, concurrent continuous or intermittent nitrate therapy, hypersensitivity to vardenafil or its components

Interactions

DRUGS

alpha blockers, nitrates: Profound hypotension
atazanavir, clarithromycin, erythromycin, indinavir, itraconazole, ketoconazole, ritonavir, saquinavir: Increased vardenafil effects
class IA (procainamide, quinidine) and class III (amiodarone, sotalol) antiarrhythmics: Possibly increased QT-interval prolongation
indinavir, ritonavir: Reduced blood levels of indinavir and ritonavir

FOODS

grapefruit juice: Possibly increased vardenafil effect

Adverse Reactions

CNS: Dizziness, headache, seizures, transient global amnesia

CV: Hypotension

EENT: Decreased vision, hearing loss, nonarteritic anterior ischemic optic neuropathy, rhinitis, sinusitis, tinnitus

GI: Indigestion, nausea

MS: Back pain

SKIN: Flushing

Other: Flulike symptoms, increased creatine kinase level

Nursing Considerations

- Vardenafil shouldn't be used by men taking class IA (procainamide, quinidine) or class III (amiodarone, sotalol) antiarrhythmics or by men who have congenital prolonged QT interval. Drug may potentiate prolonged QT interval.
- Use vardenafil cautiously in men with renal or hepatic dysfunction, in elderly men, and in men with penile abnormalities that may predispose them to priapism.
- Also use cautiously in patients with left ventricular outflow obstruction, such as aortic stenosis, and those with severely impaired autonomic control of blood pressure. These conditions increase sensitivity to vasodilators, such as vardenafil.
- Monitor blood pressure and heart rate before and after giving drug, especially if patient takes an alpha blocker, because of

increased risk of symptomatic hypotension.

- Monitor patient's vision, especially if he's over age 50; has diabetes, hypertension, coronary artery disease, or hyperlipidemia; or smokes, because vardenafil rarely leads to nonarteritic ischemic optic neuropathy and decreased vision, possibly permanent.
- Monitor patient's hearing. Sudden decrease or loss, possibly with tinnitus and dizziness, may occur with vardenafil use. Report such changes immediately, and expect drug to be discontinued.

PATIENT TEACHING

- For best results, tell patient to take drug 1 hour before anticipated sexual activity.

WARNING Tell patient not to take vardenafil if he takes an organic nitrate, continuously or intermittently, or within 4 hours of taking an alpha blocker because profound hypotension and death could result.

- Caution patient not to take vardenafil more than once daily or to exceed 20 mg daily.
- Tell patient to stop taking vardenafil and notify prescriber if he has a sudden loss of vision in one or both eyes, sudden hearing loss, seizures, or trouble remembering.
- Advise patient to seek sexual counseling to enhance drug's effects.
- To avoid possible penile damage and permanent loss of erectile function, urge patient to notify prescriber at once if erection is painful or lasts longer than 4 hours.

varenicline

Chantix

Class and Category

Chemical class: Tartrate salt

Therapeutic class: Nicotinic blocker

Pregnancy classification: C

Indications and Dosages

↗ *As adjunct to smoking cessation treatment*

TABLETS

Adults. *Initial:* 0.5 mg daily for 3 days; then increased to 0.5 mg b.i.d. for 4 days, and then increased to 1 mg b.i.d. for a total of 12 wk of therapy. If effective, an additional 12 wk of therapy may be given.

DOSAGE ADJUSTMENT If patient has severe renal impairment, maximum dosage is

0.5 mg b.i.d. If patient is having hemodialysis for end-stage renal disease, maximum dosage is 0.5 mg daily.

Mechanism of Action

Blocks nicotine from activating $\alpha_4\beta_2$ receptors by binding to them. This inhibits nicotine stimulation of the central nervous mesolimbic dopamine system, which probably is the area that produces pleasure in and reinforcement of smoking.

Contraindications

Hypersensitivity to varenicline or its components

Interactions

DRUGS

nicotine (transdermal): Increased adverse reactions

Adverse Reactions

CNS: Abnormal dreams, agitation, anxiety, asthenia, attention difficulties, behavior changes, delusions, depression, dizziness, dysgeusia, fatigue, hallucinations, headache, homicidal ideation, hostility, insomnia, irritability, lethargy, loss of consciousness, malaise, mania, mental impairment, panic, paranoia, psychosis, restlessness, sensory disturbances, seizures, somnolence, stroke, suicidal ideation, thirst

CV: Angina, chest pain, edema, hypertension, MI, peripheral ischemia, thrombosis, ventricular extrasystoles

EENT: Dry mouth, epistaxis, gingivitis, rhinorrhea

ENDO: Hot flashes

GI: Abdominal pain, acute pancreatitis, anorexia, constipation, diarrhea, dyspepsia, flatulence, gastroesophageal reflux disease, GI hemorrhage, increased appetite, liver enzyme abnormalities, nausea, vomiting

GU: Acute renal failure, polyuria, urine retention

HEME: Leukocytosis, lymphadenopathy, splenomegaly, thrombocytopenia

RESP: Asthma, dyspnea, pulmonary embolism

MS: Arthralgia, back pain, muscle cramp, musculoskeletal pain, myalgia

SKIN: Diaphoresis, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome, urticaria

Other: Angioedema, flulike syndrome, hyperkalemia, hypersensitivity, hypokalemia

Nursing Considerations

- Use cautiously in patients with renal disease because varenicline is substantially excreted by the kidneys.
- Review patient's medication history before starting varenicline because dosage adjustments may be needed for such drugs as theophylline, warfarin, and insulin.

WARNING Monitor patient for angioedema, difficult breathing, rash with mucosal lesions, or other signs of hypersensitivity. Report immediately, stop varenicline therapy, and provide supportive emergency care, as prescribed.

- If patient has nausea, the most common adverse reaction to varenicline, notify prescriber. Dosage reduction may help.
- Even with varenicline therapy, nicotine withdrawal symptoms and worsening of underlying psychiatric illness may occur with smoking cessation. Monitor patient for neuropsychiatric symptoms, including changes in behavior, hostility, agitation, depressed mood, suicidal ideation, and worsening of pre-existing psychiatric illness. If present, notify prescriber immediately, institute safety measures, and expect drug to be discontinued.
- Watch patient closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.

PATIENT TEACHING

- Explain that using nicotine patches while taking varenicline won't increase its effectiveness and may increase adverse reactions such as dizziness, nausea, and vomiting.
- Instruct patient to set a date to quit smoking and then start taking varenicline 1 week before the quit date.
- Explain how to adjust dose when drug is used for smoking cessation. Tell patient to take drug after eating and with a full glass of water.
- Encourage patient to continue trying to stop smoking even if an early relapse occurs during varenicline therapy.

WARNING Tell patient to seek medical attention immediately if he develops swelling of his face, mouth, limbs, or neck; difficulty breathing; mucosal lesions; or any other signs of hypersensitivity during therapy.

- Inform patient that the most common

- adverse reactions to varenicline therapy are nausea and insomnia, usually transient. If they persist, patient should notify prescriber; dosage reduction may help.
- Caution patient to avoid hazardous activities until CNS effects of drug are known. Explain that near miss traffic accidents and other accidental injuries have occurred in patients taking varenicline.
 - Explain that vivid, unusual, or strange dreams may occur during therapy.
 - Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
 - Tell patient that nicotine withdrawal can occur even with varenicline use and that pre-existing mental illness may worsen during smoking cessation. Advise patient or family to notify prescriber about abnormal thinking or behavior and to stop taking drug immediately.

vasopressin (antidiuretic hormone [ADH])

Pitressin, Pressyn (CAN)

Class and Category

Chemical class: Peptide hormone

Therapeutic class: Antidiuretic

Pregnancy category: C

Indications and Dosages

➤ *To prevent or control symptoms of central diabetes insipidus caused by*

insufficient ADH

I.M. OR SUBCUTANEOUS INJECTION

Adults. 5 to 10 units b.i.d. or t.i.d., as needed.

Children. 2.5 to 10 units t.i.d. or q.i.d., as needed.

➤ *To prevent or treat abdominal distention*

I.M. INJECTION

Adults. 5 units, increased to 10 units every 3 to 4 hr, as needed.

Route	Onset	Peak	Duration
I.M., SubQ	Unknown	Unknown	2–8 hr

Contraindications

Chronic nephritis with nitrogen retention, hypersensitivity to vasopressin or its components

Interactions

DRUGS

carbamazepine, chlorpropamide, clofibrate, fludrocortisone, tricyclic antidepressants: Increased antidiuretic effect
demeclocycline, lithium, norepinephrine: Decreased antidiuretic effect

Adverse Reactions

CNS: Dizziness, headache, light-headedness, tremor

CV: Angina, MI

EENT: Circumoral pallor

ENDO: Water intoxication

GI: Abdominal cramps, diarrhea, eructation, flatulence, intestinal hypermotility, nausea, vomiting

SKIN: Diaphoresis, pallor

Other: Allergic reaction

Mechanism of Action

Vasopressin, a synthetic form of antidiuretic hormone, treats diabetes insipidus by decreasing urine output and raising urine osmolality. When vasopressin attaches to vasopressin2 (V₂) receptors on cell membranes in the nephron's collecting duct, it activates the enzyme adenylyl cyclase to convert adenosine triphosphate (ATP) to cyclic adenosine monophosphate (cAMP). This action increases the collecting duct's permeability and enhances water reabsorption into the blood.

Nursing Considerations

- Use vasopressin with extreme caution in patients with coronary artery disease because it may cause angina or MI; in those with hypertension because it may increase blood pressure; and in those with asthma, epilepsy, heart failure, or migraine headache because extracellular fluid may increase rapidly.
- Monitor fluid and electrolyte balance during therapy. Check intake and output at least every 8 hours, and watch for evidence of water intoxication and hyponatremia, including anuria, confusion, drowsiness, headache, listlessness, and weight gain.

PATIENT TEACHING

- Teach patient how to administer vasopressin; stress the need to rotate injection sites.
- Urge patient to notify prescriber immediately if he has evidence of possible water intoxication, including anuria, confusion, drowsiness, headache, listlessness, and unexplained weight gain.
- Inform patient that abdominal cramps, nausea, and skin blanching will subside after a few minutes and can be minimized by drinking one or two glasses of water.

venlafaxine hydrochloride

Effexor, Effexor XR

desvenlafaxine succinate

Pristiq

Class and Category

Chemical class: Phenylethylamine derivative

Therapeutic class: Antidepressant

Pregnancy category: C

Indications and Dosages

↗ *To treat and prevent relapse of major depression*

E.R. CAPSULES (EFFEXOR XR)

Adults. 75 mg daily with a meal at same time each day, morning or evening (for some patients, 37.5 mg daily for 4 to 7 days before increasing to 75 mg daily); then increased by 75 mg daily every 4 days, as prescribed. *Maximum:* 225 mg daily.

DOSAGE ADJUSTMENT Initial daily dose decreased by 25% to 50% for patients with mild to moderate renal impairment and by 50% for patients with hepatic impairment.

E.R. TABLETS (PRISTIQ)

Adults. 50 mg daily, with a meal, at the same time each day morning or evening

DOSAGE ADJUSTMENT For patients with severe renal impairment and for elderly patients having difficulty tolerating drug, 50 mg every other day.

TABLETS (EFFEXOR)

Adults. 75 mg daily in divided doses b.i.d. or t.i.d., increased by 75 mg daily every 4 days, as prescribed. *Maximum:* 375 mg daily (225 mg/day for outpatients).

↗ *To treat generalized anxiety disorder or social anxiety disorder*

E.R. CAPSULES (EFFEXOR XR)

Adults. 75 mg daily with a meal at same time each day, morning or evening (for some patients, 37.5 mg daily for 4 to 7 days before increasing to 75 mg daily); then increased by 75 mg daily every 4 days, as prescribed. *Maximum:* 225 mg daily.

DOSAGE ADJUSTMENT Initial daily dose decreased by 25% to 50% for patients with mild to moderate renal impairment and by 50% for patients with hepatic impairment.

Route	Onset	Peak	Duration
P.O.	2 wk	Unknown	Unknown

Mechanism of Action

Inhibits neuronal reuptake of serotonin and norepinephrine, along with its active metabolite, *O*-desmethylvenlafaxine. These actions raise serotonin and norepinephrine levels at nerve synapses, elevating mood and reducing depression.

Contraindications

Hypersensitivity to desvenlafaxine, venlafaxine, or their components; use of an MAO inhibitor within 14 days

Interactions

DRUGS

amitriptyline, clomipramine, desipramine, doxepin, haloperidol, imipramine, linezolid, lithium, nortriptyline, protriptyline, St. John's wort, tramadol, trazodone, triptans: Possibly serotonin syndrome
aspirin, NSAIDs, warfarin: Increased risk of bleeding

cimetidine: Decreased clearance and increased levels of desvenlafaxine and venlafaxine

clozapine: Possibly increased blood clozapine level and serious adverse reactions, including seizures

CYP3A4 inhibitors, ketoconazole: Increased plasma venlafaxine level and risk of adverse reactions

MAO inhibitors: Increased risk of hypertension; hyperthermia; mental status changes, including coma and delirium; muscle rigidity; and severe myoclonus

metoprolol: Increased plasma metoprolol level but decreased effectiveness in lowering blood pressure

warfarin: Possibly increased PT, partial thromboplastin time, and INR

Adverse Reactions

CNS: Abnormal dreams, agitation, amnesia, anxiety, asthenia, cerebral ischemia, chills, confusion, delusions, depersonalization, depression, dizziness, dream disturbances, drowsiness, dyskinesia, fever, headache, hypesthesia, hypomania, impaired balance and coordination, insomnia, mania, migraine, mood changes, nervousness, neuroleptic malignant syndrome, paresthesia, seizures, serotonin syndrome, somnolence, suicidal ideation, syncope, tremor, vertigo

CV: Arrhythmias, AV block, chest pain, congestive heart failure, elevated cholesterol and triglyceride levels, edema, extrasystoles, hypertension, hypotension, MI, palpitations, sinus tachycardia, thrombophlebitis, vasodilation, worsening of peripheral vascular disease

EENT: Abnormal vision, accommodation abnormality, angle-closure glaucoma, blurred vision, dry mouth, mydriasis, pharyngitis, rhinitis, taste alteration, tinnitus

ENDO: Hyperglycemia, syndrome of inappropriate ADH secretion

GI: Abdominal pain, anorexia, colitis, constipation, diarrhea, elevated liver enzymes, flatulence, GI hemorrhage, indigestion, nausea, vomiting

GU: Anorgasmia (women), decreased libido, ejaculation disorder, impotence, urinary incontinence or urgency, urine retention

HEME: Anemia, leukocytosis, leukopenia, lymphadenopathy, thrombocytopenia

MS: Neck pain, rhabdomyolysis

RESP: Cough, eosinophilic pneumonia, increased dyspnea, interstitial lung disease

SKIN: Diaphoresis, ecchymosis, pruritus, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Angioedema, hyponatremia, weight loss

Nursing Considerations

- Use cautiously in patients with a history of mania because desvenlafaxine and venlafaxine therapy may worsen condition. Also use cautiously in patients with a history of seizures, and expect to discontinue drug, as ordered, if seizures occur.
- Use cautiously in patients who have medical conditions that might be made worse by an increased heart rate, as in hyperthyroidism, heart failure, or recent MI.

WARNING Be aware that serotonin syndrome in its most severe form may resemble neuroleptic malignant syndrome, which includes hyperthermia, muscle rigidity, autonomic instability with possibly rapid changes in vital signs, and mental status changes. Stop drug immediately and provide supportive care.

- Monitor blood pressure often during therapy because it may cause dose-related sustained increase in supine diastolic pressure. Expect to reduce or stop drug, as prescribed, if increase develops.
- Assess patient's electrolyte balance, as ordered, because drug can cause hyponatremia, especially in elderly patients and in patients who take diuretics or are volume-depleted. If patient has evidence of hyponatremia (headache, trouble concentrating, confusion, weakness, unsteadiness), notify prescriber. If imbalance is confirmed, expect to stop drug and give appropriate care.
- Watch patient for suicidal tendencies, especially when therapy starts and dosage changes.

WARNING Drug shouldn't be stopped abruptly because doing so may cause multiple adverse effects, including asthenia, dizziness, headache, insomnia, nervousness, and flu-like symptoms.

PATIENT TEACHING

- Instruct patient not to crush or chew E.R. capsules or tablets. If she has trouble swallowing capsules, tell her to open capsule, sprinkle contents on a spoonful of apple-

sauce, and swallow immediately without chewing, followed by a glass of water.

- Advise patient to avoid alcohol during venlafaxine therapy.
- Advise patient not to stop taking desvenlafaxine or venlafaxine abruptly.
- Caution patient to notify prescriber if she becomes pregnant during therapy because she'll need a different antidepressant. Taking desvenlafaxine or venlafaxine during third trimester of pregnancy increases risk of complications in the newborn.
- Advise patient to tell prescriber about all other prescribed drugs or OTC products she takes because of risk of interactions.
- Urge caregivers to monitor patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Caution patient to avoid aspirin and NSAIDs, if possible, while taking desvenlafaxine or venlafaxine.

WARNING Tell patient to immediately report sudden onset, severe, or persistent symptoms.

verapamil

Apo-Verap (CAN), Calan, Isoptin, Novo-Veramil (CAN), Nu-Verap (CAN)

verapamil hydrochloride

Calan SR, Isoptin SR, Verelan

Class and Category

Chemical class: Phenylalkylamine derivative

Therapeutic class: Antianginal, antiarrhythmic, antihypertensive

Pregnancy category: C

Indications and Dosages

➤ To treat chronic angina pectoris

TABLETS (VERAPAMIL)

Adults and adolescents age 15 and over.

Initial: 80 to 120 mg t.i.d., increased every day or wk, as needed and prescribed.

Maximum: 480 mg daily in divided doses.

Infants and children up to age 15. 4 to 8 mg/kg daily in divided doses.

➤ To manage hypertension

E.R. CAPSULES (VERAPAMIL HYDROCHLORIDE)

Adults and adolescents. *Initial:* 240 mg daily, increased every day or wk, as needed

and prescribed. *Maximum:* 480 mg daily.

E.R. TABLETS (VERAPAMIL HYDROCHLORIDE)

Adults and adolescents. *Initial:* 180 mg daily, increased every day or wk, as needed and prescribed, according to following schedule: 240 mg daily in the morning; 180 mg every 12 hr or 240 mg in the morning and 120 mg in the evening; then 240 mg every 12 hr. *Maximum:* 480 mg daily in divided doses.

TABLETS (VERAPAMIL)

Adults and adolescents age 15 and over.

Initial: 80 to 120 mg t.i.d., increased every day or wk, as needed and prescribed.

Maximum: 480 mg daily in divided doses.

Infants and children up to age 15. 4 to 8 mg/kg daily in divided doses.

➤ To prevent or treat supraventricular tachycardia

TABLETS (VERAPAMIL)

Adults and adolescents age 15 and over.

Initial: 80 to 120 mg t.i.d., increased every day or wk, as needed and prescribed.

Maximum: 480 mg daily in divided doses.

DOSAGE ADJUSTMENT Initial P.O. dosage possibly reduced to 40 mg t.i.d. (120 mg daily for E.R. tablets or capsules) for elderly patients and those with impaired hepatic or left ventricular function.

I.V. INJECTION (VERAPAMIL HYDROCHLORIDE)

Adults and adolescents age 15 and over.

Initial: 5 to 10 mg slowly over 2 min; then 10 mg, as prescribed, if response isn't adequate after 30 min.

Children ages 1 to 15. *Initial:* 100 to 300 mcg/kg slowly over 2 min, up to maximum of 5 mg; then 10 mg, as prescribed, if response isn't adequate after 30 min.

Infants up to age 1. *Initial:* 100 to 200 mcg/kg slowly over 2 min.

DOSAGE ADJUSTMENT I.V. drug administered over 3 minutes in elderly patients.

Mechanism of Action

Inhibits calcium movement into coronary and vascular smooth-muscle cells by blocking slow calcium channels in cell membranes. The resulting decrease in intracellular calcium level has the following effects:

- inhibits smooth-muscle cell contractions
- decreases myocardial oxygen demand by relaxing coronary and vascular smooth muscle, reducing peripheral vascular resistance, and decreasing systolic and diastolic pressures

- slows AV conduction time and prolongs AV nodal refractoriness
- interrupts reentry circuit in AV nodal reentrant tachycardias.

Route	Onset	Peak	Duration
P.O.	1–2 hr	30–90 min	6–8 hr
P.O. (E.R.)	1–2 hr	30–90 min	Unknown
I.V.	1–5 min	3–5 min	10 min–6 hr

Incompatibilities

Don't mix I.V. verapamil with albumin, amphotericin B injection, hydralazine hydrochloride injection, nafcillin, or sulfamethoxazole and trimethoprim injection. Solutions with pH above 6.0 cause precipitation.

Contraindications

Cardiogenic shock, concomitant use of beta blockers (with I.V. verapamil), hypersensitivity to verapamil or its components, hypotension, severe heart failure unless secondary to supraventricular tachycardia that responds to verapamil, severe left ventricular dysfunction, sick sinus syndrome or second- or third-degree heart block unless artificial pacemaker is in place, ventricular tachycardia (with I.V. verapamil)

Interactions

DRUGS

alpha blockers, antihypertensives, general anesthetics (hydrocarbon), prazosin: Hypotensive effects

aspirin: Increased bleeding time

beta blockers: Increased risk of heart failure, hypotension, and severe bradycardia

calcium supplements: Decreased response to verapamil

carbamazepine, cyclosporine, theophylline, valproate: Increased risk of toxicity from these drugs

cimetidine: Decreased metabolism and increased blood level of verapamil

clonidine: Increased risk of severe sinus bradycardia

cyclophosphamide, oncovin, procarbazine, prednisone (COPP) regimen; vindesine, adriamycin, cisplatin (VAC) regimen:

Decreased verapamil absorption

dantrolene: Increased risk of hyperkalemia and myocardial depression

digoxin: Increased blood digoxin level and risk of digitalis toxicity

disopyramide, flecainide: Additive negative inotropic effects

doxorubicin: Increase plasma doxorubicin level

erythromycin, ritonavir: Increased blood verapamil level

lithium: Increased risk of neurotoxicity

neuromuscular blockers: Prolonged recovery from neuromuscular blockade

NSAIDs, sympathomimetics: Decreased anti-hypertensive effect of verapamil

paclitaxel: Decreased paclitaxel clearance

phenobarbital: Increased verapamil clearance

procainamide: Increased QT interval, additive negative inotropic effects

protein-bound drugs (hydantoins, salicylates, sulfonamides, sulfonyleureas, and warfarin and other oral anticoagulants): Altered blood levels of these drugs

quinidine: Increased risk of quinidine toxicity, increased QT interval, additive negative inotropic effects

rifampin: Decreased bioavailability of oral verapamil

telithromycin: Increased risk of bradyarrhythmias, hypotension, and lactic acidosis

FOODS

grapefruit juice: Increased verapamil level

ACTIVITIES

alcohol use: Increased blood alcohol level and prolonged CNS effects

Adverse Reactions

CNS: Astenia, confusion, disequilibrium, dizziness, equilibrium disorders, extrapyramidal reactions, fatigue, headache, insomnia, paresthesia, psychosis, shakiness, somnolence, stroke, syncope

CV: Abnormal ECG, angina, AV conduction disorders, bradycardia, claudication, heart failure, hypertension, hypotension, MI, palpitations, peripheral edema, tachycardia, vasculitis

EENT: Blurred vision, dry mouth, tinnitus

ENDO: Gynecomastia, hyperprolactinemia

GI: Constipation, diarrhea, elevated liver function test results, GI distress, nausea

GU: Galactorrhea, impotence, increased urination, menstrual irregularities

MS: Arthralgia, muscle spasms

RESP: Dyspnea, pulmonary edema,

SKIN: Alopecia, diaphoresis, ecchymosis, erythema multiforme, exanthema, flushing, hyperkeratosis, rash, Stevens-Johnson syndrome, urticaria

Other: Allergy aggravated

Nursing Considerations

- Administer I.V. verapamil with compatible solutions, including Ringer's injection, D₅W, or normal saline solution.
- Maintain continuous ECG monitoring and keep emergency resuscitative equipment and drugs readily available during I.V. therapy.
- Assess patient with hypertrophic cardiomyopathy or idiopathic hypertrophic subaortic stenosis for early development of hypotension and pulmonary edema because second-degree AV block and sinus arrest can result.
- Assess for bradycardia and hypotension, and notify prescriber if heart rate or blood pressure declines significantly.
- Disopyramide or flecainide shouldn't be given within 48 hours before or 24 hours after verapamil because additive negative inotropic effects can result.
- Institute measures to prevent constipation, including a high-fiber diet and a stool softener, as prescribed.

PATIENT TEACHING

- Instruct patient not to crush or chew verapamil E.R. tablets or capsules. Inform her that she may break E.R. tablets in half if necessary to aid swallowing.
- Direct patient to check her pulse before taking verapamil and to notify prescriber if it's below 50 beats/minute or as instructed by prescriber.
- Caution patient about possible dizziness and the need to avoid potentially hazardous activities until drug's CNS effects are known.
- Inform patient that adverse skin reactions may subside with continued verapamil use. Advise her to notify prescriber if rash persists.
- Encourage patient to increase dietary fiber intake to help prevent constipation. Advise her to notify prescriber if problem becomes persistent or severe.

vigabatrin

Sabril

Class and Category

Chemical class: Amino-hexenoic acid

Therapeutic: class Anticonvulsant

Pregnancy category: C

Indications and Dosages

↗ *As adjunct therapy for refractory complex partial seizures in patients with inadequate response to several alternative treatments and for whom potential benefits outweigh the risk of vision loss*

TABLETS

Adults. *Initial:* 500 mg twice daily, increased weekly in 500 mg increments, as needed. *Maximum:* 1.5 g twice daily.

DOSAGE ADJUSTMENT For patient with mild renal impairment (creatinine clearance 51 to 80 ml/min/1.73 m²), reduce dose by 25%. For patients with moderate renal impairment (creatinine clearance 31 to 50 ml/min/1.73 m²), reduce dose by 50%. For patients with severe renal impairment (creatinine clearance 11 to 30 ml/min/1.73 m²), reduce dose by 75%.

↗ *As monotherapy for pediatric patients with infantile spasms for whom potential benefits outweigh risk of vision loss*

ORAL SOLUTION

Children age 1 month to 2 years. *Initial:* 50 mg/kg/day in 2 divided doses, increased every 3 days by 25 to 50 mg/kg/day, as needed. *Maximum:* 150 mg/kg/day.

DOSAGE ADJUSTMENT For patient with mild renal impairment (creatinine clearance 51 to 80 ml/min), reduce dose by 25%. For patients with moderate renal impairment (creatinine clearance 31 to 50 ml/min/1.73 m²), reduce dose by 50%. For patients with severe renal impairment (creatinine clearance 11 to 30 ml/min/1.73 m²), reduce dose by 75%.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	Unknown

Mechanism of Action

Inhibits the action of gamma aminobutyric acid transaminase (GABA-T), the enzyme responsible for metabolism of the inhibitory neurotransmitter GABA. This increases GABA level in the CNS, which may play a role in suppression of seizure activity.

Contraindications

Hypersensitivity to vigabatrin and its components

Interactions

DRUGS

phenytoin: Decreased serum phenytoin level

Adverse Reactions

CNS: Abnormal magnetic resonance imaging (MRI), abnormal behavior or dreams, acute psychosis, anxiety, apathy, asthenia, attention disturbance, confusion, coordination abnormality, delirium, depression, dizziness, encephalopathy, expressive language disorder, fatigue, fever, gait disturbance, headache, hyperreflexia, hypertonia, hypoaesthesia, hyporeflexia, hypomania, hypotonia, insomnia, irritability, lethargy, malaise, malignant hyperthermia, memory loss, myoclonus, nervousness, paraesthesia, peripheral neuropathy, postictal state, seizures, sensory disturbance, somnolence, status epilepticus, suicidal ideation, thirst, tremor, vertigo

CV: Chest pain, edema, peripheral edema

EENT: Asthenopia, blurred vision, deafness, diplopia, eye pain, laryngeal edema, nasopharyngitis, nystagmus, optic neuritis, pharyngolaryngeal pain, tinnitus, toothache, vision loss (severe), visual field defect

GI: Abdominal or stomach pain, cholestasis, constipation, decreased liver enzymes, diarrhea, distention, dyspepsia, esophagitis, GI hemorrhage, nausea, vomiting

GU: Dysmenorrhea, erectile dysfunction, UTI

HEME: Anemia

MS: Arthralgia; back or limb pain; dysarthria; muscle spasticity, spasms or twitching

RESP: Bronchitis, cough, pulmonary edema, respiratory failure, stridor, upper respiratory infection

SKIN: Facial edema, maculopapular rash, pruritus,

Other: Angioedema, birth defects, developmental delay, influenza, multi-organ failure, weight gain

Nursing Considerations

- Vigabatrin therapy is only available under a restricted distribution program called the SHARE program (1-888-45-SHARE).

WARNING Monitor patient's vision, and make sure patient has been examined by an ophthalmic professional in which visual fields and retinal examination has been performed no later than 4 weeks after vigabatrin therapy has begun and then

periodically thereafter because drug can cause progressive and permanent bilateral concentric visual field constriction and reduce visual acuity. Be aware that while risk increases with total dose and duration of therapy, all patients are at risk for visual abnormalities even after drug has been stopped. Because of the risk of permanent and possibly severe vision loss, drug can be prescribed and obtained only through the SHARE distribution program. Report any visual abnormalities immediately, and expect drug to be discontinued.

- Abnormal MRI results have been noted in some infants receiving vigabatrin.
- Monitor patient for suicidal ideation throughout therapy but especially when therapy starts or dosage changes.
- When discontinuing vigabatrin therapy, expect to do so gradually by decreasing daily dose by 1 gram each week until drug is discontinued, as ordered.
- When discontinuing vigabatrin therapy in children, expect to do so gradually by decreasing dose by 25 to 50 mg/kg/day every 3 to 4 days.
- Monitor patient for evidence of peripheral neuropathy, such as numbness or tingling in toes or feet, reduced distal lower limb vibration or position sense, or progressive loss of reflexes, starting at the ankles. Alert prescriber if abnormalities are present.
- Assess patient routinely for edema, including peripheral edema.

PATIENT TEACHING

- Explain the risk of possibly permanent vision loss before patient starts vigabatrin.
- Warn patient not to stop taking vigabatrin abruptly; it will need to be weaned off gradually over several weeks.
- Advise female patient of childbearing age to use effective contraception if sexually active and to report suspected or confirmed pregnancy immediately.
- Advise patient or caregiver to notify prescriber if patient has unusual feelings or behaviors, especially if related to suicidal ideation and particularly at the beginning of therapy and during dosage adjustments.
- Caution patient not to perform hazardous activities such as operating equipment until CNS effects of the drug are known.
- Alert patient to monitor his weight because drug may cause weight gain.

voriconazole

Vfend

Class and Category

Chemical class: Triazole

Therapeutic class: Antifungal

Pregnancy category: D

Indications and Dosages

↗ *To treat invasive aspergillosis; to treat serious fungal infections caused by *Scedosporium apiospermum* and *Fusarium species*, including *Fusarium solani*, in patients intolerant of or refractory to other therapy*

I.V. INFUSION

Adults and children age 12 and over.

Initial: 6 mg/kg over 1 to 2 hr at no more than 3 mg/kg/hr every 12 hr for 2 doses.

Maintenance: 4 mg/kg over 1 to 2 hr at no more than 3 mg/kg/hr every 12 hr.

TABLETS

Adults and children age 12 and over weighing 40 kg (88 lb) or more.

Maintenance: 200 mg every 12 hr, increased to 300 mg every 12 hr, as needed, and taken at least 1 hr before or after a meal.

Adults and children age 12 and over weighing less than 40 kg.

Maintenance: 100 mg every 12 hr, increased to 150 mg every 12 hr, as needed, and taken at least 1 hr before or after a meal.

↗ *To treat candidemia in nonneutropenic patients and other deep-tissue disseminated *Candida* infections involving the abdomen, kidney, bladder wall, skin, or a wound*

I.V. INFUSION

Adults. *Initial:* 6 mg/kg over 1 to 2 hr at no more than 3 mg/kg/hr every 12 hr for 2 doses.

Maintenance: 3 to 4 mg/kg over 1 to 2 hr at no more than 3 mg/kg/hr every 12 hr for at least 14 days after symptoms resolve or last positive culture, whichever takes longer.

TABLETS

Adults. *Maintenance:* 200 mg every 12 hr taken at least 1 hr before or after a meal.

↗ *To treat esophageal candidiasis*

TABLETS

Adults. 200 mg every 12 hr taken at least 1 hr before or after a meal for at least 14 days and at least 7 days after signs and

symptoms resolve.

DOSE ADJUSTMENT If patient can't tolerate drug, I.V. maintenance dose may be reduced to 3 mg/kg every 12 hr and oral maintenance dose by 50-mg decrements to at least 200 mg every 12 hr (100 mg every 12 hr for patients weighing less than 40 kg). For use with phenytoin, maintenance dose may be increased to 5 mg/kg I.V. every 12 hr or from 200 mg to 400 mg P.O. every 12 hr (100 mg to 200 mg every 12 hr for patients weighing less than 40 kg). For patients with mild to moderate hepatic cirrhosis, standard loading dose should be used but maintenance dose halved for I.V. or P.O. use. For patients with moderate to severe renal insufficiency (creatinine clearance greater than 50 ml/min/1.73 m²), only the oral form should be given, if possible.

Mechanism of Action

Prevents fungal ergosterol biosynthesis by inhibiting fungal cytochrome P-450-mediated 14 alpha-lanosterol demethylation. The loss of ergosterol in the fungal cell wall renders the fungal cell inactive.

Incompatibilities

Don't infuse into the same line or cannula with other drugs, including parenteral nutrition, to prevent an increase in subvisible particulate matter. Avoid infusion with blood products and any electrolyte supplements. Don't dilute with 4.2% sodium bicarbonate infusion because the mildly alkaline nature of the diluent causes slight degradation of voriconazole after 24 hours of storage at room temperature.

Contraindications

Coadministration with long-acting barbiturates, carbamazepine, CYP3A4 substrates (astemizole, cisapride, pimozone, quinidine, or terfenadine), efavirenz, ergot alkaloids, rifabutin, rifampin, ritonavir, sirolimus, or St. John's wort; hypersensitivity to voriconazole or its components; galactose intolerance, glucose-galactose malabsorption, or Lapp lactase deficiency (oral form only contains lactose)

Interactions

DRUGS

alfentanil: Increased plasma alfentanil level and increased risk of adverse reactions
benzodiazepines: Possibly prolonged seda-

tive effect of benzodiazepines
calcium channel blockers; *HMG-CoA reductase inhibitors, such as lovastatin; omeprazole; sirolimus*: Possibly increased plasma levels of these drugs, leading to increased risk of adverse reactions and toxicity
carbamazepine, long-acting barbiturates, phenytoin, rifampin: Decreased plasma voriconazole concentration
coumarin, warfarin: Possibly increased PTT
cyclosporine, sirolimus, tacrolimus: Increased serum concentrations of these drugs and risk of toxicity, especially nephrotoxicity
CYP3A4 substrates (astemizole, cisapride, pimozide, quinidine, terfenadine): Increased plasma levels of these drugs, which may lead to prolonged QT interval and, rarely, torsades de pointes
ergot alkaloids (ergotamine, dihydroergotamine): May increase plasma level of ergot alkaloids, leading to ergotism
HIV protease inhibitors (amprenavir, nelfinavir, ritonavir, saquinavir), non-nucleoside reverse transcriptase inhibitors (delavirdine, efavirenz): Possibly inhibited metabolism of these drugs and voriconazole
methadone: Increased plasma level of methadone, possibly leading to toxicity, including QT-interval prolongation
oral contraceptives: Increased plasma voriconazole level and risk of toxicity
rifabutin: Increased rifabutin plasma level; decreased voriconazole plasma level
St. John's wort: Decreased plasma voriconazole level
sulfonylureas: Possibly increased plasma level of sulfonylureas and increased risk of hypoglycemia
vinca alkaloids: Possibly increased risk of neurotoxicity

Adverse Reactions

CNS: Chills, dizziness, fever, hallucinations, headache

CV: Chest pain, hypertension, hypotension, peripheral edema, tachycardia, vasodilation
EENT: Abnormal or blurred vision, altered or enhanced visual perception, change in color perception, chromatopsia, dry mouth, eye hemorrhage, photophobia, visual disturbances

GI: Abdominal pain, diarrhea, elevated liver function test results, nausea, pancreatitis, vomiting

GU: Abnormal kidney function, acute renal

failure, elevated serum creatinine level
HEME: Anemia, leukopenia, pancytopenia, thrombocytopenia

RESP: Respiratory disorders

SKIN: Cholestatic jaundice, erythema multiforme, jaundice, maculopapular rash, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis (I.V. form), elevated alkaline phosphatase, hypokalemia, hypomagnesemia, sepsis

Nursing Considerations

- Use voriconazole cautiously in patients hypersensitive to other azoles and in patients at risk for proarrhythmic events (such as those receiving cardiotoxic chemotherapy or those who have cardiomyopathy or hypokalemia) because some azoles may prolong the QT interval.
- Determine if patient has any problems with galactose intolerance, Lapp lactase deficiency, or glucose-galactose malabsorption before starting therapy because voriconazole tablets contain lactose and shouldn't be given to patients with these conditions.
- Obtain specimens for fungal culture and other relevant laboratory studies (including histopathology), as ordered, before giving first dose. Expect to begin drug before test results are known.
- Assess patient's liver function, including bilirubin, as ordered, at the start of voriconazole therapy and periodically thereafter. Be aware that drug may be discontinued if liver abnormalities occur.
- Check patient's electrolyte levels and correct any imbalances, as ordered, before giving voriconazole because electrolyte imbalances increase the risk of adverse reactions.
- For I.V. infusion, reconstitute powder with 19 ml water for injection to obtain 20 ml of concentrate containing 10 mg/ml voriconazole. To make sure exact amount of water is injected into vial, use a standard 10-ml non-automated syringe. Shake vial until all powder is dissolved. Further dilute so final concentration is no less than 0.5 mg/ml and no more than 5 mg/ml. This requires withdrawing and discarding at least an equal volume of diluent from infusion bag or bottle before instillation

of concentrate.

- Discard partially used vials after mixing. If infusion isn't administered immediately, store at 2° to 8° C (37° to 46° F) for no longer than 24 hours.
- Administer I.V. infusion over 1 to 2 hours at no more than 3 mg/kg/hr.
- Monitor renal function, especially serum creatinine level, when giving I.V. form of voriconazole because drug may accumulate in body when creatinine clearance is less than 50 ml/min/1.73 m², increasing the risk of adverse reactions.

WARNING Observe patient receiving I.V. voriconazole closely for anaphylactoid-type reactions—such as flushing, fever, sweating, tachycardia, chest tightness, dyspnea, faintness, nausea, pruritus, and rash—which may occur immediately after starting infusion. Stop infusion if these reactions occur, and notify prescriber immediately.

- Monitor patient closely throughout therapy for rash, which may indicate a serious cutaneous reaction, such as Stevens-Johnson syndrome. If rash occurs, notify prescriber, and expect that voriconazole may be discontinued.
- Monitor cyclosporine, tacrolimus, and warfarin closely for elevated levels when voriconazole is given with any of these drugs.
- Monitor diabetic patients also taking sulfonylureas closely for hypoglycemia, and check blood glucose levels regularly.
- Voriconazole dosage will need to be adjusted when given with phenytoin. Expect to monitor plasma phenytoin level and observe patient closely for phenytoin-related adverse reactions.
- Assess patient's visual function, including visual acuity, visual field, and color perception, if voriconazole therapy continues longer than 28 days.
- Monitor patient closely for pancreatitis, especially if patient is a child or has risk factors for acute pancreatitis, such as recent chemotherapy or hematopoietic stem cell transplantation.

PATIENT TEACHING

- Instruct patient taking oral voriconazole to take the tablets at least 1 hour before or 1 hour after a meal.
- Inform female patient of possible fetal

risk, and stress need to avoid pregnancy.

- Tell her to use effective contraception during therapy and to notify prescriber immediately if pregnancy is suspected.
- Caution patient not to drive at night and to avoid hazardous activities because drug may cause visual disturbances, including blurring or photophobia.
- Advise patient to avoid exposure to direct sunlight or UV light and to wear sunscreen when outdoors.

warfarin sodium

Coumadin

Class and Category

Chemical class: Coumarin derivative

Therapeutic class: Anticoagulant

Pregnancy category: X

Indications and Dosages

↗ *To prevent or treat pulmonary embolism; recurrent MI; thromboembolic complications from atrial fibrillation, heart valve replacement, or MI; and venous thrombosis (and its extension)*

TABLETS

Adults. *Initial:* 2 to 5 mg daily for 2 to 4 days. *Usual:* 2 to 10 mg daily based on target PT and INR results. *Maximum:* Determined by target PT and INR results, as prescribed.

I.V. INJECTION

Adults. *Initial:* 2 to 5 mg daily infused over 1 to 2 min. *Usual:* 2 to 10 mg daily infused over 1 to 2 min. *Maximum:* Determined by target PT and INR results, as prescribed.

DOSAGE ADJUSTMENT For patients with hepatic dysfunction, dosage reduced to 0.1 mg/kg, as prescribed. For elderly patients, dosage possibly reduced based on PT and INR results.

Route	Onset	Peak	Duration
P.O.	24 hr	3–4 days	2–5 days
I.V.	Unknown	3–4 days	2–5 days

Mechanism of Action

Interferes with the liver's ability to synthesize vitamin K–dependent clotting factors, depleting clotting factors II (prothrombin), VII, IX, and X. This action, in turn, inter-

feres with the clotting cascade. By depleting vitamin K–dependent clotting factors and interfering with the clotting cascade, warfarin prevents coagulation.

Incompatibilities

Don't mix warfarin in solution with amikacin sulfate, epinephrine hydrochloride, metaraminol tartrate, oxytocin, promazine hydrochloride, tetracycline hydrochloride, or vancomycin hydrochloride.

Contraindications

Bleeding or bleeding tendencies; blood dyscrasias; cerebral or dissecting aneurysm; cerebrovascular hemorrhage; diverticulitis; eclampsia or preeclampsia; history of warfarin-induced necrosis; hypersensitivity to warfarin or its components; malignant or severe uncontrolled hypertension; malnutrition and emaciation; mental state or condition that leads to lack of patient cooperation; pericardial effusion; pericarditis; polyarthritis; pregnancy; prostatectomy; recent or planned neurosurgery, ophthalmic surgery, or spinal puncture; severe hepatic or renal disease

Interactions

DRUGS

acetaminophen, agrimony, aminoglycosides, amiodarone, androgens, argatroban, beta blockers, bivalirudin, capecitabine, cephalosporins, chloral hydrate, chloramphenicol, chlorpropamide, cimetidine, clofibrate, corticosteroids, cyclophosphamide, dextrothyroxine, diflunisal, disulfiram, erythromycin, ezetimibe, fluconazole, gemfibrozil, glucagon, hydantoin, ifosfamide, influenza virus vaccine, isoniazid, ketoconazole, lepirudin, loop diuretics, lovastatin, metronidazole, miconazole, mineral oil, moricizine, nalidixic acid, NSAIDs, omeprazole, penicillins, phenylbutazones, propafenone, propoxyphene, quinidine, quinine, quinolones, salicylates, streptokinase, sulfamethoxazole-trimethoprim, sulfapyrazole, sulfonamides, tamoxifen, tetracyclines, thyroid hormones, urokinase, valdecoxib, vitamin E: Increased anticoagulant effect of warfarin, increased risk of bleeding
aminoglutethimide, barbiturates, carbamazepine, cholestyramine, dicloxacillin, estrogens, ethchlorvynol, etretinate, glutethimide, griseofulvin, nafcillin, oral contraceptives,

rifampin, spironolactone, sucralfate, thiazide diuretics, trazodone, vitamin C, vitamin K: Decreased anticoagulant effect of warfarin
atorvastatin, pravastatin: Increased or decreased anticoagulant effect of warfarin
herbal remedies (including bromelains, dan-shen, dong quai, garlic, ginkgo biloba, and ginseng): Increased anticoagulant effect of warfarin, increased risk of bleeding
I.V. lipid emulsion, other medical products that contain soybean oil: Possibly decreased vitamin K absorption and increased anticoagulant effect of warfarin
nicotine patch: Altered response to warfarin

FOODS

certain multivitamins, enteral feedings, vitamin K–rich foods: Decreased warfarin effects

ACTIVITIES

alcohol use: Increased risk of hypoprothrombinemia

smoking, smoking cessation: Altered response to warfarin

Adverse Reactions

CNS: Coma, intracranial hemorrhage, loss of consciousness, syncope, weakness

CV: Angina, chest pain, hypotension

EENT: Epistaxis, intraocular hemorrhage

GI: Abdominal cramps and pain, diarrhea, hepatitis, nausea, vomiting

GU: Hematuria, vaginal bleeding (abnormal)

HEME: Anemia, potentially fatal hemorrhage (from any tissue or organ)

SKIN: Alopecia, ecchymosis, jaundice, petechiae, pruritus, purple-toe syndrome, tissue necrosis

Other: Anaphylaxis

Nursing Considerations

- Reconstitute parenteral warfarin just before administration with 2.7 ml sterile water for injection to yield 2 mg/ml. Then give slowly over 1 to 2 minutes through peripheral I.V.
- Expect to give another parenteral anticoagulant, such as heparin or enoxaparin, with oral warfarin for at least 3 days, or until desired response occurs, before giving warfarin only.
- Avoid I.M. injections during warfarin therapy, if possible, because they can result in bleeding, bruising, and hematoma.
- Monitor INR (daily in acute care setting) and assess for therapeutic effects, as pre-

scribed. Therapeutic INR levels are 2.0 to 3.0 for bioprosthetic heart valve, nonvalvular atrial fibrillation, and venous thromboembolism, and 2.5 to 3.5 after MI and for mechanical heart valve.

- Expect treatment to last up to 12 weeks for bioprosthetic heart valve, 1 to 3 months for nonvalvular atrial fibrillation or venous thromboembolism, and for rest of life after MI and for mechanical heart valve replacement.

WARNING Be aware of the increased risk for intracranial hemorrhage if patient has cerebral ischemia (such as recent transient ischemic attack or minor ischemic stroke) and INR of 3 to 4.5. As prescribed, withhold next warfarin dose and give vitamin K if INR exceeds 4 because of the risk of bleeding.

- Assess for occult bleeding if patient receives I.V. lipid emulsion or other medical product that contains soybean oil. Such products can decrease vitamin K absorption and increase warfarin's anticoagulant effect.

PATIENT TEACHING

- Explain that warfarin therapy aims to prevent thrombosis by decreasing clotting ability while avoiding the risk of spontaneous bleeding.
- Instruct patient to take drug exactly as prescribed at the same time each evening.
- Urge patient to keep weekly follow-up appointments for blood tests after discharge until PT and INR levels are stabilized.
- Advise patient to avoid alcohol during warfarin therapy.
- Urge patient to take precautions against bleeding, such as using an electric shaver and a soft-bristled toothbrush. Advise him to continue these precautions for 2 to 5 days after therapy stops, as directed, because anticoagulant effect may persist during this time.
- Caution patient to avoid activities that could cause traumatic injury and bleeding.
- Advise patient to eat consistent amounts of vitamin K-rich foods, such as dark green, leafy vegetables.
- Urge patient to notify prescriber immediately about unusual bleeding and any unexplained symptoms, such as abnormal vaginal bleeding; dizziness; easy bruising;

gum bleeding; headache; nosebleeds; prolonged bleeding from cuts; red, black, or tarry stool; red or dark brown urine; swelling; and weakness.

- Advise patient to consult prescriber before taking other drugs—including OTC drugs and herbal remedies—during therapy.
- Instruct female patient of childbearing age to stop taking warfarin and notify prescriber immediately if she is or could be pregnant.
- Explain that drug may cause reversible purple-toe syndrome and that this syndrome isn't harmful.
- Urge patient to carry medical identification that reveals he's taking warfarin.

XYZ

zafirlukast

Accolate

Class and Category

Chemical class: Peptide leukotriene receptor antagonist

Therapeutic class: Antiasthmatic

Pregnancy category: B

Indications and Dosages

➤ *To treat chronic asthma*

TABLETS

Adults and children over age 11. 20 mg b.i.d.

Children ages 5 to 11. 10 mg b.i.d.

Route	Onset	Peak	Duration
P.O.	1 wk	Unknown	Unknown

Mechanism of Action

Inhibits the selective binding of cysteinyl leukotrienes (arachidonic acid derivatives that usually mediate inflammation in asthma and other inflammatory disorders) by competitively blocking receptor sites. This action causes bronchial relaxation and decreases vascular leakage and edema, mucus secretion, eosinophil movement, and bronchial hyperresponsiveness.

Contraindications

Hypersensitivity to zafirlukast or its components

Interactions

DRUGS

alprazolam, amitriptyline, calcium channel blockers, carbamazepine, citalopram, corticosteroids, cyclosporine, diazepam, diclofenac, ibuprofen, imipramine, irbesartan, lidocaine, lovastatin, midazolam, phenytoin, quinidine, simvastatin, tolbutamide, tolterodine, triazolam: Inhibited metabolism and, possibly, additive adverse effects of these drugs
aspirin: Increased blood zafirlukast level
erythromycin, terfenadine: Decreased response to zafirlukast
sildenafil: Increased adverse sildenafil effects
theophylline: Decreased zafirlukast level
warfarin: Prolonged PT

FOODS

any food: Possibly decreased bioavailability of zafirlukast

Adverse Reactions

CNS: Asthenia, dizziness, fever, headache, insomnia, malaise

GI: Abdominal pain, diarrhea, elevated liver function test results, hepatic failure, indigestion, nausea, vomiting

MS: Back pain, myalgia

SKIN: Pruritus

Other: Generalized pain

Nursing Considerations

- Zafirlukast shouldn't be used to treat bronchospasm during an acute asthma attack or status asthmaticus; it can't relieve symptoms quickly enough.
- Assess respiratory rate, depth, and quality as well as breath sounds before and during treatment to evaluate response to therapy.
- If patient is being weaned from corticosteroids while taking zafirlukast, monitor her for Churg-Strauss syndrome, a rare allergic reaction characterized by eosinophilia, fever, myalgia, weight loss, as cardiac complications, neuropathy, and worsening pulmonary symptoms.

PATIENT TEACHING

- Instruct patient to take drug exactly as prescribed, in evenly spaced doses, every day, even during symptom-free periods and acute exacerbations.
- Instruct patient to take drug on an empty stomach at least 1 hour before or 2 hours after meals.
- Urge patient to continue using prescribed rescue inhalants for acute asthma attacks.
- Teach patient how to use peak-flow meter to monitor pulmonary function.
- Tell patient to immediately report evidence of liver dysfunction, such as right upper-quadrant abdominal pain, nausea, fatigue, lethargy, pruritus, jaundice, flulike symptoms, and anorexia.

zaleplon

Sonata

Class, Category, and Schedule

Chemical class: Imidazopyridine derivative

Therapeutic class: Sedative-hypnotic

Pregnancy category: C

Controlled substance schedule: IV

Indications and Dosages

➤ *Short-term treatment of insomnia*

CAPSULES

Adults up to age 65. 10 mg daily at bedtime, as prescribed, for up to 35 days.

Usual: 10 mg daily at bedtime for 7 to 10 days. *Maximum:* 20 mg daily.

DOSE ADJUSTMENT For patients who are elderly, have hepatic impairment, or take cimetidine, dosage possibly reduced to 5 mg daily.

Route	Onset	Peak	Duration
P.O.	30 min	Unknown	4 hr

Mechanism of Action

Selectively binds with type 1 benzodiazepine (BZ1 or ω_1) receptors on the gamma-aminobutyric acid-A receptor complex. This binding produces muscle relaxation and sedation as well as antianxiety and anticonvulsant effects.

Contraindications

Hypersensitivity to zaleplon or its components

Interactions

DRUGS

amitriptyline; amoxapine; azatadine; benzodiazepines; brompheniramine; chlorpheniramine; clemastine; clomipramine; clozapine; cyproheptadine; dexchlorpheniramine; diphenhydramine; doxepin; entacapone; haloperidol; hydroxyzine; imipramine; maprotiline; mirtazapine; molindone; nefazodone; nortriptyline; olanzapine; opioid analgesics; other anxiolytics, sedatives, and hypnotics; phenindamine; phenothiazines; pimozone; pramipexole; promethazine; quetiapine; risperidone; ropinirole; thioridazine; trazodone; trimipramine; triptelenamine: Possibly additive CNS depression

carbamazepine, phenobarbital, phenytoin, rifampin: Reduced zaleplon effects
cimetidine: Increased blood zaleplon level
flumazenil: Reversal of zaleplon's sedation

FOODS

high-fat foods: Prolonged absorption time and reduced effectiveness of zaleplon

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Amnesia, anxiety, complex behaviors (such as sleep driving), depression, dizziness, drowsiness, fever, hallucinations, hypertonia, insomnia, paresthesia, seizures, suicidal ideation, tremor, vertigo

EENT: Dry mouth, gingivitis, glossitis, mouth ulcers, stomatitis, throat tightness

GI: Anorexia, colitis, constipation, eructation, esophagitis, flatulence, gastritis, gastroenteritis, increased appetite, indigestion, melena, nausea, rectal bleeding, vomiting

MS: Back pain

RESP: Dyspnea

SKIN: Photosensitivity, pruritus, rash

Other: Anaphylaxis, angioedema, physical and psychological dependence

Nursing Considerations

- Give zaleplon just before bedtime because its onset of action is rapid.
- Avoid giving drug with or after a heavy, high-fat meal because decreased absorption may reduce drug's effects.
- Watch patient closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.
- Monitor patient for signs of drug abuse because zaleplon has an abuse potential similar to that of benzodiazepines and benzodiazepine-like hypnotics.

WARNING Monitor patient closely for hypersensitivity reactions, such as dyspnea, throat tightness, nausea, vomiting, and swelling. If present, discontinue zaleplon immediately, notify prescriber, and provide supportive care.

PATIENT TEACHING

- Explain that zaleplon is intended for short-term use. Advise against using it for any condition other than insomnia.
- Caution patient against exceeding prescribed dosage.
- Instruct patient to take zaleplon immediately before bedtime or right after having trouble falling asleep because of drug's rapid onset of action.
- Teach patient alternative measures for relaxation and sleep induction.
- Advise patient to consult prescriber before taking other CNS depressants.
- Urge patient to avoid alcohol during zaleplon therapy.

plon therapy because it increases risk of abnormal behaviors, such as sleep driving.

- Warn patient that zaleplon contains FD & C Yellow No. 5 (tartrazine), which can cause an allergic reaction, especially in those with an aspirin sensitivity. Instruct patient to report allergic reactions, such as rash or difficulty breathing, to prescriber.
- Instruct patient to notify prescriber if inability to sleep continues. Dosage may need to be adjusted.
- Instruct patient to stop taking zaleplon and seek emergency care if she has trouble breathing, throat tightness, nausea, vomiting, or abnormal swelling.
- Explain that drug may cause abnormal behaviors during sleep, such as driving a car, eating, talking on the phone, or having sex without any recall of the event. If family notices any such behavior or patient sees evidence of such behavior upon awakening, prescriber should be notified.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.

ziconotide

Prialt

Class and Category

Chemical class: 25 amino acid polybasic peptide

Therapeutic class: Analgesic

Pregnancy category: C

Indications and Dosages

➤ *To manage severe chronic pain in patients intolerant of or refractory to other pain management measures*

INTRATHECAL

Adults. *Initial:* 2.4 mcg daily (0.1 mcg/hr), increased as needed by 2.4 mcg daily but no more than 3 times/wk. *Maximum:* 19.2 mcg/day (0.8 mcg/hr) by day 21.

Contraindications

History of psychosis; hypersensitivity to ziconotide or its components; conditions or treatment that make intrathecal use hazardous (infection at microinfusion site, uncontrolled bleeding diathesis, spinal canal obstruction that impairs CSF circulation).

Interactions

DRUGS

CNS depressants: Increased risk of adverse CNS reactions

Adverse Reactions

CNS: Abnormal gait, agitation, anxiety, aphasia, asthenia, ataxia, chills, confusion, CSF abnormality, decreased reflexes, depression, difficulty concentrating, dizziness, dysesthesia, emotional lability, fever, hallucinations, headache, hostility, hyperesthesia, hypertonia, incoordination, insomnia, malaise, memory loss, meningitis, nervousness, neuralgia, paranoia, paresthesia, psychosis, seizures, somnolence, speech disorder, stroke, stupor, suicidal ideation, syncope, tremor, twitching, unusual dreams, vertigo

CV: Atrial fibrillation, bradycardia, chest pain, edema, hypertension, hypotension, orthostatic hypotension, peripheral edema, tachycardia, T-wave changes on ECG, vasodilation

EENT: Abnormal vision, diplopia, dry mouth, nystagmus, pharyngitis, photophobia, rhinitis, sinusitis, taste perversion, tinnitus

GI: Abdominal pain, anorexia, constipation, diarrhea, indigestion, nausea, vomiting

GU: Acute renal failure, dysuria, urinary hesitancy or incontinence, urine retention, UTI

HEME: Anemia

MS: Arthralgia, arthritis, back pain, leg cramps, muscle spasms or weakness, myalgia, myasthenia, neck pain or rigidity, rhabdomyolysis

RESP: Aspiration pneumonia, bronchitis, cough, dyspnea, lung disorder, pneumonia, respiratory distress

SKIN: Cellulitis, diaphoresis, dry skin, ecchymosis, pruritus, rash

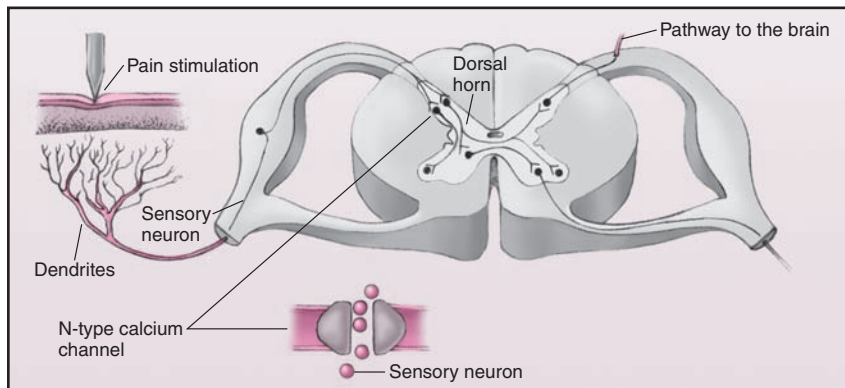

Other: Catheter site infection or pain, dehydration, elevated CK level, flulike symptoms, generalized pain, hypokalemia, sepsis, viral infection, weight loss

Nursing Considerations

- Determine if patient will receive ziconotide therapy by implanted variable-rate microinfusion device or by external microinfusion device and catheter. Then, follow manufacturer guidelines for programming the microinfusion device and

Mechanism of Action

Pain sensations are transmitted by sensory neurons that travel through N-type calcium channels in the dorsal horn of the spinal cord and ascend to the brain, as shown below.

Ziconotide binds to N-type calcium channels on primary nociceptive afferent nerves in superficial layers of the dorsal horn, as shown below. By blocking these channels the drug prevents excitatory neurotransmitter release in primary afferent nerve terminals and relieves pain.

doing an initial pump fill, including priming using only undiluted 25-mcg/ml solution and rinsing the internal pump surfaces with 2 ml of drug three times.

- Use strict aseptic technique when preparing ziconotide solution and filling, refilling, or handling the microinfusion device.
- Be aware that initial ziconotide dosage shouldn't exceed 2.4 mcg daily.
- Know that refills can use diluted or undiluted ziconotide solutions. If diluting ziconotide, use only normal saline solution without preservatives, following manufacturer guidelines. Refrigerate solution

up to 24 hours if it isn't used immediately. Expect device to need refilling about every 40 days if ziconotide is given diluted or about 60 days if given undiluted.

- Assess patient's response to ziconotide regularly. Notify prescriber if pain relief isn't adequate, and expect to increase dosage.
- Check infusion site regularly, and be aware that meningitis can occur within 24 hours after contamination of delivery system; a disconnected catheter is the most common problem with external devices.
- Monitor patient closely for evidence of meningitis, such as headache, stiff neck,

altered mental status, nausea, vomiting, and occasionally seizures caused by inadvertent contamination of microinfusion device or catheter tract used to deliver ziconotide. Notify prescriber immediately if you suspect meningitis.

- Monitor patient closely for cognitive impairment, hallucinations, or changes in mood or consciousness because ziconotide may cause severe psychiatric symptoms and neurologic impairment. If present, notify prescriber and expect to decrease dosage or stop ziconotide. Provide supportive care, as prescribed, for adverse effects. Tell prescriber again if adverse effects are still present after 2 weeks.
- Expect to stop ziconotide temporarily if patient becomes unresponsive or stuporous during therapy; drug may be continued when patient reverts to previous mental status.
- Ziconotide can be stopped abruptly without causing withdrawal symptoms.
- Monitor patient's serum CK level every other week for first month of therapy and monthly thereafter, as ordered. If levels become elevated, notify prescriber and expect to decrease ziconotide dosage or stop drug until levels return to normal.

PATIENT TEACHING

- Teach caregiver how to care for external device, if present. Stress the need for strict aseptic technique with the microinfusion device and connections and the need to check the site often for problems, such as a disconnected catheter, which increase the risk of meningitis.
- Review evidence of meningitis with caregiver, and tell her to contact prescriber immediately if she suspects meningitis.
- Advise patient to notify prescriber if pain relief isn't adequate.
- Tell patient and caregiver to notify prescriber immediately about muscle pain, soreness, and weakness with or without dark urine or a change in mental status or mood, including depression or suicidal ideation.
- Advise patient to avoid hazardous activities that require mental alertness or motor coordination while receiving ziconotide.
- Caution patient to avoid taking OTC preparations that contain CNS depressants because of the risk of adverse CNS effects.

zileuton

Zyflo CR

Class and Category

Chemical class: Leukotriene inhibitor

Therapeutic class: Antiasthmatic

Pregnancy category: C

Indications and Dosages

↗ *To prevent or treat chronic asthma*

E.R. TABLETS

Adults and adolescents. 600 mg b.i.d.

Maximum: 2,400 mg daily.

Route	Onset	Peak	Duration
P.O.	2 hr	Unknown	Unknown

Mechanism of Action

Inhibits formation of leukotrienes found mainly in neutrophils, eosinophils, monocytes, macrophages, and mast cells. Normally, leukotrienes augment neutrophil and eosinophil migration, neutrophil and monocyte aggregation, leukocyte adhesion, capillary permeability, and smooth-muscle contraction. By inhibiting leukotriene formation, zileuton causes bronchial relaxation and decreases vascular leakage and edema, mucus secretion, eosinophil movement, and bronchial hyperresponsiveness.

Contraindications

Hepatic impairment, hypersensitivity to zileuton or its components

Interactions

DRUGS

propranolol, terfenadine: Increased effects of these drugs

theophylline: Doubled theophylline level

warfarin: Prolonged PT and INR

Adverse Reactions

CNS: Asthenia, dizziness, fever, headache, hypertonía, insomnia, malaise, nervousness, neuropsychiatric events, sleep disorders, somnolence

CV: Chest pain

EENT: Conjunctivitis

GI: Abdominal pain, constipation, flatulence, indigestion, nausea, vomiting

GU: UTI, vaginitis

MS: Arthralgia, myalgia, neck pain or rigidity

SKIN: Pruritus, rash, urticaria

Other: Lymphadenopathy

Nursing Considerations

- Zileuton shouldn't be used to treat bronchospasm during an acute asthma attack or status asthmaticus; it can't relieve symptoms quickly enough.
- Monitor serum ALT level, as ordered, usually before treatment starts, once a month for 3 months, every 2 to 3 months for remainder of first year, and periodically thereafter during therapy.
- Monitor results of liver and pulmonary function tests and CBC during therapy.
- Monitor patient taking zileuton for neuropsychiatric symptoms including worsening of pre-existing psychiatric illness. If present, notify prescriber immediately, institute safety measures and expect drug to be discontinued.

PATIENT TEACHING

- Advise patient to take drug exactly as prescribed, in evenly spaced doses, every day. Stress need to take drug even during symptom-free periods and acute exacerbations.
- Urge patient not to chew, cut, or crush capsule but to swallow it whole.
- Instruct patient to continue using rescue inhalants, as prescribed, for acute attacks.
- Teach patient how to use peak-flow meter to assess and monitor pulmonary function.
- Instruct patient to report any abnormal thoughts or behavior.

zinc acetate

(contains 25 or 50 mg of elemental zinc per capsule)

Galzin

zinc chloride

(contains 1 mg of elemental zinc per ml for I.V. infusion)

zinc gluconate

(contains 1.4 mg of elemental zinc per lozenge; 1.4, 2, 4, 7, 8, 10, 11, 13, 31, 50, or 52 mg of elemental zinc per tablet)

Orazinc

zinc sulfate

(contains 25 or 50 mg of elemental zinc

per capsule; 15, 25, 45, or 50 mg of elemental zinc per tablet; 50 mg of elemental zinc per E.R. tablet; and 1 or 5 mg of elemental zinc per ml for I.V. infusion)

Orazinc, Verazinc, Zinc 15, Zinc-220, Zinca-Pak, Zincate

Class and Category

Chemical class: Trace element, mineral

Therapeutic class: Copper absorption inhibitor, nutritional supplement

Pregnancy category: A (oral), C (I.V.)

Indications and Dosages

↗ *To prevent zinc deficiency based on U.S. and Canadian recommended daily allowances*

CAPSULES, E.R. TABLETS, LOZENGES, TABLETS

Men and boys age 11 and over. 15 mg (9 to 12 mg Canadian) elemental zinc daily.

Women and girls age 11 and over. 12 mg (9 mg Canadian) elemental zinc daily.

Pregnant women. 15 mg (15 mg Canadian) elemental zinc daily.

Breast-feeding women. 16 to 19 mg (15 mg Canadian) elemental zinc daily.

Children ages 7 to 10. 10 mg (7 to 9 mg Canadian) elemental zinc daily.

Children ages 4 to 6. 10 mg (5 mg Canadian) elemental zinc daily.

Children from birth to age 3. 5 to 10 mg (2 to 4 mg Canadian) elemental zinc daily.

I.V. INFUSION

Adults and children. 2.5 to 4 mg daily added to total parenteral nutrition (TPN) solution. *Maximum:* 12 mg daily.

Children from birth to age 5. 100 mcg/kg daily added to TPN solution.

Premature infants weighing up to 3 kg. 300 mcg/kg daily added to TPN solution.

↗ *To treat zinc deficiency*

CAPSULES, E.R. TABLETS, LOZENGES, TABLETS

Adults and children. Dosage individualized based on severity of deficiency.

I.V. INFUSION

Adults and adolescents. 2.5 to 4 mg daily added to TPN solution. *Maximum:* 12 mg daily.

Children from birth to age 5. 100 mcg/kg daily added to TPN solution.

Premature infants weighing up to 3 kg. 300 mcg/kg daily added to TPN solution.

↗ *As adjunct maintenance therapy for*

patients previously treated for Wilson's disease

CAPSULES

Adults. 50 mg t.i.d.

Pregnant women. 25 mg t.i.d., increased to 50 mg t.i.d. if drug effectiveness decreases.

Children age 10 and over. 25 mg t.i.d., increased to 50 mg t.i.d. if drug effectiveness decreases.

Mechanism of Action

Needed for proper function of more than 200 metalloenzymes (those with tightly bound zinc atoms as an integral part of their structure), including carbonic anhydrase, carboxypeptidase A, alcohol dehydrogenase, alkaline phosphatase, and RNA polymerase. Zinc also helps maintain nucleic acid, protein, and cell membrane structure and is essential for certain physiologic functions, including cell growth and division, sexual maturation and reproduction, dark adaptation and night vision, wound healing, host immunity, and taste acuity. This mineral also provides cellular antioxidant protection by scavenging free radicals.

In addition, zinc acetate interferes with intestinal absorption of copper and produces a protein that binds with copper, preventing its transfer to blood. Bound copper is then excreted in stools, thus decreasing copper toxicity in Wilson's disease.

Contraindications

Hypersensitivity to zinc or its components

Interactions

DRUGS

copper supplements: Impaired copper absorption (with large doses of zinc)

oral iron supplements, oral phosphate salts, penicillamine, phosphorus-containing drugs: Decreased zinc absorption

quinolones, tetracyclines: Decreased absorption and possibly decreased effectiveness of these antibiotics

thiazide diuretics: Increased urinary excretion of zinc

zinc-containing preparations: Increased blood zinc level

FOODS

fiber- or phylate-containing foods (such as bran, whole-grain breads, cereal), phosphorus-containing foods (including milk, poultry): Decreased zinc absorption

Nursing Considerations

WARNING Don't give I.V. zinc preparations that contain benzyl alcohol to neonates or premature infants because this preservative may cause a fatal toxic syndrome characterized by metabolic acidosis and CNS, respiratory, circulatory, and renal function impairment.

- Give oral zinc supplements 1 hour before or 2 to 3 hours after meals; at least 2 hours after giving oral iron supplements (to prevent decreased zinc absorption) or copper supplements (to prevent decreased copper absorption); and at least 6 hours before or 2 hours after administering quinolone or tetracycline antibiotics (to prevent decreased absorption of these drugs).
- Monitor patient receiving long-term zinc therapy for sideroblastic anemia, which may result from zinc-induced copper deficiency and is characterized by anemia, leukopenia, neutropenia, granulocytopenia, and bone marrow problems. Be aware that these effects are reversible after zinc is discontinued.
- Monitor patient with preexisting copper deficiency for exacerbation of this condition; zinc can decrease serum copper level.
- Assess for signs and symptoms of zinc deficiency, such as growth retardation, hypogonadism, delayed sexual maturation, alopecia, impaired wound healing, skin lesions, immune deficiencies, behavioral disturbances, night blindness, and impaired sense of taste.
- Monitor blood alkaline phosphatase (ALP) level monthly, as ordered; it may increase.
- Be aware that zinc chloride contains aluminum, which may accumulate to the point of toxicity if patient's kidney function is impaired. Assess kidney function regularly.

PATIENT TEACHING

- Explain the need for a zinc supplement.
- Instruct patient to take zinc on an empty stomach, at least 1 hour before or 2 hours after meals. Caution her not to take zinc within 2 hours of iron or copper supplements or phosphorus-containing drugs.
- Instruct patient to let zinc lozenges dissolve in mouth slowly and completely and not to swallow it whole or chew it. Advise her not to take zinc lozenges more often than directed.

ziprasidone hydrochloride

Geodon

ziprasidone mesylate

Geodon for Injection

Class and Category

Chemical class: Benzisoxazole derivative

Therapeutic class: Antipsychotic

Pregnancy category: C

Indications and Dosages

➤ *To treat schizophrenia*

CAPSULES

Adults. *Initial:* 20 mg b.i.d. Dosage increased as indicated every 2 or more days. *Usual:* 20 to 80 mg b.i.d. *Maximum:* 100 mg b.i.d.

I.M. INJECTION

Adults. *Initial:* 10 to 20 mg. 10 mg dose may be given every 2 hr up to maximum dose; 20 mg dose may be given every 4 hr up to maximum dose. *Maximum:* 40 mg daily.

➤ *To treat acute manic or mixed episodes of bipolar disorder*

CAPSULES

Adults. *Initial:* 40 mg b.i.d. with food on day 1; then increased to 60 or 80 mg on day 2 with further adjustments as needed.

➤ *As adjunct to lithium or valproate for maintenance treatment of bipolar I disorder*

CAPSULES

Adults. Same dose patient was initially stabilized on that falls within 40 mg to 80 mg twice daily.

Mechanism of Action

Selectively blocks serotonin and dopamine receptors in the mesocortical tract of the CNS, thereby suppressing psychotic symptoms.

Incompatibilities

Don't mix injection form with drugs or solvents other than sterile water for injection.

Contraindications

Concurrent use of other drugs that prolong QT interval, history of arrhythmia, hyper-

sensitivity to ziprasidone or its components, history of prolonged QT interval, recent acute MI, uncompensated heart failure

Interactions

DRUGS

antihypertensives: Additive antihypertensive effects

carbamazepine: Possibly decreased blood ziprasidone level

CNS depressants: Increased CNS depression

dopamine agonists, levodopa: Decreased therapeutic effects of these drugs

drugs that prolong QT interval (including quinidine, dofetilide, pimozide, sotalol, thioridazine, and sparfloxacin): Increased risk of prolonged QT or QTc interval, torsades de pointes, and sudden death

ketoconazole: Possibly increased blood ziprasidone level

FOODS

all foods: Increased ziprasidone absorption

Adverse Reactions

CNS: Agitation, akathisia, amnesia, anxiety, asthenia, CVA, depression, dizziness, dystonia, extrapyramidal reactions, headache, hypertonia, hypomania, insomnia, mania, neuroleptic malignant syndrome, paresthesia, personality or speech disorder, serotonin syndrome, somnolence, syncope, suicidal ideation, tardive dyskinesia, tremor

CV: Bradycardia, chest pain, hypercholesterolemia, hypertension, orthostatic hypotension, prolonged QT or QTc interval, tachycardia, thrombophlebitis, vasodilation

EENT: Abnormal vision, dry mouth, increased salivation, rhinitis, tongue swelling

ENDO: Dysmenorrhea, hyperglycemia

GI: Abdominal pain, anorexia, constipation, diarrhea, dysphagia, indigestion, nausea, rectal bleeding, vomiting

GU: Priapism, urinary incontinence

HEME: Agranulocytosis, leukopenia, neutropenia

MS: Arthralgia, back pain, dysarthria, myalgia

RESP: Cough, pulmonary embolism, upper respiratory tract infection

SKIN: Allergic dermatitis, diaphoresis, furunculosis, rash, urticaria

Other: Accidental injury, angioedema, flu-

like symptoms, injection site pain, weight gain

Nursing Considerations

WARNING Ziprasidone shouldn't be used to treat elderly patients with dementia-related psychosis because drug increases the risk of death in these patients.

- Protect ziprasidone vials from light. Reconstitute by adding 1.2 ml sterile water for injection to vial and shaking vigorously until drug is dissolved. Each ml of reconstituted solution contains 20 mg ziprasidone. Discard any unused portion.
- Give only by I.M. route.
- Reconstituted drug may be stored 24 hours protected from light or up to 7 days if refrigerated and protected from light.
- Administer I.M. form cautiously to patients with impaired renal function.

WARNING Assess cardiac rhythm in patients with hypokalemia or hypomagnesemia.

Dizziness, palpitations, and syncope may indicate life-threatening torsades de pointes. Be prepared to stop ziprasidone if QTc interval is greater than 500 msec.

- Monitor patient, especially elderly woman, for involuntary movements, which may become irreversible tardive dyskinesia. If symptoms develop, notify prescriber immediately and be prepared to stop drug.
- Immediately report evidence of neuroleptic malignant syndrome, a rare but potentially fatal adverse reaction including hyperpyrexia, muscle rigidity, altered mental status, irregular pulse, blood pressure changes, tachycardia, diaphoresis, arrhythmia, myoglobinuria (rhabdomyolysis), and acute renal failure.
- Monitor patient's blood glucose and lipid levels routinely, as ordered, because drug increases risk of hyperglycemia and hypercholesterolemia.
- Monitor patient's CBC, as ordered, because serious adverse hematologic reactions may occur, such as agranulocytosis, leukopenia, and neutropenia. Monitor more frequently during first few months of therapy if patient has a history of drug-induced leukopenia, neutropenia, or significantly low WBC count. If abnormalities occur during ziprasidone therapy, watch for fever and other evidence of infection, notify prescriber, and expect to

discontinue drug if severe.

- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

PATIENT TEACHING

- Instruct patient to take ziprasidone with food to increase absorption.
- Advise patient to avoid hazardous activities until CNS effects are known.
- Tell family to monitor patient closely for suicidal tendencies; patients with psychotic illness or bipolar disorder are at greater risk.
- Urge patient to rise slowly from seated or lying position to minimize orthostatic hypotension.
- Urge patient to notify prescriber immediately if he develops any sudden onset, unusual, persistent, or severe adverse reactions.

zoledronic acid

Reclast, Zometa

Class and Category

Chemical class: Bisphosphonate

Therapeutic class: Antihypercalcemic, bone resorption inhibitor

Pregnancy category: D

Indications and Dosages

➤ To treat hypercalcemia caused by cancer

I.V. INFUSION (ZOMETA)

Adults. 4 mg infused over at least 15 min. After 7 days, retreatment with 4 mg if serum calcium level doesn't remain at or return to normal. *Maximum:* 4 mg/dose.

➤ As adjunct treatment for patients with multiple myeloma or bony metastasis who are receiving standard antineoplastic therapy and have a creatinine clearance above 60 ml/min/1.73 m²

I.V. INFUSION (ZOMETA)

Adults. 4 mg infused over at least 15 min every 3 to 4 wk.

DOSE ADJUSTMENT If patient's creatinine clearance is 50 to 60 ml/min/1.73 m², dosage decreased to 3.5 mg; if it's 40 to 49 ml/min/1.73 m², dosage decreased to 3.3 mg; and if it's 30 to 39 ml/min/1.73 m², dosage decreased to 3 mg.

➤ To treat postmenopausal osteoporosis in

women; to treat osteoporosis in men; to treat and prevent glucocorticoid-induced osteoporosis in patients receiving daily prednisone doses of 7.5 mg or greater for at least 12 months

I.V. INFUSION (RECLAST)

Adults. 5 mg infused over at least 15 min once yearly.

➤ *To treat Paget's disease of the bone*

I.V. INFUSION (RECLAST)

Adults. 5 mg infused over at least 15 min after 2 wk of receiving 1,500 mg elemental calcium daily in divided doses and 800 international units vitamin D daily.

➤ *To prevent osteoporosis in postmenopausal women*

I.V. INFUSION (RECLAST)

Adults. 5 mg infused over at least 15 min every 2 years.

Mechanism of Action

Inhibits resorption of mineralized bone and cartilage by osteoclasts and induces osteoclast breakdown. In cancer-related hypercalcemia, hyperactive osteoclasts cause bone resorption and release of calcium into blood, which causes polyuria, GI disruption, progressive dehydration, and decreasing GFR. This, in turn, increases renal calcium resorption and worsens hypercalcemia. Zoledronic acid interrupts this process.

Incompatibilities

Don't mix zoledronic acid with calcium-containing I.V. solutions, such as lactated Ringer's solution.

Contraindications

Hypersensitivity to zoledronic acid, other bisphosphonates, or their components

Interactions

DRUGS

aminoglycosides: Possibly additive serum calcium-lowering effect

loop diuretics, such as furosemide: Possibly increased risk of hypocalcemia

NSAIDs: Increased risk of nephrotoxicity

Adverse Reactions

CNS: Anxiety, asthenia, chills, confusion, depression, dizziness, fatigue, fever, headache, hyperesthesia, hypoesthesia, insomnia, malaise, paresthesia, tremor, vertigo, weakness

CV: Atrial fibrillation, bradycardia, chest

pain, hypertension, hypotension, peripheral edema

EENT: Blurred vision, conjunctivitis, episcleritis, iritis, orbital edema or inflammation, scleritis, sore throat, stomatitis, taste disturbance, uveitis

GI: Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, nausea, vomiting

GU: Elevated serum creatinine level, hematuria, proteinuria, renal insufficiency or failure, UTI

HEME: Anemia, neutropenia, thrombocytopenia

MS: Arthralgia; incapacitating bone, joint, or muscle pain; muscle spasms; myalgia; osteonecrosis of the jaw

RESP: Bronchospasm, cough, dyspnea, upper respiratory tract infection

SKIN: Alopecia, dermatitis, flushing, urticaria

Other: Aggravated malignant neoplasm, anaphylaxis, angioedema, flu-like illness, hypersensitivity reaction, hyperkalemia, hyponatremia, hypocalcemia, hypomagnesemia, hypophosphatemia, infusion site redness and swelling, weight gain

Nursing Considerations

- Be aware that zoledronic acid isn't indicated for hypercalcemia from hyperparathyroidism or other non-tumor conditions.
- Use cautiously in patients with aspirin sensitivity because bisphosphonates such as zoledronic acid have caused bronchoconstriction in these patients.
- Make sure patient has had a dental check-up before zoledronic acid starts, especially if patient has cancer; is receiving chemotherapy, head or neck radiation, or a corticosteroid; or has poor oral hygiene because risk of osteonecrosis is increased in these patients, and invasive dental procedures during zoledronic acid therapy may worsen osteonecrosis.
- Expect to aggressively hydrate hypercalcemic patient with I.V. normal saline solution before and during zoledronic acid therapy, as prescribed, to achieve and maintain urine output of about 2 L daily.

WARNING During hydration, monitor fluid intake and output often and assess patient, especially one with heart failure, for evidence of life-threatening overhydration.

- Hypocalcemia and mineral metabolism

disorders must be treated before zoledronic acid therapy begins.

- Be aware that Reclast doesn't need reconstitution.
- Reconstitute Zometa by adding 5 ml of sterile water for injection to drug vial to yield solution that contains 4 mg of zoledronic acid. Make sure drug is completely dissolved before withdrawing prescribed dose. Further dilute in 100 ml normal saline solution or 5% dextrose injection, and infuse over no less than 15 minutes.
- Before giving zoledronic acid, inspect reconstituted and diluted solution and discard it if particles or discoloration are present.
- Expect to give acetaminophen, if not contraindicated, before zoledronic acid to reduce adverse reactions, such as fever, headache, myalgia, and flulike symptoms. These reactions usually occur within first 3 days after zoledronic acid administration and resolve within 3 days (although resolution may take up to 14 days for some patients).
- Refrigerate reconstituted drug at 2° to 8° C (36° to 46° F) and discard after 24 hours.
- Give drug as a single I.V. solution in a separate I.V. line.

WARNING Be aware that a single dose of Zometa shouldn't exceed 4 mg and that neither Zometa nor Reclast should be infused over less than 15 minutes because exceeding these limits may lead to significant renal function deterioration, which may progress to renal failure.

WARNING Assess patient's renal function, as ordered, before and during zoledronic acid therapy to detect renal deterioration. For patient with a normal serum creatinine level who develops an increase of 0.5 mg/dl within 2 weeks of receiving zoledronic acid, expect to withhold next dose until serum creatinine level is within 10% of patient's baseline value. For patient with an abnormal serum creatinine level who develops an increase of 1.0 mg/dl within 2 weeks of receiving drug, expect to withhold next dose until serum creatinine level is within 10% of baseline value.

- Monitor patient's serum calcium, magnesium, and phosphate levels, as ordered, during zoledronic acid therapy. If hypocalcemia, hypomagnesemia, or hypophos-

phatemia occurs, expect to give short-term supplemental therapy.

- Assess aspirin-sensitive asthma patients for worsening of respiratory symptoms during zoledronic acid therapy because other bisphosphonates have caused bronchoconstriction in these patients.
- Store drug at 25° C (77° F).

PATIENT TEACHING

- Teach patient the importance of consuming a nutritious diet, including adequate amounts of calcium and vitamin D.
- Advise patient to alert prescriber about muscle or bone pain.
- Instruct patient on proper oral hygiene and on need to notify prescriber before undergoing invasive dental procedures.
- Advise women of childbearing age to notify prescriber immediately if they are or could be pregnant because drug will need to be stopped.

zolmitriptan

Zomig, Zomig ZMT

Class and Category

Chemical class: Selective 5-hydroxytryptamine agonist

Therapeutic class: Antimigraine

Pregnancy category: C

Indications and Dosages

➤ *To treat acute migraine headache with or without aura*

DISINTEGRATING TABLETS

Adults. 2.5 mg, repeated every 2 hr p.r.n.

Maximum: 10 mg in 24 hr or three headaches/mo.

TABLETS

Adults. 2.5 mg or less, repeated every 2 hr

p.r.n. *Maximum:* 10 mg in 24 hr or three headaches/mo.

NASAL SPRAY

Adults. 5 mg, repeated in 2 hr if needed.

Maximum: 10 mg/24 hr.

DOSAGE ADJUSTMENT Dosage reduced to less than 2.5 mg for patients with hepatic impairment.

Mechanism of Action

Constricts inflamed and dilated cranial blood vessels in the carotid circulation and inhibits production of proinflammatory

neuropeptides by binding to receptors on intracranial blood vessels and sensory nerves in the trigeminal-vascular system to stimulate negative feedback, which halts the release of serotonin.

Contraindications

Basilar or hemiplegic migraine, cardiovascular disease, concurrent use of ergotamine-containing drugs, hypersensitivity to zolmitriptan or its components, ischemic heart disease, peripheral vascular disease, Prinzmetal's angina, symptomatic Wolff-Parkinson-White syndrome or other accessory pathway conduction disorder, use of another 5-hydroxytryptamine agonist within past 24 hours, use of an MAO inhibitor within 14 days

Interactions

DRUGS

acetaminophen: Delayed peak effect of acetaminophen (by 1 hour)

cimetidine: Prolonged zolmitriptan half-life

ergot alkaloids: Prolonged vasoconstriction effects

fluoxetine, fluvoxamine, paroxetine, sertraline: Hyperreflexia, lack of coordination, and weakness

MAO inhibitors: Increased zolmitriptan effects

naratriptan, rizatriptan, sumatriptan:

Prolonged zolmitriptan effects

oral contraceptives, propranolol: Increased blood zolmitriptan level

serotonin and norepinephrine reuptake

inhibitors: Increased risk of developing serotonin syndrome

Adverse Reactions

CNS: Asthenia, dizziness, hyperesthesia, paresthesia, somnolence, vertigo

CV: Angina, coronary artery vasospasm, hypertension, MI, palpitations, transient myocardial ischemia, ventricular fibrillation or tachycardia

EENT: Dry mouth, vision disturbance

GI: Abdominal pain, bloody diarrhea, dysphagia, GI or splenic infarction, indigestion, ischemic colitis, nausea, vomiting

MS: Myalgia; myasthenia; pain, pressure, or tightness in jaw, neck, or throat

SKIN: Diaphoresis, flushing

Other: Anaphylaxis, anaphylactoid reaction, angioedema

Nursing Considerations

WARNING Monitor patient for signs and symptoms of vasoconstriction, which may lead to vascular and colonic ischemia with abdominal pain and bloody diarrhea, especially if patient has peripheral vascular disease (including Raynaud's phenomenon) or ischemic bowel disease.

- Monitor elderly patients and those with hepatic impairment for increased blood pressure, and notify prescriber immediately if it occurs.
- Monitor patient closely for signs and symptoms of angina. If patient develops chest pain, notify prescriber.

WARNING Monitor patient closely for signs and symptoms of serotonin syndrome, which may include agitation, hallucinations, coma, tachycardia, labile blood pressure, hyperthermia, hyperreflexia, incoordination, nausea, vomiting, and diarrhea. Notify prescriber immediately because serotonin syndrome may be life-threatening. Be prepared to provide supportive care and discontinue zolmitriptan.

PATIENT TEACHING

- Urge patient to consult prescriber before treating more than three headaches in 30 days.
- Advise patient not to remove disintegrating tablet from blister pack until just before taking the tablet. Instruct her to peel open pack, let tablet dissolve on her tongue, and then swallow.
- Urge patient to notify prescriber about unusual or severe adverse reactions.
- Caution patient using nasal spray to avoid spraying drug into her eyes.
- Instruct patient not to take zolmitriptan within 24 hours of other drugs in the same class.

zolpidem tartrate

Ambien, Ambien CR, Tovalt

Class, Category, and Schedule

Chemical class: Imidazopyridine derivative
Therapeutic class: Antianxiety, sedative-hypnotic

Pregnancy category: B

Controlled substance schedule: IV

Indications and Dosages

➤ *To provide short-term treatment of insomnia*

TABLETS, ORALLY DISINTEGRATING TABLETS

Adults. 10 mg at bedtime for 7 to 10 days.

Maximum: 10 mg daily.

DOSE ADJUSTMENT For elderly or debilitated patients and those with hepatic impairment, dosage possibly reduced to 5 mg at bedtime, with a maximum of 5 mg daily for nursing facility residents

E.R. TABLETS

Adults. 12.5 mg immediately before at bedtime.

DOSE ADJUSTMENT For elderly or debilitated patients and those with hepatic impairment, dosage reduced to 6.25 mg immediately before at bedtime.

Mechanism of Action

May potentiate the effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters. By binding to specific benzodiazepine receptors in the limbic and cortical areas of the CNS, zolpidem increases GABA's inhibitory effects, blocks cortical and limbic arousal, and preserves deep sleep (stages 3 and 4).

Contraindications

Hypersensitivity to zolpidem or its components, ritonavir therapy

Interactions

DRUGS

azole antifungals: Increased CNS activity and additive adverse effects of zolpidem
barbiturates, chlorpromazine, general anesthetics, opioid agonists, other CNS depressants, phenothiazines, tramadol, tricyclic antidepressants: Possibly increased CNS depression and reduced psychomotor function
bupropion: Increased blood zolpidem level, possibly visual hallucinations, loss of alertness
desipramine, imipramine: Increased risk of visual hallucinations and reduced alertness
flumazenil: Antagonized sedative effect
haloperidol: Increased CNS depression
nevirapine: Decreased blood zolpidem level
rifabutin, rifampin: Increased zolpidem clearance
selective serotonin-reuptake inhibitors: Increased risk of delusions, disorientation,

and hallucinations

FOODS

all foods: Increased time to peak blood zolpidem level, decreased effects of zolpidem

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Amnesia, asthenia, ataxia, complex behaviors (such as sleep driving), confusion, dizziness, drowsiness, euphoria, hallucinations, headache, insomnia, lethargy, paradoxical CNS stimulation (including agitation, euphoria, hallucinations, hyperactivity, and nightmares), vertigo
EENT: Diplopia, throat tightness, visual abnormality

GI: Constipation, diarrhea, hiccups, indigestion, nausea, vomiting

GU: UTI

MS: Arthralgia, myalgia

RESP: Dyspnea, upper respiratory infection

Other: Anaphylaxis, angioedema, withdrawal symptoms

Nursing Considerations

- Use zolpidem cautiously in patients with additional disorders because it isn't known if zolpidem therapy might aggravate these conditions.
- Administer zolpidem just before patient's bedtime because drug has a rapid onset of action.
- Expect patient to receive no more than a 1-month supply of zolpidem for outpatient therapy.

WARNING If zolpidem is withdrawn abruptly (especially after prolonged therapy), monitor patient for withdrawal symptoms, such as abdominal cramps or discomfort, fatigue, flushing, inconsolable crying, light-headedness, nausea, nervousness, panic attack, rebound insomnia, and vomiting.

- Expect that zolpidem will produce anti-convulsant and muscle relaxant effects at high doses.
- If patient takes other CNS depressants, expect to reduce zolpidem dosage, as prescribed.

WARNING Monitor patient closely for hypersensitivity reactions such as dyspnea, throat tightness, nausea, vomiting, and swelling. If present, discontinue zolpidem immediately, notify prescriber, and pro-

vide supportive care.**PATIENT TEACHING**

- Caution patient to take drug exactly as prescribed and not to increase dosage unless directed by prescriber.
- Advise patient taking extended-release form to swallow tablet whole and not to break, crush, or chew it.
- Advise patient taking orally disintegrating form to place tablet on tongue, let it dissolve, and then swallow with saliva or, if patient prefers, with water.
- Instruct patient to take zolpidem immediately before going to bed, on an empty stomach.
- Advise patient to notify prescriber immediately about abdominal cramps or discomfort, fatigue, flushing, inconsolable crying, light-headedness, nausea, nervousness, panic attack, and vomiting.
- Instruct patient to stop taking zolpidem and seek emergency care if she has trouble breathing, throat tightness, nausea, vomiting, or abnormally swelling.
- Advise patient that zolpidem may produce abnormal behaviors during sleep, such as driving a car, eating, talking on the phone, or having sex without any recall of the event. If patient's family notices any such behavior or if patient sees evidence of such behavior upon awakening, prescriber should be notified.

zonisamide

Zonegran

Class and Category

Chemical class: Benzisoxazole derivative, sulfonamide

Therapeutic class: Anticonvulsant

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat partial seizures*

CAPSULES

Adults. *Initial:* 100 mg daily. Dosage increased by 100 mg daily every 2 wk, as needed. *Usual:* 200 to 400 mg daily. *Maximum:* 600 mg daily.

Mechanism of Action

May stop seizures and suppress their foci by

blocking sodium channels and reducing voltage-dependent, inward currents from calcium channels. This action stabilizes neuronal membranes and suppresses synchronized neuronal hyperactivity.

Contraindications

Hypersensitivity to sulfonamides, zonisamide, or their components

Interactions**DRUGS**

carbamazepine, phenobarbital, phenytoin, valproate: Possibly decreased blood zonisamide level

CNS depressants: Additive CNS depressant effects

FOODS

grapefruit juice: Possibly decreased metabolism of zonisamide

Adverse Reactions

CNS: Agitation, ataxia, dizziness, irritability, somnolence, suicidal ideation

GI: Anorexia

Other: Metabolic acidosis

Nursing Considerations

- Obtain a serum bicarbonate level before starting zonisamide and then periodically during therapy, as prescribed because drug may cause metabolic acidosis, especially in patients with predisposing conditions or therapies or who are younger in age.

WARNING Monitor results of patient's CBC and other laboratory tests for signs of blood dyscrasias because zonisamide is a sulfonamide and can be absorbed systemically. Systemic absorption may result in life-threatening reactions, including toxic epidermal necrolysis, Stevens-Johnson syndrome, fulminant hepatic necrosis, agranulocytosis, aplastic anemia, and other blood dyscrasias.

- Be aware that patients receiving doses of 300 mg daily or more are at increased risk for adverse CNS reactions, including decreased concentration, fatigue, drowsiness, and impaired speech.
- Monitor serum creatinine and BUN levels for signs of abnormally decreased glomerular filtration rate (GFR). Expect some decrease in GFR during first 4 weeks of treatment and return to baseline within 2 to 3 weeks after drug is discontinued.

- Monitor patient for signs and symptoms of renal calculi.
- Be aware that zonisamide shouldn't be discontinued abruptly because doing so may increase frequency of seizures.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

PATIENT TEACHING

- Inform patient that zonisamide is usually prescribed with other anticonvulsants and that she should continue to take all drugs as prescribed.
- Instruct patient to swallow zonisamide capsules whole and not to chew them or break them open.
- Inform patient that prescriber may have to adjust zonisamide dosage over several weeks or months before stable dose is achieved.
- Advise patient to use caution when driving or performing other activities that are hazardous or require mental alertness because zonisamide commonly causes somnolence, dizziness, and decreased concentration, particularly during first month of therapy.
- Advise patient to wear a medical identification bracelet or necklace or carry medical identification with information about her seizure disorder.
- Unless contraindicated, encourage patient to drink 6 to 8 glasses of water each day to prevent kidney stones.
- Advise patient to rise slowly from a lying or seated position to reduce the risk of dizziness.
- Urge caregivers to watch closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report concerns immediately to prescriber.
- Encourage woman who becomes pregnant while taking zonisamide to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting information about the safety of antiepileptic drugs during pregnancy.

Insulin Preparations

For each category of insulin, the following table lists the species; common trade names; onset, peak, and duration; and key nursing considerations.

CATEGORY, SPECIES, AND TRADE NAMES

KEY NURSING CONSIDERATIONS

Rapid-acting insulin

Onset: 15 min **Peak:** 30–90 min **Duration:** In 6 hr

Human

- Apidra (insulin glulisine)
- Humalog (insulin lispro)
- NovoLog (insulin aspart)

- Mix Humalog or NovoLog with other insulin types, but mix Apidra only with NPH insulin, if needed. Administer immediately after mixing.
- When mixing rapid-acting insulin with a longer-acting insulin, always draw the rapid-acting insulin into the syringe first to avoid dosage errors.
- Give Humalog only SubQ, up to 15 minutes before a meal. Give NovoLog only SubQ 5 to 10 minutes before a meal or via external insulin pump. Give Apidra SubQ up to 15 to 20 minutes before a meal or via insulin pump. If using a pump, NovoLog and Apidra shouldn't be diluted or mixed with any other insulin.
- Be aware that 1 unit of rapid-acting insulin has the same glucose-lowering ability as 1 unit of short-acting insulin.
- Rapid-acting insulin is available as a cartridge. Make sure to use the correct device for the brand of insulin prescribed, and don't add any other insulin to the cartridge.
- Absorption rate of rapid-acting insulin may slow when this type of insulin is mixed in a syringe with human isophane insulin (NPH). Monitor blood glucose level often.

Short-acting insulin

Onset: 30 min **Peak:** 2–5 hr **Duration:** 6–8 hr

Human

- Humulin-R
- Novolin ge Toronto (CAN)
- Novolin R
- Novolin R Prefilled
- Velosulin BR
- Velosulin Human (CAN)

Pork

- Regular (concentrated), Iletin II, U-500

- Don't use short-acting insulin if it's cloudy, discolored, or unusually viscous.
- Use the U-500 strength to treat insulin resistance, as prescribed.
- Mix short-acting insulin with other insulin types, if needed. However, don't mix phosphate-buffered insulin with a zinc-containing insulin because the short-acting insulin's effectiveness may be reduced.
- Administer SubQ, I.M., or I.V., as prescribed. Use a continuous SubQ infusion pump, if ordered. For an insulin pump, phosphate-buffered insulin is preferred over nonphosphate-buffered insulin. The catheter tubing and reservoir insulin should be changed every 48 hours or as specified by the pump manufacturer.
- When giving SubQ or I.M. injections, give the short-acting insulin 15 to 30 minutes before a meal or bedtime snack.
- Consider religious restrictions when choosing insulin type.

(continued)

Insulin Preparations *(continued)*

CATEGORY, SPECIES, AND TRADE NAMES

KEY NURSING CONSIDERATIONS

Intermediate-acting insulin

Onset: 1–3 hr **Peak:** 4–15 hr **Duration:** 18–24 hr

Human

- Humulin N
- Novolin ge Lente (CAN)
- Novolin ge NPH (CAN)
- Novolin N
- Novolin N Prefilled

- Don't use intermediate-acting insulin if it contains precipitate that is clumped or granular or that clings to the sides of the vial.
- Roll the vial gently between your palms to mix; don't shake it. Also gently turn the prefilled syringe up and down several times before using to achieve a uniform mixture.
- Administer by SubQ injection only, 30 minutes before a meal or bedtime snack.
- Be aware that intermediate-acting insulin rarely produces a blood glucose level that's as close to normal as possible. So expect to mix it with a short-acting insulin, as prescribed, for optimum blood glucose control.
- Consider religious restrictions when choosing insulin.

Long-acting insulin

Onset: 4–6 hr **Peak:** 8–20 hr **Duration:** 24–28 hr

Human

- Humulin-U (CAN)
- Lantus (insulin glargine)
- Levemir (insulin detemir)
- Novolin ge Ultralente (CAN)

- Don't use long-acting insulin if it contains precipitate that is clumped or granular or that clings to the sides of the vial.
- Mix Humulin-U or Novolin ge Ultralente with other insulin types—usually a short-acting insulin—if needed. Do not mix Lantus or Levemir with another insulin or solution.
- Roll the vial gently between your palms to obtain a uniform mixture; don't shake it.
- Administer by the SubQ route only. Inject Humulin-U or Novolin ge Ultralente 30 to 60 minutes before a meal or bedtime snack. Inject Lantus once daily at any time, keeping the daily injection time consistent. Inject Levemir prescribed once daily with the evening meal or at bedtime; inject Levemir prescribed twice daily with the morning meal and with the evening meal, at bedtime, or 12 hours after the morning dose.
- Give Lantus at bedtime, if possible, so that additional insulin can be given while patient is awake if Lantus effects decline before 24 hours pass. If Lantus is given in the morning and its effects don't last 24 hours, hyperglycemia may occur while patient sleeps.

Insulin Preparations *(continued)*

CATEGORY, SPECIES, AND TRADE NAMES

KEY NURSING CONSIDERATIONS

Combination insulins

Onset: 30 min **Peak:** 2–12 hr **Duration:** 18–24 hr

Human

- Humalog Mix 75/25
- Humalog Mix 50/50
- Humulin 10/90 (CAN)
- Humulin 20/80 (CAN)
- Humulin 30/70 (CAN)
- Humulin 40/60 (CAN)
- Humulin 70/30
- Novolin 70/30
- Novolin ge 10/90 (CAN)
- Novolin ge 20/80 (CAN)
- Novolin ge 30/70 (CAN)
- Novolin ge 40/60 (CAN)
- Novolin ge 50/50 (CAN)
- NovoLog Mix 70/30
- NovoLog Mix 50/50

- Don't use combination insulin if it contains precipitate that is clumped or granular.
- Roll the vial gently between your palms to mix; don't shake it. Also gently turn the prefilled syringe up and down several times before using to achieve a uniform mixture.
- Administer combination insulin by the SubQ route only, 30 minutes before a meal.
- Be aware that Canadian and American products contain the same insulin ratio but express it differently. For example, the Canadian Humulin 30/70 and the American Humulin 70/30 both contain 30 units of a short-acting insulin and 70 units of an intermediate-acting insulin. Canadian products list the short-acting insulin first; American products list it second.

Selected Ophthalmic Drugs

Although less commonly prescribed than oral drugs, drugs instilled into the eyes are frequently brought into the clinical setting by patients with chronic conditions. In most cases, the patient or a family member has administered these preparations at home. Your patient teaching should include a review of proper administration and storage of these drugs. Have the patient or a family member demonstrate proper use of the drug to make sure it will be administered correctly at home. Use this time to reassess the patient's ability to continue self-medication. Also, instruct him to report any

changes in the condition being treated, either negative or positive. A properly educated patient not only ensures safe drug administration, but also is more likely to detect adverse reactions that require a dosage reduction or drug discontinuation, thus preventing the development of more serious health problems.

The following chart lists the generic and trade names, FDA-approved indications, and usual adult dosages for those ophthalmic preparations you're most likely to see in your practice setting. The drugs are divided according to therapeutic use.

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Ophthalmic antibiotics		
bacitracin AK-Tracin	To treat surface bacterial infections affecting the conjunctiva and cornea	Small amount of ointment applied to conjunctival sac p.r.n.
chloramphenicol Diochloram, Dioptic (CAN), Pentamycetin (CAN), Sopamycetin (CAN)	To treat surface bacterial infections affecting the conjunctiva and cornea	Apply small amount of ointment to lower conjunctival sac every 3 to 6 hr and p.r.n. for at least 48 hr after eye resumes normal appearance
ciprofloxacin hydrochloride 0.3% Ciloxan	To treat corneal ulcers due to <i>Pseudomonas aeruginosa</i> , <i>Staphylococcus aureus</i> , <i>Staphylococcus epidermidis</i> , <i>Streptococcus pneumoniae</i> , and possibly <i>Serratia marcescens</i> and <i>Streptococcus viridans</i> To treat bacterial conjunctivitis due to <i>Haemophilus influenzae</i> , <i>S. aureus</i> , <i>S. epidermidis</i> , and possibly <i>S. pneumoniae</i>	2 gtt in affected eye every 15 min for first 6 hr, then 2 gtt every 30 min for rest of first day; on day 2, 2 gtt in affected eye every hr; on days 3 to 14, 2 gtt in affected eye every 4 hr 1 or 2 gtt in conjunctival sac of affected eye every 2 hr while awake for first 2 days and then 1 or 2 gtt every 4 hr while awake for next 5 days; or 1/2-inch strip of ointment in affected eye t.i.d. for 2 days, then b.i.d. for next 5 days
erythromycin Ilotycin	To treat acute or chronic conjunctivitis and other eye infections To treat chlamydial ophthalmic infections (trachoma)	1 cm (0.39 in) of ointment applied in infected eye up to 6 times/day, depending on severity of infection Small amount applied in each eye b.i.d. for 2 mo; or b.i.d. on first 5 days of each month for 6 mo
ganciclovir 0.15% Zirgan	To treat acute herpes keratitis (dendritic ulcers)	1 gtt 5 times daily (about every 3 hr while awake) until corneal ulcer heals; then 1 gtt t.i.d. for 7 days

Selected Ophthalmic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Ophthalmic antibiotics <i>(continued)</i>		
gatifloxacin 0.3% Zymar	To treat bacterial conjunctivitis due to <i>Corynebacterium propinquum</i> , <i>Staphylococcus aureus</i> , <i>Staphylococcus epidermidis</i> , <i>Streptococcus mitis</i> , <i>Streptococcus pneumoniae</i> , and <i>Haemophilus influenzae</i>	1 gtt every 2 hr while awake, up to 8 times daily on days 1 and 2; then 1 gtt up to q.i.d. while awake on days 3 to 7
gentamicin sulfate Garamycin, Genoptic, Gentacidin, Gentak	To treat blepharitis, blepharoconjunctivitis, conjunctivitis, corneal ulcers, dacryocystitis, keratoconjunctivitis, or meibomianitis due to susceptible organisms	1 or 2 gtt every 4 hr or, for severe infection, up to 2 gtt/hr; alternatively, 1 cm (.39 in) of ointment applied to lower conjunctival sac b.i.d. or t.i.d.
levofloxacin 0.5% Quixin	To treat bacterial conjunctivitis	On days 1 and 2: 1 or 2 gtt every 2 hr while awake, up to 8 times/day; on days 3 to 7: 1 or 2 gtt every 4 hr while awake, up to 4 times/day
moxifloxacin 0.5% Vigamox	To treat bacterial conjunctivitis due to <i>Staphylococcus aureus</i> , <i>Staphylococcus epidermidis</i> , <i>Staphylococcus haemolyticus</i> , <i>Staphylococcus hominis</i> , <i>Streptococcus pneumoniae</i> , <i>Streptococcus viridans</i> group, <i>Haemophilus influenzae</i> , <i>Chlamydia trachomatis</i>	1 gtt t.i.d. for 7 days
ofloxacin 0.3% Ocuflox	To treat conjunctivitis due to <i>Staphylococcus aureus</i> , <i>Staphylococcus epidermidis</i> , <i>Streptococcus pneumoniae</i> , <i>Enterobacter cloacae</i> , <i>Haemophilus influenzae</i> , <i>Proteus mirabilis</i> , <i>Pseudomonas aeruginosa</i> , and <i>Propionibacterium acnes</i> To treat bacterial corneal ulcers due to <i>S. aureus</i> , <i>S. epidermidis</i> , <i>S. pneumoniae</i> , <i>E. cloacae</i> , <i>H. influenzae</i> , <i>P. mirabilis</i> , <i>P. aeruginosa</i> , <i>Serratia marcescens</i> , and <i>P. acnes</i>	1 or 2 gtt in conjunctival sac every 2 to 4 hr while awake for first 2 days; then 1 gtt q.i.d. for up to 5 more days 1 or 2 gtt every 30 min while awake and 1 or 2 gtt every 4 to 6 hr after retiring for 2 days; then 1 or 2 gtt/hr while awake for up to 7 more days; then 1 gtt q.i.d. until end of treatment

(continued)

Selected Ophthalmic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Ophthalmic antibiotics <i>(continued)</i>		
polymyxin B sulfate	To treat superficial eye infections involving the conjunctiva or cornea caused by <i>Pseudomonas</i> or other gram-negative organisms	1 to 3 gtt of 0.1% to 0.25% (10,000 to 25,000 units/ml) every hr; or up to 10,000 units in lower conjunctival sac daily.
sulfacetamide sodium 10% AK-Sulf, Bleph-10, Ocusulf-10, Sodium Sulamyd 10% (CAN), Sulf-10	To treat inclusion conjunctivitis, corneal ulcers, and chlamydial infections	1 or 2 gtt solution (10%) in lower conjunctival sac every 2 to 3 hr during day, less often at night; or 1 or 2 gtt (15%) in conjunctival sac every 1 to 2 hr; or 1 gtt (30%) in conjunctival sac every 2 hr; or 1.25 to 2.5 cm ointment (10%) in conjunctival sac q.i.d. and bedtime.
sulfacetamide sodium 15% Isopto Cetamide	To treat trachoma	2 gtt (30%) in lower conjunctival sac every 2 hr in combination with systemic sulfonamide or tetracycline
sulfacetamide sodium 30%		
tobramycin AKTob, Tobrex	To treat superficial ocular infections involving the conjunctiva or cornea	1 to 2 gtt every 1 to 4 hr, depending on severity of infection; or 1 cm (.39 in) of ointment applied to lower conjunctival sac every 8 to 12 hr for mild to moderate infections or every 3 to 4 hr for severe infections
tobramycin 0.3% (3 mg) and dexamethasone 0.1% (1 mg) TobraDex	To treat steroid-responsive inflammatory ocular conditions for which a corticosteroid is indicated and where superficial bacterial ocular infection or a risk of bacterial ocular infection exists	1 to 2 gtt every 4 to 6 hr; during first 24 to 48 hrs, dosage may be increased to 1 to 2 gtt every 2 hr; or apply 1 cm (.39 inch) of ointment into the conjunctival sac up to q.i.d.
Ophthalmic anti-inflammatory drugs		
bromfenac 0.09% Xibrom	To treat postoperative inflammation and reduce ocular pain after cataract extraction	1 gtt in operative eye b.i.d., starting 24 hr after cataract surgery and continuing through first 2 wk of postoperative period

Selected Ophthalmic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Ophthalmic anti-inflammatory drugs <i>(continued)</i>		
<p>dexamethasone Maxidex</p> <p>dexamethasone sodium phosphate AK-Dex, Boldex, R.O. Dexasone (CAN)</p>	<p>To treat allergic conjunctivitis; corneal injury from chemical or thermal burns or from penetration of foreign bodies; inflammatory conditions of the anterior segment of globe, conjunctiva, cornea, or eyelids; iridocyclitis; suppression of graft rejection after keratoplasty; and uveitis</p>	<p>1 or 2 gtt of suspension or solution or 1.25 to 2.5 cm of ointment in conjunctival sac from every hr (in severe disease) to 6 times/day; or ointment may be applied t.i.d. or q.i.d., then tapered to b.i.d., and then daily.</p>
<p>diclofenac sodium 0.1% Voltaren, Voltaren Ophtha (CAN)</p>	<p>To treat postoperative inflammation after removal of cataract</p> <p>To treat photophobia in incisional refractive surgery</p>	<p>1 gtt in conjunctival sac q.i.d., starting 24 hr after surgery through first 2 postoperative wk</p> <p>1 or 2 gtt in operative eye 1 hr before surgery. Then 1 or 2 gtt 15 min after surgery. Then 1 gtt q.i.d. starting 4 to 6 hr after surgery for up to 3 days, p.r.n.</p>
<p>difluprednate Durezol</p>	<p>To treat inflammation and pain associated with ocular surgery</p>	<p>1 gtt in conjunctival sac of affected eye(s) q.i.d. for 2 wk starting 24 hr after surgery. Then 1 gtt b.i.d. for 1 wk.</p>
<p>fluorometholone Fluor-Op, FML Forte, FML Liquifilm, FML S.O.P.</p> <p>fluorometholone acetate Eflone, Flarex</p>	<p>To treat inflammatory and allergic conditions of the anterior uvea, conjunctiva, cornea, or sclera</p>	<p>1 or 2 gtt suspension in conjunctival sac b.i.d. to q.i.d. or, in severe conditions, up to every 2 hr during first 1 to 2 days p.r.n.; or 1 cm (0.39 in) ointment in conjunctival sac once daily to t.i.d.</p>
<p>flurbiprofen sodium Ocufen</p>	<p>To inhibit intraoperative miosis</p>	<p>1 gtt in affected eye every 30 min, beginning 2 hr before surgery, up to total of 4 gtt</p>
<p>ketorolac tromethamine Acular</p>	<p>To relieve ocular itching due to seasonal allergic conjunctivitis</p>	<p>1 gtt in conjunctival sac of each eye q.i.d.</p>
<p>Acuvail</p>	<p>To treat postoperative inflammation in patients who have undergone cataract extraction</p> <p>To treat postoperative inflammation in patients who have undergone cataract extraction</p>	<p>1 gtt in operative eye q.i.d., starting 24 hr after surgery through first 2 postoperative wk</p> <p>1 gtt in affected eye b.i.d., starting 1 day before surgery, continuing through day of surgery and first 2 wk of postoperative period</p>

Selected Ophthalmic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Ophthalmic anti-inflammatory drugs <i>(continued)</i>		
loteprednol etabonate Alrex, Lotemax	To relieve seasonal allergic conjunctivitis and to treat steroid-responsive inflammatory conditions of the palpebral and bulbar conjunctiva, cornea, and anterior segment of the globe To treat postoperative inflammation following ocular surgery	1 gtt of 0.2% suspension in affected eyes q.i.d.; or 1 or 2 gtt of 0.5% suspension in conjunctival sac of affected eye q.i.d. up to 1 gtt/hr 1 or 2 gtt in conjunctival sac of operated eye q.i.d., beginning 24 hr after surgery and continuing through first 2 wk of postoperative period
medrysone HMS Liquifilm	To treat allergic conjunctivitis, episcleritis, ephedrine sensitivity, and vernal conjunctivitis	1 gtt into conjunctival sac up to every 4 hr
olopatadine hydrochloride 0.1% Patanol	To treat signs and symptoms of allergic conjunctivitis	1 gtt b.i.d. at 6- to 8-hr intervals
prednisolone acetate suspension Econopred Plus, Pred Forte, Pred Mild prednisolone sodium phosphate solution AK-Pred, Inflamase Forte, Inflamase Mild	To treat inflammation of the anterior segment of globe, cornea, and palpebral and bulbar conjunctiva	1 or 2 gtt in conjunctival sac b.i.d. to q.i.d. (suspension) or up to 6 times/day (solution)
rimexolone Vexol	To treat anterior uveitis To treat postoperative inflammation after ocular surgery	1 or 2 gtt in conjunctival sac every hr while awake in first week; 1 gtt every 2 hr while awake in second week; then tapered until uveitis resolves 1 or 2 gtt in conjunctival sac of affected eye q.i.d., starting 24 hr after surgery and continuing through first 2 postoperative wk
Ophthalmic cycloplegic mydriatics		
atropine sulfate Atropisol, Isopto Atropine, Minims Atropine (CAN)	To treat acute iritis or uveitis To produce dilation for cycloplegic refraction	1 gtt up to q.i.d.; or small strip of ointment applied to conjunctival sac up to b.i.d. 1 or 2 gtt of 1% solution 1 hr before refraction

Selected Ophthalmic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Ophthalmic cycloplegic mydriatics <i>(continued)</i>		
cyclopentolate hydrochloride AK-Pentolate, Cyclogyl, Minims Cyclopentolate (CAN), Pentolair	To produce mydriasis and cycloplegia required in specific diagnostic procedures	1 gtt of 0.5%, 1%, or 2% solution in each eye; then 1 or 2 gtt in 5 to 10 min p.r.n.
homatropine hydrobromide Isopto Homatropine, Minims Homatropine (CAN)	To dilate pupils for cycloplegic refraction To treat uveitis	1 or 2 gtt in each eye, repeated in 5 to 10 min for 2 or 3 doses p.r.n. 1 or 2 gtt in each eye every 3 to 4 hr
scopolamine hydrobromide Isopto Hyoscine	To dilate pupils for cycloplegic refraction To treat iritis or uveitis	1 or 2 gtt of 0.25% solution 1 hr before refraction 1 or 2 gtt of 0.25% solution once daily to q.i.d.
tropicamide Mydracyl, Opticyl, Tropicacyl	To dilate pupils for cycloplegic refraction	1 gtt of 1% solution, repeated in 5 min; additional 1 gtt in 20 to 30 min p.r.n.
Ophthalmic miotics		
acetylcholine chloride Miochol-E	To produce papillary miosis in anterior segment surgery	0.5 to 2 ml gently into anterior chamber before or after sutures secured
carbachol 0.01% Carbostat, Miostat carbachol 0.75%, 1.5%, 2.25%, 3% Carboptic, Isopto Carbachol	To produce papillary miosis in ocular surgery To treat open-angle glaucoma	0.5 ml (solution) into anterior chamber before or after sutures secured 1 or 2 gtt up to t.i.d.
pilocarpine Ocuser Pilo-20, Ocuser Pilo-40	To treat primary open-angle glaucoma	1 or 2 gtt up to q.i.d.; or 1-cm (0.39 cm) ribbon of 4% gel at bedtime; or 1 Ocuser Pilo (20 or 40 mcg/hr) every 7 days
pilocarpine hydrochloride Adsorbocarpine, Akarpine, Isopto Carpine, Miocarpine (CAN), Pilocar, Pilopine HS, Pilostat	To treat acute angle-closure glaucoma as emergency therapy	1 gtt of 2% solution every 5 to 10 min for 3 to 6 doses; then 1 gtt every 1 to 3 hr until pressure is controlled
pilocarpine nitrate Pilagan, P.V. Carpine Liquifilm (CAN), Minims Pilocarpine (CAN)	To treat mydriasis due to mydriatic or cycloplegic drug therapy	1 gtt of 1% solution

(continued)

Selected Ophthalmic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Ophthalmic vasoconstrictors		
naphazoline hydrochloride Ak-Con, Albalon Liquifilm, Allerest, Clear Eyes, Comfort Eye Drops, Degest 2, Vasocon Regular	To treat ocular congestion, irritation, or itching	1 gtt of 0.1% solution every 3 to 4 hr; or 1 gtt of 0.012% to 0.03% solution up to q.i.d. for no more than 72 hr
oxymetazoline hydrochloride OcuClear, Visine L.R.	To provide relief from eye redness due to minor eye irritations	1 or 2 gtt in conjunctival sac b.i.d. to q.i.d. (at least 6 hr apart)
phenylephrine hydrochloride Ak-Dilate, Ak-Nefrin, Isopto Frin, Mydfrin, Phenoptic, Relief Eye Drops for Red Eyes	To produce mydriasis without cycloplegia To produce mydriasis and vasoconstriction To treat chronic mydriasis To treat posterior adhesion of iris	1 gtt of 2.5% or 10% solution before eye exam, then repeated in 1 hr p.r.n. 1 gtt of 2.5% or 10% solution as single dose 1 gtt of 2.5% or 10% solution b.i.d. or t.i.d. 1 gtt of 2.5% or 10% solution as single dose
proparacaine hydrochloride Alcaine, Ophthaine, Ophthetic	To provide deep anesthesia during cataract extraction To provide anesthesia during removal of eye sutures To provide anesthesia during removal of foreign bodies To provide anesthesia during tonometry	1 gtt every 5 to 10 min for 5 to 7 doses 1 or 2 gtt 2 to 3 min before procedure 1 or 2 gtt in affected eye before surgery 1 or 2 gtt immediately before measurement
tetracaine Pontocaine	To provide eye anesthesia (short term)	1 or 2 gtt p.r.n.
tetrahydrozoline hydrochloride Collyrium Fresh Eye Drops, Eyesine, Murine Plus, Optigene 3, Tetrasine, Visine Moisturizing, Visine Extra	To treat conjunctival congestion, irritation, and allergic conditions	1 or 2 gtt of 0.05% solution up to q.i.d. or as directed
Miscellaneous ophthalmic drugs		
apraclonidine hydrochloride lopidine	To prevent or control elevated intraocular pressure (IOP) before and after ocular laser surgery	1 gtt of 1% solution 1 hr before laser surgery on anterior segment; then 1 drop immediately after surgery

Selected Ophthalmic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Miscellaneous ophthalmic drugs <i>(continued)</i>		
azelastine hydrochloride 0.05% Optivar	To treat itching of the eye associated with allergic conjunctivitis	1 gtt in affected eye b.i.d.
bepotastine besilate Bepreve	To treat itching of the eye associated with allergic conjunctivitis	1 gtt in affected eye b.i.d.
betaxolol hydrochloride Betoptic, Betoptic S	To treat chronic open-angle glaucoma or ocular hypertension	1 or 2 gtt of 0.5% solution or 0.25% suspension b.i.d.
bimatoprost 0.03% Lumigan	To reduce elevated IOP in patients with open-angle glaucoma or ocular hypertension who can't tolerate or have insufficiently responded to other IOP-lowering medications	1 gtt in affected eye daily in evening
brimonidine tartrate Alphagan, Alphagan P	To reduce IOP in open-angle glaucoma or ocular hypertension	1 gtt in affected eye t.i.d., about 8 hr apart
brinzolamide 1% Azopt	To reduce IOP in ocular hypertension or open-angle glaucoma	1 gtt t.i.d.
carteolol hydrochloride Ocupress	To treat chronic open-angle glaucoma or intraocular hypertension	1 gtt in conjunctival sac of affected eye b.i.d.
cyclosporine emulsion 0.05% Restasis	To increase tear production in keratoconjunctivitis sicca	1 gtt every 12 hr
dipivefrin hydrochloride Ophto-Dipivefrin (CAN), Propine	To reduce IOP in chronic open-angle glaucoma	1 gtt of 0.1% solution every 12 hr
dorzolamide hydrochloride Trusopt	To treat increased IOP in ocular hypertension or open-angle glaucoma	1 gtt in conjunctival sac of affected eye t.i.d.
emedastine difumarate Emadine	To treat allergic conjunctivitis	1 gtt in affected eye up to q.i.d.

(continued)

Selected Ophthalmic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Miscellaneous ophthalmic drugs <i>(continued)</i>		
fluorescein sodium AK-Fluor, Fluorescite, Fluor-I-Strip, Fluor-I-Strip-A.T., Ful-Glo, Funduscein-10, Funduscein-25, Ophthifluor	To diagnose corneal abrasions and foreign bodies, fit hard contact lenses, determine lacrimal patency, and assist in fundus photography and applanation tonometry	1 or 2 gtt of 2% solution followed by irrigation; or moisten strip with sterile water, then touch conjunctiva or fornix with moistened tip, and flush with irrigating solution; have patient blink several times after application
ketotifen fumarate Zaditor	To treat allergic conjunctivitis	1 gtt in affected eye b.i.d. every 8 to 12 hr
latanoprost Xalatan	To reduce IOP in ocular hypertension or open-angle glaucoma	1 gtt in conjunctival sac of affected eye daily in evening
levobunolol hydrochloride AKBeta, Betagan, Novo-Levobunolol (CAN)	To treat chronic open-angle glaucoma or ocular hypertension	1 or 2 gtt of 0.5% solution once daily or 0.25% solution b.i.d.
levocabastine hydrochloride 0.05% Livostin	To treat signs and symptoms of seasonal allergic conjunctivitis	1 gtt q.i.d.
metipranolol hydrochloride OptiPranolol	To reduce IOP in ocular hypertension or chronic open-angle glaucoma	1 gtt in affected eye b.i.d.
nedocromil sodium 2% Alocril	To treat itching associated with both seasonal and perennial allergic conjunctivitis	1 or 2 gtt b.i.d.
sodium chloride, hypertonic Adsorbonac, AK-NaCl, Muro-128, Muroptic-5	To provide temporary relief from corneal edema	1 or 2 gtt every 3 to 4 hr; or 6 mm (1/4 in) of ointment applied every 3 to 4 hr
timolol hemihydrate Betimol timolol maleate Apo-Timop (CAN), Timoptic timolol maleate extended-release solution Timoptic-XE	To reduce IOP in ocular hypertension or open-angle glaucoma	1 gtt of 0.25% or 0.5% solution in affected eye b.i.d., then 1 gtt daily; or 1 gtt extended-release solution in affected eye daily

Selected Ophthalmic Drugs *(continued)*

unoprostone isopropyl 0.15% Rescula	To reduce elevated IOP in patients with open-angle glaucoma or ocular hypertension who can't tolerate or have insufficiently responded to other IOP-lowering medications	1 gtt in affected eye b.i.d.
---	--	------------------------------

Antihistamines

Antihistamines are usually used to relieve immediate hypersensitivity reactions. They're also used as sedatives, antiemetics (especially in motion sickness), antitussives, antidyskinetics, and adjuncts to preoperative or postoperative analgesia.

Antihistamines are contraindicated in patients taking drugs that prolong the QT interval (including some macrolide antibiotics, quinidine, itraconazole, ketoconazole, mibefradil, and zileuton). They're also contraindicated in patients hypersensitive to antihistamines or their components.

The table below includes trade names; usual dosages; and onset, peak, and duration for antihistamines your patient is most likely to use daily or intermittently to control symptoms of allergic rhinitis. When caring for a patient who takes an antihistamine, individualize your plan of care but be sure to include these general interventions:

- Use antihistamines cautiously in patients with a history of glaucoma, peptic ulcer, or urine

retention because anticholinergic effects may worsen these conditions.

- Before antihistamine therapy, assess the patient for hypokalemia and correct the imbalance, as prescribed, to reduce the risk of arrhythmias.
- Before antihistamine therapy, obtain a detailed medication history to help prevent drug interactions.
- Give antihistamines with food if GI distress occurs.
- Urge patient to avoid alcohol and other CNS depressants during antihistamine use because the combination can cause additive CNS depression.
- Monitor blood pressure because these drugs' anticholinergic effects may cause hypertension.
- Be aware that short- and long-acting antihistamines may be combined and H₂ blockers added to increase antihistamine effects.
- Be aware that products containing pseudoephedrine should be used for less than 7 days.

GENERIC AND TRADE NAMES	USUAL ADULT DOSAGE	ONSET, PEAK, AND DURATION
acrivastine Semprex-D (also includes pseudoephedrine)	8 mg P.O. every 4 to 6 hr	Onset: 30 min Peak: Unknown Duration: 6 to 8 hr
azatadine Optimine Trinalin Repetabs (also includes pseudoephedrine)	1 to 2 mg P.O. every 8 to 12 hr 1 tablet P.O. every 12 hr	Onset: 15 to 60 min Peak: 4 hr Duration: 12 hr
azelastine Astelin Astepro 0.1% Astepro 0.15%	2 sprays (137 mcg/spray) in each nostril b.i.d. 1 to 2 sprays (137 mcg/spray) in each nostril b.i.d. 1 to 2 sprays (205.5 mcg/spray) in each nostril b.i.d.	Onset: In 3 hr Peak: Unknown Duration: 12 hr

loratadine Claritin Claritin-D12 (also includes pseudoephedrine) Claritin-D24 (also includes pseudoephedrine)	10 mg P.O. daily 1 tablet P.O. every 12 hr 1 tablet P.O. every 24 hr	Onset: 1 to 3 hr Peak: 8 to 12 hr Duration: At least 24 hr
olopatadine Patanase	2 sprays (665 mcg/spray) in each nostril b.i.d.	Onset: Unknown Peak: 15 to 120 minutes Duration: Unknown

Selected Topical Drugs

Topical drugs consist of an active drug prepared in a specified medium that promotes absorption through the skin. Media commonly are chosen based on drug solubility; rate of drug release; ability to hydrate the outer skin layer; ability to enhance penetration; drug stability; and interactions between the chosen medium, skin, and active ingredient.

Topical media include aerosols, creams, gels, lotions, ointments, powders, tinctures, and wet dressings. Aerosols, gels, lotions, and tinctures are convenient for application to the scalp and other hairy areas. Acutely inflamed areas are best treated with drying preparations, such as lotions, tinctures, and wet dressings. Chronic inflammation does well with applications of lubricating preparations, including creams and ointments.

Because of its physical properties, the skin can act as a holding area for many drugs, allowing slow penetration and prolonged duration of action. (This characteristic makes it important to understand the patient's allergies.) However, when administering topical or transdermal drugs that aren't prescribed for a specific location, keep in mind that penetration properties may vary in different areas of the body. For example, the scrotum, face, axillae, and scalp are more permeable than the limbs, and ventral surfaces typically are more permeable than dorsal surfaces.

Topical Drug Types

Topical drugs are classified as antibacterials, antifungals (the largest group), antivirals, corticosteroids, retinoids, and other miscellaneous preparations.

- *Antibacterials* may be useful in the early treatment of minor skin infections and wounds. Minor skin infections may respond well to topical drugs applied at the infection site. Minor wounds should be treated at the site and in the immediately surrounding area to prevent other pathogens from colonizing the area.
- *Antifungals* usually are used to treat mucocutaneous infections, such as tinea, primarily ringworm and athlete's foot. Systemic use of antifungals is limited by their potentially toxic adverse effects, most commonly renal or hepatic damage. All fungi are completely resistant to conventional antibacterial drugs.
- *Antivirals* are used to inhibit viral replication. They work by targeting any one of the steps involved in viral replication: penetration into

susceptible host cells; uncoating of the viral nucleic acid; synthesis of regulatory proteins, RNA and DNA, and structural proteins; assembly of viral particles; and release of the virus from the cell. Topical antivirals such as penciclovir can shorten the duration of herpetic lesions, lessen lesion pain, and minimize viral shedding.

- *Corticosteroids* reduce the signs and symptoms of inflammation. Topical corticosteroids cause vasoconstriction, probably by suppressing cell degranulation. They also cause decreased cell permeability by reducing histamine release from basal and mast cells.
- *Retinoids*, typically derivatives of vitamin A, are very effective in treating acne vulgaris, although the acne may appear to worsen before it improves. Retinoids are also useful for reducing wrinkles. When applied to the skin, retinoids remain primarily in the dermis; less than 10% of the drug is absorbed into the circulation. Prolonged use of retinoids promotes new dermal growth, new blood vessel formation, and thickening of the epidermis. Because these drugs are absorbed systemically and may have teratogenic effects, they shouldn't be used by pregnant women.
- *Miscellaneous topical drugs* are used to treat a variety of topical skin conditions, including dry skin, ichthyosis, parasitic infestations, psoriasis, and unwanted hair growth.

Administration Tips

Before you apply a topical drug, clean the site and let it dry. Use gloves or a finger cot during application to prevent the drug from being absorbed through your own skin. Inform your patient of any expected discomfort, such as temporary stinging or burning. After application, cover the site only if required; some topical drugs shouldn't be covered with an occlusive dressing.

Be sure to teach the patient and a family member correct administration technique. Also, review possible adverse reactions, highlighting those that should be reported to the prescriber. Stress the importance of complying with the drug regimen because some topical drugs require weeks or months of therapy to eradicate the underlying condition.

The following table includes the generic and trade names of many commonly prescribed topical drugs as well as their FDA-approved indications and usual adult dosages.

Selected Topical Drugs (continued)

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Antibacterials		
azelaic acid cream Azelex, Finacea, Fineven	To treat mild to moderate inflammatory acne vulgaris	Gently massage thin film into affected area b.i.d., morning and evening.
bacitracin	To treat topical infections, abrasions, cuts, and minor burns or wounds	Apply thin film to affected area once daily to t.i.d. up to 3 wk.
benzoyl peroxide Benzac AC Wash, Clearasil Maximum Strength, Desquam-E 2.5 Gel, Fostex 10 BPO Gel, Triaz	To treat mild to moderate inflammatory acne vulgaris	Apply to affected area once daily, gradually increasing to b.i.d. or t.i.d.
clindamycin phosphate Cleocin, Cleocin T Gel, Cleocin T Lotion, Clinda-Derm, Dalacin, Dalacin T Topical Solution (CAN)	To treat inflammatory acne vulgaris To treat bacterial vaginosis	Apply to affected area b.i.d., morning and evening. 1 applicatorful (100 mg) intravaginally at bedtime for 7 days.
clindamycin 1% and benzoyl peroxide 5% Benzaclin gel DUAC	To treat acne vulgaris	Apply once or twice daily (morning and/or evening) to affected areas
erythromycin Akne-Mycin, A/T/S, Erycette, EryDerm, Erygel, Erymax, Ery-Sol (CAN), Erythrogel, ETS (CAN), Sans-Acne (CAN), Staticin, T-Stat (CAN)	To treat inflammatory acne vulgaris	Apply to affected areas b.i.d., morning and evening.
erythromycin 3% and benzoyl peroxide 5% Benzamycin	To treat moderate inflammatory acne	Apply to affected areas b.i.d., morning and evening.
gentamicin sulfate Garamycin, G-myticin	To prevent or treat superficial skin infections due to susceptible bacteria; to treat superficial burns	Rub small amount gently into skin t.i.d. or q.i.d.
mafenide gel 1% Sulfamylon	As adjunct to treat second- and third-degree burns	Apply 1/16-inch layer aseptically to affected areas once or twice daily

(continued)

Selected Topical Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Antibacterials <i>(continued)</i>		
metronidazole MetroCream, MetroGel, MetroGel-Vaginal	To treat inflammatory papules and pustules of acne rosacea To treat bacterial vaginosis	Apply thin film to affected area b.i.d., morning and evening. 1 applicatorful (37.5 mg) intravaginally at bedtime or b.i.d. for 5 days.
mupirocin 2% Bactroban, Bactroban Cream, Bactroban Nasal	To treat impetigo To treat secondary infections of traumatic skin lesions due to <i>Staphylococcus aureus</i> and <i>Streptococcus pyogenes</i> To eradicate nasal colonization of methicillin-resistant <i>S. aureus</i>	Apply to affected areas t.i.d. for 1 to 2 wk. Apply thin film and cover with an occlusive dressing t.i.d. for 10 days. Apply half of the contents of a unit-dose tube to each nostril b.i.d. for 5 days.
neomycin sulfate Myciguent	To prevent or treat superficial bacterial infections	Rub fingertip-size dose into affected area once daily to t.i.d.
nitrofurazone Furacin	As adjunct to treat third-degree burns and to treat infection in skin grafts	Apply aseptically, directly to lesions or on gauze; repeat p.r.n.
povidone-iodine Betadine, Betadine Cream, Betadine Spray	To disinfect wounds and burns	Apply or spray to affected area p.r.n.
silver sulfadiazine Flamazine (CAN), Silvadene, Thermazine	To prevent and treat bacterial and fungal infection in second- and third-degree burns	Apply 1/16-inch layer aseptically once to twice daily to clean debrided burns; reapply promptly if removed.
sulfacetamide sodium 10% Klaron	To treat acne vulgaris	Apply thin film b.i.d.
sulfacetamide sodium 10% and sulfur 5% Sulfacet-R	To treat acne rosacea, acne vulgaris, and seborrheic dermatitis	Apply thin film, and massage into affected area once daily to t.i.d.
tetracycline hydrochloride Achromycin, Topicycline	To treat acne vulgaris To prevent or treat superficial skin infections due to susceptible bacteria	Rub solution into affected area b.i.d. Apply to affected area b.i.d. (morning and evening) or t.i.d.

Selected Topical Drugs (continued)

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Antifungals		
butenafine hydrochloride 1% Lotrimin Ultra, Mentax	To treat tinea corporis, tinea cruris, or tinea versicolor	Apply to affected surrounding area once daily for 2 wk.
	To treat interdigital tinea pedis due to <i>Epidermophyton floccosum</i> , <i>Trichophyton mentagrophytes</i> , or <i>T. rubrum</i>	Apply to affected and immediately surrounding area once daily for 4 wk or b.i.d. for 1 wk.
butoconazole nitrate Femstat, Femstat One, Mycelex 3	To treat vulvovaginal mycotic infections caused by <i>Candida</i> species	1 applicatorful (100 mg) intravaginally at bedtime for 3 days; may repeat course for total of 6 days.
	Gynazole-1	To treat vulvovaginal infections caused by <i>Candida albicans</i>
ciclopirox olamine 1% Loprox 0.77%	To treat candidiasis due to <i>Candida albicans</i> ; tinea corporis, tinea cruris, and tinea pedis due to <i>E. floccosum</i> , <i>T. mentagrophytes</i> , <i>T. rubrum</i> , or <i>Microsporum canis</i> ; tinea versicolor due to <i>Malassezia furfur</i> ; onychomycosis due to <i>T. rubrum</i> ; and seborrheic dermatitis	Massage gently into affected and surrounding area b.i.d., morning and evening.
	ciclopirox olamine 8% Penlac	To treat onychomycosis of the fingernails and toenails
clotrimazole Canesten (CAN), Gyne-Lotrimin, Gyne-Lotrimin 3, Lotrimin, Lotrimin Antifungal, Mycelex, Mycelex-7, Mycelex-G, Mycelex OTC, Trivagizole 3	To treat superficial fungal infections (tinea corporis, tinea cruris, tinea pedis, tinea versicolor, candidiasis)	Apply thin film and massage into affected and surrounding area b.i.d., morning and evening, for 2 to 4 wk.
	To treat vulvovaginal candidiasis	Insert 100-mg vaginal tablet at bedtime for 7 days; or 500-mg vaginal tablet at bedtime for 1 day; or 1 applicatorful intravaginally at bedtime for 7 days (or 3 days if using Trivagizole 3).
	To treat oropharyngeal candidiasis	Dissolve oral troche over 15 to 30 min 5 times/day for 14 days.
	To prevent oropharyngeal candidiasis	Dissolve oral troche over 15 to 30 min t.i.d. for duration of chemotherapy or until corticosteroid dosage is reduced to maintenance levels.

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Miscellaneous topical drugs (continued)		
permethrin 1% Nix	To prevent or treat head lice	Wash and dry hair, saturate scalp with 1% cream, leave on hair for 10 min, then rinse; remove nits with provided comb; repeat in 7 days if living mites are still present.
permethrin 5% Acticin, Elimate	To treat scabies	Massage 5% cream into skin from head to soles of feet, and remove after 8 to 10 hr; repeat in 14 days if living mites are still present.
pimecrolimus 1% Elidel	To treat mild-to-moderate atopic dermatitis	Apply to affected areas b.i.d.
podofilox Condylox	To treat anogenital warts (gel); to treat external genital warts (gel or solution)	Apply 0.5% gel to anogenital warts for 3 days, then withhold for 4 days; repeat cycle up to 4 times. Apply 0.5% solution or gel to external genital warts every 12 hr in the morning and evening for 3 days, then withhold for 4 days; repeat cycle up to 4 times
pyrethrum extract and piperonyl butoxide RID, End Lice, Tegrin-LT	To treat head, pubic, and body lice	Apply to dry hair or affected body area. Massage through all hairy areas until hair is wet. Leave on hair for 10 min; then wash with warm water and soap or shampoo. Repeat in 7 to 10 days.
tacrolimus Protopic	To treat moderate to severe atopic dermatitis in patients unresponsive to other therapies	Apply thin layer to affected areas b.i.d., rubbing in gently and completely. Continue for 1 wk after signs and symptoms have disappeared.

Selected Antivirals

Antivirals are used to treat viral infections, such as influenza, human immunodeficiency virus (HIV), herpes simplex virus (HSV) I and II, herpes zoster, and cytomegalovirus (CMV) infections.

The following table lists the generic and trade names, indications, and usual adult dosages for some commonly used antivirals. Although you must individualize your care for a patient who receives an antiviral, be sure to include these general interventions in your plan of care:

- Avoid administering HIV drugs all at once.
- If patient takes an antacid, administer it 1 hour before or 2 hours after an antiviral because

antacids may reduce antiviral absorption.

- Monitor hepatic enzyme levels to detect elevations and help prevent hepatotoxicity.
- Monitor BUN and serum creatinine levels to detect signs of impaired renal function.
- Monitor I.V. injection site for pain or phlebitis, which may result from the high pH of reconstituted solutions.
- Assess the immunosuppressed patient for opportunistic infections during antiviral therapy.
- Inform female patient that oral contraceptives may be ineffective when taken with HIV drugs. Suggest alternate contraceptive methods.

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Antivirals used for HIV infection		
abacavir sulfate Ziagen	To treat HIV infection	300 mg P.O. b.i.d. or 600 mg P.O. once daily
abacavir sulfate and lamivudine Epzicom	To treat HIV-1 infection	600 mg abacavir and 300 mg lamivudine (1 tablet) P.O. daily
abacavir sulfate, lamivudine, and zidovudine Trizivir	To treat HIV infection	300 mg abacavir, 150 mg lamivudine, and 300 mg zidovudine (1 tablet) P.O. b.i.d.
atazanavir sulfate Reyataz	To treat HIV infection in patients not previously treated	400 mg P.O. daily
	To treat HIV infection in patients previously treated	300 mg P.O. daily with ritonavir 100 mg P.O. daily
darunavir Prezista	To treat HIV-1 infection along with ritonavir in patients not previously treated	800 mg P.O. b.i.d.
	To treat HIV-1 infection along with ritonavir in patients previously treated	600 mg P.O. b.i.d.
delavirdine Rescriptor	To treat HIV infection	400 mg P.O. t.i.d.

Antivirals used for herpes virus infection		
acyclovir Zovirax	To treat HSV encephalitis	10 mg/kg I.V. over 1 hr every 8 hr for 21 days.
	To treat HSV genitalis	200 mg P.O. every 4 hr while awake, up to 5 times/day, for 10 days.
	To treat herpes zoster infection	800 mg P.O. every 4 hr while awake, up to 5 times/day, for 7 to 10 days; or 10 mg/kg I.V. over 1 hr every 8 hr for 7 days
famciclovir Famvir	To treat HSV genitalis	125 mg P.O. b.i.d. for 5 days.
	To treat herpes zoster infection	500 mg P.O. every 8 hr for 7 days.
foscarnet Foscavir	To treat acyclovir-resistant HSV I and II infections	40 mg/kg I.V. every hr every 8 to 12 hr for 2 to 3 wk or until healed.
idoxuridine Herplex Liquifilm, Stoxil	To treat HSV keratitis	1 cm applied to conjunctiva every 4 hr while awake, up to 5 times/day; or 1 gtt of 0.1% solution every hr during daytime and every 2 hr during nighttime for 7 to 10 days.
penciclovir Denavir	To treat HSV labialis	1% cream applied to lips every 2 hr while awake for 4 days.

(continued)

Selected Antivirals *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Antivirals used for herpes virus infection <i>(continued)</i>		
valacyclovir Valtrex	To treat HSV genitalis	1 g P.O. b.i.d. for 10 days for initial episode; 500 mg P.O. b.i.d. for 3 days for recurrent episodes
	To suppress recurrent HSV genitalis	1 g P.O. daily; or, 500 mg P.O. daily for patients with a history of nine or fewer recurrences/year or who have HIV
	To reduce transmission of genital herpes	500 mg P.O. daily for source partner with a history of nine or fewer recurrences/year
	To treat herpes zoster infection To treat herpes labialis (cold sores)	1 g P.O. t.i.d. for 7 days 2 g P.O. b.i.d. for 1 day taken 12 hr apart
vidarabine Vira-A	To treat acute viral conjunctivitis and recurrent epithelial keratitis caused by HSV infection	1.25 cm applied to conjunctiva every 3 hr until re-epithelialized; then 1.25 cm b.i.d. for 7 days
Antivirals used for CMV infection		
cidofovir Vistide	To treat CMV retinitis	5 mg/kg I.V. over 1 hr every wk for 2 wk
foscarnet Foscavir	To treat CMV infection	<i>Induction:</i> 90 mg/kg I.V. over 1.5 to 2 hr every 12 hr; or, 60 mg/kg I.V. over 1 hr every 8 hr for 2 to 3 wk. <i>Maintenance:</i> 90 to 120 mg/kg I.V. over 2 hr every 24 hr
ganciclovir Cytovene	To treat CMV infection	5 mg/kg I.V. over 1 hr every 12 hr for 14 to 21 days. <i>Maintenance:</i> 1,000 mg P.O. t.i.d.
valganciclovir hydrochloride Valcyte	To treat CMV retinitis	900 mg P.O. b.i.d. for 21 days. Then 900 mg P.O. daily
	To prevent CMV infection in high-risk kidney, heart, and kidney-pancreas transplant patients	900 mg P.O. daily, starting within 10 days of transplantation and continuing until 100 days after transplantation

Selected Antivirals (continued)

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Antivirals used for influenza infection		
oseltamivir phosphate Tamiflu	To treat uncomplicated, acute infections caused by influenza virus A or B in adults who have had symptoms for no more than 2 days	75 mg P.O. b.i.d. for 5 days, starting within 2 days after symptoms begin. <i>Maximum:</i> 75 mg b.i.d. for 5 days
	To prevent influenza following close contact with an infected person	75 mg P.O. daily for 7 days; start within 2 days of exposure
	To prevent influenza during a community outbreak	75 mg P.O. daily during period of potential exposure
zanamivir Relenza	To treat infections caused by influenza virus A or B	2 inhalations (10 mg) every 12 hr for 5 days
Antivirals used for hepatitis B infection		
adefovir dipivoxil Hepsera	To treat chronic hepatitis B	10 mg P.O. daily
		For patients with creatinine clearance of 20 to 49 ml/min/1.73 m ² , dosage interval changed to every 48 hr
		For creatinine clearance of 10 to 19 ml/min/1.73 m ² , dosage interval changed to every 72 hr
		For patients receiving hemodialysis, drug given every 7 days following dialysis
lamivudine Epivir HBV	To treat chronic hepatitis B	100 mg P.O. daily
telbivudine Tyzeka	To treat chronic hepatitis B	600 mg P.O. daily

(continued)

Selected Antivirals *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Antivirals used for hepatitis C infection		
ribavirin Copegus, Rebetol, Ribasphere	To treat chronic hepatitis C in combination with interferon alfa-2b in patients who weigh more than 75 kg (165 lb)	400 mg in the morning and 600 mg in the evening daily
	To treat chronic hepatitis C in combination with interferon alfa-2b in patients who weigh 75 kg (165 lb) or less	600 mg b.i.d.
	To treat chronic hepatitis C in combination with peginterferon alfa-2b	400 mg b.i.d.
	To treat chronic hepatitis C in combination with interferon alfa-2a in patients with compensated liver disease who have never received interferon alfa	400 to 600 mg b.i.d.

Selected Antineoplastic Drugs

Antineoplastic drugs are the standard of treatment for most types of cancer today. Most of these drugs work by inhibiting cell proliferation, which leads to cell death. They're most effective at killing actively dividing cells.

Cell-specific antineoplastics exert their actions during one or more phases of the cell cycle. S-phase antineoplastics interfere with deoxyribonucleic acid (DNA) synthesis; M-phase drugs interfere with the formation of microtubules and disrupt mitosis.

Most antineoplastics impair DNA in one of the following four ways:

- preventing separation of DNA strands
- inhibiting DNA repair
- mimicking DNA bases
- disrupting the triplicate codons or producing oxygen free radicals that damage the DNA.

Antineoplastic drugs are cytotoxic, which means that they affect both neoplastic cells and normal cells. As a result, they may cause serious and sometimes life-threatening adverse reactions.

Antineoplastics are most harmful to normal cells that exhibit rapid activity and growth, such as bone marrow tissue, the epithelium of the GI mucosa, and hair follicles. When these drugs suppress bone marrow activity, the patient may develop leukopenia, thrombocytopenia, or anemia. When they affect the GI mucosa, the patient may experience nausea, vomiting, anorexia, bowel dysfunction, and mucosal ulcerations. When antineoplastic drugs affect the hair follicles, the result is hair loss (alopecia), one of the most common adverse reactions. Although not life-threatening, hair loss can be emotionally traumatic for patients, especially women.

Antineoplastic Classification

Antineoplastic drugs are classified according to their mechanism of action.

ALKYLATING DRUGS

The first drugs developed to fight cancer, alkylating drugs are most effective against slow-growing tumors. These agents can damage tissue at the injection site and produce systemic toxicity. They can damage cells during all stages of growth, causing mitotic arrest. Because their actions are not limited to neoplastic cells, they also cause myelosuppression, a predictable adverse reaction. They can also result in secondary tumor development, even years after the initial therapy.

ANTIBIOTICS

Antibiotic antineoplastics originated from a

genus of fungus-like bacteria called *Streptomyces*. Their classification is based on their origin, not on mechanism of action, toxicity, pharmacokinetics, or varying clinical indications. Many of these drugs bind to specific bases and block DNA synthesis to interfere with cell replication.

ANTIMETABOLITES

These are cell-cycle-specific drugs that act by preventing synthesis of nucleotides or inhibiting enzymes by mimicking nucleotides. These drugs are often more effective when used in combination.

ANTIMITOTICS

Antimitotic antineoplastics disrupt the formation of microtubule structures in the cell during mitosis. This breakdown of microtubule production stops the formation of the mitotic spindle, inhibiting cellular reproduction.

BIOLOGICAL RESPONSE MODIFIERS

These drugs alter tumor-host metabolic and immunologic relationships.

ANTINEOPLASTIC ENZYMES

Antineoplastic enzymes interfere with the breakdown of extracellular asparagine, an endogenous enzyme that leukemic cells depend on for their survival. The rapid depletion of asparagine eventually kills leukemic cells by fragmenting them into membrane-bound particles that are eliminated by phagocytosis.

HORMONAL DRUGS

These drugs act as agonists to inhibit tumor cell growth or as antagonists to compete with endogenous growth-promoting hormones. Steroid hormones form specific receptor complexes that bind to certain nuclear proteins necessary for DNA transcription.

MISCELLANEOUS ANTINEOPLASTICS

These drugs act in a variety of ways, such as by destroying microtubules that are essential for tumor cell structure before mitosis and by inhibiting topoisomerase, the enzyme that affects the degree of supercoiling in DNA by cutting one or both strands. This inhibition causes DNA strands to break and synthesizes toxic compounds that inhibit DNA strand repair.

The following chart lists the generic and common trade names of common antineoplastic drugs, which are grouped according to mechanism of action. It also includes FDA-approved indications and the usual adult dosage for each drug.

(continued)

Selected Antineoplastic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Alkylating drugs		
bendamustine Treanda	<p>To treat chronic lymphocytic leukemia (CLL)</p> <p>To treat indolent B-cell non-Hodgkin's lymphoma (NHL) that has progressed within 6 months of treatment with rituximab or a rituximab-containing regimen</p>	<p>100 mg/m² I.V. infused over 30 minutes on days 1 and 2 of a 28-day cycle for up to 6 cycles</p> <p>120 mg/m² I.V. infused over 60 minutes on days 1 and 2 of a 21-day cycle for up to 8 cycles</p>
busulfan Busulfex, Myleran	<p>To provide palliative treatment of chronic myelocytic leukemia (CML)</p> <p>To prepare for hematopoietic progenitor cell transplantation for CML</p>	<p><i>Initial:</i> 0.06 mg/kg P.O. daily until WBC count is below 15,000/mm³. <i>Usual:</i> 4 to 8 mg P.O. daily (but may range from 1 to 12 mg P.O. daily) <i>Maintenance:</i> 1 to 3 mg daily. During remission, treatment resumed when WBC count reaches 50,000/mm³</p> <p>0.8 mg/kg I.V. over 2 hr every 6 hr for 4 days for a total of 16 doses as an adjunct with cyclophosphamide</p>
carmustine (BCNU) BiCNU, Gliadel Wafer	<p>To treat primary brain tumors and glioblastoma multiforme</p> <p>To treat primary brain tumors, Hodgkin's disease, non-Hodgkin's lymphoma, and multiple myeloma</p>	<p>Up to 8 implants per surgical procedure</p> <p>150 to 200 mg/m² by slow I.V. infusion as a single dose every 6 to 8 wk; or 75 to 100 mg/m² by slow I.V. infusion daily for 2 days every 6 wk</p>
chlorambucil Leukeran	<p>To provide palliative treatment of chronic lymphocytic leukemia, Hodgkin's disease, malignant lymphomas (including lymphosarcoma and giant follicular lymphoma), and non-Hodgkin's lymphoma</p>	<p>0.1 to 0.2 mg/kg/day as a single dose or in divided doses for 3 to 6 wk. <i>Usual:</i> 4 to 10 mg/day as a single dose or in divided doses for 3 to 6 wk</p>
cyclophosphamide Cytoxan, Neosar, Procytox (CAN)	<p>To treat acute lymphocytic leukemia, acute nonlymphocytic leukemia, chronic lymphocytic leukemia, chronic myelocytic leukemia, breast cancer, epithelial ovarian cancer, Hodgkin's disease, multiple myeloma, neuroblastoma, non-Hodgkin's lymphoma, and retinoblastoma</p>	<p>1 to 5 mg/kg P.O. daily; or 40 to 50 mg/kg I.V. in divided doses over 2 to 5 days; or 10 to 15 mg/kg I.V. every 7 to 10 days; or 3 to 5 mg/kg I.V. 2 times/wk; or 1.5 to 3 mg/kg I.V. daily</p>

Selected Antineoplastic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Alkylating drugs <i>(continued)</i>		
ifosfamide IFEX	To treat germ cell testicular tumors	1.2 g/m ² /day by I.V. infusion for 5 days every 3 wk
Iomustine (CCNU) CeeNU	To treat primary brain tumors and Hodgkin's disease	100 to 130 mg/m ² P.O. as a single dose every 6 wk
mechlorethamine hydrochloride (nitrogen mustard) Mustargen	To treat bronchiogenic carcinoma, CML, Hodgkin's disease, lymphosarcoma, and mycosis fungoides	0.4 mg/kg I.V. as a single dose or in divided doses over 2 to 4 days
	To treat malignant pericardial, peritoneal, or pleural effusions	0.4 mg/kg (peritoneal or pleural effusion); 0.2 mg/kg into affected cavity (pericardial effusion)
melfhalan (L-phenylalanine mustard) Alkeran melfhalan hydrochloride Alkeran	To treat multiple myeloma	0.15 mg/kg P.O. daily for 7 days; then 0.05 mg/kg daily after 3 wk of no drug. Or, 0.1 to 0.15 mg/kg daily for 2 to 3 wk or 0.25 mg/kg for 4 days; then 2 to 4 mg daily after 2 to 4 wk of no drug 16 mg/m ² /I.V. over 15 min every 2 wk for 4 doses, then at 4 wk
	To treat epithelial ovarian cancer	0.2 mg/kg P.O. daily for 5 days, repeated every 4 to 5 wk
oxaliplatin Eloxatin	To provide adjuvant treatment of stage III colon cancer	85 mg/m ² I.V. over 2 hr every 2 wk for 12 cycles with 5-fluorouracil
	To treat advanced colorectal cancer	85 mg/m ² I.V. over 2 hr every 2 wk with fluorouracil until disease progression or unacceptable toxicity
streptozocin Zanosar	To treat islet cell or pancreatic carcinoma	500 mg/m ² I.V. for 5 days every 6 wk, or 1,000 mg/m ² I.V. every wk for 2 wk
temozolomide Temodar	To treat astrocytoma	150 mg/m ² P.O. daily for first 5 days of 28-day cycle, followed by 200 mg/m ² P.O. daily, if tolerated, for first 5 days of subsequent 28-day cycles
	To treat glioblastoma multiforme	75 mg/m ² P.O. or I.V. over 90 min for 42 consecutive days, followed by maintenance dose of 150 mg/m ² P.O. or I.V. over 90 min daily for first 5 days of every 28 days for 6 cycles as adjunct to radiotherapy
	To treat refractory anaplastic astrocytoma	150 mg/m ² P.O. or I.V. over 90 min daily for first 5 days of every 28 days

(continued)

Selected Antineoplastic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Alkylating drugs <i>(continued)</i>		
thiotepa (TESPA, triethylenethiophosphoramide, TSPA) Thioplex	To treat malignant pericardial or pleural effusions	0.6 to 0.8 mg/kg into affected cavity
	To treat breast cancer, epithelial ovarian cancer, and Hodgkin's disease	0.3 to 0.4 mg/kg I.V. every 1 to 4 wk, or 0.2 mg/kg for 4 to 5 days every 2 to 3 wk
	To treat bladder tumors	30 to 60 mg mixed in 30 to 60 ml of normal saline, instilled into bladder every wk for 4 wk
Antibiotic antineoplastics		
bleomycin sulfate Blenoxane	To treat non-Hodgkin's lymphoma, squamous cell carcinoma, and testicular cancer	0.25 to 0.5 unit/kg or 10 to 20 units/m ² 1 to 2 times/wk I.V., I.M., or SubQ; or 0.25 unit/kg or 15 units/m ² daily by I.V. infusion over 24 hr
	To treat Hodgkin's disease	0.25 to 0.5 unit/kg I.V., I.M., or SubQ, or 10 to 20 units/m ² 1 to 2 times/wk
	To treat malignant pleural effusions	60 units intrapleural single bolus dissolved in 50–100 ml of normal saline solution
	To treat squamous cell carcinoma of the cervix, head and neck, penis, or vulva	30 to 60 units by arterial infusion over 1 to 24 hr
cisplatin Platinol, Platinol-AQ	To treat bladder cancer	50 to 70 mg/m ² by I.V. infusion as a single dose every 3 to 4 wk with other agents
	To treat advanced ovarian cancer	75 to 100 mg/m ² by I.V. infusion as a single dose every 21 days with paclitaxel
	To treat testicular cancer	20 mg/m ² by I.V. infusion daily for 5 days with bleomycin and etoposide; repeated every 3 wk for two or more cycles
dactinomycin (actinomycin-D) Cosmegen	To treat Ewing's sarcoma, gestational trophoblastic or Wilms' tumors, rhabdomyosarcoma, sarcoma botryoides, and testicular cancer or tumors	0.15 to 500 mcg/kg/day I.V. daily for 5 days; may repeat after 3 wk
	To treat Ewing's sarcoma and sarcoma botryoides	0.05 mg/kg for lower extremity or pelvis; 0.035 mg/kg for upper extremity as an isolation-perfusion

Selected Antineoplastic Drugs (continued)

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Antibiotic antineoplastics (continued)		
daunorubicin hydrochloride Cerubidine	To treat acute lymphocytic leukemia	45 mg/m ² daily for first 3 days of a 32-day course of vincristine, prednisone, and asparaginase combination therapy
	To treat acute nonlymphocytic leukemia	45 mg/m ² daily for first 3 days of first course of cytarabine combination therapy and first 2 days of second course of cytarabine combination therapy
daunorubicin, liposomal DaunoXome	To treat AIDS-related Kaposi's sarcoma	40 mg/m ² I.V. over 60 min every 2 wk
doxorubicin hydrochloride Adriamycin PFS, Adriamycin RDF, Rubex	To treat acute lymphocytic leukemia, acute nonlymphocytic leukemia; bladder, breast, gastric, epithelial ovarian, or thyroid cancer; Hodgkin's disease; neuroblastoma or Wilms' tumor; non-Hodgkin's lymphoma; small-cell lung carcinoma; and soft-tissue sarcoma or osteosarcoma	60 to 75 mg/m ² I.V. as single dose every 21 days; or 25 to 30 mg/m ² I.V. daily for 2 to 3 days every 3 to 4 wk; or 20 mg/m ² every wk; or 40 to 60 mg/m ² every 21 to 28 days in combination with other chemotherapeutic drugs
doxorubicin, liposomal Caelyx (CAN), Doxil	To treat AIDS-related Kaposi's sarcoma	20 mg/m ² I.V. over 30 min every 3 wk as tolerated
epirubicin hydrochloride Ellence	To treat breast cancer	100 to 120 mg/m ² by I.V. infusion over 3 to 5 min via a free-flowing I.V. solution as a single dose on day 1 or in divided doses on days 1 and 8, repeated every 3 to 4 wk for 6 cycles in combination with other chemotherapy agents
everolimus Afinitor	To treat advanced renal cancer after failure with sunitinib or sorafenib	10 mg P.O. daily
idarubicin hydrochloride Idamycin	To treat acute nonlymphocytic leukemia	12 mg/m ² /day I.V. over 10 to 15 min for 3 days in combination with cytarabine therapy
mitomycin (mitomycin-C) Mutamycin	To treat gastric or pancreatic cancer	20 mg/m ² as a single dose every 6 to 8 wk

(continued)

Selected Antineoplastic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Antibiotic antineoplastics <i>(continued)</i>		
pentostatin (2'-deoxycoformycin) Nipent	To treat hairy cell leukemia	4 mg/m ² by rapid I.V. injection or diluted for infusion over 20 to 30 min as a single dose every other wk
plicamycin (mithramycin) Mithracin	To treat testicular cancer To treat hypercalcemia and hypercalciuria	0.025 to 0.03 mg/kg I.V. daily over 4 to 6 hr for 8 to 10 days 0.015 to 0.025 mg/kg I.V. daily over 4 to 6 hr for 3 to 4 days; may repeat dose every wk as needed
romidepsin Istodax	To treat cutaneous T-cell lymphoma in patients who have received one previous systemic therapy	14 mg/m ² I.V. over 4 hr on days 1, 8, and 15 of a 28-day cycle, repeated every 28 days
valrubicin Valstar	To treat bladder cancer	800 mg every wk for 6 wk into affected cavity
Antimetabolites		
capecitabine Xeloda	To treat locally advanced or metastatic breast cancer or metastatic colorectal cancer	1,250 mg/m ² P.O. after a meal b.i.d. (morning and evening) for 2 wk, followed by 1-wk rest period; dose repeated in 3-wk cycles
cladribine (2-CdA, 2-chlorodeoxyadenosine) Leustatin	To treat hairy cell leukemia	0.1 mg/kg/day by continuous I.V. infusion for 7 days
cytarabine (ARA-C, cytosine arabinoside) Cytosar, Cytosar-U	To treat acute nonlymphocytic leukemia To treat meningeal leukemia To prevent or treat acute lymphocytic leukemia and chronic myelocytic leukemia	Initially, 100 mg/m ² /day by continuous I.V. infusion for 7 days, alone or with other agents; or 100 mg/m ² I.V. every 12 hr on days 1 to 7, then consult manufacturer's literature for specific dosing; or high-dose therapy of 2 to 3 g/m ² I.V. over 1 to 3 hr for 2 to 6 days, then consult manufacturer's literature for specific dosing 30 mg/m ² intrathecally as a single dose every 4 days Consult manufacturer's literature for specific dosage.

Selected Antineoplastic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Antimetabolites <i>(continued)</i>		
cytarabine, liposomal DepoCyt, Depro Tech	To treat lymphomatous meningitis	Initially, 50 mg intrathecally (intraventricular or lumbar puncture) over 1 to 5 min every 14 days for two doses (wk 1 and 3); then 50 mg intrathecally every 14 days for three doses (wk 5, 7, and 9), followed by 1 50-mg dose at wk 13; then 50 mg intrathecally every 28 days for four doses (wk 17, 21, 25, and 29) in combination with dexamethasone 4 mg P.O. or I.V. b.i.d. for 5 days
floxuridine (fluorodeoxyuridine) FUDR	To treat colorectal or hepatic cancer	0.1 to 0.6 mg/kg/day by continuous intra-arterial infusion for 14 to 21 days, followed by 2 wk of no drug; dose repeated in 5-wk cycles
fludarabine phosphate Fludara	To treat chronic lymphocytic leukemia	25 mg/m ² I.V. infused over 30 min for 5 days; cycle repeated every 28 days
fluorouracil (5-fluorouracil, 5-FU) Adrucil, Carac, Efudex, Fluoroplex	To treat colorectal, breast, gastric, or pancreatic cancer	7 to 12 mg/kg/day I.V. for 4 days, followed by no drug for 3 days, then 7 to 10 mg/kg every 3 to 4 days for total of 2 wk; or 12 mg/kg/day for 4 days, followed by 1 day of no drug, then 6 mg/kg every other day for 4 or 5 days, for total of 12 days; thereafter, 7 to 12 mg/kg/day I.V. every 7 to 10 days
	To treat multiple actinic (solar) keratoses	0.5% cream (face, anterior scalp), 1% cream (head, neck, chest), or 2% to 5% cream (hands) applied to skin once or twice daily to cover lesions
	To treat superficial basal cell carcinoma	5% cream applied to skin b.i.d. for up to 12 wk to cover lesions
hydroxyurea Droxia, Hydrea	To treat epithelial ovarian cancer	60 to 80 mg/kg P.O. as a single dose every 3 days alone or with radiation therapy; or 20 to 30 mg/kg P.O. daily
	To treat resistant chronic myelocytic leukemia	20 to 30 mg/kg P.O. once daily or in divided doses b.i.d.

(continued)

Selected Antineoplastic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Antimetabolites <i>(continued)</i>		
mercaptopurine (6-mercaptopurine, 6-MP) Purinethol	To treat acute lymphocytic leukemia or acute nonlymphocytic leukemia	2.5 mg/kg/day or 80 to 100 mg/m ² /day (rounded to nearest 25 mg) P.O. as a single dose or in divided doses, followed by 1.5 to 2.5 mg/kg/day P.O. or 50 to 100 mg/m ² /day
methotrexate (amethopterin) methotrexate sodium	To treat chorioadenoma destruens, choriocarcinoma, or hydatidiform mole To treat acute lymphocytic leukemia or meningeal leukemia To treat Burkitt's lymphoma (stage I or II) To treat Burkitt's lymphoma (stage III) To treat lymphosarcoma (stage III) To treat mycosis fungoides To treat osteosarcoma To treat breast or head and neck cancer and non-small-cell or small-cell lung carcinoma	15 to 30 mg/day P.O. or I.M. for 5 days; repeat three to five times with 2 to 3 wk between courses Initially, 3.3 mg/m ² /day P.O., I.M., or I.V. in combination with prednisone or other drug; as maintenance dose, 30 mg/m ² /wk P.O. or I.M. in two divided doses or 2.5 mg/kg I.V. every 14 days 10 to 25 mg/day P.O. for 4 to 8 days, followed by no drug for 7 to 10 days; course repeated as needed Same as for stage I or II in combination with other drug 0.625 to 2.5 mg/kg/day P.O. 2.5 to 10 mg/day P.O. for weeks or months; or 50 mg I.M. every wk or 25 mg I.M. 2 times/wk 12 g/m ² by I.V. infusion over 12 hr, followed by leucovorin rescue on weeks 4, 5, 6, 7, 11, 12, 15, 16, 29, 30, 44, and 45 after surgery in combination with bleomycin, cisplatin, cyclophosphamide, dactinomycin, and doxorubicin Consult manufacturer's literature for specific dosing.
pemetrexed disodium Alimta	To treat nonsquamous non-small-cell lung cancer or malignant pleural mesothelioma To treat nonsquamous non-small-cell lung cancer	500 mg/m ² I.V. over 10 min on day 1 of each 21-day cycle as adjunct to cisplatin 500 mg/m ² I.V. over 10 min on day 1 of each 21-day cycle

Selected Antineoplastic Drugs (continued)

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Antimetabolites (continued)		
pralatrexate Folotyln	To treat peripheral T-cell lymphoma	30 mg/m ² I.V. over 3 to 5 min once weekly for 6 wk in 7-wk cycles
thioguanine (6-TG, 6-thioguanine) Lanvis (CAN), Tabloid	To treat acute nonlymphocytic leukemia	2 mg/kg/day P.O. as a single dose; if no improvement after 4 wk, increase to 3 mg/kg/day
Antimitotic antineoplastics		
docetaxel Taxotere	To treat breast cancer	60 to 100 mg/m ² by I.V. infusion over 1 hr every 3 wk
	To treat non-small-cell lung carcinoma	75 mg/m ² by I.V. infusion over 1 hr every 3 wk
ixabepilone Ixempra	To treat advanced breast cancer	40 mg/m ² I.V. over 3 hr every 3 wk, as adjunct to capecitabine, as needed
paclitaxel Taxol	To treat ovarian cancer	135 or 175 mg/m ² by I.V. infusion over 3 or 24 hr every 21 days
	To treat breast cancer	175 mg/m ² by I.V. infusion over 3 or 24 hr every 21 days
	To treat AIDS-related Kaposi's sarcoma	135 mg/m ² by I.V. infusion over 3 or 24 hr every 21 days; or 100 mg/m ² by I.V. infusion over 3 or 24 hr every 14 days
	To treat non-small-cell lung carcinoma	135 mg/m ² by I.V. infusion over 3 or 24 hr, followed by cisplatin 75 mg/m ² I.V. every 21 days
vinblastine sulfate (VLB) Velban, Velbe (CAN)	To treat breast cancer, Hodgkin's disease, lymphomas, Kaposi's sarcoma, Letterer-Siwe disease, mycosis fungoides, non-Hodgkin's lymphoma, testicular cancer, and trophoblastic gestational tumors	0.15 to 0.2 mg/kg I.V. every wk
vincristine sulfate (VCR) Oncovin, Vincasar PFS	To treat acute lymphocytic leukemia, Hodgkin's disease, lymphomas, non-Hodgkin's lymphoma, rhabdomyosarcoma, and Wilms' tumor	0.01 to 0.03 mg/kg I.V.; or 0.4 to 1.4 mg/m ² I.V. every wk as a single dose (maximum of 2 mg)

Selected Antineoplastic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Antimitotic antineoplastics <i>(continued)</i>		
vinorelbine tartrate Navelbine	To treat non–small-cell lung carcinoma	30 mg/m ² I.V. over 6 to 10 min every wk alone, or 25 mg/m ² I.V. over 6 to 10 min every wk with cisplatin 100 mg/m ² every 4 wk
Antineoplastic enzymes		
asparaginase Colaspase, Elspar, Kidrolase (CAN)	To treat acute lymphocytic leukemia	200 international units/kg I.V. daily for 28 days
pegaspargase (PEG-L-asparaginase) Oncaspar	To treat acute lymphoblastic leukemia in adults up to age 21	2,500 international units/m ² I.M. or I.V. every 14 days
Biological response modifiers		
aldesleukin (IL-2, interleukin-2) Proleukin	To treat renal cancer and metastatic melanoma	600,000 international units/kg by I.V. infusion over 15 min every 8 hr for 14 doses; then 9 days of no drug; then repeat course of 14 doses for total of 28 doses
alemtuzumab Campath	To treat B-cell chronic lymphocytic leukemia	<i>Initial:</i> 3 mg I.V. over 2 hr daily, then increased to 10 mg I.V. over 2 hr daily. <i>Maintenance:</i> 30 mg I.V. over 2 hr 3 times/wk on alternate days for up to 12 wk
bacillus Calmette-Guérin (BCG) live, Connaught strain ImmuCyst (CAN), TheraCys	To treat bladder cancer	81 mg (reconstitute and dilute with 50 ml preservative-free normal saline solution to 53 ml or less) instilled into bladder for 1 to 2 hr every wk for 6 wk, then as a single-dose treatment at 3, 6, 12, 18, and 24 mo
bacillus Calmette-Guérin, Tice strain TICE BCG		50 mg (reconstitute and dilute with 50 ml preservative-free normal saline to 50 ml or less) for 1 to 2 hr every 6 wk; may repeat once, followed by single-dose treatment every mo for 6 to 12 mo

Selected Antineoplastic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Biological response modifiers <i>(continued)</i>		
denileukin diftitox Ontak	To treat cutaneous or T-cell lymphomas, including mycosis fungoides	9 or 18 mcg/kg/day by I.V. infusion over at least 15 min for 5 days; repeated every 21 days
interferon alfa-2a, recombinant Roferon-A	To treat hairy cell leukemia	3 million units/day I.M. or SubQ for 16 to 24 wk, followed by 3 million units 3 times/wk
	To treat AIDS-related Kaposi's sarcoma	36 million units/day I.M. or SubQ for 10 to 12 wk; or 3 million units/day I.M. or SubQ on days 1 to 3, 9 million units/day on days 4 to 6, 18 million units/day on days 7 to 9, and 36 million units/day from day 10 until completion of 10- to 12-wk course; maintenance dose, 36 million units 3 times/wk
interferon alfa-2b, recombinant Intron A	To treat hairy cell leukemia	2 million units/m ² I.M. or SubQ 3 times/wk
	To treat AIDS-related Kaposi's sarcoma	30 million units/m ² I.M. or SubQ 3 times/wk
	To treat malignant melanoma	20 million units/m ² by I.V. infusion on days 1 to 5 every wk for 4 wk, followed by 10 million units/m ² I.V. 3 times/wk for 48 wk
levamisole hydrochloride Ergamisol	To treat colorectal cancer	Beginning 7 to 30 days after surgery, 50 mg P.O. every 8 hr for 3 days, repeated every 2 wk for 1 yr, with fluorouracil 450 mg/m ² by rapid I.V. infusion daily for 5 days, starting with first or second course of levamisole
Hormonal antineoplastics		
anastrozole Arimidex	To treat breast cancer	1 mg P.O. daily
bicalutamide Casodex	To treat prostate cancer	50 mg P.O. daily in combination with luteinizing hormone-releasing hormone (LHRH) analog or after surgical castration

(continued)

Selected Antineoplastic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Hormonal antineoplastics <i>(continued)</i>		
degarelix Firmagon	To treat advanced prostate cancer	<i>Initial:</i> 240 mg SubQ divided into 2 injections; then 80 mg SubQ every 28 days
estramustine phosphate sodium Emcyt	To treat prostate cancer To treat postmenopausal breast cancer	14 mg/kg/day P.O. in three or four divided doses 1 hr before or 2 hr after meals
exemestane Aromasin	To treat prostate cancer As adjunct for postmenopausal women with estrogen receptor-positive early breast cancer who have received 2 to 3 yr of tamoxifen therapy To treat advanced breast cancer in postmenopausal women whose disease has progressed after tamoxifen therapy	25 mg P.O. daily after a meal 25 mg P.O. daily until completion of 5 years with combined therapy 25 mg P.O. daily
flutamide Euflex (CAN), Eulexin	To treat breast cancer	250 mg P.O. every 8 hr
goserelin acetate Zoladex, Zoladex LA, Zoladex 3-Month	To treat prostate cancer	3.6 mg SubQ into upper abdominal wall every 28 days 3.6 mg SubQ into upper abdominal wall every 28 days; or 10.8 mg SubQ every 12 wk
letrozole Femara	To treat breast cancer	2.5 mg P.O. daily
leuprolide acetate Lupron, Lupron Depot, Lupron Depot-3 Month, Lupron Depot-4 Month, Viadur	To treat prostate cancer	<i>Regular:</i> 1 mg SubQ daily; <i>Depot:</i> 7.5 mg every mo; or 22.5 mg every 3 mo; or 30 mg every 4 mo; <i>Implant:</i> 1 every 12 mo
medroxyprogesterone acetate Depo-Provera	To treat endometrial or renal cancer	400 to 1,000 mg every wk until stable, then 400 mg or more every mo

Selected Antineoplastic Drugs (continued)

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Hormonal antineoplastics (continued)		
megestrol acetate Megace	To treat breast cancer To treat endometrial cancer	160 mg/day P.O. daily or in divided doses 40 to 320 mg P.O. daily or in divided doses
nilutamide Anandron (CAN), Nilandron	To treat prostate cancer	300 mg P.O. daily up to 30 days, then 150 mg P.O. daily
tamoxifen citrate Apo-Tamox (CAN), Gen-Tamoxifen (CAN), Nolva-dex, Nolvadex-D (CAN), NovoTamoxifen (CAN), Tamofen (CAN), Tamone (CAN)	To prevent breast cancer or reduce the risk of invasive breast cancer in women with ductal carcinoma in situ To treat breast cancer (node-negative or node-positive)	20 mg P.O. daily for 5 yr 10 mg P.O. b.i.d. or, in metastatic disease, 10 to 20 mg P.O. b.i.d.
testolactone Teslac	To treat breast cancer	250 mg P.O. q.i.d.
toremifene citrate Fareston	To treat breast cancer	60 mg P.O. daily
triptorelin pamoate Trelstar LA	To provide palliative treatment of advanced prostate cancer	11.25 mg I.M. every 84 days
Miscellaneous antineoplastics		
arsenic trioxide Trisenox	To treat acute promyelocytic leukemia	<i>Induction:</i> 0.15 mg/kg I.V. daily until bone marrow remission occurs. <i>Maximum:</i> 60 doses. <i>Consolidation:</i> Begun 3 to 6 wk after completion of induction, 0.15 mg/kg I.V. daily for 25 doses over up to 5 wk

(continued)

Selected Antineoplastic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Miscellaneous antineoplastics <i>(continued)</i>		
bexarotene Targretin	To treat cutaneous manifestations of cutaneous T-cell lymphoma	300 mg/m ² P.O. daily with food; after 8 wk, may increase to 400 mg/m ² P.O. daily with food, as needed and tolerated.
Targretin Gel	To treat cutaneous lesions of cutaneous T-cell lymphoma (stages IA and IB)	Apply generously to cover only lesions every other day on 1st wk; then increased as tolerated to once daily on 2nd wk, b.i.d. on 3rd wk, t.i.d. on 4th wk and, finally, q.i.d. on 5th wk
bevacizumab Avastin	To treat metastatic colorectal cancer	5 or 10 mg/kg I.V. over 90 min every 2 wk as adjunct to I.V. fluorouacil-based chemotherapy
	To treat non-squamous, non-small-cell lung cancer	15 mg/kg I.V. over 90 min every 3 wk as adjunct to carboplatin and paclitaxel
	To treat metastatic breast cancer	10 mg/kg I.V. over 90 min every 2 wk as adjunct to paclitaxel
	To treat glioblastoma	10 mg/kg I.V. over 90 min every 2 wk
	To treat metastatic renal cell cancer	10 mg/kg I.V. over 90 min every 2 wk as adjunct to interferon alfa
dacarbazine DTIC (CAN), DTIC-Dome	To treat Hodgkin's disease	150 mg/m ² I.V. daily for 5 days in combination with other drugs; may repeat every 28 days; or 375 mg/m ² every 15 days in combination with other drugs
	To treat malignant melanoma	2 to 4.5 mg/kg I.V. daily for 10 days and every 28 days thereafter; or 250 mg/m ² I.V. daily for 5 days and every 21 days thereafter
etoposide (VP-16) Toposar, VePesid	To treat germ-cell testicular tumors	50 to 100 mg/m ² /day I.V. on days 1 through 5 up to 100 mg/m ² I.V. on days 1, 3, and 5; course repeated every 3 to 4 wk
	To treat small-cell lung carcinoma	35 mg/m ² /day I.V. for 4 days up to 50 mg/m ² /day I.V. for 5 days, repeated every 3 to 4 wk; or 70 mg/m ² /day P.O. for 4 days to 100 mg/m ² /day P.O. for 5 days, repeated every 3 to 4 wk

Selected Antineoplastic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Miscellaneous antineoplastics <i>(continued)</i>		
etoposide phosphate Etopophos	To treat germ-cell testicular tumors	50 to 100 mg/m ² /day by I.V. infusion on days 1 through 5 to 100 mg/m ² /day by I.V. infusion on days 1, 3, and 5; course repeated every 3 to 4 wk
	To treat small-cell lung carcinoma	35 mg/m ² /day by I.V. infusion for 4 days to 50 mg/m ² /day by I.V. infusion for 5 days, repeated every 3 to 4 wk
gemcitabine hydrochloride Gemzar	To treat non–small-cell lung carcinoma	1,000 mg/m ² by I.V. infusion over 30 min daily on days 1, 8, and 15 every 28 days with cisplatin 100 mg/m ² on day 28; or 1,250 mg/m ² I.V. daily on days 1 and 8 every 21 days in combination with cisplatin 100 mg/m ² I.V. on day 21
	To treat pancreatic cancer	1,000 mg/m ² by I.V. infusion over 30 min every wk for 7 wk, followed by 1 wk of no drug; then every wk for 3 wk, followed by 1 wk of no drug; then repeat 4-wk cycle
gemtuzumab ozogamicin Mylotarg	To treat first relapse in patients with CD33-positive acute myeloid leukemia who are age 60 or over and who are not candidates for cytotoxic therapy	9 mg/m ² by I.V. infusion over 2 hr; repeated in 14 days
imatinib mesylate Gleevec	To treat chronic myeloid leukemia in accelerated phase or blast crisis, or in chronic phase after failure of interferon-alpha therapy	400 mg P.O. daily with food (chronic phase) or 600 mg P.O. daily with food (accelerated phase or blast crisis); after 3 mo, dosage may be increased to 600 mg P.O. daily (chronic phase) or 800 mg P.O. given in 2 divided doses of 400 mg (accelerated phase or blast crisis), as needed.
	To treat GI stromal tumor	400 mg/day P.O. or 600 mg/day P.O.
irinotecan hydrochloride Camptosar	To treat colorectal cancer	125 mg/m ² I.V. over 90 min every wk for 4 wk, followed by 2 wk of no drug, then repeat 6-wk cycle; or 350 mg/m ² I.V. over 90 min every 3 wk

(continued)

Selected Antineoplastic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Miscellaneous antineoplastics <i>(continued)</i>		
iressa Gefitinib	To treat refractory metastatic non–small-cell lung cancer	250 mg P.O. daily
ixabepilone Ixempra	To treat metastatic or locally advanced breast cancer in combination with capecitabine after failure with an anthracycline and a taxane; to treat metastatic or locally advanced breast cancer after failure with an anthracycline, a taxane, and capecitabine	40 mg/m ² I.V. infused over 3 hr every 3 wk
mitotane (o,p'-DDD) Lysodren	To treat adrenocortical carcinoma	2 to 6 g P.O. daily in divided doses t.i.d. or q.i.d.
mitoxantrone hydrochloride Novantrone	To treat hormone-refractory prostate cancer To treat acute nonlymphocytic leukemia	12 to 14 mg/m ² I.V. every 21 days 12 mg/m ² by I.V. infusion in free-flowing normal saline solution or D ₅ W over 3 min daily on days 1 to 3, with cytarabine 100 mg/m ² /day by continuous I.V. infusion on days 1 to 7; if response is inadequate, second course at same dosage may be given
nilotinib Tasigna	To treat Philadelphia chromosome positive chronic myelogenous leukemia	400 mg P.O. every 12 hr
porfimer sodium Photofrin	To treat esophageal cancer and non–small-cell lung carcinoma	2 mg/kg I.V. over 3 to 5 min, followed by laser light illumination and debridement of tumor; may repeat course every 30 days three times
procarbazine hydrochloride Matulane, Natulan (CAN)	To treat Hodgkin's disease	2 to 4 mg/kg/day (rounded to nearest 50 mg) P.O. as a single dose or in divided doses for 1 wk, followed by 4 to 6 mg/kg/day until leukopenia, thrombocytopenia, or maximal response
rituximab Rituxan	To treat non-Hodgkin's lymphomas	375 mg/m ² /day by I.V. infusion every wk for 4 or 8 doses

Selected Antineoplastic Drugs *(continued)*

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Miscellaneous antineoplastics <i>(continued)</i>		
sorafenib Nexavar	To treat unresectable hepatocellular carcinoma; to treat advanced renal cell carcinoma	400 mg P.O. b.i.d.
sunitinib malate Sutent	To treat GI stromal tumor progression To treat advanced renal cell cancer	50 mg P.O. daily for 4 wk, followed by 2 wk off; then cycle repeated as needed
topotecan hydrochloride Hycamtin	To treat ovarian cancer and small-cell lung carcinoma	1.5 mg/m ² I.V. over 30 min daily for 5 days, repeated every 21 days
trastuzumab Herceptin	To treat breast cancer	4 mg/kg I.V. over 90 min, followed by 2 mg/kg I.V. over 30 min every 7 days
velcade Bortezomib	To treat multiple myeloma	1.3 mg/m ² I.V. bolus on days 1, 4, 8, and 11 for 2 wk, followed by rest on days 12–21; then repeat 3-wk cycle

Selected Antihypertensive Combinations

Antihypertensive drugs are used along with lifestyle changes to manage hypertension. Antihypertensive combinations, which commonly include one or two antihypertensives

and a diuretic, are used to simplify patients' drug regimens and, in some cases, to enhance drug actions.

The table below lists the generic and trade

ANTIHYPERTENSIVE COMBINATION TRADE NAMES	ANTIHYPERTENSIVE GENERIC NAMES	DIURETIC GENERIC NAMES
Aldoril-15	methyldopa 250 mg	hydrochlorothiazide (HCTZ) 15 mg
Aldoril-25	methyldopa 250 mg	HCTZ 25 mg
Aldoril D30	methyldopa 500 mg	HCTZ 30 mg
Aldoril D50	methyldopa 500 mg	HCTZ 50 mg
Apresazide 25/25	hydralazine hydrochloride (HCl) 25 mg	HCTZ 25 mg
Apresazide 50/50	hydralazine HCl 50 mg	HCTZ 50 mg
Apresazide 100/50	hydralazine HCl 100 mg	HCTZ 50 mg
Atacand HCT 16/12.5	candesartan cilexetil 16 mg	HCTZ 12.5 mg
Atacand HCT 32/12.5	candesartan cilexetil 32 mg	HCTZ 12.5 mg
Avalide-150	irbesartan 150 mg	HCTZ 12.5 mg
Avalide-300	irbesartan 300 mg	HCTZ 12.5 mg
Azor 5/20	amlodipine 5 mg, olmesartan 20 mg	None
Azor 5/40	amlodipine 5 mg, olmesartan 40 mg	
Azor 10/20	amlodipine 10 mg, olmesartan 20 mg	
Azor 10/40	amlodipine 10 mg, olmesartan 40 mg	
Benicar HCT 20/12.5	olmesartan medoxomil 20 mg	HCTZ 12.5 mg
Benicar HCT 40/12.5	olmesartan medoxomil 40 mg	HCTZ 12.5 mg
Benicar HCT 40/25	olmesartan medoxomil 40 mg	HCTZ 25 mg
Capozide 25/15	captopril 25 mg	HCTZ 15 mg
Capozide 25/25	captopril 25 mg	HCTZ 25 mg
Capozide 50/15	captopril 50 mg	HCTZ 15 mg
Capozide 50/25	captopril 50 mg	HCTZ 25 mg

names; functional classes; usual adult dosages; and onset, peak, and duration for commonly used antihypertensive combinations. For information about the mechanisms of action, inter-

actions, adverse reactions, and nursing considerations related to antihypertensive combinations, review the entries for the specific antihypertensives and diuretics that they contain.

Vitamins

As you know, an adequate daily intake of vitamins is essential to vital bodily functions, such as embryonic development (vitamin A), regulation of serum calcium and phosphate (vitamin D), and blood clotting (vitamin K).

Vitamins are classified as one of two types:

fat soluble (vitamins A, D, E, and K) and water soluble (vitamin C and all forms of vitamin B). Fat-soluble vitamins can accumulate in body tissue over time; when excessive amounts are ingested through diet or supplementation, severe and life-threatening toxicity can devel-

GENERIC AND TRADE NAMES

vitamin A (retinol)

Aquasol A

RECOMMENDED DAILY INTAKE

Adult men and boys over age 10. 1,000 mcg/day.

Adult women and girls over age 10. 800 mcg/day.

Pregnant women. 800 mcg/day. (900 mcg/day [CAN].)

Breast-feeding women. 1,200 to 1,300 mcg/day. (1,200 mcg/day [can].)

Children ages 7 to 10. 700 mcg/day. (700 to 800 mcg/day [CAN].)

Children ages 4 to 7. 500 mcg/day.

Neonates and children to age 4. 375 to 400 mcg/day. (400 mcg/day [CAN].)

vitamin B₁ (thiamine hydrochloride)

Betaxin (CAN), Bewon (CAN), Biamine

Adult men and boys over age 10. 1.2 to 1.5 mg/day. (0.8 to 1.3 mg/day [CAN].)

Adult women and girls over age 10. 1 to 1.1 mg/day. (0.8 to 0.9 mg/day [CAN].)

Pregnant women. 1.5 mg/day. (0.9 to 1 mg/day. [CAN].)

Breast-feeding women. 1.6 mg/day. (1 to 1.2 mg/day [CAN].)

op. Water-soluble vitamins don't accumulate in the body; they are excreted daily so that toxicity is not usually a concern with excessive intake.

The following chart lists the generic and trade names of fat-soluble and water-soluble

vitamins, the recommended daily intake to prevent vitamin deficiency, dosages when deficiency occurs, other indications and dosages for vitamin therapy, and guidelines for parenteral administration of vitamins.

OTHER INDICATIONS AND DOSAGES

TO TREAT VITAMIN A DEFICIENCY

CAPSULES, ORAL SOLUTION, TABLETS

Adults and adolescents. Dosage individualized based on severity of deficiency, as prescribed.

I.M. INJECTION

Adults and children age 8 and over. 15,000 to 30,000 retinol equivalent (RE)/day (50,000 to 100,000 international units (IU)/day) for 3 days, followed by 15,000 RE/day (50,000 IU/day) for 2 wk.

Children ages 1 to 8. 1,500 to 4,500 RE/day (5,000 to 15,000 IU/day) for 10 days; for severe deficiency, 5,250 to 10,500 RE/day (17,500 to 35,000 IU/day) for 10 days.

Infants to age 1 year. 1,500 to 3,000 RE/day (5,000 to 10,000 IU/day) for 10 days; for severe deficiency, 2,250 to 4,500 RE/day (7,500 to 15,000 IU/day) for 10 days.

I.V. INFUSION

Adults and children. Dosage individualized as part of total parenteral nutrition solution, as prescribed.

TO TREAT XEROPHTHALMIA

CAPSULES, ORAL SOLUTION, TABLETS

Children age 1 and over. 60,000 RE (200,000 IU) as a single dose. Dose repeated on day 2 and again in 4 wk.

Children ages 6 months to 1 year. 30,000 RE (100,000 IU) as a single dose. Dose repeated on day 2 and again in 4 wk.

AS AN ADJUNCT TO TREAT MEASLES

CAPSULES, ORAL SOLUTION, TABLETS

Children age 1 and over. 60,000 RE (200,000 IU) as a single dose when measles are diagnosed.

Children ages 6 months to 1 year. 30,000 RE (100,000 IU) as a single dose when measles are diagnosed.

TO TREAT VITAMIN B₁ DEFICIENCY (BERIBERI)

ELIXIR, TABLETS

Adults. 5 to 10 mg t.i.d.

Children and infants. 10 mg/day.

I.V. OR I.M. INJECTION

Adults. *Initial:* 5 to 100 mg every 8 hr, switched to P.O. vitamin B₁ therapy as soon as possible and continued for total of 1 mo.

PARENTERAL ADMINISTRATION GUIDELINES

- Be aware that anaphylaxis and death have occurred after I.V. administration of vitamin A. I.V. administration is restricted to special solutions, such as in total parenteral nutrition solution. Typically, parenteral administration of vitamin A is by I.M. injection.
- Take precautions to protect vitamin A solution from exposure to light because it's light sensitive.

- Be aware that I.V. administration of vitamin B₁ has caused severe and life-threatening reactions, especially with repeat administration. Monitor patient closely for angioedema, GI bleeding, respiratory distress, throat tightness, urticaria, vascular collapse, and weakness during and after administration.

(continued)

Vitamins (continued)

GENERIC AND TRADE NAMES

RECOMMENDED DAILY INTAKE

vitamin B₁ (continued)

Children ages 7 to 10. 1 mg/day. (0.8 to 1 mg/day [CAN].)

Children ages 4 to 7. 0.9 mg/day. (0.7 mg/day [CAN].)

Children ages 1 to 4. 0.3 to 0.7 mg/day. (0.3 to 0.6 mg/day [CAN].)

vitamin B₃ (niacin)

Endur-Acin, Nia-Bid, Niac, Niacels, Niacor, Nico-400, Nicobid Tempules, Nicolar, Nicotinex Elixir, Novo-Niacin (CAN), Slo-Niacin

Adult men and boys age 11 and over. 15 to 20 mg/day. (14 to 23 mg/day [CAN].)

Adult women and girls age 11 and over. 13 to 15 mg/day. (14 to 16 mg/day [CAN].)

Pregnant women. 17 mg/day. (14 to 16 mg/day [CAN].)

Breast-feeding women. 20 mg/day. (14 to 16 mg/day [CAN].)

Children ages 7 to 11. 13 mg/day. (14 to 18 mg/day [CAN].)

Children ages 4 to 7. 12 mg/day. (13 mg/day [can].)

Neonates and children to age 4. 5 to 9 mg/day. (4 to 9 mg/day [CAN].)

vitamin B₆ (pyridoxine hydrochloride)

Beesix, Doxine, Nestrex, Pyri, Rodex, Vita-bee 6

Adult men and boys age 11 and over. 1.7 to 2 mg/day.

Adult women and girls age 11 and over. 1.4 to 1.6 mg/day.

Pregnant women. 2.2 mg/day.

Breast-feeding women. 2.1 mg/day.

Children ages 7 to 10. 1.4 mg/day.

Children ages 4 to 6. 1.1 mg/day.

Neonates and children to age 3. 0.3 to 1 mg/day.

OTHER INDICATIONS AND DOSAGES

TO TREAT WERNICKE'S ENCEPHALOPATHY

I.V. OR I.M. INJECTION

Adults. *Initial:* 100 mg I.V. *Maintenance:* 50 to 100 mg I.V. or I.M. daily until normal recommended daily intake is achieved.

TO TREAT VITAMIN B₃ DEFICIENCY

E.R. CAPSULES, E.R. TABLETS, ORAL SOLUTION, TABLETS

Adults and children age 11 and over. Dosage individualized based on severity of deficiency, as prescribed.

Maximum: 6 g/day.

I.V. INJECTION

Adults and children age 11 and over. 25 to 100 mg at least b.i.d.

Children to age 11. Up to 300 mg daily

I.M. INJECTION

Adults and children age 11 and over. 50 to 100 mg at least 5 times/day.

Children to age 11. Dosage individualized based on severity of deficiency.

TO TREAT HYPERLIPIDEMIA (NIACIN ONLY)

E.R. CAPSULES, E.R. TABLETS, ORAL SOLUTION, TABLETS

Adults. *Initial:* 1,000 mg t.i.d. Dosage increased by 500 mg/day every 2 to 4 wk, as needed. *Maintenance:* 1 to 2 g t.i.d. *Maximum:* 6 g/day.

Dosage Adjustment To reduce or prevent facial flushing, initial dosage reduced to 100 mg/day (tab) or 500 mg/day (E.R. tab), and then gradually increased to 3 to 4 g/day.

TO TREAT VITAMIN B₆ DEFICIENCY

E.R. CAPSULES, TABLETS

Adults and children. Dosage individualized based on severity of deficiency, as prescribed.

E.R. TABLETS

Adults. Dosage individualized based on severity of deficiency, as prescribed.

I.V. INFUSION

Adults and children. Dosage individualized as part of total parenteral nutrition.

PARENTERAL ADMINISTRATION GUIDELINES

- Rotate sites for I.M. administration of vitamin B₁ to help prevent tenderness and induration that may occur following administration.
- I.M. administration may be painful; use the Z-track method of administration.
- Because of incompatibilities, don't add parenteral vitamin B₁ to alkaline or neutral solutions; also, don't mix it with oxidizing and reducing agents, including barbiturates, carbonates, citrates, and copper
- Take precautions to protect vitamin B₁ solution from exposure to light because it's light sensitive.

- Be aware that I.V. administration of vitamin B₃ may cause CNS or CV adverse reactions, such as arrhythmias, dizziness, headache, peripheral vasodilation, and syncope. Rate of I.V. administration shouldn't exceed 2 mg/min, regardless of method of I.V. administration.
- Vitamin B₃ must be diluted for I.V. use. For direct injection, dilute to 2 mg/ml; for intermittent or continuous infusion, dilute dose in 500 ml of normal saline or other compatible solution
- Give I.M. injection following routine I.M. administration guidelines. Vitamin B₃ doesn't need to be diluted for I.M. injection.
- Be aware that parenteral administration shouldn't be used to treat hyperlipidemia.

- Be aware that SubQ or I.M. administration of vitamin B₆ may cause injection site burning or stinging. Before giving injection, alert patient that this adverse effect may occur.
- Know that I.V. administration is given as part of a multivitamin solution; follow the guidelines for administering an I.V. multivitamin solution as recommended for the product being used.

GENERIC AND TRADE NAMES

RECOMMENDED DAILY INTAKE

vitamin B₆ *(continued)*

Adult men and boys age 11 and over. 1.7 to 2 mg/day.
Adult women and girls age 11 and over. 1.4 to 1.6 mg/day.
Pregnant women. 2.2 mg/day.
Breast-feeding women. 2.1 mg/day.
Children ages 7 to 10. 1.4 mg/day.
Children ages 4 to 6. 1.1 mg/day.
Neonates and children to age 3. 0.3 to 1 mg/day.

vitamin B₉ (folic acid)

Apo-Folic (CAN), Folvite,
Novo-Folacid (CAN)

Adult men and boys age 11 and over. 150 to 400 mcg/day. (150 to 220 mcg/day [CAN].)
Adult women and girls age 11 and over. 150 to 400 mcg/day. (145 to 190 mcg/day [CAN].)
Pregnant women. 400 to 800 mcg/day. (445 to 475 mcg/day [CAN].)
Breast-feeding women. 260 to 800 mcg/day. (245 to 275 mcg/day [CAN].)
Children ages 7 to 11. 100 to 400 mcg/day. (125 to 180 mcg/day [CAN].)
Children ages 4 to 7. 75 to 400 mcg/day. (90 mcg/day [CAN].)
Neonates and children to age 4. 25 mcg/day. (50 to 80 mcg/day [CAN].)

vitamin B₁₂ (cyanocobalamin, hydroxy- cobalamin)

Adults age 19 and over. 2.4 mcg/day.
Pregnant women. 2.6 mcg/day.
Breast-feeding women. 2.8 mcg/day.
Adolescents ages 14 to 19. 2.4 mcg/day.
Children ages 9 to 14. 1.8 mcg/day.
Children ages 4 to 9. 1.2 mcg/day.
Children ages 1 to 4. 0.9 mcg/day.
Infants ages 6 to 12 months. 0.4 mcg/day.
Neonates and infants to 6 months. 0.5 mcg/day.

OTHER INDICATIONS AND DOSAGES

TO TREAT PYRIDOXINE DEPENDENCY SYNDROME

I.V. OR I.M. INJECTION

Adults and children age 11 and over. 30 to 600 mg daily.**Infants with seizures.** *Initial:* 10 to 100 mg, then individualized based on severity of deficiency, as prescribed.**TO TREAT DRUG-INDUCED PYRIDOXINE DEFICIENCY**

I.V. OR I.M. INJECTION

Adults and children age 11 and over. 50 to 200 mg/day for 3 wk, then 25 to 100 mg/day, as needed.**TO TREAT VITAMIN B₉ DEFICIENCY**

TABLETS

Adults and children. Dosage individualized based on severity of deficiency, as prescribed.

I.V. INFUSION, I.M. OR SUBCUTANEOUS INJECTION

Adults and children. 0.25 to 1 mg daily until hematologic response occurs.**TO TREAT VITAMIN B₁₂ DEFICIENCY***Caused by nutritional intake imbalance (not for use to treat pernicious anemia)*

LOZENGES, TABLETS

Adults and children. Dosage individualized based on severity of deficiency, as prescribed.*Caused by pernicious anemia; malabsorption disorders (tropical or nontropical sprue, partial or total gastrectomy, regional enteritis, gastroenterostomy, ileal resection); or malignancies, granulomas, strictures, or anastomoses involving the ileum.*

SUBCUTANEOUS INJECTION (CYANOCOBALAMIN)

Adults. *Initial:* 30 mcg daily for 5 to 10 days, then switched to I.M. administration for maintenance therapy.

PARENTERAL ADMINISTRATION GUIDELINES

- Vitamin B₆ may increase AST (SGOT) levels. Be aware that at least one manufacturer warns against I.V. administration of vitamin B₆ to patients with heart disease.
- Take precautions to protect vitamin B₆ solution from exposure to light because it's light sensitive.

- Be aware that some vitamin B₉ solutions contain benzyl alcohol. Don't administer these solutions to neonates or immature infants because of a risk of fatal toxic syndrome, which may include CNS, respiratory, circulatory, and renal impairment and metabolic acidosis.
- Unless ordered otherwise, dilute 5 mg/ml of vitamin B₉ with 49 ml of sterile water for injection to provide a solution containing 0.1 mg of vitamin/ml.
- Know that parenteral administration may cause anaphylaxis. Parenteral administration should be used only in patients with severe vitamin deficiency or in those with severely impaired GI absorption.
- Be aware that SubQ administration should be injected deep.
- Take precautions to protect vitamin B₉ solution from exposure to light because it's light sensitive.

- Be aware that parenteral vitamin B₁₂ solution is incompatible with many drugs, including ascorbic acid, chlorpromazine hydrochloride, dextrose, heavy metals, phytonadione, prochlorperazine edisylate, warfarin sodium, oxidizing or reducing agents, and alkaline or strongly acidic solutions. Do not administer vitamin with other drugs.
- Know that both cyanocobalamin and hydroxycobalamin may be administered by I.M. injection, but only cyanocobalamin may be administered as an SubQ injection. Be alert to which form is being administered to ensure correct route of administration.

(continued)

Vitamins (continued)**GENERIC AND TRADE NAMES****RECOMMENDED DAILY INTAKE****vitamin B₁₂** (continued)**vitamin C**
(ascorbic acid)Ascorbic Acid, Cecon Drops, Cenolate,
Cevi-Bid, Vicks Vitamin C Drops**Adult men.** 90 mg/day.**Adult women.** 75 mg/day.**Pregnant women age 19 and over.** 85 mg/day.**Breast-feeding women age 19 and over.**
120 mg/day.**Adolescent boys ages 14 to 19.** 75 mg/day.**Adolescent girls ages 14 to 19.** 65 mg/day.**Pregnant girls ages 14 to 19.** 80 mg/day.**Breast-feeding girls ages 14 to 19.** 115 mg/day.**Children ages 9 to 14.** 45 mg/day.**Children ages 4 to 9.** 25 mg/day.**Children ages 1 to 4.** 15 mg/day.**Infants ages 7 to 12 months.** 50 mg/day.**Neonates and infants to age 7 months.**
40 mg/day.

Dosage Adjustment Recommended daily intake for people who smoke is 100 mg/day because of an increased utilization of vitamin C. Recommended daily intake should be increased to promote wound healing and for those with a chronic illness, fever, hemovascular disorder, or infection; the amount of vitamin C increase depends on the severity of the underlying condition.

OTHER INDICATIONS AND DOSAGES

Children. *Initial:* 1,000 to 5,000 mcg given in single daily doses of 100 mcg over 2 or more wk.

Maintenance: 60 or more mcg/mo.

I.M. INJECTION (CYANOCOBALAMIN OR HYDROXYCOBALAMIN)

Adults. *Initial:* 30 mcg daily for 5 to 10 days.

Maintenance: 100 to 200 mcg every mo.

Children. *Initial:* 1,000 to 5,000 mcg, given in single daily doses of 100 mcg over 2 or more wk.

Maintenance: 60 or more mcg/mo.

Dosage Adjustment Dosage adjusted, as needed, to maintain normal hematologic morphology and an erythrocyte count greater than 4.5 million/mm³.

TO TREAT FAMILIAL SELECTIVE B₁₂ MALABSORPTION

I.M. INJECTION (CYANOCOBALAMIN)

Adults. *Initial.* 1 mg/wk for 3 wk. *Maintenance:* 250 mcg/mo.

TO TREAT HEREDITARY DEFICIENCY OF TRANSCOBALAMIN II

I.M. INJECTION (CYANOCOBALAMIN)

Adults. 1 to 2 mg/wk.

TO TREAT VITAMIN C DEFICIENCY (SCURVY)

E.R. CAPSULES; LOZENGES; ORAL SOLUTION;

E.R. TABLETS; TABLETS; SUBCUTANEOUS, I.M., OR I.V. INJECTION

Adults. 100 to 250 mg once or twice daily until skeletal changes and signs and symptoms of hemorrhagic disorder are reversed (usually within 2 to 21 days).

ORAL SOLUTION; TABLETS; SUBCUTANEOUS, I.M.,

OR I.V. INJECTION

Infants and children. 100 to 300 mg/day in divided doses until skeletal changes and signs and symptoms of hemorrhagic disorder are reversed (usually within days).

PARENTERAL ADMINISTRATION GUIDELINES

- Be aware that SubQ administration of cyanocobalamin should be injected deeply.
 - Know that vitamin B₁₂ is excreted more rapidly after I.V. injection; I.V. administration isn't recommended.
 - Take precautions to protect vitamin B₁₂ solution from exposure to light because it's light sensitive.
-
- Be aware that I.M. injection is the preferred parenteral route for administering vitamin C, although it may be administered I.V. or SubQ when necessary.
 - Rotate sites for I.M. and SubQ administration to help prevent transient mild soreness that may occur following administration. Inform patient that this adverse effect may occur.
 - If giving I.V. vitamin C, avoid rapid administration to prevent faintness or dizziness.
 - Administer vitamin C solution by itself because it's incompatible with many drugs.
 - Be aware that vitamin C solution rapidly oxidizes in air and in alkaline solutions. Take precautions to protect vitamin solution from exposure to air and light.
 - Open vitamin C ampules carefully because increased pressure may develop after prolonged storage.

E-Complex 600, E-Vitamin succinate,
Liqui-E, Pheryl E, Vita-Plus E, Webber
Vitamin E (CAN)

Adult men and adolescent boys. 16.7 international units (IU)/day. (10 to 16.7 IU/day [CAN].)
Adult women and adolescent girls. 13 IU/day. (8.3 to 11.7 IU/day [CAN].)
Pregnant women. 16.7 IU/day. (13 to 15 IU/day [CAN].)
Breast-feeding women. 18 to 20 IU/day. (15 to 16.7 IU/day [CAN].)
Children ages 7 to 10. 11.7 IU/day. (10 to 13 IU/day [CAN].)
Children ages 4 to 7. 11.7 IU/day. (8.3 IU/day [CAN].)
Infants and children to age 4. 5 to 10 IU/day. (5 to 6.7 IU/day [CAN].)

OTHER INDICATIONS AND DOSAGES

TO TREAT VITAMIN D₂ DEFICIENCY

CAPSULES, ORAL SOLUTION, TABLETS

Adults and children. Dosage individualized based on severity of deficiency, as prescribed.**TO TREAT VITAMIN D-RESISTANT RICKETS**

CAPSULES, ORAL SOLUTION, TABLETS

Adults. 12,000 to 150,000 international units daily**TO TREAT VITAMIN D-DEPENDENT RICKETS**

CAPSULES, ORAL SOLUTION, TABLETS

Adults. 10,000 to 60,000 international units daily*Maximum:* 150,000 international units daily.**Children.** 3,000 to 10,000 international units daily.*Maximum:* 50,000 international units daily.**TO TREAT OSTEOMALACIA CAUSED BY LONG-TERM ANTICONVULSANT USE**

CAPSULES, ORAL SOLUTION, TABLETS

Adults. 1,000 to 4,000 international units daily.**Children.** 1,000 international units daily.**TO TREAT FAMILIAL HYPOPHOSPHATEMIA**

CAPSULES

Adults. 50,000 to 100,000 international units daily.

To treat hypoparathyroidism

CAPSULES

Adults. 50,000 to 150,000 international units daily.**Children.** 50,000 to 200,000 international units daily.**TO TREAT INTESTINAL MALABSORPTION**

I.M. INJECTION

Adults and children. 10,000 international units daily.

PARENTERAL ADMINISTRATION GUIDELINES

- Be aware that vitamin D₂ is usually given orally. However, I.M. injection may be required for patients with GI, liver, or biliary disease associated with malabsorption of vitamin D analogues.
- Take precautions to protect parenteral vitamin D₂ solution from exposure to light because light causes it to decompose.

TO TREAT VITAMIN E DEFICIENCY

CAPSULES (ADULTS ONLY), ORAL SOLUTION, TABLETS

Adults and children. Dosage individualized based on severity of deficiency, as prescribed.*Vitamin E isn't administered parenterally.**(continued)*

Vitamins (continued)**GENERIC AND TRADE NAMES**

vitamin K₁
(phytonadione)
AquaMEPHYTON, Mephyton

RECOMMENDED DAILY INTAKE

Recommended daily intake hasn't been established for vitamin K₁. However, adequate intake is suggested as follows:

Adult men age 19 and over. 120 mcg/day.

Adult women age 19 and over, pregnant and breastfeeding women. 90 mcg/day.

Adolescents ages 14 to 19. 75 mcg/day.

Children ages 9 to 14. 60 mcg/day.

Children ages 4 to 9. 55 mcg/day.

Children ages 1 to 4. 30 mcg/day.

Infants ages 7 to 12 months. 2.5 mcg/day.

Neonates and infants to age 7 months. 2 mcg/day.

OTHER INDICATIONS AND DOSAGES

TO PREVENT HYPOPROTHROMBINEMIA DURING PROLONGED USE OF TOTAL PARENTERAL NUTRITION

I.M. INJECTION

Adults. 5 to 10 mg/wk.**Children.** 2 to 5 mg/wk.**TO PREVENT HYPOPROTHROMBINEMIA IN INFANTS WITH DIETS DEFICIENT IN VITAMIN K (LESS THAN 100 MCG/L)**

I.M. INJECTION

Infants. 1 mg/mo.**TO TREAT ANTICOAGULANT-INDUCED HYPOPROTHROMBINEMIA**

TABLETS, I.M. OR SUBCUTANEOUS INJECTION

Adults. 2.5 to 25 mg, repeated 12 to 48 hr after P.O. dose or 6 to 8 hr after SubQ or I.M. dose, as prescribed. *Maximum:* 50 mg/dose.**Children.** 2.5 to 10 mg SubQ or I.M., repeated in 6 to 8 hr, as prescribed.**Infants.** 1 to 2 mg SubQ or I.M., repeated in 4 to 8 hr, as prescribed.**TO TREAT HYPOPROTHROMBINEMIA FROM OTHER CAUSES**

TABLETS, I.M. OR SUBCUTANEOUS INJECTION

Adults. 2 to 25 mg. *Usual:* 25 mg. *Maximum:* 50 mg/dose.**Children.** 5 to 10 mg SubQ or I.M.**Infants.** 2 mg SubQ or I.M.**TO PREVENT HEMORRHAGIC DISEASE IN NEONATES**

I.M. OR SUBCUTANEOUS INJECTION

Neonates. 0.5 to 1 mg within 1 hr after birth, repeated in 6 to 8 hr, as prescribed.**TO TREAT HEMORRHAGIC DISEASE IN NEONATES**

I.M. OR SUBCUTANEOUS INJECTION

Neonates. 1 mg (or higher dose if mother took an oral anticoagulant or anticonvulsant during pregnancy).

PARENTERAL ADMINISTRATION GUIDELINES

- Be aware that severe adverse reactions, including anaphylaxis, cardiac and respiratory arrest, hypersensitivity, and shock, may occur during or immediately after I.M. or I.V. administration of vitamin K₁, even if it's diluted to avoid rapid infusion. Administer vitamin by SubQ route whenever possible.
- If vitamin K₁ must be administered I.V., do not exceed rate of 1 mg/min, as prescribed.
- Be aware that some vitamin K₁ solutions contain benzyl alcohol. Don't administer these solutions to neonates or immature infants because of a risk of fatal toxic syndrome, which may include CNS, respiratory, circulatory, and renal impairment and metabolic acidosis.
- Take precautions to protect vitamin K₁ solution from exposure to light because it's light sensitive.

Interferons

Interferons are classified as biological response modifiers or antineoplastics. They fall into three major categories—alpha, beta, and gamma—which are described below.

The table on the following pages lists the trade names, indications, usual adult dosages, adverse reactions, and nursing considerations for these interferons.

Interferon alpha

Highly purified proteins produced by a recombinant DNA process, drugs in this category exhibit antiviral and antitumor activity. Antiviral activity depends on their inhibition of viral protein synthesis. Antitumor activity results from their ability to exert a cytostatic effect, reducing the rate of cell proliferation by delaying RNA and protein production. This delay induces cells

to enter a resting stage. These drugs also increase the activity of human natural killer (NK) cells, which have the ability to lyse certain tumor cells and normal targets. They also selectively increase the number of cytotoxic T-cells, thereby affecting tumor growth. Phagocytic activity of macrophages also is increased.

INTERFERON ALFACON

This specific form of interferon is produced by fermentation of genetically engineered *Escherichia coli*. It's structurally and functionally related to interferon beta and has greater biological activity than other interferon alphas.

Interferon beta

Produced by fibroblasts and epithelial cells, drugs in this category neutralize the activity of endogenous interferon gamma (IFNG), the sub-

GENERIC AND TRADE NAMES

INDICATIONS AND USUAL ADULT DOSAGES

Interferon alpha drugs

interferon alfa-n3
Alferon N

To treat condyloma acuminatum: 250,000 units intralesionally at base of wart 2 times/wk for up to 8 wk.

peginterferon alfa-2a
PEGASYS

As monotherapy to treat patients with chronic hepatitis C who have compensated liver disease and have never received an interferon alpha: 180 mcg/wk SubQ for 48 wk.

As adjunct to treat patients with chronic hepatitis C who have compensated liver disease and have never received an interferon alpha: 180 mcg/wk SubQ with ribavirin (Copegus) 800 to 1,200 mg/day P.O. in 2 divided doses with food for 48 wk.

peginterferon alfa-2b
PEG-Intron

To treat patients with chronic hepatitis C: 1 mcg/kg/wk SubQ every wk on the same day of the wk for 1 year.

To treat patients with chronic hepatitis C in combination with ribavirin: 1.5 mcg/kg SubQ every wk on the same day of the wk for 48 wk.

recombinant interferon alfa-2b
Intron A

To treat hairy cell leukemia: 2 million units/m² I.M. or SubQ 3 times/wk.

stance believed to be responsible for triggering the autoimmune process that leads to multiple sclerosis. In multiple sclerosis, an initial viral infection may stimulate IFNG production by T cells. Then IFNG induces macrophages to produce proteinases that degrade the myelin sheath around the nerves and spinal cord. Cytotoxic T cells then move to the site of inflammation, recognizing antigens as receptor sites, where they attack the tissue affected by IFNG, resulting in progressive neurologic dysfunction. Interferon beta drugs interfere with IFNG production by lymphocytes and the mRNA transcription caused by IFNG. As a result, cytotoxic T cells can't locate receptor sites and cause further damage in the CNS.

Interferon gamma

Produced from genetically engineered *E. coli*,

this type of interferon is chemically and therapeutically distinct from interferon alpha. Drugs in this category have potent phagocyte-activating properties. By enhancing oxidative metabolism, they produce toxic oxygen metabolites in phagocytes, which permits more efficient killing of certain fungi, bacteria, and protozoal microbes. Enhanced antibody-dependent cellular cytotoxicity and NK-cell activity reduce the risk of developing a serious infection in patients with chronic disease. These drugs also stimulate production of cytokines, such as interleukin-1-beta, and regulate the immune system by suppressing the IgE level and inhibiting collagen production.

ADVERSE REACTIONS

CNS: Dizziness, fatigue, headache, homicidal ideation, psychosis, seizures, peripheral neuropathy, vertigo
CV: Hypertriglyceridemia, hypertension, hypotension, palpitations
EENT: Dry mouth, hearing loss, retinal detachment (with ribavirin)
GI: Anorexia, diarrhea, hepatotoxicity, nausea, vomiting
GU: Renal failure
HEME: Anemia, leukopenia, pure red cell aplasia, thrombocytopenia, thrombotic thrombocytopenic purpura
MS: Myositis, rhabdomyolysis
SKIN: Alopecia, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria
Other: Anaphylaxis, angioedema, bacterial infections, flulike symptoms, sepsis, systemic lupus erythematosus

NURSING CONSIDERATIONS

- Use interferon alpha drugs cautiously in patients with renal impairment and in elderly patients.
- Be aware that cross-sensitivity may occur among interferon alpha drugs.
- Be aware that interferon alpha drugs aren't interchangeable.
- Be aware that patients who are sensitive to mouse immunoglobulin also may be sensitive to recombinant interferon alfa-2a.
- Unless contraindicated, ensure that patient is well hydrated at the start of and throughout therapy to reduce the risk of hypotension.
- Reconstitute by adding 3 ml of diluent provided by manufacturer and swirling gently to dissolve.
- Be aware that reconstitution of peginterferon alfa-2a and interferon alfa-n3 is not necessary.
- Don't shake vial.
- Be aware that cross-sensitivity with interferon alfa-n3 to mouse immunoglobulin, egg protein, or neomycin may occur.

WARNING Because interferon alpha drugs may cause or aggravate fatal or life-threatening autoimmune, ischemic, infectious, or neuropsychiatric disorders, monitor patient periodically with clinical and laboratory evaluations and expect drug to be discontinued if he develops severe or worsening signs and symptoms of these conditions.

GENERIC AND TRADE NAMES

INDICATIONS AND USUAL ADULT DOSAGES

Interferon alpha drugs (continued)

recombinant interferon alfa-2b

Intron A
(continued)

To treat condyloma acuminatum: 1 million units (using only the 10-million units/ml strength) intralesionally at base of wart (up to 5 warts/course) 3 times/wk on alternate days for 3 wk. If response is inadequate 12 to 16 wk after initial treatment, repeat course, as prescribed.

To treat AIDS-related Kaposi's sarcoma: 30 million units/m² (using 50 million units/ml) I.M. or SubQ 3 times/wk.

To treat chronic, active hepatitis B and C: 3 million units I.M. or SubQ 3 times/wk.

To treat chronic hepatitis B: 5 million units/day or 10 million units 3 times/wk I.M. or SubQ for 16 wk.

To treat malignant melanoma: 20 million units/m² as I.V. infusion for 5 consecutive days/wk for 4 wk, followed by 10 million units/m² SubQ 3 times/wk for 48 wk.

Interferon alphacon drugs

interferon alfacon-1

Infergen

To treat chronic, active hepatitis C: 9 mcg SubQ 3 times/wk, at intervals of at least 48 hours, for 24 wk. If inadequate response or relapse occurs, 15 mcg 3 times/wk for 6 mo.

Interferon beta drugs

interferon beta-1a

Avonex

To treat initial attack or relapsing forms of multiple sclerosis: 30 mcg I.M. once/wk.

Rebif

To treat relapsing forms of multiple sclerosis: 44 mcg SubQ 3 times/wk.

interferon beta-1b

Betaseron, Extavia

To treat relapsing forms of multiple sclerosis: 0.25 mg SubQ every other day.

ADVERSE REACTIONS**NURSING CONSIDERATIONS**

- Obtain CBC before and regularly during treatment, as ordered, because interferon alpha drugs may cause bone marrow suppression. Expect drug to be discontinued if patient develops severe decreases in platelet or neutrophil count.
- Implement bleeding and infection-control measures, according to facility policy.
- Use gamma interferon cautiously in patients previously exposed to cytotoxic drugs or radiation therapy.
- Be aware that cross-sensitivity may occur with *Escherichia coli*-derived products.
- Discard vial if left at room temperature for more than 12 hours.
- Implement bleeding and infection-control measures, according to facility policy.
- Administer acetaminophen, as prescribed, to prevent or treat headache and fever.

CNS: Anxiety, confusion, decreased concentration, depression, insomnia, nervousness

EENT: Abnormal vision

HEME: Leukopenia, thrombocytopenia

- Be aware that use of interferon alfacon-1 isn't recommended for patients with autoimmune hepatitis or psychiatric disorders.
- Be aware that cross-sensitivity may occur with other interferon alfa drugs or *Escherichia coli*-derived products.
- Don't shake vial.
- Implement bleeding and infection-control measures, according to facility policy.
- Monitor patient for signs and symptoms of vision abnormalities.

CNS: Depression, fatigue, headache, suicidal ideation, weakness

GI: Diarrhea, elevated liver enzyme levels, nausea

HEME: Anemia, leukopenia, thrombocytopenia

Other: Anaphylaxis, flulike symptoms, infection, injection site reactions (including necrosis)

- Use beta interferons with extreme caution in patients with depression or seizure disorder.
- Be aware that cross-sensitivity may occur with natural or recombinant interferon beta or human albumin.
- Reconstitute following manufacturer's directions and refrigerate. Use interferon beta-1a within 6 hours of reconstitution. Use interferon beta-1b within 3 hours of reconstitution.
- Implement bleeding and infection-control measures, according to facility policy.

- Administer acetaminophen, as prescribed, to prevent or treat headache and fever.

Compatible Drugs in a Syringe

The table below lets you know at a glance whether particular drugs are compatible for at least 15 minutes when mixed together in a syringe for immediate administration. However, keep in mind that drugs listed as compatible when mixed in a syringe may not be compatible when prepared for other routes of adminis-

tration. Drug combinations prepared for immediate administration usually require a more concentrated solution than those prepared for infusion.

Key: C = Compatible; I = Incompatible; n/a = Compatibility information not available; no recommendations can be given.

* Compatible only with morphine doses of 1 mg, 2 mg, and 5 mg.

Drug Formulas and Calculations

When giving drugs, you must be familiar with drug formulas and calculation methods to make sure your patient receives the prescribed drug in the correct dosage, strength, or flow rate. This appendix offers a quick review of ways to calculate the strength of a solution, drug dosages, and I.V. flow rates.

Calculating the Strength of a Solution

Most solutions are prepared in the required strength by the pharmacy or medical supply source. But sometimes only a concentrated form is available, and you'll need to dilute the solution or solid to administer the prescribed strength.

When a solid form of a drug is used to prepare a solution, the drug must be completely dissolved. Solid drug forms, such as tablets, crystals, and powders, are considered 100% strength. (An exception to this is boric acid, which is only 5% at full strength.) The final diluted solution is stated in terms of liquid measurement. To prepare a solution, you'll need to add the prescribed solid or liquid form of the drug (the solute) to the prescribed amount of diluent (the solvent). Two of the most common clinical diluents are normal saline solution and sterile water.

You can use two formulas to calculate the strength of a solution, as shown in the examples below.

Method 1: Calculating percentage and volume

Use the following formula:

$$\frac{\text{Weaker solution}}{\text{Stronger solution}} = \frac{\text{Solute}}{\text{Solvent}}$$

Example: You need to dilute a stock solution of 100% strength to a 5% solution. How much solute will you need to add to obtain 500 ml of the 5% solution?

Calculate as follows:

$$\frac{5 (\%) \text{ (weaker solution)}}{100 (\%) \text{ (stronger solution)}} = \frac{X \text{ (g) (solute)}}{500 \text{ ml (solvent)}}$$

$$100 X = (500)(5) \text{ or } 2,500$$

$$X = 25 \text{ g}$$

Answer: You'll need to add 25 g of solute to each 500 ml of solvent to prepare a 5% solution.

Method 2: Calculating percentage and volume

Use the following formula:

$$\frac{(\text{Desired strength})}{(\text{Available strength})} \times \text{Total amount of desired solution} = X \text{ (amount of undiluted drug needed to make solution)}$$

Example: You need to make 100 ml of a 20% solution, using an 80% solution. How much of the 80% solution must you add to the sterile water to yield a final volume of 100 ml of a 20% solution?

Calculate as follows:

$$\frac{20 (\%) \text{ (Desired strength)}}{80 (\%) \text{ (Available strength)}} \times 100 \text{ ml (Total amount of desired solution)} = X$$

$$\frac{0.20}{0.80} = 0.25$$

$$0.25 \times 100 \text{ (ml)} = X$$

$$X = 25 \text{ ml of } 80\% \text{ solution}$$

Answer: You'll need to add 25 ml of the 80% solution to the water to make a final volume of 100 ml of a 20% solution.

Drug Formulas and Calculations *(continued)*

Calculating Drug Dosages

You may be required to calculate drug dosages when you need to administer a drug that's available only in one measure, but prescribed in another. You should also be prepared to convert various units of measure, such as milligrams (mg) to grains (gr), and dry measurements to liquid. You can use three common methods of ratio and proportion to calculate drug dosages, as shown in the examples below.

CALCULATING ORAL DRUG DOSAGES

Example: You need to give a patient 0.25 mg of digoxin, which comes only in 0.125-mg tablets. How many tablets will you need to give him to attain the proper dosage?

Method 1: Using labeled amount of drug

In this method, true proportions between the drug label and the prescribed dose are used to determine ratio and proportion. The drug label, which states the amount of drug in one unit of measurement—in this case, 0.125-mg in each tablet of digoxin—is the first ratio, expressed as follows:

$$\begin{aligned} \text{milligrams} : \text{tablets} &= \text{milligrams} : \text{tablets} \\ 0.125 \text{ mg (amount of drug)} : 1 \text{ tablet (unit of measure)} \end{aligned}$$

The prescribed dose—in this case, 0.25-mg—is the second ratio; it must be stated in the same order and units of measure as the first, as follows:

$$0.125 \text{ mg} : 1 \text{ tablet} = 0.25 \text{ mg} : X \text{ (tablets)}$$

Calculate as follows:

$$\begin{aligned} 0.125 X &= 0.25 \\ X &= \frac{0.25}{0.125} \\ X &= 2 \end{aligned}$$

Answer: You'll need to give the patient 2 tablets of digoxin 0.125 mg.

Be sure to use critical thinking to assess whether your answer is correct. Because the amount of drug prescribed is greater than the amount of drug in one tablet, it's reasonable to expect the required number of tablets to be greater than one.

Method 2: Using an established formula

To determine the correct number of digoxin tablets to give using this method, use the following formula:

$$\frac{\text{Prescribed dose}}{\text{Dose available}} \times \text{Quantity (unit of measure)} = X \text{ (unknown quantity to be given)}$$

Calculate as follows:

$$\frac{0.25 \text{ mg}}{0.125 \text{ mg}} \times 1 \text{ tablet} = X \text{ (number of 0.125-mg tablets)}$$

$$\frac{0.25}{0.125} = 2X$$

$$2 = X$$

Answer: You'll need to give the patient 2 tablets of digoxin 0.125 mg.

(continued)

Drug Formulas and Calculations *(continued)*

Method 3: Calculating according to proportion size

This method uses the same components as method #1, but the ratio is based on proportions according to size. To determine the correct number of digoxin tablets to give using this method, use the following formula:

$$\frac{\text{smaller}}{\text{larger}} = \frac{\text{smaller}}{\text{larger}}$$

Substitute 0.125 into the smaller part and 0.25 into the greater part of the first ratio. Critical thinking leads us to believe that you'll need more than 1 tablet of the weaker 0.125-mg strength to equal the stronger 0.25 mg. Set up the proportion as follows:

$$\frac{0.125 \text{ mg}}{0.25 \text{ mg}} = \frac{1 \text{ (tablet)}}{X \text{ (tablets)}}$$

Calculate as follows:

$$\begin{aligned} 0.125 X &= 0.25 \\ X &= \frac{0.25}{0.125} \\ X &= 2 \text{ tablets} \end{aligned}$$

Answer: You'll need to give the patient 2 tablets of digoxin 0.125 mg.

CALCULATING PARENTERAL DRUG DOSAGES

The same methods used for calculating oral drugs and solutions can be used for preparing parenteral injections.

Example: You need to administer a prescribed dose of 1 mg morphine sulfate from a unit-dose cartridge containing 4 mg per 2 ml. How many milliliters will you need to give to equal the prescribed dose of 1 mg?

Method 1: Using labeled amount of drug

Using the same ratio as for oral drugs, the drug label—in this case, 4 mg—is the first ratio, and the prescribed dose—in this case, 1 mg—is the second ratio, expressed as follows:

$$4 \text{ mg (the amount of drug)} : 2 \text{ ml (the unit of measure)}$$

Calculate as follows:

$$\begin{aligned} 4 \text{ mg} : 2 \text{ ml} &= 1 \text{ mg} : X \text{ ml} \\ 4X &= 2 \\ X &= \frac{2}{4} \\ X &= 0.5 \text{ ml} \end{aligned}$$

Answer: You'll need to give 0.5 ml of morphine sulfate to equal the prescribed dose of 1 mg.

Method 2: Using an established formula

Use this formula:

$$\frac{\text{Prescribed dose}}{\text{Dose available}} \times \text{Quantity (unit of measure)} = X \text{ (unknown quantity to be given)}$$

Drug Formulas and Calculations *(continued)*

Calculate as follows:

$$\frac{1 \text{ mg}}{4 \text{ mg}} \times 2 \text{ ml} = X \text{ (number of ml)}$$

$$\frac{4}{2} = 0.5$$

Answer: You'll need to give 0.5 ml of morphine sulfate to equal the prescribed dose of 1 mg.

Method 3: Calculating according to proportion size

To determine the correct amount of morphine sulfate to give using this method, use the following formula:

$$\begin{aligned} \text{smaller} : \text{greater} &= \text{smaller} : \text{greater} \\ \text{milligrams} : \text{milligrams} &= \text{milliliters} : \text{milliliters} \end{aligned}$$

Critical thinking leads us to believe that 1 mg is less than 4 mg and that you'll need less than 2 ml to give 1 mg of drug; therefore, 1 mg goes into the smaller part of the first ratio, and X goes into the smaller part of the second ratio. Set up the proportion as follows:

$$\begin{aligned} 1 \text{ mg} : 4 \text{ mg} &= X \text{ (ml)} : 2 \text{ ml} \\ 4X &= 2 \\ X &= \frac{2}{4} \\ X &= 0.5 \end{aligned}$$

Answer: You'll need to give 0.5 ml of morphine sulfate to equal the prescribed dose of 1 mg.

Calculating I.V. Flow Rates

When an I.V. solution is delivered by gravity, you must calculate the number of drops needed per minute for proper infusion. To calculate I.V. flow rates, you need to know three things:

- the drip factor—or the number of drops contained in 1 ml for the type of I.V. set you'll be using. This information is provided on the individual package label.
- the amount and type of fluid that you'll be infusing based on the medication order.
- the infusion duration time in minutes.

Once you've gathered this information, you can calculate the I.V. flow rate using the following equation:

$$\frac{\text{Total number of ml}}{\text{Total number of minutes}} \times \text{drip factor (gtt/ml)} = \text{flow rate (gtt/min)}$$

Example 1: If the physician prescribes 1,000 ml of D₅W to infuse over 10 hours, and the drip rate for your administration set is 15 drops (gtt) per ml, calculate as follows:

$$\frac{1,000 \text{ ml}}{10 \text{ hours} \times 60 \text{ minutes}} \times 15 \text{ gtt/ml} = X \text{ gtt/minute}$$

$$\frac{1,000 \text{ ml}}{600 \text{ minutes}} \times 15 \text{ gtt/ml} = X \text{ gtt/minute}$$

Drug Formulas and Calculations *(continued)*

$$1.67 \text{ ml/minute} \times 15 \text{ gtt/ml} = X \text{ gtt/minute}$$

$$25.05 \text{ gtt/minute} = X$$

Answer: To infuse, round off 25.05 to 25 gtt/minute or according to your institution's policy.

Example 2: If the physician prescribes 500 ml of half-normal (0.45%) saline solution to infuse over 2 hours, and the drip rate for your administration set delivers 10 gtt/ml, calculate as follows:

$$\frac{500 \text{ ml}}{2 \text{ hours} \times 60 \text{ minutes}} \times 10 \text{ gtt/ml} = X \text{ gtt/minute}$$

$$\frac{500 \text{ ml}}{120 \text{ minutes}} \times 10 \text{ gtt/ml} = X \text{ gtt/minute}$$

$$4.17 \text{ ml/minute} \times 10 \text{ gtt/ml} = X \text{ gtt/minute}$$

$$41.7 \text{ gtt/minute} = X$$

Answer: To infuse, round off 41.7 to 42 gtt/minute or according to your institution's policy.

Note: When preparing for I.V. administration using a controlled infusion device, the electronic flow-regulator will either count drops using an electronic eye or use a controlled pumping action to deliver the fluid in milliliters. Your final calculation will be based on the unit of measure used by the device: drops per minute, or ml per hour.

Weights and Equivalents

The following three tables show approximate equivalents among systems of measurement.

Table 1. Liquid Equivalents Among Household, Apothecaries', and Metric Systems

HOUSEHOLD	APOTHECARIES'	METRIC
1 teaspoon (tsp)	1 fluid dram	5 milliliters (ml)
1 tablespoon (tbs)	0.5 fluid oz	15 ml
2 tbs (1 ounce [oz])	1 fluid oz	30 ml
1 cupful	8 fluid oz	240 ml
1 pint	16 fluid oz	473 ml
1 quart (qt)	32 fluid oz	946 ml (1 liter)

Table 2. Solid Equivalents Among Apothecaries' and Metric Systems

APOTHECARIES'	METRIC
15 grains (gr)	1 gram (g) (1,000 milligrams [mg])
10 gr	0.6 g (600 mg)
7.5 gr	0.5 g (500 mg)
5 gr	0.3 g (300 mg)
3 gr	0.2 g (200 mg)
1.5 gr	0.1 g (100 mg)
1 gr	0.06 g (60 mg) or 0.065 g (65 mg)
0.75 gr	0.05 g (50 mg)
0.5 gr	0.03 g (30 mg)
0.25 gr	0.015 g (15 mg)
1/60 gr	0.001 g (1 mg)
1/100 gr	0.6 mg
1/120 gr	0.5 mg
1/150 gr	0.4 mg

(continued)

Weights and Equivalents *(continued)***Table 3. Solid Equivalents Among Avoirdupois, Apothecaries', and Metric Systems**

AVOIRDUPOIS	APOTHECARIES'	METRIC
1 gr	1 gr	0.065 g
15.4 gr	15 gr	1 g
1 ounce (oz)	480 gr	28.35 g

1 pound (lb)	1.33 lb	454 g
0.75 lb	1 lb	373 g
2.2 lb	2.7 lb	1 kg

Equianalgesic Doses for Opioid Agonists

An equianalgesic dose of a synthetic opioid agonist is the dose that produces the same level of analgesia as 10 mg of I.M. or SubQ morphine, the principal opioid obtained from opium poppies. If your patient is switched from one opioid to another, expect to use the

equianalgesic dose to decrease the risk of adverse reactions while increasing the likelihood of adequate pain relief. The chart below compares equianalgesic doses (oral and parenteral) for adults and children who weigh 50 kg (110 lb) or more.

OPIOID	ORAL DOSE	PARENTERAL DOSE
codeine	200 mg (not recommended)	120 to 130 mg
hydrocodone	30 mg	Not applicable
hydromorphone	7.5 mg	1.5 mg
levorphanol	4 mg	2 mg
meperidine	300 mg	75 to 100 mg
morphine (around-the-clock dosing)	30 mg	10 mg
morphine (single or intermittent dosing)	60 mg	10 mg
oxycodone	30 mg	Not applicable

Abbreviations

The following abbreviations, which are common to nursing practice, may be used throughout the book.

ABG	arterial blood gas	ECG	electrocardiogram

AIDS	acquired immunodeficiency syndrome	E.R.	extended-release
ALT	alanine aminotransferase	°F	degrees Fahrenheit
ANA	antinuclear antibodies	FDA	Food and Drug Administration
APTt	activated partial thromboplastin time	g	gram
AST	aspartate aminotransferase	GABA	gamma aminobutyric acid
ATP	adenosine triphosphate	GFR	glomerular filtration rate
AV	atrioventricular	GI	gastrointestinal
b.i.d.	twice a day	gtt	drop
BUN	blood urea nitrogen	GU	genitourinary
°C	degrees Celsius	H₁	histamine ₁
cAMP	cyclic adenosine monophosphate	H₂	histamine ₂
(CAN)	Canadian drug trade name	HDL	high-density lipoprotein
cap	capsule	HEME	hematologic
CBC	complete blood count	HIV	human immunodeficiency virus
cGMP	cyclic guanosine monophosphate	HMG-CoA	hydroxymethylglutaryl-coenzyme A
CK	creatine kinase	HPV	human papilloma virus
Cl	chloride	hr	hour
cm	centimeter	HSV	herpes simplex virus
CMV	cytomegalovirus	HZV	herpes zoster virus
CNS	central nervous system	ICP	intracranial pressure
COPD	chronic obstructive pulmonary disease	I.D.	intradermal
C.R.	controlled-release	IgA	immunoglobulin A
CSF	cerebrospinal fluid	IgE	immunoglobulin E
CV	cardiovascular	I.M.	intramuscular
CVA	cerebrovascular accident	INR	international normalized ratio
D₅LR	dextrose 5% in lactated Ringer's solution	I.V.	intravenous
D₅NS	dextrose 5% in normal saline solution	IVPB	intravenous piggyback
D₅/0.2NS	dextrose 5% in quarter-normal saline solution	kg	kilogram
D₅/0.45NS	dextrose 5% in half-normal saline solution	KIU	kallikrein inactivator units
D₅W	dextrose 5% in water	L	liter
D₁₀W	dextrose 10% in water	LA	long-acting
D₅₀W	dextrose 50% in water	lb	pound
dl	deciliter	LD	lactate dehydrogenase
DNA	deoxyribonucleic acid	LDL	low-density lipoprotein
DS	double-strength	LOC	level of consciousness
EC	enteric-coated	LR	lactated Ringer's solution
		M	molar
		m²	square meter
		MAO	monoamine oxidase
		mcg	microgram
		mEq	milliequivalent
		mg	milligram
		MI	myocardial infarction

Abbreviations *(continued)*

min	minute	T ₄	thyroxine
ml	milliliter	t.i.d.	three times a day
mm	millimeter	USP	United States Pharmacopeia
mm ³	cubic millimeter	UTI	urinary tract infection
mmol	millimole	VLDL	very-low-density lipoprotein
mo	month	WBC	white blood cell
MS	musculoskeletal	wk	week
msec	millisecond		
Na	sodium		
NaCl	sodium chloride		
NG	nasogastric		
ng	nanogram		
NPH	human isophane insulin		
NPO	nothing by mouth		
NS	normal saline solution		
0.225NS	quarter-normal saline (0.225%) solution		
0.45NS	half-normal saline (0.45%) solution		
NSAID	nonsteroidal anti-inflammatory drug		
NYHA	New York Heart Association		
OTC	over the counter		
oz	ounce		
p.c.	after meals		
PCA	patient-controlled analgesia		
P.O.	by mouth		
P.R.	by rectum		
p.r.n.	as needed		
PSVT	paroxysmal supraventricular tachycardia		
PT	prothrombin time		
PTCA	percutaneous transluminal coronary angioplasty		
PTT	partial thromboplastin time		
PVC	premature ventricular contraction		
q.i.d.	four times a day		
RBC	red blood cell		
REM	rapid eye movement		
RESP	respiratory		
RNA	ribonucleic acid		
RSV	respiratory syncytial virus		
SA	sinoatrial		
sec	second		
S.L.	sublingual		
S.R.	sustained-release		
stat	immediately		
SubQ	subcutaneous		
supp	suppository		
tab	tablet		
T ₃	triiodothyronine

Body Mass Index Calculation

Body mass index (BMI) is a formula used to determine obesity; it's calculated by dividing a person's weight in kilograms by height in meters squared (kg/m^2). A BMI of 25 or higher increases your patient's risk of developing hypertension, cardiovascular disease, type 2 diabetes mellitus, and stroke. It also increases the risk that he won't respond effectively to the usual drug dosages. If your patient has an abnormal BMI, be prepared to make dosage adjustments that are individualized based on body weight, as prescribed.

The table below will help you find your patient's BMI easily. The table converts pounds to kilograms and inches to meters, and then it shows the BMI. To use it, simply find the patient's height on either side of the table, then move across the row to the weight that matches your patient's most closely. At the bottom of the column containing the weight, you'll find the BMI for that patient. For example, the BMI for a patient who is 70 inches tall and weighs 208 lb is 30.

		WEIGHT (POUNDS)																																					
HEIGHT (INCHES)	58	91	96	100	105	110	115	119	124	129	134	138	143	148	153	158	162	167	172	172

Mechanism of Action Illustrations

For your reference, this table lists all the drugs whose mechanisms of action are illustrated in this book, along with drugs that have the same mechanism of action as the illustrated ones.

Drugs with illustrated mechanisms of action	Drugs with similar mechanisms of action
acamprosate calcium	none
albuterol, albuterol sulfate	bitolterol mesylate, formoterol fumarate dihydrate, levalbuterol hydrochloride, pirbuterol acetate, salmeterol xinafoate, terbutaline sulfate
alprostadil	none
amitriptyline hydrochloride	amoxapine, clomipramine hydrochloride, desipramine hydrochloride, doxepin hydrochloride, imipramine hydrochloride, imipramine pamoate, nortriptyline hydrochloride, protriptyline hydrochloride, trimipramine maleate
anastrozole	none
bosentan	none
bretylium tosylate	none
carbamazepine	ethotoin, fosphenytoin, lamotrigine, mephenytoin, oxcarbazepine, phenytoin, phenytoin sodium
casprofungin acetate	none
cephalexin hydrochloride, cephalexin monohydrate	amoxicillin trihydrate, amoxicillin and clavulanate potassium, ampicillin, ampicillin sodium, ampicillin sodium and sulbactam sodium, ampicillin trihydrate, aztreonam, carbenicillin indanyl sodium, cefaclor, cefadroxil, cefamandole nafate, cefazolin sodium, cefdinir, cefditoren pivoxil, cefepime hydrochloride, cefixime, cefmetazole sodium, cefonicid sodium, cefoperazone sodium, cefotaxime sodium, cefotetan disodium, cefoxitin sodium, cefpodoxime proxetil, cefprozil, ceftazidime, ceftibuten, ceftizoxime sodium, ceftriaxone sodium, cefuroxime axetil, cefuroxime sodium, cephapirin sodium, cephradine, cloxacillin sodium, dicloxacillin sodium, imipenem and cilastatin sodium, loracarbef, meropenem, methicillin sodium, mezlocillin sodium, nafcillin sodium, oxacillin sodium, penicillin G benzathine, penicillin G potassium, penicillin G procaine, penicillin G sodium, penicillin V potassium, piperacillin sodium, piperacillin sodium and tazobactam sodium, ticarcillin disodium, ticarcillin disodium and clavulanate potassium
colchicine	none
cromolyn sodium	nedocromil sodium
diltiazem hydrochloride	bepidil hydrochloride, felodipine, isradipine, nicardipine hydrochloride, nifedipine, verapamil, verapamil hydrochloride
dutasteride	none

Mechanism of Action Illustrations (cont'd)

Drugs with illustrated mechanisms of action	Drugs with similar mechanisms of action
enoxacin	alatrofloxacin mesylate, cinoxacin, ciprofloxacin, gatifloxacin, levofloxacin, lomefloxacin hydrochloride, moxifloxacin hydrochloride, nalidixic acid, norfloxacin, ofloxacin, sparfloxacin, trovafloxacin mesylate
etanercept	infliximab
exenatide	none
ezetimibe	none
famotidine	cimetidine, nizatidine, ranitidine hydrochloride
hydrochlorothiazide	chlorothiazide, chlorothiazide sodium, chlorthalidone, indapamide, metolazone
ipratropium bromide	none
isosorbide dinitrate, isosorbide mononitrate	nitroglycerin
lanthanum carbonate	sevelamer hydrochloride
levodopa	none
linezolid	none
memantine hydrochloride	none
milrinone lactate	inamrinone (formerly amrinone lactate)
nateglinide	repaglinide
olmesartan medoxomil	irbesartan, losartan potassium, valsartan
omeprazole	esomeprazole magnesium, lansoprazole, pantoprazole sodium, rabeprazole sodium
orlistat	none
palonosetron	alosectron, dolasetron, granisetron, ondansetron
pegvisomant	none
phenelzine sulfate	isocarboxazid, tranlycypromine sulfate

(continued)

Mechanism of Action Illustrations (cont'd)

Drugs with illustrated mechanisms of action	Drugs with similar mechanisms of action
remifentanyl hydrochloride	codeine phosphate, codeine sulfate, fentanyl citrate, fentanyl transdermal, fentanyl transmucosal, hydrocodone bitartrate and acetaminophen, hydrocodone and ibuprofen, hydromorphone hydrochloride, levomethadyl acetate hydrochloride, levorphanol tartrate, meperidine hydrochloride, methadone hydrochloride, morphine sulfate, oxycodone and acetaminophen, oxycodone hydrochloride, oxymorphone hydrochloride, propoxyphene hydrochloride
reserpine	guanadrel sulfate, guanethidine monosulfate
spironolactone	none
tacrine hydrochloride	donepezil hydrochloride, galantamine hydrobromide, rivastigmine tartrate
teriparatide	none
ticlopidine hydrochloride	clopidogrel bisulfate
tubocurarine chloride	atracurium besylate
vasopressin	desmopressin acetate, lypressin
ziconitide	none

2011

A new and updated version of this best-selling resource!

Jones & Bartlett Learning **2011 Nurse's Drug Handbook** is the most up-to-date, practical, and easy-to-use nursing drug reference.

It provides:

- ▶ Accurate, timely facts on hundreds of drugs from abacavir sulfate to Zyxor
- ▶ Concise, consistently formatted drug entries organized alphabetically
- ▶ No-nonsense writing style that speaks your language in terms you use every day
- ▶ Index of all generic, trade, and alternate drug names for quick reference
- ▶ Chemical and therapeutic classes, FDA pregnancy risk category, and controlled substance schedule
- ▶ Indications and dosages, as well as route, onset, peak, and duration information
- ▶ Incompatibilities; contraindications; interactions with drugs, food, and activities; and adverse reactions
- ▶ Nursing considerations, including key patient-teaching points
- ▶ Vital features include mechanism-of-action illustrations showing how drugs at the cellular, tissue, or organ levels and dosage adjustments help individualize care for elderly patients, patients with renal impairment, and others with special needs
- ▶ Warnings and precautions that keep you informed and alert
