Drug
Handbook**

The Drug Reference That Gives You More!

Take drug information with you wherever you go!

Powered by Skyscape, this software offers instant access to all of the content found in the **2011 Nurse's Drug Handbook**.

- ▶ Accurate index of all generic, trade, and alternate drug names for quick reference with timely facts on hundreds of drugs from abacavir sulfate to Zyvox
- ▶ No-nonsense writing style that speaks your language in terms you use every day
- ▶ Mechanism-of-action illustrations show how drugs work at the cellular, tissue, or organ levels

Download it to your mobile device!

All rights reserved. No part of the material protected by this copyright may be reproduced or utilized in any form, electronic or mechanical, including photocopying, recording, or by any information storage and retrieval system, without written permission from the copyright owner.

The authors, editors, and publisher have made every effort to provide accurate information. However, they are not responsible for errors, omissions, or any outcomes related to the use of the contents of this book and take no responsibility for the use of the products and procedures described. Treatments and side effects described in this book may not be applicable to all people; likewise, some people may require a dose or experience a side effect that is not described herein. Drugs and medical devices are discussed that may have limited availability controlled by the Food and Drug Administration (FDA) for use only in a research study or clinical trial. Research, clinical practice, and government regulations often change the accepted standard in this field. When consideration is being given to use of any drug in the clinical setting, the health care provider or reader is responsible for determining FDA status of the drug, reading the package insert, and reviewing prescribing information for the most up-to-date recommendations on dose, precautions, and contraindications, and determining the appropriate usage for the product. This is especially important in the case of drugs that are new or seldom used.

How to Use This Book

Jones & Bartlett Learning *2011 Nurse's Drug Handbook* gives you what today's nurses and nursing students need: accurate, concise, and reliable drug facts. This book emphasizes the vital information you need to know before, during, and after drug administration. The information is presented in easy-to-understand language and organized alphabetically, so you can find what you need quickly.

What's Special

In addition to the drug information you expect to find in each entry (see "Drug Entries" for details), the *2011 Nurse's Drug Handbook* boasts these special features:

- **A new design** makes it easy to find the most need-to-know drug information, such as indications, dosages, dosage adjustments, and warnings.
- **A new size** makes the *2011 Nurse's Drug Handbook* easier and more convenient to carry and use. But even though the book is now smaller and more convenient, this new edition contains more drug information than ever. We made the book smaller and better without taking anything out.
- **Practical trim size** allows the book to open flat so you can find the information you need without wrestling with a book that wants to close. You can hold the book in one hand, see complete pages at a glance, and use your other hand to document or perform other activities.
- **Introductory material** reviews essential general information you need to know to administer drugs safely and effectively, including an overview of pharmacology and the principles of drug administration. In addition, the five steps of the nursing process are explained and related specifically to drug therapy.
- **Highly useful illustrations** throughout the text help you visualize selected mechanisms of action by showing how drugs work at the cellular, tissue, and

organ levels. In addition, the inside front cover features a table listing all the drugs whose mechanisms of action are illustrated as well as other drugs with the same mechanisms of action.

- **No-nonsense writing style** speaks everyday language and uses the terms and abbreviations you typically encounter in your practice and your studies. To avoid sexist language, we alternate between male and female pronouns throughout the book.
- **Up-to-date drug information** includes the latest FDA-approved drugs, new and changed indications, new warnings, and newly reported adverse reactions.
- **Dosage adjustment**, headlined in color, alerts you to expected dosage changes for a patient with a specific condition or disorder, such as advanced age or renal impairment.
- **Warning**, displayed in color, calls attention to important facts that you need to know before, during, and after drug administration. For example, in the alatrofloxacin entry, this feature informs you that the drug usually is reserved for hospitalized patients and is given for no more than 2 weeks because of the high risk of severe liver damage.
- **Easy-to-use tables** showing route, onset, peak, and duration (see page *xv* for more details) and other tables in the appendices provide a timesaving way to track and check information. The appendices give you an overview of the most important facts and nursing considerations for important drug groups, including insulin preparations and selected antihistamines, topical drugs, antivirals, antineoplastic drugs, interferons, and antihypertensive combination drugs. You'll also find handy instructions for calculating drug dosages and I.V. flow rates.

Drug Entries

The *2011 Nurse's Drug Handbook* clearly and concisely presents all the vital facts

on the drugs that you'll typically administer. To help you find the information you need quickly, drug entries are organized alphabetically by generic drug name—from abatacept to zonisamide. For ease of use, every drug entry follows a consistent format. However, if specific details are unknown or don't apply, the heading isn't included so you can go right to the next section.

GENERIC AND TRADE NAMES

First, each entry identifies the drug's main generic name as well as alternate generic names. (For drugs prescribed by trade name, you can quickly check the comprehensive index, which refers you to the appropriate generic name and page.)

Next, the entry lists the most common U.S. trade names for each drug. It also includes common trade names available only in Canada, marked (CAN).

CLASS, CATEGORY, AND SCHEDULE

Each entry lists the drug's chemical and therapeutic classes. With this information, you can compare drugs in the same chemical class but in different therapeutic classes and vice versa.

The entry also lists the FDA's pregnancy risk category, which categorizes drugs based on their potential to cause birth defects. (For details, see *FDA pregnancy risk categories*.)

Where appropriate, the entry also includes the drug's controlled substance schedule. (For details, see *Controlled substance schedules*, page *xvi*.)

INDICATIONS AND DOSAGES

This section lists FDA-approved therapeutic indications. For each indication, you'll find the applicable drug form or route, age-group (adults, adolescents, or children), and dosage (which includes amount per dose, timing, and duration, when known and appropriate).

ROUTE, ONSET, PEAK, AND DURATION

Quick-reference tables show the drug's onset, peak, and duration (when known)

FDA pregnancy risk categories

Each drug may be placed in a pregnancy risk category based on the FDA's estimate of risk to the fetus. If the FDA hasn't provided a category, the *Drug Handbook* notes that the drug is "Not rated." The categories range from A to X, signifying least to greatest fetal risk.

A Controlled studies show no risk

Adequate, well-controlled studies with pregnant women have failed to demonstrate a risk to the fetus in any trimester of pregnancy.

B No evidence of risk in humans

Adequate, well-controlled studies with pregnant women haven't shown increased risk of fetal abnormalities despite adverse findings in animals, or, in the absence of adequate human studies, animal studies show no fetal risk. The chance of fetal harm is remote, but remains possible.

C Risk can't be ruled out

Adequate, well-controlled human studies are lacking, and animal studies have shown a risk to the fetus or are lacking as well. A chance of fetal harm exists if the drug is given during pregnancy, but the potential benefits may outweigh the risk.

D Positive evidence of risk

Studies in humans, or investigational or post-marketing data, have shown fetal risk. Nevertheless, potential benefits from the drug's use may outweigh risks. For example, the drug may be acceptable if needed in a life-threatening situation or serious disease for which safer drugs can't be used or are ineffective.

X Contraindicated in pregnancy

Studies in animals or humans, or investigational or post-marketing reports, have shown positive evidence of fetal abnormalities or risks that clearly outweigh any possible benefit to the patient.

Controlled substance schedules

The Controlled Substances Act of 1970 mandated that certain prescription drugs be categorized in schedules based on their potential for abuse. The greater their abuse potential, the greater the restrictions on their prescription. The controlled substance schedules range from I to V, signifying highest to lowest abuse potential.

I High potential for abuse

No accepted medical use exists for Schedule I drugs, which include heroin and lysergic acid diethylamide (LSD).

II High potential for abuse

Use may lead to severe physical or psychological dependence. Prescriptions must be written in ink or typewritten and must be signed by the prescriber. Oral prescriptions must be confirmed in writing within 72 hours and may be given only in a genuine emergency. No renewals are permitted.

III Some potential for abuse

Use may lead to low-to-moderate physical dependence or high psychological dependence. Prescriptions may be oral or written. Up to five renewals are permitted within 6 months.

IV Low potential for abuse

Use may lead to limited physical or psychological dependence. Prescriptions may be oral or written. Up to five renewals are allowed within 6 months.

V Subject to state and local regulation

Abuse potential is low; a prescription may not be required.

for each administration route. The onset of action is the time a drug takes to be absorbed, reach a therapeutic blood level, and elicit an initial therapeutic response. The peak therapeutic effect occurs when a drug reaches its highest blood concentration and the greatest amount of drug reaches the site of action to produce the

maximum therapeutic response. The duration of action is the amount of time the drug remains at a blood level that produces a therapeutic response.

MECHANISM OF ACTION

This section concisely describes how a drug achieves its therapeutic effects at cellular, tissue, and organ levels, as appropriate. Illustrations of selected mechanisms of action lend exceptional clarity to sometimes complex processes.

INCOMPATIBILITIES

In this section, you'll be alerted to drugs or solutions that are incompatible with the topic drug when mixed in a syringe or solution or infused through the same I.V. line.

CONTRAINDICATIONS

An alphabetical list details the conditions and disorders that preclude administration of the topic drug.

INTERACTIONS

This section includes drugs, foods, and activities (such as alcohol use and smoking) that can cause important, problematic, or life-threatening interactions with the topic drug. For each interacting drug, food, or activity, you'll learn the effects of the interaction.

ADVERSE REACTIONS

Organized by body system, this section highlights common, serious, and life-threatening adverse reactions.

NURSING CONSIDERATIONS

Warnings, general precautions, and key information that you must know before, during, and after drug administration are detailed in this section. Examples include whether a pill can be crushed and how to properly reconstitute, dilute, store, handle, or dispose of a drug.

Patient teaching information is also included here. You'll find important guidelines for patients, such as how and when to take each prescribed drug, how to spot and manage adverse reactions, which cautions to observe, when to call the prescriber, and more. To save you

Teaching your patient about drug therapy

Your teaching about drug therapy will vary with your patient's needs and your practice setting. To help guide your teaching, each drug entry provides key information that you must teach your patient about that drug. For all patients, however, you also should:

- Teach the generic and trade name for each prescribed drug that he'll take after discharge—even if he took the drug before admission.
- Clearly explain why each drug was prescribed, how it works, and what it's supposed to do. To help your patient understand the drug's therapeutic effects, relate its action to her disorder or condition.
- Review the drug form, dosage, and route with the patient. Tell him whether the drug is a tablet, suppository, spray, aerosol, or other form, and explain how to take it correctly. Also, tell him how often to take the drug and for what length of time. Emphasize that he should take the drug exactly as prescribed.
- Describe the drug's appearance, and explain that scored tablets can be broken in half for safe, accurate dosing. Warn the patient not to break unscored tablets because doing so may alter the drug dosage. If your patient has trouble swallowing capsules, explain that she can open ones that contain sprinkles and take them with food or a drink but that she shouldn't do this with capsules that contain powder. Also, warn her not to crush or chew enteric-coated, extended-release, sustained-release, or similar drug forms.
- Teach the patient about common adverse reactions that may occur. Advise him to notify the prescriber at once if a dangerous adverse reaction, such as syncope, occurs.
- Warn her not to suddenly stop taking a drug if she's bothered by unpleasant adverse reactions, such as a rash and mild itching. Instead, encourage her to discuss the reactions with her prescriber, who may adjust the dosage or substitute a drug that causes fewer adverse reactions.
- Because drugs may cause adverse reactions, such as dizziness and drowsiness, that can impair the patient's ability to perform activities that require alertness, help him develop a dosing schedule that prevents these adverse reactions.
- Inform the patient which adverse reactions resolve with time.
- Teach the patient how to store the drug properly. Let him know if the drug is sensitive to light or temperature and how to protect it from these elements.
- Instruct the patient to store the drug in its original container, if possible, with the drug's name and dosage clearly printed on the label.
- Inform the patient which devices to use—and which to avoid—for drug storage or administration. For example, warn him not to take liquid cyclosporine with a plastic cup or utensils.
- Teach the patient what to do if she misses a dose. Generally, she should take a once-daily drug as soon as she remembers—provided that she remembers within the first 24 hours. If 24 hours have elapsed, she should take the next scheduled dose, but not double the dose. If she has questions or concerns about missed doses, tell her to contact the prescriber.
- Provide information specific to the prescribed drug. For example, if a patient takes a diuretic to manage heart failure, instruct him to weigh himself daily at the same time of day, using the same scale, and wearing the same amount of clothing. Or if the patient takes digoxin or an antihypertensive drug, teach him how to measure his pulse and blood pressure and how to record the measurements. Then instruct him to bring the diary to his regular appointments so the prescriber can monitor his response to the drug.
- Advise the patient to refill prescriptions promptly, unless she no longer needs the drug. Also instruct her to discard expired drugs because they may become ineffective or even dangerous over time.
- Warn the patient to keep all drugs out of the reach of children at all times.

time, however, this section doesn't repeat basic patient-teaching points. (For a summary of those, see *Teaching your patient about drug therapy*, page xvii, and *Federal guidelines for drug disposal*, page xviii.)

In short, Jones & Bartlett Learning *2011 Nurse's Drug Handbook* is designed expressly to give you more of what you need. It puts vital drug information at your fingertips and helps you stay ALWAYS CURRENT in this critical part of your practice or studies.

Federal guidelines for drug disposal

Give patients these important instructions for properly disposing of their unwanted prescription drugs:

- Take unused, unneeded, or outdated prescription drugs out of their original containers and throw them in the trash.
- Consider mixing discarded prescription drugs with a substance like coffee grounds or used cat litter and putting them in impermeable, non-descript containers, such as empty cans or sealable bags.
- Flush prescription drugs down the toilet only if the label or accompanying patient information specifically tells you to do so.
- See if your community has a pharmaceutical take-back program that allows citizens to bring unused drugs to a central location for proper disposal.

Safe, effective drug therapy is one of your most important responsibilities. Not infrequently, a patient's life will depend on your ability to give drugs accurately and safely. In addition, you must keep up with the latest drug information, including newly approved drugs and recently reported life-threatening adverse reactions, as well as those drugs withdrawn from the market after widespread use.

Despite all the drug information available, medication errors remain one of the greatest threats to patients' well-being and a leading cause of lawsuits against nurses, physicians, and hospitals.

Your Responsibilities in Drug Therapy

Your basic responsibilities in drug therapy include:

- administering the right drug in the right dose by the right route at the right time to the right patient
- knowing the therapeutic use, dosage, interactions, adverse reactions, and warnings of each administered drug
- being aware of newly approved drugs that may be prescribed
- knowing about changes to existing drugs, such as new indications and dosages and recently discovered adverse reactions and interactions
- concentrating fully when preparing and administering drugs
- responding promptly and appropriately to serious or life-threatening adverse reactions, interactions, and complications
- instructing each patient about the drug, how it's administered, which effects it causes or may cause, and which reactions to watch for and report.

Several factors may reduce your ability to meet these basic responsibilities—and contribute to medication errors. First, hospitals and other health care facilities have budget constraints that may result in the elimination of professional nursing positions or the hiring of less qualified

technicians to fill them. This forces the remaining nurses to care for more patients. Second, hospital patients are older and more acutely ill, and they typically receive more complex drug therapy than ever. Together, these factors place greater demands on you—increasing your stress level, reducing the time you have to concentrate on drug administration, and increasing your risk of making medication errors or overlooking serious adverse reactions or interactions.

The same factors reduce your time and energy for learning the latest drug facts—which you need to have at your command. You must have this information at your fingertips because your next patient may need a recently approved drug or a complex and unfamiliar drug regimen.

How can you balance your limited time, on the one hand, with your need to know the latest developments, on the other?

Meeting Your Needs

Nurses and students need a reliable, accurate, easy-to-use, quick-reference drug book. They need a book clearly written by and for nurses that has been reviewed by experts in nursing and pharmacology. You hold such a book in your hands: *Jones & Bartlett Learning 2011 Nurse's Drug Handbook*, with its ALWAYS CURRENT features.

The content of *2011 Nurse's Drug Handbook* was developed, written, and edited by experienced practicing nurses. Expert consultants, reviewers, and advisors—both nurses and pharmacists—help ensure the accuracy and reliability of the information covered in each entry and help target that information to your needs. What's more, every drug fact is checked against the most prominent drug references today, including the *American Hospital Formulary Service Drug Information*, *Drug Facts and Comparisons*,

The Physicians' Desk Reference, the FDA's website of new drug approvals, and the USP DI's *Drug Information for the Health Care Professional*.

In addition, to help you quickly access much-needed information, the book is organized alphabetically by generic drug name, follows a consistent format, and is concise.

To ensure that you're always current, Jones & Bartlett Learning *Nurse's Drug Handbook* is updated every year. This newest edition contains:

- important new drug entries in the main part of the book and in the appendices
- new drug facts on hundreds of existing entries, including updated information on new indications and dosages, new incompatibilities and interactions, new adverse reactions, and new nursing considerations
- hundreds of patient-teaching guidelines and suggestions
- thoroughly updated appendices on insulin preparations, antiviral drugs, topical drugs, antihistamines, combination antihypertensive drugs, interferons, ophthalmic drugs, and antineoplastic drugs
- a comprehensive new index.

And as always, you'll find the same color-coded, highly readable type that reduces eyestrain as you speed to the information you need.

Getting More from Your Drug Reference

Whether you work in or are preparing to work in acute care, home care, long-term care, or another health care setting, you'll want your own copy of the *2011 Nurse's Drug Handbook*. That's because this book can help you:

- reduce your risk of medication errors

because you'll have easy access to accurate, reliable drug information that's relevant to your practice

- stay current on the most up-to-date drug developments of the year
- improve your drug administration skills and patient care before, during, and after drug therapy
- quickly detect and manage serious or life-threatening adverse reactions and complications or prevent them from occurring
- save time because you won't have to sift through volumes of information to find what you need, search for a book that's up-to-date, or look through several drug handbooks to get enough information
- increase your confidence about drug administration and enhance your professional interactions with other health care team members
- ensure the delivery of safe, effective care
- improve the depth and quality of your patient teaching.

Reaping the Rewards

Your patients deserve the best and safest care possible—and you deserve to have the tools to deliver that care. Whether you're a student or an experienced clinician, Jones & Bartlett Learning *2011 Nurse's Drug Handbook* will help you provide safe, effective drug therapy because of its practical, easy-to-understand, accurate, and reliable information on virtually all the drugs you're likely to administer.

This handbook has aided thousands of nurses in their patient care. Take it with you to the clinical setting, share it with your peers, and use it to enhance your present and future position in the nursing profession.

Kathleen Dracup, RN, FNP, DNSc, FAAN
Dean and Professor
School of Nursing
University of California, San Francisco
San Francisco, CA

Overview of Pharmacology

Understanding the basics of pharmacology is an essential nursing responsibility. Pharmacology is the science that deals with the physical and chemical properties, and biochemical and physiologic effects, of drugs. It includes the areas of pharmacokinetics, pharmacodynamics, pharmacotherapeutics, pharmacognosy, and toxicodynamics.

The *2011 Nurse's Drug Handbook* deals primarily with pharmacokinetics, pharmacodynamics, and pharmacotherapeutics—the information you need to administer safe and effective drug therapy (discussed below). Pharmacognosy is the branch of pharmacology that deals with the biological, biochemical, and economic features of naturally occurring drugs. Toxicodynamics is the study of the harmful effects that excessive amounts of a drug produce in the body; in a drug overdose or drug poisoning, large drug doses may saturate or overwhelm normal mechanisms that control absorption, distribution, metabolism, and excretion.

Drug Nomenclature

Most drugs are known by several names—chemical, generic, trade, and official—each of which serves a specific function. (See How drugs are named.) However, multiple drug names can also contribute to medication errors. You may find a familiar drug packaged with an unfamiliar name if your institution changes suppliers or if a familiar drug is newly approved in a different dose or for a new indication.

Drug Classification

Drugs can be classified in various ways. Most pharmacology textbooks group drugs by their functional classification, such as psychotherapeutics, which is based on common characteristics. Drugs can also be classified according to their therapeutic use, such as antipanic or antiobsessional drugs. Drugs within a certain therapeutic class may be further divided into subgroups based on their

mechanisms of action. For example, the therapeutic class antineoplastics can be further classified as alkylating agents, antibiotic antineoplastics, antimetabolites, antimitotics, biological response

How drugs are named

A drug's chemical, generic, trade, and official names are determined at different phases of the drug development process and serve different functions. For example, the various names of the commonly prescribed anticonvulsant divalproex sodium are:

- Chemical name: Pentanoic acid, 2-propyl-, sodium salt (2:1) or $(C_{16}H_{31}O_4Na)$
- Generic name: divalproex sodium
- Trade name: Depakote
- Official name: Divalproex Sodium Delayed-Release Tablets, USP

A drug's chemical name describes its atomic and molecular structure. The chemical name of divalproex sodium—pentanoic acid, 2-propyl-, sodium salt (2:1), or $C_{16}H_{31}O_4Na$ (pronounced valproate semisodium)—indicates that the drug is a combination of two valproic acid compounds with a sodium molecule attached to only one side.

Once a drug successfully completes several clinical trials, it receives a generic name, also known as the nonproprietary name. The generic name is usually derived from but shorter than the chemical name. The United States Adopted Names Council is responsible for selecting generic names, which are intended for unrestricted public use.

Before submitting the drug for FDA approval, the manufacturer creates and registers a trade name (or brand name) when the drug appears ready to be marketed. Trade names are copyrighted and followed by the symbol ® to indicate that they're registered and that their use is restricted to the drug manufacturer. Once the original patent on a drug has expired, any manufacturer may produce the drug under its own trade name.

A drug's official name is the name under which it's listed in the United States Pharmacopoeia (USP) and the National Formulary (NF).

modifiers, antineoplastic enzymes, and hormonal antineoplastics.

Pharmacokinetics

Pharmacokinetics is the study of a drug's actions—or fate—as it passes through the body during absorption, distribution, metabolism, and excretion.

ABSORPTION

Before a drug can begin working, it must be transformed from its pharmaceutical dosage form to a biologically available (bioavailable) substance that can pass through various biological cell membranes to reach its site of action. This process is known as absorption. A drug's absorption rate depends on its route of administration, its circulation through the tissue into which it's administered, and its solubility—that is, whether it's more water-soluble (*hydrophilic*) or fat-soluble (*lipophilic*).

Although drugs may penetrate cellular membranes either actively or passively, most drugs do so by *passive diffusion*, moving inertly from an area of higher concentration to an area of lower concentration. Passive diffusion may occur through water or fat. Passive diffusion through water—*aqueous diffusion*—occurs within large water-filled compartments, such as interstitial spaces, and across epithelial membrane tight junctions and pores in the epithelial lining of blood vessels. Aqueous diffusion is driven by concentration gradients. Drug molecules that are bound to large plasma proteins, such as albumin, are too large to pass through aqueous pores in this way. Passive diffusion through fat—*lipid diffusion*—plays an important role in drug metabolism because of the large number of lipid barriers that separate the aqueous compartments of the body. The tendency of a drug to move through lipid layers between aqueous compartments often depends on the pH of the medium—that is, the ability of the water-soluble or fat-soluble drug to form weak acid or weak base.

Drugs with molecules that are too

large to readily diffuse may rely on *active diffusion*, in which special carriers on molecules, including peptides, amino acids, and glucose, transport the drug through the membranes. However, some molecules with selective membrane carriers can expel foreign drug molecules; this is why many drugs can't cross the blood-brain barrier.

Drug absorption begins at the administration route. The three main administration route categories are enteral, parenteral, and transcutaneous. Depending on its nature or chemical makeup, a drug may be better absorbed from one site than from another.

Enteral Administration

Enteral administration consists of the oral, nasogastric, and rectal routes.

Oral: Drugs administered orally are absorbed in the GI tract and then proceed by the hepatic portal vein to the liver and into the systemic circulation. Although generally considered the preferred route, oral drug administration has a number of disadvantages:

- The oral route doesn't always yield sufficiently high blood concentrations to be effective.
- Bioavailability may be less than optimal because of incomplete absorption and first-pass elimination (the part of metabolism that occurs during transit through the liver before the drug reaches the general circulation).
- Drug absorption may be incomplete if the drug is degraded by digestive enzymes or the acidic pH in the stomach or if it's excreted from the liver into the bile.
- Food in the GI tract, gastric emptying time, and intestinal motility may also impede drug absorption.

Nasogastric: Drugs administered through a nasogastric tube enter the stomach directly and are absorbed in the GI tract.

Rectal: Rectal drugs and suppositories also enter the GI tract directly after being inserted in the rectum and absorbed through the rectal mucosa. After being

absorbed into the lower GI tract, rectal drugs enter the circulation through the inferior vena cava, bypassing the liver and thus avoiding first-pass metabolism. Suppositories, however, tend to travel upward into the rectum, where veins, such as the superior hemorrhoidal vein, lead to the liver. As a result, drug absorption by this route is often unreliable and difficult to predict.

Parenteral Administration

Parenteral routes may be used whenever enteral routes are contraindicated or inadequate. These routes include intramuscular (I.M.), intravenous (I.V.), subcutaneous (SubQ) and intradermal (I.D.) administration. Drug absorption is much faster and more predictable after parenteral administration than after enteral administration.

I.M.: Drugs administered by the I.M. route are injected deep into the muscle, where they're absorbed relatively quickly. The rate of drug absorption depends on the vascularity of the injection site, the physiochemical properties of the drug, and the solution in which the drug is contained.

I.V.: I.V. drug administration involves injecting or infusing the drug directly into the blood circulation, allowing for rapid distribution throughout the body. This route usually provides the greatest bioavailability.

SubQ: Drugs administered by the subcutaneous route are injected into the alveolar connective tissue just below the skin and are absorbed by simple diffusion from the injection site. The factors that affect I.M. absorption also affect subcutaneous absorption. Absorption by the subcutaneous route may be slower than by the I.M. route.

I.D.: Drugs administered intradermally, such as purified protein derivative (PPD), are injected into the dermis, from which they diffuse slowly into the local microcapillary system.

Transcutaneous Administration

Transcutaneous drug administration

allows drug absorption through the skin or soft-tissue surface. Drugs may be inhaled, inserted sublingually, applied topically, or administered by the eyes, ears, nose, or vagina.

Inhalation: Inhaled drugs may be given as a powder and aerosolized or mixed in solution and nebulized directly into the respiratory tract, where they're absorbed through the alveoli. Inhaled drugs are usually absorbed quickly because of the abundant blood flow in the lungs.

Sublingual: Sublingual drug administration involves placing a tablet, troche, or lozenge under the tongue. The drug is absorbed across the epithelial lining of the mouth, usually quickly. This route avoids first-pass metabolism.

Topical: Topical drugs—creams, ointments, lotions, and patches—are placed on the skin and then cross the epidermis into the capillary circulation. They may also be absorbed through sweat glands, hair follicles, and other skin structures. Absorption by the skin is enhanced if the drug is in a solution.

Ophthalmic: Ophthalmic drugs include solutions and ointments that are instilled or applied directly to the cornea or conjunctiva as well as small, elliptical disks that are placed directly on the eyeball behind the lower eyelid. The movements of the eyeball promote distribution of these drugs over the surface of the eye. Although ophthalmic drugs produce a local effect on the conjunctiva or anterior chamber, some preparations may be absorbed systemically and therefore produce systemic effects.

Otic: Drops administered into the external auditory canal, otic drugs are used to treat infection or inflammation and to soften and remove ear wax. Otic solutions exert a local effect and may result in minimal systemic absorption with no adverse effects.

Nasal: Nasal solutions and suspensions are applied directly to the nasal mucosa by instillation or inhalation to produce local effects, such as vasoconstriction to reduce nasal congestion. Some nasal

solutions, such as vasopressin, are administered by this route specifically to produce systemic effects.

Vaginal: Vaginal drugs include creams, suppositories, and troches that are inserted into the vagina, sometimes using a special applicator. These drugs are absorbed locally to treat such conditions as bacterial and fungal infections.

DISTRIBUTION

Distribution is the process by which a drug is transported by the circulating fluids to various sites, including its sites of action. To ensure maximum therapeutic effectiveness, the drug must permeate all membranes that separate it from its intended site of action. Drug distribution is influenced by blood flow, tissue availability, and protein binding.

METABOLISM

Drug metabolism is the enzymatic conversion of a drug's structure into substrate molecules or polar compounds that are either less active or inactive and are readily excreted. Drugs can also be synthesized to larger molecules. Metabolism may also convert a drug to a more toxic compound. Because the primary site of drug metabolism is the liver, children, the elderly, and patients with impaired hepatic function are at risk for altered therapeutic effects.

Biotransformation is the process of changing a drug into its active metabolite. Compounds that require metabolic biotransformation for activation are known as *prodrugs*. During phase I of biotransformation, the parent drug is converted into an inactive or partially active metabolite. Much of the original drug may be eliminated during this phase. During phase II, the inactive or partially active metabolite binds with available substrates, such as acetic acid, glucuronic acid, sulfuric acid, or water, to form its active metabolite. When biotransformation leads to synthesis, larger molecules are produced to create a pharmacologic effect.

EXCRETION

The body eliminates drugs by both

metabolism and excretion. Drug metabolites—and, in some cases, the active drug itself—are eventually excreted from the body, usually through bile, feces, and urine. The primary organ for drug elimination is the kidney. Impaired renal function may alter drug elimination, thereby altering the drug's therapeutic effect. Other excretion routes include evaporation through the skin, exhalation from the lungs, and secretion into saliva and breast milk.

A drug's elimination half-life is the amount of time required for half of the drug to be eliminated from the body. The half-life roughly correlates with the drug's duration of action and is based on normal renal and hepatic function. Typically, the longer the half-life, the less often the drug has to be given and the longer it remains in the body.

Pharmacodynamics

Pharmacodynamics is the study of the biochemical and physiologic effects of drugs and their mechanisms of action. A drug's actions may be structurally specific or nonspecific. Structurally specific drugs combine with cell receptors, such as proteins or glycoproteins, to enhance or inhibit cellular enzyme actions. Drug receptors are the cellular components affected at the site of action. Many drugs form chemical bonds with drug receptors, but a drug can bond with a receptor only if it has a similar shape—much the same way that a key fits into a lock. When a drug combines with a receptor, channels are either opened or closed and cellular biochemical messengers, such as cyclic adenosine monophosphate or calcium ions, are activated. Once activated, cellular functions can be turned either on or off by these messengers.

Structurally nonspecific drugs, such as biological response modifiers, don't combine with cell receptors; rather, they produce changes within the cell membrane or interior.

The mechanisms by which drugs interact with the body are not always known. Drugs may work by physical action (such

as the protective effects of a topical ointment) or chemical reaction (such as an antacid's effect on the gastric mucosa), or by modifying the metabolic activity of invading pathogens (such as an antibiotic) or replacing a missing biochemical substance (such as insulin).

AGONISTS

Agonists are drugs that interact with a receptor to stimulate a response. They alter cell physiology by binding to plasma membranes or intracellular structures. *Partial agonists* can't achieve maximal effects even though they may occupy all available receptor sites on a cell. *Strong agonists* can cause maximal effects while occupying only a small number of receptor sites on a cell. *Weak agonists* must occupy many more receptor sites than strong agonists to produce the same effect.

ANTAGONISTS

Antagonists are drugs that attach to a receptor but don't stimulate a response; instead, they inhibit or block responses that would normally be caused by agonists. *Competitive antagonists* bind to receptor sites that are also compatible with an agonist, thus preventing the agonist from binding to the site. *Noncompetitive antagonists* bind to receptor sites that aren't occupied by an agonist; this changes the receptor site so that it's no longer recognized by the agonist. *Irreversible antagonists* work in much the same way that noncompetitive ones do, except that they permanently bind with the receptor.

Antagonism plays an important role in drug interactions. When two agonists that cause opposite therapeutic effects, such as a vasodilator and a vasoconstrictor, are combined, the effects cancel each other out. When two antagonists, such as morphine and naloxone, are combined, both drugs may become inactive.

Pharmacotherapeutics

Pharmacotherapeutics is the study of how drugs are used to prevent or treat disease. Understanding why a drug is pre-

scribed for a certain disease can assist you in prioritizing drug administration with other patient care activities. Knowing a drug's desired and unwanted effects may help you uncover problems not readily apparent from the admitting diagnosis. This information may also help you prevent such problems as adverse reactions and drug interactions.

A drug's *desired effect* is the intended or expected clinical response to the drug. This is the response you start to evaluate as soon as a drug is given. Dosage adjustments and the continuation of therapy often depend on your accurate evaluation and documentation of the patient's response.

An *adverse reaction* is any noxious and unintended response to a drug that occurs at therapeutic doses used for prophylaxis, diagnosis, or therapy. Adverse reactions associated with excessive amounts of a drug are considered drug overdoses. Be prepared to follow your institution's policy for reporting adverse drug reactions.

An *idiosyncratic response* is a genetically determined abnormal or excessive response to a drug that occurs in a particular patient. The unusual response may indicate that the drug has saturated or overwhelmed mechanisms that normally control absorption, distribution, metabolism, or excretion, thus altering the expected response. You may be unsure whether a reaction is adverse or idiosyncratic. Once you report the reaction, the pharmacist usually determines the appropriate course of action.

An *allergic reaction* is an adverse response that results from previous exposure to the same drug or to one that's chemically similar to it. The patient's immune system reacts to the drug as if it were a foreign invader and may produce a mild hypersensitivity reaction, characterized by localized dermatitis, urticaria, angioedema, or photosensitivity. Allergic reactions should be reported to the prescriber immediately and the drug should be discontinued. Follow-up care may

include giving drugs, including antihistamines and corticosteroids, to counteract the allergic response.

An *anaphylactic reaction* involves an immediate hypersensitivity response characterized by urticaria, pruritus, and angioedema. Left untreated, an anaphylactic reaction can lead to systemic involvement, resulting in shock. It's often associated with life-threatening hypotension and respiratory distress. Be prepared to assist with emergency life support measures, especially if the reaction occurs in response to I.V. drugs, which have the fastest rate of absorption.

A *drug interaction* occurs when one drug alters the pharmacokinetics of another drug—for example, when two or more drugs are given concurrently. Such concurrent administration can increase or decrease the therapeutic or adverse effects of either drug. Some drug interactions are beneficial. For example, when taken with penicillin, probenecid decreases the excretion rate of penicillin, resulting in higher blood levels of penicillin. Drug interactions also may occur when a drug's metabolism is altered, often owing to the induction of or competition for metabolizing enzymes. For example, H₂-receptor agonists, which reduce secretion of the enzyme gastrin, may alter the breakdown of enteric coatings on other drugs. Drug interactions due to carrier protein competition typically occur when a drug inhibits the kidneys' ability to reduce excretion of other drugs. For example, probenecid is completely reabsorbed by the renal tubules and is metabolized very slowly. It competes with the same carrier protein as sulfonamides for active tubular secretion and so decreases the renal excretion of sulfonamides. This particular competition can lead to an increased risk of sulfonamide toxicity.

Special Considerations

Although every drug has a usual dosage range, certain factors—such as a patient's age, weight, culture and ethnicity, gender,

pregnancy status, and renal and hepatic function—may contribute to the need for dosage adjustments. When you encounter special considerations such as these, be prepared to reassess the prescribed dosage to make sure that it's safe and effective for your patient.

CULTURE AND ETHNICITY

Certain drugs are more effective or more likely to produce adverse effects in particular ethnic groups or races. For example, blacks with hypertension respond better to thiazide diuretics than do patients of other races; on the other hand, blacks also have an increased risk of developing angioedema with angiotensin-converting enzyme (ACE) inhibitors. A patient's religious or cultural background also may call for special consideration. For example, a drug made from porcine products may be unacceptable to a Jewish or Muslim patient.

ELDERLY PATIENTS

Because aging produces certain changes in body composition and organ function, elderly patients present unique therapeutic and dosing problems that require special attention. For example, the weight of the liver, the number of functioning hepatic cells, and hepatic blood flow all decrease as a person ages, resulting in slower drug metabolism. Renal function may also decrease with aging. These processes can lead to the accumulation of active drugs and metabolites as well as increased sensitivity to the effects of some drugs in elderly patients. Because they're also more likely to have multiple chronic illnesses, many elderly patients take multiple prescription drugs each day, thus increasing the risk of drug interactions.

CHILDREN

Because their bodily functions aren't fully developed, children—particularly those under age 12—may metabolize drugs differently than adults. In infants, immature renal and hepatic function delay metabolism and excretion of drugs. As a result, pediatric drug dosages are very different

from adult dosages.

The FDA has provided drug manufacturers with guidelines that define pediatric age categories. Unless the manufacturer provides a specific age range, use these categories as a guide when administering drugs:

- neonates—birth up to age 1 month
- infants—ages 1 month to 2 years
- children—ages 2 to 12
- adolescents—ages 12 to 16.

PREGNANCY

The many physiologic changes that take place in the body during pregnancy may affect a drug's pharmacokinetics and alter its effectiveness. Additionally, exposure to drugs may pose risks for the developing fetus. Before administering a drug to a pregnant patient, be sure to check its assigned FDA pregnancy risk category and intervene appropriately.

Principles of Drug Administration

Because there are thousands of drugs and hundreds of facts about each one, taking responsibility for drug administration can seem overwhelming. One way that you can enhance your understanding of the principles of drug administration is to *associate*, *ask*, and *predict* during the critical thinking process. For example, *associate* each drug with general information you may already know about the drug or drug class. *Ask* yourself why a drug is administered by a certain route and why it's given multiple times throughout the day rather than only once. Learn to *predict* a drug's actions, uses, adverse effects, and possible drug interactions based on your knowledge of the drug's mechanism of action. As you apply these principles to drug administration, you'll begin to intuitively know which facts you need to make rational clinical decisions.

Prescriptions for patients in hospitals and other institutions typically are written by a physician on a form called the *physician's order sheet* or they're directly input into a computerized system with an electronic signature. Drugs are prescribed based not only on their specific mechanisms of action but also on the patient's profile, which commonly includes age, ethnicity, gender, pregnancy status, smoking and drinking habits, and use of other drugs.

“Rights” of Drug Administration

Always keep in mind the following “rights” of drug administration: the right drug, right time, right dose, right patient, right route, and right preparation and administration.

RIGHT DRUG

Many drugs have similar spellings, different concentrations, and several generic forms. Before administering any drug, compare the exact spelling and concentration of the prescribed drug that appears on the label with the information contained in the medication administra-

tion record or drug profile. Regardless of which drug distribution system your facility uses, you should read the drug label and compare it to the medication administration record at least three times:

- before removing the drug from the dispensing unit or unit dose cart
- before preparing or measuring the prescribed dose
- before opening a unit dose package (just before administering the drug to the patient).

RIGHT TIME

Various factors can affect the time that a drug is administered, such as the timing of meals and other drugs, scheduled diagnostic tests, standardized times used by the institution, and factors that may alter the consistency of blood levels and drug absorption. Before administering any p.r.n. drug, check the patient's chart to ensure that no one else has already administered it and that the specified time interval has passed. Also, document administration of a p.r.n. drug immediately.

RIGHT DOSE

Whenever you're dispensing an unfamiliar drug or in doubt about a dosage, check the prescribed dose against the range specified in a reliable reference. Be sure to consider any reasons for a dosage adjustment that may apply to your particular patient. Also, make sure you're familiar with the standard abbreviations your institution uses for writing prescriptions.

RIGHT PATIENT

Always compare the name of the patient on the medication record with the name on the patient's identification bracelet. When using a unit dose system, compare the name on the drug profile with that on the identification bracelet.

RIGHT ROUTE

Each drug prescription should specify the administration route. If the administra-

tion route is missing from the prescription, consult the prescriber before giving the drug. Never substitute one route for another unless you obtain a prescription for the change.

RIGHT PREPARATION AND ADMINISTRATION

For drugs that need to be mixed, poured, or measured, be sure to maintain aseptic technique. Follow any specific directions included by the manufacturer regarding diluent type and amount and the use of filters, if needed. Clearly label any drug that you've reconstituted with the patient's name, the strength or dose, the date and time that you prepared the drug, the amount and type of diluent that you used, the expiration date, and your initials.

Administration Routes

Drugs may be administered by a variety of routes and dosage forms. A particular route may be chosen for convenience or to maximize drug concentration at the site of action, to minimize drug absorption elsewhere, to prolong drug absorption, or to avoid first-pass metabolism.

Different dosage forms of the same drug may have different drug absorption rates, times of onset, and durations of action. For example, nitroglycerin is a coronary vasodilator that may be administered by the I.V., sublingual, oral, or buccal route, or as a topical ointment or disk. The I.V., sublingual, and buccal forms of nitroglycerin provide a rapid onset of action, whereas the oral, ointment, and disk forms have a slower onset and a prolonged duration of action.

Drug administration routes include the enteral, parenteral, and transcutaneous routes.

ENTERAL

The enteral route consists of oral, nasogastric, and rectal administration. Drugs administered enterally enter the blood circulation by way of the GI tract. This route is considered the most natural and convenient route as well as the safest. As a result, most drugs are taken enterally, usually to provide systemic effects.

Oral

- **Tablets:** Tablets, the most commonly used dosage form, come in a variety of colors, sizes, and shapes. Some tablets are specially coated for various purposes. Enteric coatings permit safe passage of a tablet through the stomach, where some drugs may be degraded or may produce unwanted effects, to the environment of the intestine. Some coatings protect the drug from the destructive influences of moisture, light, or air during storage; some coatings actually contain the drug, such as procainamide; still others conceal a bad taste. Coatings are also used to ensure appropriate drug release and absorption. Some tablets shouldn't be crushed or broken because doing so may alter drug release.
- **Capsules:** Capsules are solid dosage forms in which the drug and other ingredients are enclosed in a hard or soft shell of varying size and shape. Drugs typically are released faster from capsules than from tablets.
- **Solutions:** Drugs administered in solution are absorbed more rapidly than those administered in solid form; however, they don't always produce predictable drug levels in the blood. Some drugs in solution should be administered with meals or snacks to minimize their irritating effect on the gastric mucosa.
- **Suspensions:** Suspensions are preparations consisting of finely divided drugs in a suitable vehicle, usually water. Suspensions should be shaken before administration to ensure the uniformity of the preparation and administration of the proper dosage.

Nasogastric

Drugs administered through a nasogastric or gastrostomy tube enter the stomach directly, bypassing the mouth and esophagus. They're usually administered in liquid form because an intact tablet or capsule could cause an obstruction in a gastric tube. Sometimes a tablet may be crushed or a capsule opened for nasogastric administration; however, doing so

will affect the drug's release. You may need to consult a pharmacist to determine which tablets can be crushed or capsules opened.

Rectal

Some enteral drugs are administered rectally—as suppositories, solutions, or ointments—to provide either local or systemic effects. When inserted into the rectum, suppositories soften, melt, or dissolve, releasing the drug contained inside them. The rectal route may be preferred for drugs that are destroyed or inactivated by the gastric or intestinal environment or that irritate the stomach. It also may be indicated when the oral route is contraindicated because of vomiting or difficulty swallowing. The drawbacks of rectal administration include inconvenience, noncompliance, and incomplete or irregular drug absorption.

PARENTERAL

In parenteral drug administration, a drug enters the circulatory system through an injection rather than through GI absorption. This administration route is chosen when rapid drug action is desired; when the patient is uncooperative, unconscious, or unable to accept medication by the oral route; or when a drug is ineffective by other routes. Drugs may be injected into the joints, spinal column, arteries, veins, and muscles. However, the most common parenteral routes are the intramuscular (I.M.), intravenous (I.V.), subcutaneous (SubQ), and intradermal (I.D.) routes. Drugs administered parenterally may be mixed in either a solution or a suspension; those mixed in a solution typically act more rapidly than those mixed in a suspension. Parenteral administration has several disadvantages: The drug can't be removed or the dosage reduced once it has been injected, and injections typically are more expensive to administer than other dosage forms because they require strict sterility.

Intramuscular

I.M. injections are administered deep into the anterolateral aspect of the thigh

(vastus lateralis), the dorsogluteal muscle (gluteus maximus), the upper arm (deltoid), or the ventrogluteal muscle (gluteus medius). I.M. injections typically provide sustained drug action. This route is commonly chosen for drugs that irritate the subcutaneous tissue. The drug should be injected as far as possible from major nerves and blood vessels.

Intravenous

In I.V. drug administration, an aqueous solution is injected directly into the vein—typically of the forearm. Drugs may be administered as a single, small-volume injection or as a slow, large-volume infusion. Because drugs injected I.V. don't encounter absorption barriers, this route produces the most rapid drug action, making it vital in emergency situations. Except for I.V. fat emulsions used as nutritional supplements, oleaginous preparations aren't usually administered by this route because of the risk of fat embolism.

Subcutaneous

The subcutaneous route may be used to inject small volumes of medication, usually 1 ml or less. Subcutaneous injections typically are given below the skin in the abdominal area, lateral area of the anterior thigh, posterior surface of the upper arm, or lateral lumbar area. Injection sites should be rotated to minimize tissue irritation if the patient receives frequent subcutaneous injections—as, for example, in a patient who takes insulin.

Intradermal

Common sites for I.D. injection are the arm and the back. Because only about 0.1 ml may be administered intradermally, this route is rarely used except in diagnostic and test procedures, such as screening for allergic reactions.

TRANSCUTANEOUS

In transcutaneous administration, a drug crosses the skin layers from either the outside (dermal) or the inside (mucocutaneous). This route includes sublingual (S.L.), inhalation, ophthalmic, otic, nasal, topical, and vaginal administration.

Sublingual

In S.L. administration, tablets are placed under the tongue and allowed to dissolve. Nitroglycerin is commonly administered by this route, which allows rapid drug absorption and action. The S.L. route also avoids first-pass metabolism.

Inhalation

Some drugs may be inhaled orally or nasally to produce a local effect on the respiratory tract or a systemic effect. Although drugs given by inhalation avoid first-pass hepatic metabolism, the lungs can also serve as an area of first-pass metabolism by providing respiratory conversion to more water-soluble compounds.

Ophthalmic

Ophthalmic solutions and ointments are applied directly to the cornea or conjunctiva for enhanced local penetration and decreased systemic absorption. These drugs usually are used in eye examinations and to treat glaucoma. Ophthalmic solutions pose a greater risk of drug loss through the nasolacrimal duct into the nasopharynx than ophthalmic ointments do.

Otic

Otic solutions are instilled directly into the external auditory canal for local penetration and decreased systemic absorption. These drugs, which include anesthetics, antibiotics, and anti-inflammatory drugs, usually require occlusion of the ear canal with cotton after instillation.

Nasal

Nasal solutions and suspensions are applied directly to the nasal mucosa for enhanced local penetration and decreased systemic absorption. These drugs are usually used to reduce the inflammation typically associated with seasonal or perennial rhinitis.

Topical

Topical drugs—including creams, ointments, lotions, and pastes—are applied directly to the skin. Transdermal delivery systems, usually in the form of an adhe-

sive patch or a disk, are among the latest developments in topical drug administration. Because they provide slow drug release, these systems are typically used to avoid first-pass metabolism and ensure prolonged duration of action.

Vaginal

Vaginal troches, suppositories, and creams are inserted into the vagina for slow, localized absorption. Body pH that differs from blood pH causes drug trapping or reabsorption, which delays drug excretion through the renal tubules. Vaginal secretions are alkaline, with a pH of 3.4 to 4.2, whereas blood has a pH of 7.35 to 7.45.

Drug Therapy and the Nursing Process

A systematic approach to nursing care, the nursing process helps guide you as you develop, implement, and evaluate your care and ensures that you'll deliver safe, consistent, and effective drug therapy to your patients. The nursing process consists of five steps, including assessment, nursing diagnosis, planning, implementation, and evaluation. Even though documentation is not a step in the nursing process, you're legally and professionally responsible for documenting all aspects of your care before, during, and after drug administration.

Assessment

The first step in the nursing process, assessment involves gathering information that's essential to guide your patient's drug therapy. This information includes the patient's drug history, present drug use, allergies, medical history, and physical examination findings. Assessment is an ongoing process that serves as a baseline against which to compare any changes in your patient's condition; it's also the basis for developing and individualizing your patient's plan of care.

DRUG HISTORY

The patient's drug history is critical in your planning of drug-related care. Ask about his previous use of over-the-counter and prescription drugs as well as herbal remedies. For each drug, determine:

- the reason the patient took it
- the prescribed dosage
- the administration route
- the frequency of administration
- the duration of the drug therapy
- any adverse reactions the patient may have experienced and how he handled them.

Also determine if the patient has a history of drug abuse or addiction. Depending on his physical and emotional state, you may need to obtain the drug

history from other sources, such as family members, friends, other caregivers, and the medical record.

PRESENT DRUG USE

Ask about the patient's current use of over-the-counter and prescription drugs as well as herbal remedies. As you did in the drug history, find out the specific details for each drug (dosage, route, frequency, and reason for taking). Also ask the patient if he thinks the drug has been effective and when he took the last dose.

If the patient uses herbal remedies, similarly explore the use of these products because herbs may interact with certain drugs. Also ask about the patient's use of recreational drugs, such as alcohol and tobacco, as well as illegal drugs, such as marijuana and heroin. If the patient acknowledges use of these drugs, be alert for possible drug interactions. This information also may provide you with insight about the patient's response—or lack of response—to his current drug treatment plan.

Try to find out if the patient has any other problems that might affect his compliance with the drug treatment plan, and intervene appropriately. For instance, a patient who is unemployed and has no health insurance may fail to fill a needed prescription. In such a case, contact an appropriate individual in your facility who may be able to help the patient obtain financial assistance.

Be sure to ask the patient if his drug treatment plan requires special monitoring or follow-up laboratory tests. For example, patients who take antihypertensives need to have their blood pressure checked routinely, and those who take warfarin must have their prothrombin time tested regularly. Other patients must undergo periodic blood tests to assess their hepatic and renal function. Determine whether the patient has complied with this part of his treatment plan,

and ask him if he knows the results of the latest monitoring or laboratory tests.

ALLERGIES

Find out if the patient is allergic to any drugs or foods. If he has an allergy, explore it further by determining the type of drug or food that triggers a reaction, the first time he experienced a reaction, the characteristics of the reaction, and other related information. Keep in mind that some patients consider annoying symptoms, such as indigestion, an allergic reaction. However, be sure to document a true allergy according to your facility's policy to ensure that the patient doesn't receive that drug or any related drug that may cause a similar reaction. Also, document allergies to foods because they may lead to drug interactions or adverse drug reactions. For example, sulfite is a food additive as well as a drug additive, so a patient with a known allergy to sulfite-containing foods is likely to react to sulfite-containing drugs.

MEDICAL HISTORY

While reviewing your patient's medical history, determine if he has any acute or chronic conditions that may interfere with his drug therapy. Certain disorders involving major body systems, such as the cardiovascular, GI, hepatic, and renal systems, may affect a drug's absorption, transport, metabolism, or excretion and interfere with its action; they also may increase the incidence of adverse reactions and lead to toxicity. For each disorder identified, try to determine when the condition was diagnosed, what drugs were prescribed, and who prescribed them. This information can help you determine whether the patient is receiving incompatible drugs and whether more than one prescriber is managing his drug therapy.

Ask a female patient if she is or may be pregnant or if she's breast-feeding. Many drugs are safe to use during pregnancy, but others may harm the fetus. Also, some drugs are distributed into breast

milk. If your patient is or might be pregnant, check the FDA's pregnancy risk category for the prescribed drug and notify the prescriber if the drug may pose a risk to the fetus. If the patient is breast-feeding, find out if the drug is distributed in breast milk and intervene appropriately.

PHYSICAL EXAMINATION FINDINGS

As part of the physical examination, note the patient's age and weight. Be aware that age determines the dosage of certain drugs, such as sedatives and hypnotics, whereas weight determines the dosage of others, including some I.V. antibiotics and anticoagulants. As you perform the physical examination, note any abnormal findings that may point to body organ or system dysfunction. For example, if you detect liver enlargement and ascites, the patient may have impaired hepatic function, which can affect the metabolism of a drug he's taking and lead to harmful adverse or toxic effects. Also note whether a body organ or system appears to be responding to drug treatment. For example, if a patient has been taking an antibiotic to treat chronic bronchitis, thoroughly evaluate his respiratory status to measure his progress. And be sure to assess the patient for possible adverse reactions to the drugs he's taking.

Assess the patient's neurologic function to make sure that he can understand his drug regimen and carry out required tasks, such as performing a fingerstick to obtain blood for glucose measurement. If the patient can't understand essential drug information, you'll need to identify a family member or another person who is willing to become involved in the teaching process.

Nursing Diagnosis

Based on information derived from the assessment and physical examination findings, the nursing diagnoses are statements of actual or potential problems that a nurse is licensed to treat or manage alone or in collaboration with other members of the health care team. They're worded according to guidelines estab-

lished by the North American Nursing Diagnosis Association (NANDA).

One of the most common nursing diagnoses related to drug therapy is *knowledge deficit*, which indicates that the patient doesn't have sufficient understanding of his drug regimen. However, adverse reactions are the basis for most nursing diagnoses related to drug administration. For example, a patient receiving an opioid analgesic might have a nursing diagnosis of *constipation* related to decreased intestinal motility or *ineffective breathing pattern* related to respiratory depression. A patient receiving long-term, high-dose corticosteroids may have a *risk for impaired skin integrity* related to cortisone acetate or *self-concept disturbance* related to physical changes from prednisone therapy. Many antiarrhythmics cause orthostatic hypotension and thus may place an elderly patient at *high risk for injury* related to possible syncope. Broad-spectrum antibiotics, especially penicillin, may lead to the overgrowth of *Clostridium difficile*, a bacterium that normally is present in the intestine. This overgrowth in turn may lead to pseudomembranous colitis, characterized by abdominal pain and severe diarrhea. The nursing diagnoses in such a case might include *potential for infection* related to bacterial overgrowth, *alteration in comfort* related to abdominal pain, and *fluid balance deficit* related to diarrhea.

Planning

During the planning phase, you'll establish expected outcomes—or goals—for the patient and then develop specific nursing interventions to achieve them. Expected outcomes are observable or measurable goals that should occur as a result of nursing interventions and sometimes in conjunction with medical interventions. Developed in collaboration with the patient, the outcomes should be realistic and objective and should clearly communicate the direction of the plan of care to other nurses. They should be written as behaviors or responses for the

patient, not the nurse, to achieve and should include a time frame for measuring the patient's progress. An example of a typical expected outcome is, *The patient will accurately demonstrate self-administration of insulin before discharge*. Based on each outcome statement you establish, you'd then develop appropriate nursing interventions, which might include drug administration techniques, patient teaching, monitoring of vital signs, calculation of drug dosages based on weight, and recording of intake and output.

Implementation

As you implement the nursing interventions, be sure to stringently follow the classic rule of drug administration: administer the right dose of the right drug by the right route to the right patient at the right time. Also, keep in mind that you have a legal and professional responsibility to follow institutional policy regarding standing orders, prescription renewal, and the use of nursing judgment. During the implementation phase, you'll also begin to evaluate the patient's expected outcomes and nursing interventions and make necessary changes to the plan of care.

Evaluation

Evaluation is an ongoing process rather than a single step in the nursing process. During this phase, you evaluate each expected outcome to determine whether or not it has been achieved and whether the original plan of care is working or needs to be modified. In evaluating a patient's drug treatment plan, you should determine whether or not the drug is controlling the signs and symptoms for which it was prescribed. You also should evaluate the patient for psychological or physiologic responses to the drug, especially adverse reactions. This constant monitoring allows you to make appropriate and timely suggestions for changes to the plan of care, such as dosage adjustments or changes in delivery routes, until each expected outcome has been achieved.

Documentation

You're responsible for documenting all your actions related to the patient's drug therapy, from the assessment phase to evaluation. Each time you administer a drug, document the drug name, dose, time given, and your evaluation of its effect. When you administer drugs that require additional nursing judgment, such as those prescribed on an as-needed basis, document the rationale for administering the drug and follow-up assessment or interventions for each dose administered.

If you decide to withhold a prescribed drug based on your nursing judgment, document your action and the rationale for it, and notify the prescriber of your action in a timely manner. Whenever you notify a prescriber about a significant finding related to drug therapy, such as an adverse reaction, document the date and time, the person you contacted, what you discussed, and how you intervened.

A

abatacept

Orencia

Class and Category

Chemical class: Soluble fusion protein, human recombinant fusion protein

Therapeutic class: Antirheumatic

Pregnancy category: C

Indications and Dosages

➤ *To reduce signs and symptoms, induce major clinical response, inhibit progression of structural damage, and improve physical function in patients with moderate to severe active rheumatoid arthritis and an inadequate response to methotrexate or a tumor necrosis factor antagonist*

I.V. INFUSION

Adults weighing more than 100 kg

(220 lb). *Initial:* 1,000 mg infused over 30 min, repeated in 2 to 4 wk. *Maintenance:* 1,000 mg infused over 30 min every 4 wk starting at wk 8.

Adults weighing 60 to 100 kg (132 to

220 lb). *Initial:* 750 mg infused over 30 min, repeated in 2 to 4 wk. *Maintenance:* 750 mg infused over 30 min every 4 wk starting at wk 8.

Adults weighing less than 60 kg. *Initial:*

500 mg infused over 30 min, repeated in 2 to 4 wk. *Maintenance:* 500 mg infused over 30 min every 4 wk starting at wk 8.

➤ *To reduce signs and symptoms of moderate to severe active polyarticular juvenile idiopathic arthritis*

I.V. INFUSION

Children ages 6 to 17 weighing more than

100 kg. *Initial:* 1,000 mg infused over 30 min, repeated in 2 to 4 wk. *Maintenance:* 1,000 mg infused over 30 min every 4 wk starting at wk 8.

Children ages 6 to 17 weighing 75 to

100 kg. *Initial:* 750 mg infused over 30 min, repeated in 2 to 4 wk. *Maintenance:* 750 mg infused over 30 min every 4 wk starting at wk 8.

Children ages 6 to 17 weighing less than

75 kg. *Initial:* 10 mg/kg infused over 30 min, repeated in 2 to 4 wk. *Maintenance:* 10 mg/kg infused over 30 min every 4 wk starting at wk 8.

Mechanism of Action

Inhibits T-cell activation by binding to CD80 and CD86 to block interaction with CD28. CD28 is part of the co-stimulatory signal needed for full activation of T cells. Activated T cells have been implicated in the pathogenesis of rheumatoid arthritis. With decreased proliferation of T cells, inflammation and other evidence of rheumatoid arthritis decrease.

Incompatibilities

Don't infuse abatacept solution with other drugs in the same intravenous line concurrently because it isn't known if the drugs may interact.

Contraindications

Hypersensitivity to abatacept or its components

Interactions

DRUGS

immunosuppressants: Possibly increased risk of serious infection

live-virus vaccines: Possibly decreased response to vaccine, and risk of infection with live virus

tumor necrosis factor antagonists: Increased risk of serious infection

Adverse Reactions

CNS: Dizziness, fever, headache

CV: Hypertension, hypotension

EENT: Nasopharyngitis, rhinitis, sinusitis

GI: Abdominal pain, diarrhea, diverticulitis, dyspepsia, nausea

GU: Acute pyelonephritis, UTI

MS: Back or limb pain

RESP: Bronchitis, COPD worsening, cough, dyspnea, pneumonia, upper respiratory tract infection, wheezing

SKIN: Cellulitis, flushing, pruritus, rash, urticaria

Other: Anaphylaxis, antibody formation, herpes simplex, herpes zoster infection, influenza, malignancies, varicella infection

Nursing Considerations

- Screen patient for latent tuberculosis with a tuberculin skin test before starting abatacept. If test is positive, expect to provide

treatment, as ordered, before starting abatacept. Also screen patient for hepatitis B. If present, expect abatacept to be withdrawn because anti-rheumatic therapies such as abatacept may reactivate hepatitis B.

- Review patient's immunization record, and make sure all immunizations are current before therapy starts. Drug may blunt effectiveness of some vaccines and increase the risk of infection with live viruses.
- Use cautiously in patients with a history of recurrent infections, underlying conditions that may predispose them to infection, or existing chronic, latent, or localized infection. They have an increased risk of infection with abatacept therapy.
- Use cautiously in patients with COPD and monitor respiratory status closely because abatacept may worsen COPD and increase the risk of adverse respiratory reactions.
- Tumor necrosis factor antagonists shouldn't be given with abatacept because of an increased risk of serious infection.
- Reconstitute each vial with 10 ml of sterile water for injection. Use only the silicone-free disposable syringe provided with each vial because a siliconized syringe may cause translucent particles to form in solution. After injecting sterile water into vial, gently swirl vial until contents are completely dissolved. To minimize foaming, don't shake. Vent the vial with a needle to dissipate any foam that may be present.
- Further dilute reconstituted solution with 0.9% sodium chloride injection to achieve a final solution of 100 ml. Slowly add solution into infusion bag or bottle using the same silicone-free disposable syringe provided with each vial. Mix gently. Do not shake the bag or bottle.
- Give entire dose of fully diluted drug over 30 minutes using an infusion set and a sterile, nonpyrogenic, low protein-binding filter with a pore size of 0.2 μm .
- Once fully diluted, solution may be kept for 24 hours at room temperature or refrigerated. If reconstituted solution isn't used within 24 hours, discard.
- After giving abatacept, monitor patient closely for evidence of hypersensitivity reaction such as rash, pruritus, urticaria, dyspnea, or wheezing. If present, stop drug immediately, notify prescriber, and provide emergency care, as ordered.

- Monitor patient closely for evidence of infection or malignancy because abatacept inhibits T-cell activation, increasing the risk of these disorders.

PATIENT TEACHING

- Instruct patient not to receive immunizations with live vaccines during abatacept therapy and for 3 months afterward.
- Stress need to report any evidence of infection or hypersensitivity to prescriber.
- Alert patient that abatacept may increase the risk of malignancy.
- Warn patient to avoid crowds and people with infections.

abciximab

ReoPro

Class and Category

Chemical class: Fab fragment of chimeric 7E3 antibody

Therapeutic class: Platelet aggregation inhibitor

Pregnancy category: C

Indications and Dosages

➤ *To prevent acute myocardial ischemic complications after percutaneous transluminal coronary angioplasty (PTCA) in patients at high risk for abrupt closure of treated coronary artery*

I.V. INFUSION OR INJECTION

Adults. 250-mcg/kg bolus 10 to 60 min before PTCA. *Maintenance:* 0.125 mcg/kg/min by continuous infusion for 12 hr.

Maximum: 10 mcg/min.

➤ *To treat unstable angina in patients who haven't responded to conventional therapy and are scheduled for PTCA within 24 hr*

I.V. INFUSION OR INJECTION

Adults. 250-mcg/kg by bolus; then 10 mcg/min by continuous infusion over 18 to 24 hr, concluding 1 hr after PTCA.

Route	Onset	Peak	Duration
I.V.	Unknown	Unknown	48 hr

Mechanism of Action

Binds to glycoprotein IIb/IIIa receptor sites on the surface of activated platelets. Circulating fibrinogen can bind to these receptor sites and link platelets together,

forming a clot that eventually blocks a coronary artery. By binding to receptor sites, abciximab prevents normal binding of fibrinogen and other factors and inhibits platelet aggregation.

Incompatibilities

Don't mix abciximab with other drugs. Give through separate I.V. line when possible.

Contraindications

Active internal bleeding, arteriovenous malformation or aneurysm, bleeding disorders, stroke in past 2 years or that caused significant neurologic deficit at any time, GI or GU bleeding in past 6 weeks, hypersensitivity to abciximab, intracranial neoplasm, I.V. dextran use before or during PTCA, oral anticoagulant therapy in past 7 days unless PT is less than 1.2 times control, severe uncontrolled hypertension, surgery in past 6 weeks, thrombocytopenia, vasculitis

Interactions

DRUGS

dipyridamole, heparin, NSAIDs, oral anticoagulants, thrombolytic drugs, ticlopidine:

Increased risk of bleeding

Adverse Reactions

CNS: Confusion, dizziness, hyperesthesia

CV: Atrial fibrillation or flutter, bradycardia, embolism, hypotension, peripheral edema, pseudoaneurysm, supraventricular tachycardia, third-degree AV block, thrombophlebitis, weak pulse

GI: Dysphagia, hematemesis, nausea, vomiting

GU: Dysuria, hematuria, renal dysfunction, urinary frequency, urinary incontinence, urine retention

HEME: Anemia, bleeding, leukocytosis, thrombocytopenia

RESP: Bronchitis, bronchospasm, crackles, dyspnea, pleural effusion, pneumonia, pulmonary edema, pulmonary embolism, wheezing

SKIN: Pruritus, rash, urticaria

Other: Development of human anti-chimeric antibodies

Nursing Considerations

- Know that abciximab may be used with heparin and aspirin therapy.
- Inspect abciximab for particles; don't use if opaque particles are present.
- For continuous I.V. infusion, withdraw

4.5 ml from 2-mg/ml solution and inject prescribed amount into 250-ml bag of normal saline solution or D₅W using an in-line sterile, nonpyrogenic, low-protein-binding 0.2- to 0.22-micron filter. Discard unused portion.

- Give I.V. bolus with sterile, nonpyrogenic, low-protein-binding 0.2- to 0.22-micron filter.
- Avoid I.M. injections, venipunctures, and use of indwelling urinary catheters, NG tubes, and automatic blood pressure cuffs during therapy to prevent bleeding. If appropriate, insert an intermittent I.V. access device to obtain blood samples.
- Watch for GI, GU, and retroperitoneal bleeding and bleeding at puncture sites.

WARNING If hemorrhage occurs, prepare to stop infusion immediately. Expect to treat severe thrombocytopenia with platelet transfusions if needed.

- Monitor patient for hypersensitivity reactions, such as rash, pruritus, wheezing, and dysphagia from laryngeal edema. If such reactions occur, stop infusion and notify prescriber immediately. If anaphylaxis occurs, give epinephrine, antihistamines, and corticosteroids, as prescribed.
- Obtain platelet count 2 to 4 hours after initial bolus and every 24 hours during therapy as ordered. Expect platelet function to return to normal within 48 hours after therapy ends.
- Monitor vital signs and continuous ECG tracings during treatment.

PATIENT TEACHING

- Teach about possible adverse reactions, including bleeding and hypersensitivity reactions, which may cause rash, urticaria, and dyspnea.
- Tell patient to prevent injury from falls by maintaining bed rest and from bleeding by keeping limb immobile while catheter sheath is in place.

acamprostate calcium

Campral

Class and Category

Chemical class: Synthetic endogenous amino acid homotaurine, gamma-

aminobutyric acid (GABA) analogue

Therapeutic class: Antialcoholic

Pregnancy category: C

Indications and Dosages

➤ *To maintain abstinence from alcohol for alcohol-dependent patients who are abstinent at the start of treatment*

E.R. TABLETS

Adults. 666 mg t.i.d.

DOSAGE ADJUSTMENT For patients with moderate renal impairment (creatinine clearance of 30 to 50 ml/min), 333 mg t.i.d.

Route	Onset	Peak	Duration
P.O.	Unknown	3–8 hr	Unknown

Contraindications

Hypersensitivity to acamprosate or its com-

Mechanism of Action

Chronic alcoholism may alter the balance between excitation and inhibition in neurons in the brain; acamprosate restores it.

When the neurotransmitter gamma-aminobutyric acid (GABA) binds to its receptors in the CNS, it opens the chlo-

ride ion channel and releases chloride (Cl⁻) into the cell (below left), thereby reducing neuronal excitability by inhibiting depolarization. By interacting with GABA receptor sites, acamprosate prevents GABA from binding (below right).

When glutamate binds to its receptors, it closes the chloride ion channel, increasing neuronal excitability by promoting depolarization (below left). This imbal-

ance fosters a craving for alcohol. By interacting with glutamate receptor sites, acamprosate prevents glutamate from binding (below right).

ponents, severe hepatic (Child-Pugh class C) or renal impairment

Interactions

DRUGS

antidepressants: Increased weight gain

tetracyclines: Decreased absorption of tetracyclines

Adverse Reactions

CNS: Abnormal thinking, amnesia, anxiety, asthenia, chills, depression, dizziness, headache, insomnia, paresthesia, somnolence, suicidal ideation, syncope, tremor

CV: Chest pain, hypertension, palpitations, peripheral edema, vasodilation

EENT: Abnormal vision, dry mouth, pharyngitis, rhinitis, taste perversion

GI: Abdominal pain, anorexia, constipation, diarrhea, flatulence, increased appetite, indigestion, nausea, vomiting

GU: Acute renal failure, decreased libido, impotence

HEME: Leukopenia, lymphocytosis, thrombocytopenia

MS: Arthralgia, back pain, myalgia

RESP: Bronchitis, cough, dyspnea

SKIN: Diaphoresis, pruritus, rash

Other: Flulike symptoms, infection, weight gain

Nursing Considerations

- Acamprosate should start as soon as possible after patient has undergone alcohol withdrawal and achieved abstinence.
- Continue to give acamprosate even during periods of alcohol relapse.

PATIENT TEACHING

- Instruct patient to take acamprosate exactly as prescribed, even if a relapse occurs, and to seek help for a relapse.
- Warn patient that acamprosate won't reduce symptoms of alcohol withdrawal if relapse occurs followed by cessation.
- Urge caregivers to monitor patient for evidence of depression (lack of appetite or interest in life, fatigue, excessive sleeping, difficulty concentrating) or suicidal tendencies because a small number of patients taking acamprosate have attempted suicide.
- Advise patient to use caution when performing hazardous activities until adverse CNS effects of drug are known.
- Tell female patient to notify prescriber if she is or intends to become pregnant while

taking acamprosate; the drug may need to be stopped because fetal risks are unknown.

acarbose

Precose

Class and Category

Chemical class: Alpha-glucosidase inhibitor, oligosaccharide

Therapeutic class: Antidiabetic drug

Pregnancy category: B

Indications and Dosages

↗ *To control blood glucose level in patients with type 2 (non-insulin-dependent) diabetes mellitus when the level can't be controlled by diet alone*

TABLETS

Adults. *Initial*: 25 mg t.i.d. with first bite of each meal. *Maintenance*: Increased to maximum at 4- to 8-wk intervals p.r.n.

Maximum: 50 mg t.i.d. for patients weighing 65 kg (143 lb) or less; 100 mg t.i.d. for patients weighing more than 65 kg.

Mechanism of Action

Inhibits action of alpha-amylase and alpha-glucosidase enzymes. Normally, alpha-amylase hydrolyzes complex starches to oligosaccharides in the small intestine and alpha-glucosidase hydrolyzes oligosaccharides, trisaccharides, and di-saccharides to glucose and other monosaccharides in the brush border of the small intestine. In diabetic patients, acarbose inhibits these actions and delays glucose absorption, reducing blood glucose level after meals.

Contraindications

Chronic intestinal disease, cirrhosis, colonic ulceration, conditions that may deteriorate because of increased gas formation in intestines, diabetic ketoacidosis, digestive or absorption disorders, history of bowel obstruction, hypersensitivity to acarbose, inflammatory bowel disease

Interactions

DRUGS

calcium channel blockers, digestive enzymes (such as pancreatin), diuretics, estrogen, intestinal adsorbents (such as activated charcoal), isoniazid, nicotinic acid, oral contra-

ceptives, phenothiazines, phenytoin, sympathomimetics, thyroid hormones: Possibly decreased therapeutic effects of acarbose
digoxin: Decreased serum level and therapeutic effects of digoxin
insulin, sulfonyleureas: Decreased insulin action, possibly increased risk of hypoglycemia

Adverse Reactions

CV: Edema

GI: Abdominal distention and pain, diarrhea, flatulence, hepatitis, hepatotoxicity, ileus, jaundice

SKIN: Erythema, exanthema, rash, urticaria

Nursing Considerations

WARNING Be aware that acarbose isn't recommended for patients with significant renal dysfunction and a serum creatinine level above 2 mg/dl.

- If patient is receiving acarbose and a sulfonyleurea or insulin to enhance glucose control, check blood glucose level often, as appropriate.
- Store drug in sealed container in cool environment.
- Expect to decrease dosage to control GI upset.
- Monitor glycosylated hemoglobin level as ordered every 3 months for first year to evaluate glucose control and patient compliance.
- Monitor hematocrit and serum AST level every 3 months during first year of therapy and periodically thereafter, as ordered, because acarbose may decrease hematocrit and increase serum AST level.

PATIENT TEACHING

- Explain importance of self-monitoring glucose level during acarbose therapy.
- Teach patient to recognize hypoglycemia and hyperglycemia.
- Warn patient that noncompliance with treatment can increase risk of diabetic complications, including neuropathy, retinopathy, and renal insufficiency.
- Explain that temporary insulin therapy may be needed if fever, trauma, infection, illness, surgery, or other stress alters blood glucose control.
- Warn patient not to take other drugs within 2 hours of acarbose unless specifically instructed by prescriber.
- Tell him to consult prescriber before tak-

- ing OTC drugs during acarbose therapy.
- Advise patient who also takes another antidiabetic to carry glucose with him at all times in case hypoglycemia occurs.

acebutolol hydrochloride

Monitan (CAN), Sectral

Class and Category

Chemical class: Beta₁-selective (cardioselective) adrenergic receptor blocker

Therapeutic class: Antihypertensive, class II antiarrhythmic

Pregnancy category: B

Indications and Dosages

↗ *To treat hypertension*

TABLETS

Adults. *Initial:* 400 mg daily or 200 mg b.i.d. *Usual:* 200 to 800 mg daily. Increased to 1,200 mg daily in divided doses b.i.d. for severe hypertension or hypertension that isn't well controlled with usual dosage.

↗ *To treat premature ventricular arrhythmias*

TABLETS

Adults. *Initial:* 200 mg b.i.d. *Usual:* 600 to 1,200 mg daily.

DOSAGE ADJUSTMENT Maximum of 800 mg daily for elderly patients. Dosage reduced by 50% for patients with creatinine clearance less than 50 ml/min/1.73 m². Dosage reduced by 75% for patients with creatinine clearance less than 25 ml/min/1.73 m².

Route	Onset	Peak	Duration
P.O.	1–1.5 hr	2–8 hr	24 hr or longer

Mechanism of Action

Inhibits stimulation of beta₁ receptors in the heart, decreasing cardiac excitability, heart rate, cardiac output, and myocardial oxygen demand. Acebutolol also decreases kidneys' release of renin, which helps reduce blood pressure. Drug suppresses SA node automaticity and AV node conductivity, which suppresses atrial and ventricular ectopy. By decreasing myocardial oxygen demand, acebutolol decreases myocardial ischemia. At high doses, it inhibits stimula-

tion of beta₂ receptors in the lungs and may cause bronchoconstriction.

Contraindications

Cardiogenic shock, heart failure unless from tachyarrhythmia, hypersensitivity to acebutolol, overt heart failure, second- and third-degree heart block, severe bradycardia

Interactions

DRUGS

alpha agonists, nasal decongestants:

Increased risk of hypertension

aluminum salts, barbiturates, calcium salts, cholestyramine, colestipol, indomethacin, NSAIDs, penicillins, rifampin, salicylates, sulfonpyrazone: Decreased antihypertensive effects

anticholinergics, hydralazine, methyldopa, prazosin, reserpine: Increased risk of bradycardia and hypotension

beta₂ agonists, theophylline: Decreased bronchodilation

epinephrine: Increased risk of blocked sympathomimetic effects

ergot alkaloids: Increased risk of peripheral ischemia and gangrene

flecainide: Possibly increased effects of both drugs

lidocaine: Possibly increased serum lidocaine level, causing toxicity

oral contraceptives, quinidine: Possibly increased serum acebutolol level

sulfonylureas: Possibly decreased hypoglycemic effects

verapamil: Increased cardiac effects, leading to bradycardia and hypotension

Adverse Reactions

CNS: Abnormal dreams, anxiety, confusion, depression, dizziness, fatigue, fever, headache, insomnia

CV: Bradycardia, chest pain, edema, heart block, heart failure, hypotension

EENT: Abnormal vision, conjunctivitis, dry eyes, eye pain, pharyngitis, rhinitis

GI: Constipation, diarrhea, flatulence, hepatotoxicity, indigestion, nausea

GU: Dysuria, impotence, polyuria

MS: Arthralgia, myalgia

RESP: Bronchospasm, cough, dyspnea, wheezing

SKIN: Rash

Nursing Considerations

- Before therapy begins, obtain baseline

renal function tests, as ordered.

- Check apical and radial pulses before giving acebutolol. Also, frequently monitor blood pressure and pulse rate, rhythm, and quality during treatment.
- Give drug with food to prevent GI upset.
- Acebutolol may elevate uric acid, potassium, triglyceride, lipoprotein, and antinuclear antibody levels; it also may interfere with accuracy of glucose tolerance tests.
- Monitor diabetic patient's blood glucose level to spot alterations.
- Notify prescriber if you detect a heart rate below 50 beats/min or signs of heart failure, such as dyspnea, crackles, unexplained weight gain, and jugular vein distention.
- Monitor patient for peripheral edema, and evaluate fluid intake and output.

PATIENT TEACHING

- Tell patient that tablets may be crushed or swallowed whole.
- Warn against stopping acebutolol abruptly because doing so could cause angina or dangerously high blood pressure.
- Instruct patient to take a missed dose as soon as possible up to 6 hours before next scheduled dose but not to double the next dose.
- Advise patient to consult prescriber before taking OTC drugs that contain alpha agonists, such as nasal decongestants and cold preparations.
- Instruct patient to report dizziness, confusion, and fever immediately.
- Urge patient to maintain diet and lifestyle changes to help control blood pressure.

acetaminophen

Abenol (CAN), Acephen, Aceta Elixir, Acetaminophen Uniserts, Aceta Tablets, Apacet Capsules, Apacet Elixir, Apacet Extra Strength Tablets, Apacet Regular Strength Tablets, Aspirin Free Pain Relief, Exdol (CAN), FEVERALL, FEVERALL Sprinkle Caps, Genapap Infants' Drops, Genebs Extra Strength, Halenol Children's Junior Strength, Liqueprin Elixir, Liqueprin Infants' Drops, Meda Cap, Neopap, Oraphen-PD, Panadol, Panadol Infants' Drops, PEDIAPHEN, Redutemp, Robigesic (CAN), St. Joseph Aspirin-Free Infant Drops, Tapanol

Extra Strength, Tempra, Tempra Drops, Tylenol, Tylenol Caplets, Tylenol Children's Chewable Tablets, Tylenol Extra Strength, Tylenol Gelscaps, Tylenol Infants' Drops

Class and Category

Chemical class: Nonsalicylate, para-aminophenol derivative

Therapeutic class: Antipyretic, nonopioid analgesic

Pregnancy category: B

Indications and Dosages

➤ *To relieve mild to moderate pain from headache, muscle ache, backache, minor arthritis, common cold, toothache, or menstrual cramps; to reduce fever*

CAPLETS, CAPSULES, CHEWABLE TABLETS, ELIXIR, E.R. CAPLETS, GELCAPS, LIQUID, SOLUTION, SPRINKLES, SUSPENSION, TABLETS

Adults. 325 to 650 mg every 4 to 6 hr, or 1,000 mg t.i.d. or q.i.d., or 2 E.R. caplets every 8 hr. *Maximum:* 4,000 mg daily.

Children over age 14. 650 mg every 4 hr. *Maximum:* 5 doses in 24 hr.

Children ages 12 to 14. 640 mg every 4 hr. *Maximum:* 5 doses in 24 hr.

Children age 11. 480 mg every 4 hr. *Maximum:* 5 doses in 24 hr.

Children ages 9 to 10. 400 mg every 4 hr. *Maximum:* 5 doses in 24 hr.

Children ages 6 to 8. 320 mg every 4 hr. *Maximum:* 5 doses in 24 hr.

Children ages 4 to 5. 240 mg every 4 hr. *Maximum:* 5 doses in 24 hr.

Children ages 2 to 3. 160 mg every 4 hr. *Maximum:* 5 doses in 24 hr.

Children age 1. 120 mg every 4 hr. *Maximum:* 5 doses in 24 hr.

Children ages 4 to 11 months. 80 mg every 4 hr. *Maximum:* 5 doses in 24 hr.

Children ages 0 to 3 months. 40 mg every 4 hr. *Maximum:* 5 doses in 24 hr.

SUPPOSITORIES

Adults and adolescents. 650 mg every 4 to 6 hr. *Maximum:* 4,000 mg daily.

Children ages 6 to 12. 325 mg every 4 to 6 hr. *Maximum:* 2,600 mg daily.

Children ages 3 to 6. 120 to 125 mg every 4 to 6 hr. *Maximum:* 720 mg daily.

Children ages 1 to 3. 80 mg every 4 hr.

Children ages 3 months to 11 months. 80 mg every 6 hr.

Mechanism of Action

Inhibits the enzyme cyclooxygenase, blocking prostaglandin production and interfering with pain impulse generation in the peripheral nervous system. Acetaminophen also acts directly on temperature-regulating center in the hypothalamus by inhibiting synthesis of prostaglandin E₂.

Route	Onset	Peak	Duration
P.O., P.R.	Varies	1–3 hr	3–4 hr

Contraindications

Hypersensitivity to acetaminophen or its components

Interactions

DRUGS

anticholinergics: Decreased onset of acetaminophen action
barbiturates, carbamazepine, hydantoins, isoniazid, rifampin, sulfipyrazone: Decreased therapeutic effects and increased hepatotoxic effects of acetaminophen
lamotrigine, loop diuretics: Possibly decreased therapeutic effects of these drugs
oral contraceptives: Decreased effectiveness of acetaminophen
probenecid: Possibly increased therapeutic effects of acetaminophen
propranolol: Possibly increased action of acetaminophen
zidovudine: Possibly decreased zidovudine effects

ACTIVITIES

alcohol use: Increased risk of hepatotoxicity

Adverse Reactions

GI: Abdominal pain, hepatotoxicity, nausea, vomiting

HEME: Hemolytic anemia (with long-term use), leukopenia, neutropenia, pancytopenia, thrombocytopenia

SKIN: Jaundice, rash, urticaria

Other: Angioedema, hypoglycemic coma

Nursing Considerations

- Before and during long-term therapy, monitor liver function test results, including AST, ALT, bilirubin, and creatinine levels, as ordered.
- Monitor renal function in patient on long-term therapy. Keep in mind that blood or albumin in urine may indicate nephritis; decreased urine output may indicate renal

failure; and dark brown urine may indicate presence of the metabolite phenacetin.

- Expect to reduce dosage for patients with renal dysfunction.
- Store suppositories under 80° F (26.6° C).

WARNING Be aware that Pediaphen is a concentrated form of acetaminophen containing 80 mg/0.8 ml (standard liquid forms contain 32 mg/ml). Make sure to use correct concentration and dosage of liquid acetaminophen because serious adverse reactions can result from confusing concentrated form with regular liquid form.

PATIENT TEACHING

- Tell patient that tablets may be crushed or swallowed whole.
- Instruct patient to read manufacturer's label and follow dosage guidelines precisely. Explain that infants' and children's acetaminophen liquid aren't equal in drug concentration and aren't interchangeable.
- Advise patient to use manufacturer's dropper or dosage cup for measuring liquid acetaminophen.
- Advise him to contact prescriber before taking other prescription or OTC products because they may contain acetaminophen.
- Teach patient to recognize signs of hepatotoxicity, such as bleeding, easy bruising, and malaise, which commonly occurs with chronic overdose.

acetazolamide

Acetazolam (CAN), Ak-Zol, Apo-Acetazolamide (CAN), Dazamide, Diamox, Diamox Sequels, Storzolamide

Class and Category

Chemical class: Sulfonamide derivative

Therapeutic class: Anticonvulsant, anti-glaucoma, diuretic

Pregnancy category: C

Indications and Dosages

➤ *To treat chronic simple (open-angle) glaucoma*

S.R. CAPSULES, TABLETS, I.V. OR I.M. INJECTION

Adults. 250 to 1,000 mg daily (divided for doses exceeding 250 mg).

➤ *As short-term therapy to treat secondary glaucoma and preoperatively to treat*

acute congestive (closed-angle) glaucoma

S.R. CAPSULES, TABLETS, I.V. OR I.M. INJECTION

Adults. 250 mg b.i.d. or every 4 hr; or 1 S.R. capsule (500 mg) b.i.d.; or 500 mg initially, followed by 125 to 250 mg every 4 to 6 hr for severe acute glaucoma. To initially lower intraocular pressure rapidly, 500 mg I.V.; may repeat in 2 to 4 hr in acute cases, depending on patient response. Oral therapy usually started after initial I.V. dose.

S.R. CAPSULES, TABLETS

Children. 10 to 15 mg/kg daily in divided doses every 6 to 8 hr.

I.V. OR I.M. INJECTION

Children. 5 to 10 mg/kg/dose every 6 hr.

➤ *To induce diuresis in heart failure*

TABLETS, I.V. OR I.M. INJECTION

Adults. *Initial:* 250 to 375 mg or 5 mg/kg daily in morning. *Maintenance:* 250 to 375 mg or 5 mg/kg on alternate days or for 2 days followed by a drug-free day.

➤ *To treat drug-induced edema*

TABLETS, I.V. OR I.M. INJECTION

Adults. 250 to 375 mg daily for 1 to 2 days.

TABLETS, I.V. INJECTION

Children. 5 mg/kg/dose daily in morning.

➤ *To treat seizures, including generalized tonic-clonic, absence, and mixed seizures, and myoclonic jerk patterns*

TABLETS, I.V. OR I.M. INJECTION

Adults and children. 8 to 30 mg/kg daily in divided doses. *Optimal:* 375 to 1,000 mg daily. When used with other anticonvulsants, 250 mg daily.

➤ *To prevent or relieve symptoms of acute mountain sickness*

S.R. CAPSULES, TABLETS

Adults. 500 to 1,000 mg daily in divided doses, given 24 to 48 hr before ascent and continued for 48 hr or longer while at high altitude p.r.n. to control symptoms.

Route	Onset	Peak	Duration
P.O.	1–1.5 hr	2–4 hr	8–12 hr
P.O. (S.R.)	2 hr	8–12 hr	18–24 hr
I.V.	2 min	15 min	4–5 hr

Mechanism of Action

Inhibits the enzyme carbonic anhydrase, which normally appears in the eyes' ciliary processes, brain's choroid plexes, and kidneys' proximal tubule cells. In the eyes, enzyme inhibition decreases aqueous humor secretion, which lowers intraocular

pressure. In the brain, inhibition may delay abnormal, intermittent, and excessive discharge from neurons that cause seizures. In the kidneys, it increases bicarbonate excretion, which carries out water, potassium, and sodium, thus inducing diuresis and metabolic acidosis. This acidosis counteracts respiratory alkalosis and reduces symptoms of mountain sickness, including headache, dizziness, nausea, and dyspnea.

Contraindications

Chronic noncongestive closed-angle glaucoma; cirrhosis; hyperchloremic acidosis; hypersensitivity to acetazolamide; hypokalemia; hyponatremia; severe pulmonary obstruction; severe renal, hepatic, or adrenocortical impairment

Interactions

DRUGS

amphetamines, methenamine, phenobarbital, procainamide, quinidine: Decreased excretion and possibly toxicity of these drugs
corticosteroids: Increased risk of hypokalemia

cyclosporine: Increased cyclosporine level, possibly nephrotoxicity or neurotoxicity
diflunisal: Possibly significantly decreased intraocular pressure

lithium: Increased excretion and decreased effectiveness of lithium

primidone: Decreased serum and urine primidone levels

salicylates: Increased risk of salicylate toxicity

Adverse Reactions

CNS: Ataxia, confusion, depression, disorientation, dizziness, drowsiness, fatigue, fever, flaccid paralysis, headache, lassitude, malaise, nervousness, paresthesia, seizures, tremor, weakness

EENT: Altered taste, tinnitus, transient myopia

GI: Anorexia, constipation, diarrhea, hepatic dysfunction, melena, nausea, vomiting

GU: Crystalluria, decreased libido, glycosuria, hematuria, impotence, nephrotoxicity, phosphaturia, polyuria, renal calculi, renal colic, urinary frequency

HEME: Agranulocytosis, hemolytic anemia, leukopenia, pancytopenia, thrombocytopenia, thrombocytopenic purpura

SKIN: Photosensitivity, pruritus, rash, Stevens-Johnson syndrome, urticaria

Other: Acidosis, hyperuricemia, hypokalemia, weight loss

Nursing Considerations

- Use acetazolamide cautiously in patients with calcium-based renal calculi, diabetes mellitus, gout, or respiratory impairment.
- Know that acetazolamide may increase risk of hepatic encephalopathy in patients with hepatic cirrhosis.
- To avoid painful I.M. injections (caused by alkaline solution), give acetazolamide by mouth or I.V. injection if possible.
- Reconstitute each 500-mg vial with at least 5 ml sterile water for injection. Use within 24 hours because drug has no preservative.
- Monitor blood tests during acetazolamide therapy to detect electrolyte imbalances.
- Monitor fluid intake and output every 8 hours and body weight daily to detect excessive fluid and weight loss.

PATIENT TEACHING

- Inform patient that acetazolamide tablets may be crushed and suspended in chocolate or another sweet syrup. Or, one tablet may be dissolved in 10 ml hot water and added to 10 ml honey or syrup.
- Advise patient to avoid hazardous activities if dizziness or drowsiness occurs.
- Instruct patient who takes high doses of salicylates to notify prescriber immediately about evidence of salicylate toxicity, such as anorexia, tachypnea, and lethargy.
- If patient plans to mountain climb, urge her to descend mountain gradually and to seek immediate medical care if symptoms of mountain sickness occur.

acetohexamide

Dimelor (CAN), Dymelor

Class and Category

Chemical class: Sulfonylurea

Therapeutic class: Antidiabetic

Pregnancy category: C

Indications and Dosages

↗ *To treat stable type 2 (non-insulin-dependent) diabetes mellitus*

TABLETS

Adults. *Initial*: 250 to 1,500 mg daily.

Dosages of 1,000 mg or more daily may be divided and given b.i.d. before morning and

evening meals.

DOSAGE ADJUSTMENT For patient being switched from another antidiabetic, acetohehexamide dosage reduced to half the usual tolbutamide dosage or twice the usual chlorpropamide dosage. For patient being switched from insulin to acetohehexamide monotherapy, dosages adjusted as follows: if insulin dosage is less than 20 units daily, acetohehexamide starts at 250 mg daily and insulin is discontinued; if insulin dosage exceeds 20 units daily, acetohehexamide starts at 250 mg daily and insulin is tapered by 25% to 30% before being reduced further according to patient response.

Route	Onset	Peak	Duration
P.O.	1 hr	Unknown	12–24 hr

Mechanism of Action

Stimulates insulin release from active beta cells in the pancreas, resulting in decreased blood glucose level. Improves insulin binding to insulin receptors. Increases the number of insulin receptors (with long-term administration). May reduce basal hepatic glucose secretion.

Contraindications

Diabetes mellitus complicated by ketoacidosis or pregnancy, hypersensitivity to acetohehexamide, renal failure, sole therapy for type 1 (insulin-dependent) diabetes mellitus

Interactions

DRUGS

activated charcoal: Possibly reduced absorption and effectiveness of acetohehexamide
androgens, anticoagulants, azole antifungals, chloramphenicol, clofibrate, fluconazole, gemfibrozil, H₂-receptor antagonists, magnesium salts, MAO inhibitors, methyl dopa, probenecid, salicylates, sulfapyrazone, sulfonamides, tricyclic antidepressants, urinary acidifiers: Enhanced hypoglycemic effect of acetohehexamide

beta blockers, calcium channel blockers, cholestyramine, corticosteroids, diazoxide, estrogens, hydantoin, isoniazid, nicotinic acid, oral contraceptives, phenothiazines, rifampin, sympathomimetics, thiazide diuretics, thyroid drugs, urinary alkalisers: Decreased hypoglycemic effect

digitalis glycosides: Possibly increased serum

digitalis level

Adverse Reactions

CNS: Anxiety, chills, confusion, depression, dizziness, drowsiness, fatigue, headache, hyperesthesia, insomnia, malaise, nervousness, paresthesia, somnolence, syncope, tremor, vertigo, weakness

CV: Arrhythmias, edema, hypertension, vasculitis

EENT: Blurred vision, conjunctivitis, eye pain, pharyngitis, retinal hemorrhage, rhinitis, tinnitus

ENDO: Hypoglycemia

GI: Abdominal pain, anorexia, constipation, diarrhea, epigastric fullness, flatulence, heartburn, hepatitis, hepatotoxicity, indigestion, nausea, proctocolitis, vomiting

GU: Decreased libido, dysuria, polyuria

HEME: Agranulocytosis, aplastic anemia, eosinophilia, hemolytic anemia, leukopenia, pancytopenia, thrombocytopenia

MS: Abnormal gait, arthralgia, hypertonias, leg cramps

RESP: Dyspnea

SKIN: Diaphoresis, eczema, erythema multiforme, exfoliative dermatitis, flushing, jaundice, lichenoid reaction (skin thickening, accentuated lesions), maculopapular rash, photosensitivity, pruritus, rash, urticaria

Other: Disulfiram-like reaction (flushing, head throbbing, hypotension, nausea, tachycardia, vomiting), hyponatremia

Nursing Considerations

- Use acetohehexamide cautiously in elderly patients and in those with cardiac, hepatic, or renal disease or thyroid dysfunction. Drug's duration of action is prolonged in patients with renal disease.
- Give acetohehexamide 30 minutes before meals, crushing tablets if desired. If GI upset occurs, give in divided doses, as prescribed.
- Watch for evidence of hypoglycemia and hyperglycemia, especially after meals.
- Check blood glucose level often, as ordered. Provide additional insulin if needed during stressful periods, as prescribed.
- Monitor liver enzyme levels during therapy; acetohehexamide may increase AST, ALT, and alkaline phosphatase levels.
- Store acetohehexamide in tightly sealed container in a cool environment.

PATIENT TEACHING

- Stress need to adhere to prescribed drug regimen, diet, and exercise program.
- Advise patient to take acetoxyhexamide with food to avoid GI upset.
- Teach patient how to self-monitor blood glucose level and check urine for glucose and ketones, as appropriate.
- Teach patient to recognize and report signs of hypoglycemia and hyperglycemia.

acetoxyhydroxamic acid

Lithostat

Class and Category

Chemical class: Synthetic hydroxylamine and ethylacetate derivative

Therapeutic class: Urease inhibitor

Pregnancy category: X

Indications and Dosages

↗ *As an adjunct to antimicrobial therapy to treat chronic UTI caused by urea-splitting bacteria*

TABLETS

Adults. *Initial:* 12 mg/kg daily in divided doses every 6 to 8 hr. *Usual:* 250 mg t.i.d. or q.i.d. for a total of 10 to 15 mg/kg daily.

Maximum: 1,500 mg daily.

Children. 10 mg/kg daily.

DOSE ADJUSTMENT Maximum dosage reduced to 1,000 mg daily or 500 mg every 12 hr for patients with serum creatinine level that exceeds 1.8 mg/dl.

Mechanism of Action

Inhibits urease, the enzyme that catalyzes urea's hydrolysis to carbon dioxide and ammonia in urine infected with urea-splitting bacteria. This action reduces the urine ammonia level and pH, enhancing antimicrobial drug effectiveness.

Contraindications

Contributing disorder that's treatable by surgery or appropriate antimicrobial therapy, hypersensitivity to acetoxyhydroxamic acid, inadequate renal function (serum creatinine level above 2.5 mg/dl or creatinine clearance below 20 ml/min/1.73 m²), risk of pregnancy, UTI caused by non-urease-producing organisms, UTI that could be

controlled by appropriate antimicrobial therapy

Interactions**DRUGS**

iron: Decreased intestinal absorption of iron, decreased effects of iron and acetoxyhydroxamic acid

ACTIVITIES

alcohol use: Increased risk of severe rash 30 to 45 minutes after drinking alcohol

Adverse Reactions

CNS: Anxiety, depression, fever, lack of coordination, malaise, headache, nervousness, slurred speech, tiredness, tremor

CV: Calf pain (deep vein blood clot), palpitations, sudden chest pain

EENT: Pharyngitis, sudden change in vision

GI: Anorexia, nausea, vomiting

HEME: Reticulocytosis, unusual bleeding

RESP: Dyspnea

SKIN: Ecchymosis, hair loss, nonpruritic macular rash

Nursing Considerations

- Use acetoxyhydroxamic acid cautiously in patients with severe chronic renal disease or anemia and those who've had phlebitis or thrombophlebitis.
- Be aware that risk of adverse psychomotor effects increases if patient drinks alcohol or takes drugs that affect alertness and reflexes, such as antihistamines, tranquilizers, sedatives, analgesics, and narcotics.
- Administer tablets with food or liquid, crushing them if needed.

WARNING Acetoxyhydroxamic acid chelates with dietary iron. If patient has iron deficiency anemia, expect to administer I.M. iron as needed during acetoxyhydroxamic acid therapy.

- Monitor follow-up laboratory tests to check renal and hepatic function and urine pH, as ordered.

PATIENT TEACHING

- Instruct patient to take drug at same time each day, as prescribed.
- Tell patient to take a missed dose up to 2 hours after scheduled time. If more than 2 hours have passed, he should wait for next scheduled dose and shouldn't double that dose.
- Warn patient not to take drug with alcohol or iron and to consult prescriber before taking it with any other drug.

- Instruct patient to avoid hazardous activities during therapy.

acetylcysteine

Acetadote, Mucomyst, Mucosil

Class and Category

Chemical class: N-acetyl derivative of cysteine

Therapeutic class: Antidote (for acetaminophen overdose), mucolytic

Pregnancy category: B

Indications and Dosages

➤ *To liquefy abnormal, viscid, or thickened mucus secretions in chronic pulmonary disorders (including emphysema, bronchitis, tuberculosis, bronchiectasis, and cystic fibrosis) and in pneumonia, pulmonary complications of thoracic or cardiovascular surgery, and tracheostomy care*

SOLUTION BY DIRECT INSTILLATION INTO TRACHEOSTOMY (MUCOMYST, MUCOSIL)

Adults and children. 1 to 2 ml of 10% or 20% solution instilled every 1 to 4 hr, p.r.n.

SOLUTION BY INHALATION

Adults and children. 1 to 10 ml of 20% solution or 2 to 20 ml of 10% solution nebulized through face mask, mouthpiece, or tracheostomy every 2 to 6 hr. *Usual:* 3 to 5 ml of 20% solution or 6 to 10 ml of 10% solution t.i.d. or q.i.d.

➤ *To treat acetaminophen overdose*

SOLUTION P.O. (MUCOMYST, MUCOSIL)

Adults and children. *Loading dose:* 140 mg/kg. *Maintenance:* 70 mg/kg 4 hr after loading dose and then every 4 hr to a total of 17 doses.

I.V. INFUSION (ACETADOTE)

Adults and children weighing 40 kg (88 lb) or more. 150 mg/kg in 200 ml of diluent infused over 60 min, followed by 50 mg/kg in 500 ml of diluent infused over 4 hr, followed by 100 mg/kg in 1,000 ml of diluent infused over 16 hr.

Adults and children weighing more than 20 kg (44 lb) but less than 40 kg. 150 mg/kg in 100 ml of diluent infused over 60 min, followed by 50 mg/kg in 250 ml of diluent infused over 4 hr, followed by 100 mg/kg in 500 ml of diluent infused over 16 hr.

Children weighing 20 kg or less. 150 mg/

kg in 3 ml/kg of diluent infused over 60 min, followed by 50 mg/kg in 7 ml/kg of diluent infused over 4 hr, followed by 100 mg/kg in 14 ml/kg of diluent infused over 16 hr.

Mechanism of Action

Decreases viscosity of pulmonary secretions by breaking disulfide links that bind glycoproteins in mucus. Reduces liver damage from acetaminophen overdose. Usually, acetaminophen's toxic metabolites bind with glutathione in the liver, which detoxifies them. When acetaminophen overdose depletes glutathione stores, toxic metabolites bind with protein in liver cells, killing them. Acetylcysteine maintains or restores levels of glutathione or acts as its substitute, which reduces liver damage from acetaminophen overdose.

Incompatibilities

Don't give acetylcysteine with nebulization equipment if drug can contact iron, copper, or rubber. Don't give drug with amphotericin B, ampicillin sodium, chlortetracycline, chymotrypsin, erythromycin, hydrogen peroxide, iodized oil, oxytetracycline, tetracycline, or trypsin.

Contraindications

Hypersensitivity to acetylcysteine, no contraindications when used as antidote

Interactions

DRUGS

activated charcoal: Possibly adsorption and decreased effectiveness of oral acetylcysteine

nitroglycerin: Increased effects of nitroglycerin and possibly significant hypotension and headache

Adverse Reactions

CNS: Chills, dizziness, drowsiness, fever, headache

CV: Edema, hypertension, hypotension, tachycardia

EENT: Rhinorrhea, stomatitis, tooth damage

GI: Anorexia, constipation, hepatotoxicity, nausea, vomiting

RESP: Bronchospasm, chest tightness, cough, hemoptysis, respiratory distress, shortness of breath, stridor, wheezing

SKIN: Clammy skin, facial flushing, pruritus, rash, urticaria

Other: Anaphylaxis, angioedema

Nursing Considerations

- Acetylcysteine should be used cautiously in patients with asthma or a history of bronchospasm because drug may adversely affect respiratory function.

WARNING To avoid fluid overload and possibly fatal hyponatremia or seizures, adjust total administered volume, as ordered, for patients weighing less than 40 kg (88 lb) and for those who need fluid restriction.

- If needed, dilute 20% instillation or inhalation solution with normal saline solution or sterile water. The 10% solution may be used undiluted.
- When treating acetaminophen overdose, dilute 20% oral solution with cola or other soft drink to a concentration of 5%, and use within 1 hour. Dilute parenteral solution with D₅W or half-normal saline (0.45% sodium chloride) solution for injection following manufacturer guidelines because dilution is based on dosage. Acetadote may turn from colorless to slight pink or purple once the stopper is punctured, but color change has no effect on product quality.
- Acetylcysteine is most effective if given within 24 hours of acetaminophen ingestion. For specific instructions, contact a regional poison center at 1-800-222-1222 or a special health professional assistance hotline at 1-800-525-6115.
- If patient vomits loading dose or any maintenance dose within 1 hour of administration, repeat dose as prescribed.
- Keep in mind that suicidal patient may not provide reliable information about vomiting. Watch such a patient to ensure that he ingests all of prescribed dosage.
- During treatment for acetaminophen overdose, watch for signs of hepatotoxicity, such as prolonged bleeding time, altered coagulation, and easy bruising.
- Be aware that acetylcysteine may have a disagreeable odor, which disappears as treatment progresses.
- Because nebulization causes sticky residue on face and in mouth, have patient wash his face and rinse his mouth at the end of each treatment.
- Be aware that an open vial of solution may turn light purple but that this doesn't alter its effectiveness.
- Refrigerate opened vials and discard after

96 hours.

- Assess type, frequency, and characteristics of patient's cough. Particularly note sputum. If cough doesn't clear secretions, prepare to perform mechanical suctioning.
- Monitor patient for tachycardia.

PATIENT TEACHING

- Instruct patient to notify prescriber immediately about nausea, rash, or vomiting.
- Warn patient about acetylcysteine's unpleasant smell; reassure him that it subsides as treatment progresses.
- To decrease mucus viscosity, urge patient to consume 2 to 3 L of fluid daily unless contraindicated by another condition.

acitretin

Soriatane

Class and Category

Chemical class: Synthetic retinoid

Therapeutic class: Antipsoriatic

Pregnancy category: X

Indications and Dosages

↗ To treat severe psoriasis

CAPSULES

Adults. 25 to 50 mg once daily with a meal.

Route	Onset	Peak	Duration
P.O.	Unknown	2–5 hr	Unknown

Mechanism of Action

Binds to several retinoid receptors to regulate gene transcription. Exactly how the action of this second-generation retinoid allows normal growth and development of skin is unknown.

Contraindications

Alcohol consumption; blood donation; breast-feeding; chronic hyperlipidemia; concurrent use of etretinate, methotrexate, or tetracycline; hypersensitivity to acitretin, other retinoids, or their components; pregnancy; severe hepatic or renal impairment

Interactions

DRUGS

methotrexate: Increased risk of hepatitis
oral contraceptives containing only progestin: Possibly decreased effectiveness of oral contraceptive

phenytoin: Possibly decreased protein binding of phenytoin

sulfonylureas: Possibly increased risk of hypoglycemia

tetracyclines: Increased intracranial pressure

vitamin A and other oral retinoids: Increased risk of hypervitaminosis A

ACTIVITIES

alcohol use: Increased risk of adverse reactions and acitretin toxicity

Adverse Reactions

CNS: Aggression, depression, fatigue, headache, hyperesthesia, hypotonia, insomnia, intracranial hypertension, paresthesia, peripheral neuropathy, rigors, somnolence, stroke, suicidal ideation, thirst

CV: Chest pain, decreased high-density lipoproteins, edema, elevated cholesterol or triglyceride levels, MI, thromboembolism

EENT: Abnormal or blurred vision, blepharitis, conjunctivitis, corneal epithelial abnormality, decreased night vision, deafness, dry eyes or mouth, earache, epistaxis, eye pain, gingival bleeding, gingivitis, increased saliva, photophobia, sinusitis, stomatitis, taste perversion, tinnitus, ulcerative stomatitis

ENDO: Hot flashes, hyperglycemia

GI: Anorexia, abdominal pain, diarrhea, elevated liver enzymes, hepatitis, hepatotoxicity, nausea, pancreatitis

GU: Vulvovaginitis

HEME: Hemorrhage, increased bleeding time

MS: Arthralgia, arthrosis, back pain, hyperostosis, myalgia, myopathy

SKIN: Abnormal skin or hair texture, alopecia, bullous eruption, cold or clammy skin, dermatitis, diaphoresis, dry or peeling skin, erythematous rash, flushing, fragility or thinning of skin, photosensitivity, pruritus, purpura, pyogenic granuloma, rash, scaling, seborrhea, skin fissure or ulceration

Other: Hypervitaminosis A, increased appetite

Nursing Considerations

WARNING Don't give acitretin to a pregnant woman, a woman contemplating pregnancy, or a woman who may not use reliable contraception during drug therapy and for at least 3 years afterward because acitretin causes major fetal abnormalities.

- Make sure patient has had two negative

urine or serum pregnancy tests with a sensitivity of at least 25 mIU/ml before receiving acitretin. First test should be obtained when decision is made to use acitretin and second test during first 5 days of the menstrual period just before acitretin therapy starts. For patients with amenorrhea, second test should be done at least 11 days after the last act of unprotected sexual intercourse (which means without using two effective forms of contraception simultaneously).

- Check to make sure female patient of childbearing age has signed the patient agreement and informed consent form before starting acitretin therapy.
- Obtain a lipid profile, as ordered, before acitretin therapy starts and every 1 to 2 weeks for up to 8 weeks or until lipid effects are known. In high-risk patients, such as those with diabetes, obesity, or a history of alcohol abuse and those taking acitretin long-term, check lipid profile periodically throughout therapy.
- Monitor liver function test results, as ordered. If hepatotoxicity is suspected, expect to stop drug and investigate cause.
- If patient takes acitretin long-term or she develops a skeletal disorder, prepare her for periodic bone radiography because ossification abnormalities can occur, especially of the vertebral column, knees, and ankles.
- Monitor patient's eyes for abnormalities throughout therapy. Expect patient to stop drug and have an ophthalmologic examination if eye abnormalities occur.
- Monitor patient for evidence of increased intracranial pressure, such as papilledema, headache, nausea, vomiting, and visual disturbances. If papilledema occurs, stop drug therapy immediately and obtain a neurologic evaluation, as ordered. Patient should never receive a tetracycline while taking acitretin because combined use can increase intracranial pressure.
- Assess patient for suicidal ideation because depression and other psychiatric symptoms, including thoughts of self-harm, may occur with acitretin use. Expect drug to be discontinued if psychiatric symptoms develop.
- Significantly lower doses of phototherapy are needed during acitretin therapy

because drug increases the risk of erythema.

PATIENT TEACHING

WARNING Warn women of childbearing age that acitretin causes major fetal abnormalities.

- Inform woman of childbearing age that she must have a pregnancy test before acitretin therapy starts, every month during acitretin therapy, and every 3 months for 3 years after therapy stops.
- Stress to woman of childbearing age that she must use two effective forms of contraception simultaneously unless she has chosen absolute abstinence or has had a hysterectomy. This must begin at least 1 month before acitretin therapy starts and continue throughout therapy and for at least 3 years after therapy ends.
- Caution women taking oral contraceptives that some prescribed and OTC drugs, including herbal supplements such as St. John's wort, may interfere with oral contraceptives. Urge her to tell prescriber about all drugs she takes.
- Caution patient not to consume alcohol or products that contain alcohol during acitretin therapy and for 2 months after therapy ends.
- Warn patient, male or female of any age, not to donate blood during acitretin therapy and for at least 3 years after it ends.
- Review acitretin medication guide with patient, and answer the patient's questions.
- Inform patient that psoriasis may worsen during initial treatment and that full effects of drug may not be seen for up to 3 months.
- Caution patient to avoid hazardous activities until drug's CNS and ophthalmic effects are known.
- Inform patient that tolerance to contact lenses may decrease during acitretin therapy and for a period of time after treatment ends.
- Advise patient not to take more than the minimum recommended daily allowance of vitamin A during acitretin therapy because of the risk of vitamin A toxicity.
- Caution patient not to use sun lamps and to avoid excessive exposure to sunlight because the effects of UV light are enhanced by retinoids such as acitretin.

adalimumab

HUMIRA

Class and Category

Chemical class: Recombinant human IgG1 monoclonal antibody

Therapeutic class: Disease-modifying antirheumatic

Pregnancy category: B

Indications and Dosages

↗ *To reduce signs and symptoms, induce major clinical response, inhibit progression of structural damage, and improve physical function in patients with moderately to severely active rheumatoid arthritis; to reduce signs and symptoms, inhibit progression of structural damage, and improve physical function in patients with psoriatic arthritis; to reduce signs and symptoms in patients with active ankylosing spondylitis*

SUBCUTANEOUS INJECTION

Adults. 40 mg every other wk.

DOSAGE ADJUSTMENT Dosage may be adjusted to 40 mg every wk, as needed and prescribed, for patients not taking methotrexate.

↗ *To reduce signs and symptoms and induce and maintain clinical remission in patients with moderately to severely active Crohn's disease who have had an inadequate response to conventional therapy or who have stopped responding to or have become intolerant of infliximab*

SUBCUTANEOUS INJECTION

Adults. *Initial:* 40 mg q.i.d. for 1 day or 40 mg b.i.d. for 2 consecutive days, followed by 80 mg 2 wk later. *Maintenance:* 40 mg every other wk starting at week 4.

↗ *To reduce signs and symptoms of moderately to severely active polyarticular juvenile idiopathic arthritis*

SUBCUTANEOUS INJECTION

Children age 4 and over who weigh 30 kg (66 lb) or more. 40 mg every other wk.

Children age 4 and over who weigh less than 30 kg but at least 15 kg (33 lb). 20 mg every other wk.

↗ *To treat moderate to severe chronic plaque psoriasis in patients who are*

candidates for systemic therapy or phototherapy, and when other systemic therapies are less appropriate

SUBCUTANEOUS INJECTION

Adults. *Initial:* 80 mg followed 1 wk later with 40 mg. *Maintenance:* 40 mg every other wk.

Mechanism of Action

Binds to tumor necrosis factor (TNF) to block interaction with p55 and p75 cell-surface TNF receptors, and lyses surface TNF-expressing cells in the presence of complement. TNF may be a major component of rheumatoid arthritis inflammation and joint destruction. Reduced TNF level in synovial fluid improves signs and symptoms and prevents further structural damage in rheumatoid arthritis.

Contraindications

Active infection, breast-feeding, hypersensitivity to adalimumab or its components

Interactions

DRUGS

anakinra: Possibly increased risk of serious infection and neutropenia

live vaccines: Increased risk of adverse vaccine effects

Adverse Reactions

CNS: Confusion, fever, headache, hypertensive encephalopathy, multiple sclerosis, paresthesia, subdural hematoma, syncope, tremor

CV: Arrhythmias, atrial fibrillation, cardiac arrest, chest pain, coronary artery disease, congestive heart failure, hypercholesterolemia, hyperlipidemia, hypertension, MI, palpitations, pericardial effusion, pericarditis, peripheral edema, tachycardia

EENT: Cataracts, sinusitis

ENDO: Ketosis, parathyroid disorder

GI: Abdominal pain, cholecystitis, cholelithiasis, diverticulitis, elevated alkaline phosphatase level, elevated liver enzyme levels, esophagitis, gastroenteritis, hemorrhage, hepatic necrosis, nausea, vomiting

GU: Hematuria, paraproteinemia, pyelonephritis, UTI

HEME: Agranulocytosis, aplastic anemia, granulocytopenia, leukopenia, lymphocytosis, pancytopenia, polycythemia, thrombocytopenia

MS: Arthritis (including pyogenic or septic

arthritis); back, extremity, pelvic, or thorax pain; bone disorder, fracture, or necrosis; muscle spasms; myasthenia; prosthetic infections; synovitis

RESP: Asthma, bronchitis, bronchospasm, decreased pulmonary function, dyspnea, pleural effusion, pneumonia, pulmonary tuberculosis, upper respiratory tract infection

SKIN: Cellulitis, erysipelas, erythema multiforme, herpes zoster, new or worsening psoriasis, rash, urticaria

Other: Anaphylaxis; antibody formation against adalimumab; dehydration; flare-up of disease process; flulike symptoms; healing abnormalities; injection site erythema, hemorrhage, itching, pain, or swelling; invasive fungal infection; lupus-like symptoms; lymphomas; malignancies; opportunistic infection; postsurgical infection; sepsis; tuberculosis (miliary, lymphatic, or peritoneal)

Nursing Considerations

- Use adalimumab cautiously in patients with recurrent infection or increased risk of infection, patients who live in regions where tuberculosis and mycoses are endemic, and patients with a history of CNS demyelinating disorders because they occur, rarely, during adalimumab therapy.

WARNING If patient has evidence of an active infection when drug is prescribed, therapy shouldn't start until infection has been treated. Monitor all patients for infection during therapy, especially those receiving immunosuppressants. If a serious infection develops, expect prescriber to stop drug.

- Make sure patient has a tuberculin skin test before therapy starts. If skin test is positive, treatment of latent tuberculosis will start before adalimumab, as prescribed.
- Be aware that the needle cover of the syringe contains dry rubber. Don't handle if you're allergic to latex.
- To activate the protection device on needles of prefilled syringes delivered to institutions, hold the syringe in one hand and, with the other hand, slide outer protective shield over exposed needle until it locks into place.

WARNING Stop adalimumab immediately

and tell prescriber if patient has an allergic reaction. Expect to provide supportive care.

- Watch closely for evidence of congestive heart failure (sudden, unexplained weight gain; dyspnea; crackles; anxiety), and notify prescriber if they occur.
- Monitor patient's CBC, as ordered, because adalimumab may have adverse hematologic effects. Notify prescriber about persistent fever, bruising, bleeding, or pallor.
- Be aware that adalimumab belongs to a group of drugs called tumor necrosis factor (TNF) blockers. Although rare, malignancies, especially lymphomas and leukemias, have occurred in patients receiving TNF blockers, including children. Patients with rheumatoid arthritis, especially those with very active disease, are at greatest risk. Monitor patients closely.

PATIENT TEACHING

- v Inform patient that the first injection of adalimumab must take place with a health care professional present.
- Teach patient or caregiver how to give adalimumab as a subcutaneous injection at home, if applicable. Emphasize importance of injecting the full amount in the syringe (0.8 ml) to obtain the correct dose of 40 mg.
- If patient is allergic to latex, explain that the needle cover contains rubber.
- Caution patient against reusing needles and syringes. Provide patient or caregiver with a puncture resistant container for disposal of needles and syringes at home.
- Instruct patient or caregiver to rotate injection sites and to avoid injecting in any area that's tender, bruised, red, or hard.
- Inform patient that prefilled syringes must be refrigerated (not frozen), protected from light, and stored in the original container.
- Urge patient to check expiration dates and not to use outdated drug.
- Review signs and symptoms of an allergic reaction (rash, swollen face, difficulty breathing), and tell patient to seek emergency care immediately if these occur.
- Inform patient that injection site reactions (such as redness, rash, swelling, itching, and bruising) may occur but are usually mild and transient. Instruct him to apply a

towel soaked with cold water on the injection site if it hurts or remains swollen. If reaction does not disappear or seems to worsen, tell patient to call prescriber immediately.

- Inform patient that tuberculosis may occur during adalimumab therapy. Instruct him to report persistent cough, wasting or weight loss, and low-grade fever to prescriber.
- Teach patient to recognize evidence of infection and bleeding disorders and to tell prescriber if they occur; drug may need to be stopped. Advise patient to avoid people with infections and to have all prescribed laboratory tests.
- Inform patient that the risk of certain kinds of cancer, especially lymphomas, is higher in patients taking adalimumab but still rare. Emphasize the importance of follow-up visits and reporting an unusual or sudden onset of signs or symptoms.
- Caution patient against receiving live-virus vaccines while taking adalimumab because doing so may adversely effect the immune system.
- Inform patient that blood samples may be needed periodically, but especially around week 24 of therapy, to check for autoantibody development. Explain that adalimumab therapy will need to be stopped if they're detected.
- Instruct patient to report lupus-like signs and symptoms that, although rare, may occur during therapy, such as chest pain that doesn't go away, shortness of breath, joint pain, or a rash on cheeks or arms that's sensitive to the sun. Explain that drug may be stopped if these occur.
- Advise patient to inform all health care providers about adalimumab use and to inform prescriber about any OTC medications being taken, including herbal remedies and vitamin and mineral supplements.

adenosine

Adenocard, Adenoscan

Class and Category

Chemical class: Monophosphorylated adenine riboside

Therapeutic class: Antiarrhythmic
Pregnancy category: C

Indications and Dosages

➤ *To convert paroxysmal supraventricular tachycardia (PSVT) to normal sinus rhythm*

I.V. INJECTION

Adults and children weighing 50 kg (110 lb) or more. *Initial:* 6 mg by rapid peripheral I.V. bolus over 1 to 2 sec. If PSVT continues after 1 to 2 min, 12 mg given as rapid bolus and repeated in 1 to 2 min if needed. Don't give single doses of more than 12 mg. **Children weighing less than 50 kg.** *Initial:* 0.05 to 0.1 mg/kg as rapid central or peripheral I.V. bolus followed by saline flush. If PSVT continues after 1 to 2 min, additional bolus injections are given, incrementally increasing dose by 0.05 to 0.1 mg/kg. Follow each bolus with saline flush. Injections continue until PSVT converts to normal sinus rhythm or until patient reaches maximum single dose of 0.3 mg/kg.

Route	Onset	Peak	Duration
I.V.	Immediate	Immediate	Unknown

Mechanism of Action

Slows conduction time through the AV node and can interrupt AV node reentry pathways to restore normal sinus rhythm.

Incompatibilities

Don't mix adenosine with other drugs.

Contraindications

Atrial fibrillation or flutter; hypersensitivity to adenosine; second- or third-degree heart block or sick sinus syndrome, except in patients with a functioning artificial pacemaker; ventricular tachycardia

Interactions

DRUGS

carbamazepine: Increased heart block
digoxin, verapamil: Possibly increased depressant effect on SA or AV node
dipyridamole: Increased adenosine effects
methylxanthines, such as theophylline: Antagonized adenosine effects

FOODS

caffeine: Antagonized adenosine effects

Adverse Reactions

CNS: Apprehension, dizziness, headache,

heaviness in arms, light-headedness, nervousness, paresthesia, seizures

CV: Atrial fibrillation, bradycardia, chest pain or pressure, heart block, hypertension, hypotension, MI, palpitations, prolonged asystole, sinus exit block or pause, torsades de pointes, transient hypertension, ventricular fibrillation, ventricular tachycardia
 EENT: Blurred vision, metallic taste, throat tightness

GI: Nausea, vomiting

MS: Jaw, neck, and back pain

RESP: Bronchoconstriction, bronchospasm, dyspnea, hyperventilation, respiratory arrest

SKIN: Diaphoresis, facial flushing

Other: Injection site reaction

Nursing Considerations

- Before use, inspect adenosine for crystals. If solution isn't clear, don't give it.
- Give adenosine by rapid I.V. bolus over 1 to 2 seconds. Slower delivery can cause systemic vasodilation and reflex tachycardia.
- Expect prescriber to inject adenosine directly into a vein to make sure drug reaches systemic circulation. If given into an I.V. line, give drug as close to insertion site as possible and follow with rapid saline flush.

WARNING Don't give single doses of more than 12 mg.

- Monitor heart rate and rhythm, blood pressure, and respiratory status often during adenosine therapy.
- Be aware that at the time of conversion to normal sinus rhythm, arrhythmias (such as PVCs, premature atrial contractions, sinus bradycardia, sinus tachycardia, and AV block) may occur for a few seconds, but they don't usually require intervention.

WARNING Stop drug use and notify prescriber immediately if severe respiratory difficulties develop.

- Store adenosine at room temperature. Discard unused portion.

PATIENT TEACHING

- Instruct patient to report chest pain, palpitations, difficulty breathing, or severe headache during adenosine therapy.
- Warn patient that mild, temporary reactions may occur, such as flushing, nausea, and dizziness.

alatrofloxacin mesylate

Trovan I.V.

trovafloxacin mesylate

Trovan

Class and Category

Chemical class: Fluoroquinolone

Therapeutic class: Antibacterial

Pregnancy category: C

Indications and Dosages

➤ *To treat life-threatening nosocomial pneumonia*

TABLETS, I.V. INFUSION

Adults. 300 mg I.V. every 24 hr followed by 200 mg P.O. every 24 hr when patient is stabilized for total of 10 to 14 days.

➤ *To treat life-threatening community-acquired pneumonia*

TABLETS, I.V. INFUSION

Adults. 200 mg I.V. every 24 hr followed by 200 mg P.O. every 24 hr when patient is stabilized for total of 7 to 14 days; or 200 mg P.O. every 24 hr for total of 7 to 14 days.

➤ *To treat complicated, life-threatening intra-abdominal infections, including postsurgical, gynecologic, and pelvic infections*

TABLETS, I.V. INFUSION

Adults. 300 mg I.V. every 24 hr followed by 200 mg P.O. every 24 hr when patient is stabilized for total of 7 to 14 days.

➤ *To treat complicated, life-threatening or limb-threatening skin and soft-tissue infections, including diabetic foot infections*

TABLETS, I.V. INFUSION

Adults. 200 mg P.O. every 24 hr—or 200 mg I.V. every 24 hr followed by 200 mg P.O. every 24 hr when patient is stabilized—for total of 10 to 14 days.

DOSE ADJUSTMENT For patients with mild to moderate cirrhosis, 300-mg I.V. dosage reduced to 200 mg and 200-mg I.V. and P.O. dosage reduced to 100 mg.

Mechanism of Action

Interferes with DNA gyrase, the enzyme needed for DNA replication in aerobic and

anaerobic bacteria. May be active against pathogens resistant to such antibiotics as penicillins, cephalosporins, aminoglycosides, macrolides, and tetracyclines.

Incompatibilities

Don't mix alatrofloxacin with or infuse it simultaneously through same I.V. line as other drugs. Don't dilute it with normal saline solution or lactated Ringer's solution.

Contraindications

Hypersensitivity to alatrofloxacin, quinolone antimicrobials, trovafloxacin, or their components

Interactions

DRUGS

antacids that contain aluminum, citric acid, magnesium, or sodium citrate; iron; morphine sulfate; sucalfate: Reduced absorption of trovafloxacin

Adverse Reactions

CNS: Dizziness, headache, light-headedness, seizures

CV: Hypotension

EENT: Hoarseness, throat tightness

GI: Abdominal pain, acute hepatic failure (anorexia, dark urine, dysphagia, fatigue, jaundice, pale stool, and vomiting)

GU: Vaginitis

RESP: Dyspnea

SKIN: Photosensitivity, rash, urticaria or other skin reactions

Other: Angioedema

Nursing Considerations

- Infuse alatrofloxacin over 60 minutes; rapid or bolus I.V. delivery may cause hypotension.
- Periodically assess patient's liver function test results. Results may be elevated for up to 21 days after alatrofloxacin use.

WARNING Be aware that alatrofloxacin may cause severe liver damage, requiring liver transplantation or leading to death. Expect therapy to last no longer than 2 weeks to reduce risk of liver damage. Alatrofloxacin is reserved for hospitalized patients with life- or limb-threatening infections.

PATIENT TEACHING

- Instruct patient to report rash; urticaria; trouble swallowing; swelling of the lips, face, or tongue; hoarseness; or throat tightness.

albuterol (salbutamol)

Proventil

albuterol sulfate (salbutamol sulphate)

AccuNeb, Airet, Gen-Salbutamol (CAN), Novo-Salmol (CAN), Proair HFA, Proventil, Proventil HFA, Proventil Repetabs, Proventil Syrup, Ventolin HFA, Ventolin Syrup, Volmax

Class and Category

Chemical class: Selective beta₂-adrenergic agonist, sympathomimetic

Therapeutic class: Bronchodilator

Pregnancy category: C

Indications and Dosages

↗ *To prevent exercise-induced asthma*

INHALATION AEROSOL

Adults and children over age 4. 2 inhalations 15 to 30 min before exercise.

↗ *To treat bronchospasm in patients with reversible obstructive airway disease or acute bronchospastic attack*

E.R. TABLETS

Adults and children over age 12. *Initial:* 4 or 8 mg every 12 hr. *Maximum:* 32 mg daily in divided doses every 12 hr.

Children ages 6 to 12. *Initial:* 4 mg every 12 hr. *Maximum:* 24 mg daily in divided doses every 12 hr.

REPETABS

Adults and children over age 12. *Initial:* 4 to 8 mg every 12 hr. *Maximum:* 32 mg daily in divided doses every 12 hr.

Children ages 6 to 11. *Initial:* 4 mg every 12 hr. *Maximum:* 24 mg daily in divided doses every 12 hr.

SYRUP

Adults and children over age 14. *Initial:* 2 to 4 mg (1 to 2 tsp) t.i.d. or q.i.d. *Maximum:* 32 mg daily in divided doses.

Children ages 6 to 14. *Initial:* 2 mg (1 tsp) t.i.d. or q.i.d. *Maximum:* 24 mg daily in divided doses.

Children ages 2 to 6. *Initial:* 0.1 mg/kg t.i.d. (not to exceed 2 mg t.i.d.), increased to 0.2 mg/kg t.i.d. (not to exceed 4 mg t.i.d.).

TABLETS

Adults and children over age 12. *Initial:* 2 or 4 mg t.i.d. or q.i.d. *Maximum:* 32 mg daily in divided doses.

Children ages 6 to 12. *Initial:* 2 mg t.i.d. or q.i.d. *Maximum:* 24 mg daily in divided doses.

DOSE ADJUSTMENT For elderly patients, initial dosage reduced to 2 mg (1 tsp) of syrup t.i.d. or q.i.d. or 2 mg of tablets t.i.d. or q.i.d. (up to 32 mg daily).

INHALATION AEROSOL

Adults and children age 4 and over. 1 inhalation every 4 hr to 2 inhalations every 4 to 6 hr.

INHALATION CAPSULES (ROTOCAPS)

Adults and children age 4 and over.

200 mcg inhaled every 4 to 6 hr using inhalation device. *Maximum:* 400 mcg every 4 to 6 hr.

INHALATION SOLUTION

Adults and children age 12 and over.

2.5 mg t.i.d. or q.i.d. by nebulization over 5 to 15 min.

Children ages 2 to 12. *Initial:* 0.1 to 0.15 mg/kg t.i.d. or q.i.d. *Maximum:* 2.5 mg t.i.d. or q.i.d.

Route	Onset	Peak	Duration
P.O. (E.R. tab)	30 min	2–3 hr	12 hr
P.O. (syrup)	Rapid	2 hr	Unknown
P.O. (tab)	30 min	2–3 hr	4–8 hr
Inhalation (aerosol)	5–15 min	50–55 min	3–6 hr
Inhalation (rotocap)	5–15 min	0.5–3 hr	2–6 hr
Inhalation (solution)	5–15 min	1–2 hr	3–6 hr

Contraindications

Hypersensitivity to albuterol or its components

Interactions

DRUGS

beta blockers: Inhibited effects of albuterol bronchodilators (*sympathomimetics*), such as *theophylline*: Possibly adverse CV effects

digoxin: Decreased serum digoxin level

MAO inhibitors, tricyclic antidepressants:

Increased vascular effects of albuterol

methyl dopa: Increased vasopressor effect of methyl dopa

Mechanism of Action

Albuterol attaches to beta₂ receptors on bronchial cell membranes, which stimulates the intracellular enzyme adenylate cyclase to convert adenosine triphosphate (ATP) to cyclic adenosine monophosphate (cAMP). This reaction decreases intracellular calcium levels. It also increases intracellular levels of cAMP, as shown. Together, these effects relax bronchial smooth-muscle cells and inhibit histamine release.

potassium-lowering drugs: Possibly hypokalemia

potassium-wasting diuretics: Possibly increased hypokalemia

Adverse Reactions

CNS: Anxiety, dizziness, drowsiness, headache, hyperkinesia, insomnia, irritability, nervousness, tremor, vertigo, weakness

CV: Angina; arrhythmias, including atrial fibrillation, extrasystoles, supraventricular tachycardia, and tachycardia; chest pain; hypertension; hypotension; palpitations

EENT: Altered taste, dry mouth and throat, ear pain, glossitis, hoarseness, oropharyngeal edema, pharyngitis, rhinitis, taste perversion

ENDO: Hyperglycemia

GI: Anorexia, diarrhea, dysphagia, heartburn, nausea, vomiting

GU: UTI

MS: Muscle cramps

RESP: Bronchospasm, cough, dyspnea, paradoxical bronchospasm, pulmonary edema

SKIN: Diaphoresis, flushing, pallor, pruritus, rash, urticaria

Other: Angioedema, hypokalemia, infection, metabolic acidosis

Nursing Considerations

- Administer pressurized inhalations of albuterol during second half of inspiration, when airways are open wider and aerosol distribution is more effective.

WARNING Use cautiously in patients with cardiac disorders, diabetes mellitus, digitalis intoxication, hypertension, hyperthyroidism, or history of seizures. Albuterol can worsen these conditions.

- Monitor serum potassium level because albuterol may cause transient hypokalemia.
- Be aware that drug tolerance can develop with prolonged use.

PATIENT TEACHING

- Teach patient to use inhaler. Tell him to shake canister before use and to check that a new canister is working by spraying it the appropriate number of times (once to four times based on manufacturer instructions) into the air while looking for a fine mist.
- Instruct patient to wash mouthpiece with water once a week and let it air-dry.
- Advise patient to wait at least 1 minute between inhalations.
- Tell patient to check with his prescriber before using other inhaled drugs.
- Warn patient not to exceed prescribed dose or frequency. If doses become less effective, tell patient to contact his prescriber.
- Tell patient to immediately report signs and symptoms of allergic reaction, such as difficulty swallowing, itching, and rash.

alefacept

Amevive

Class and Category

Chemical class: Recombinant leukocyte function-associated antigen-3 immunoglobulin G1 fusion protein
Therapeutic class: Immunosuppressant
Pregnancy category: B

Indications and Dosages

➤ *To treat moderate to severe chronic plaque psoriasis in patients who are candidates for systemic therapy or phototherapy*

I.V. INJECTION

Adults. *Initial:* 7.5 mg every wk for 12 wk. After at least 12 wk in which drug isn't given, a second 12-wk course may be given, if needed and if patient's CD4 and T-lymphocyte counts are within normal ranges.

I.M. INJECTION

Adults. 15 mg every week for 12 wk. After at least 12 wk in which drug isn't given, a second 12-wk course may be given, if needed and if patient's CD4 and T-lymphocyte counts are within normal ranges.

Mechanism of Action

Interferes with T-lymphocyte activation by binding to lymphocyte antigen and CD2, inhibiting LFA-3/CD2 interaction, and reducing the subsets of CD2+ T lymphocytes. This interference helps prevent plaque formation in chronic plaque psoriasis.

Incompatibilities

Don't add other drugs to solutions containing alefacept.

Contraindications

Breast-feeding, hypersensitivity to alefacept or its components

Adverse Reactions

CNS: Chills, dizziness, headache

CV: Coronary artery disease, MI

EENT: Pharyngitis

GI: Nausea

HEME: Lymphopenia

MS: Myalgia

RESP: Increased cough

SKIN: Pruritus, urticaria

Other: Angioedema, injection site pain or inflammation, infection, malignancies

Nursing Considerations

- Use alefacept cautiously in patients at high risk for malignancy because the drug increases risk of malignancy development. Know that drug isn't recommended for use in patients with a history of a systemic malignancy.
- Also use alefacept cautiously in patients with chronic infections or history of recurrent infection. Drug may increase

risk of infection because of its immunosuppressive action.

- Obtain a CD4+ and T-lymphocyte count before starting alefacept therapy, as ordered. If counts are below normal, be aware that therapy shouldn't be started. After therapy starts, monitor patient's CD4+ and T-lymphocyte counts weekly throughout therapy. If levels drop below 250 cells/microliter, notify prescriber because drug will need to be withheld. If counts remain below 250 cells/microliter for 1 month, expect that drug will be discontinued.
- Reconstitute drug with 0.6 ml using only the supplied diluent (sterile water for injection) before administration. With the needle pointed at sidewall of vial, slowly inject diluent into vial of alefacept. Be aware that some foaming will occur. To prevent excessive foaming, don't shake or vigorously agitate vial. Instead, gently swirl vial during dissolution, which usually takes less than 2 minutes.
- Administer drug as soon as possible after reconstitution. Discard solution if not used within 4 hours.
- Don't filter reconstituted solution during preparation or administration.
- For I.M. administration, inject the full 0.5 ml of solution. Use a different injection site for each subsequent injection, injecting at least 1 inch away from previous sites. Never inject the drug into tender, bruised, red, or hard areas.
- For I.V. administration, prepare two syringes with 3 ml normal saline solution for preadministration and post-administration flush. Then prime the winged infusion set with 3 ml normal saline solution and insert into vein. Attach filled syringe to infusion set, and administer solution over no more than 5 seconds. Finish by flushing set with 3 ml of normal saline solution.
- Be aware that drug shouldn't be started in a patient with a concurrent serious infection. Monitor patient closely during and after therapy for signs and symptoms of infection. If these occur, report them to the prescriber immediately and begin treatment, as prescribed, to reduce risk of serious infection. If infection becomes serious, expect drug to be discontinued.

- Monitor patient for allergic reactions. If these occur, discontinue drug and notify prescriber immediately.

PATIENT TEACHING

- Advise patient that weekly blood tests will be required to monitor his WBC count during alefacept therapy.
- Teach patient signs and symptoms of infection and common warning signs of malignancy. Emphasize importance of complying with follow-up visits and promptly reporting any unusual or sudden signs or symptoms suggesting malignancy or infection.
- Instruct female patient to notify prescriber if she becomes pregnant while taking alefacept or within 8 weeks after stopping it.

alendronate sodium

Fosamax

Class and Category

Chemical class: Aminobisphosphonate

Therapeutic class: Bone resorption inhibitor

Pregnancy category: C

Indications and Dosages

↗ *To prevent postmenopausal osteoporosis*

TABLETS

Adults. 5 mg daily or 35 mg once/wk in the morning with a full glass of water at least 30 min before first food, drink, or drug.

↗ *To treat postmenopausal osteoporosis*

TABLETS

Adults. 10 mg daily or 70 mg once/wk in the morning with a full glass of water at least 30 min before first food, drink, or drug.

↗ *To treat Paget's disease of the bone in patients whose alkaline phosphatase level is twice the upper limit of normal or higher and who are symptomatic and at risk for further complications*

TABLETS

Adults. 40 mg daily with a full glass of water for 6 mo.

DOSAGE ADJUSTMENT Dosage increased to 10 mg daily for postmenopausal women not receiving estrogen.

↗ *To increase bone mass in men with osteoporosis*

TABLETS

Adults. 10 mg daily or 70 mg once/wk in

the morning with a full glass of water at least 30 min before first food, drink, or drug.

↗ *To treat glucocorticoid-induced osteoporosis in men and women who receive a daily glucocorticoid dosage of 7.5 mg of greater of prednisone and who have low bone mineral density*

TABLETS

Adults. 5 mg daily in the morning with a full glass of water at least 30 min before first food, drink, or drug.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	6 wk*

Mechanism of Action

Reduces activity of cells that cause bone loss, slows rate of bone loss after menopause, and increases amount of bone mass. May act by inhibiting osteoclast activity on newly formed bone resorption surfaces, which reduces the number of sites where bone is remodeled. Bone formation then exceeds bone resorption at these remodeling sites, which gradually increases bone mass. May also inhibit bone dissolution by binding to hydroxyapatite crystals, which are composed of calcium, phosphate, and hydroxide and give bone its rigid structure.

Contraindications

Esophageal abnormalities that delay esophageal emptying, such as stricture or achalasia; hypersensitivity to alendronate; hypocalcemia; inability to stand or sit upright for at least 30 minutes

Interactions**DRUGS**

antacids, calcium, iron, multivalent cations:

Decreased absorption of alendronate

aspirin: Increased risk of GI distress

FOODS

any food: Delayed absorption and decreased serum level of alendronate

Adverse Reactions

CNS: Asthenia, dizziness, headache, vertigo

CV: Peripheral edema

GI: Abdominal distention and pain, consti-

* After single 5-mg dose for osteoporosis; 6 mo after single 5-mg dose for Paget's disease.

pation, diarrhea, dysphagia, esophageal perforation or ulceration, esophagitis, flatulence, gastritis, gastroesophageal reflux disease, heartburn, indigestion, melena, nausea, vomiting

MS: Arthralgia, bone pain, focal osteomalacia, joint swelling, muscle spasms, myalgia

SKIN: Photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Hypocalcemia

Nursing Considerations

- Monitor patient's serum calcium level before, during, and after treatment. Expect hypocalcemia to be treated before alendronate therapy. If hypocalcemia occurs during therapy, expect prescriber to order a calcium supplement.
- Ensure adequate dietary intake of calcium and vitamin D before, during, and after treatment.

WARNING Alendronate may irritate upper GI mucosa, causing adverse reactions such as esophageal ulceration. To help minimize these reactions, have patient take drug with a full glass of water and remain upright for at least 30 minutes.

PATIENT TEACHING

- Advise patient to take alendronate in the morning with a full glass of water. Explain that beverages such as orange juice, coffee, and mineral water reduce alendronate's effects.
- To help reduce esophageal irritation, tell patient not to chew or suck on tablet.
- Instruct patient to wait at least 30 minutes after taking alendronate before eating, drinking, or taking other drugs. Teach patient to remain upright for 30 minutes after taking alendronate and until she has eaten the first food of the day.
- Encourage patient to consume adequate daily amounts of calcium and vitamin D.

alfuzosin hydrochloride

Uroxatral

Class and Category

Chemical class: Tetrahydro-2-furancarboxamide hydrochloride

Therapeutic class: Selective α_1 -adrenergic antagonist

Pregnancy category: B

Indications and Dosages

➤ To treat signs and symptoms of benign prostatic hyperplasia

E.R. TABLETS

Adults. 10 mg daily taken immediately after same meal each day.

Mechanism of Action

Selectively blocks α_1 -adrenergic receptors in smooth muscle of the bladder neck and prostate, causing relaxation, and blocks postsynaptic α_1 adrenoreceptors in the bladder base and neck, prostate, prostatic capsule, and urethra, preventing further action at these sites. These actions improve urine flow and bladder emptying and reduce urinary hesitancy, frequency, and nocturia.

Contraindications

Hypersensitivity to alfuzosin or its components, moderate or severe hepatic insufficiency, use with CYP3A4 inhibitors, such as itraconazole, ketoconazole, and ritonavir

Interactions

DRUGS

alpha blockers: May potentiate alfuzosin action

antihypertensives, nitrates: Possibly synergistic lowering of blood pressure and syncope
CYP3A4 inhibitors (such as itraconazole, ketoconazole, ritonavir): Increased alfuzosin effects

Adverse Reactions

CNS: Dizziness, fatigue, headache

CV: Angina, chest pain, edema, orthostatic hypotension, QT-interval prolongation, tachycardia

EENT: Intraoperative floppy iris syndrome, pharyngitis, rhinitis, sinusitis

GI: Abdominal pain, constipation, diarrhea, indigestion, jaundice, hepatotoxicity, nausea

GU: Impotence, priapism

RESP: Bronchitis, upper respiratory tract infection

SKIN: Flushing, pruritus, rash, urticaria

Other: Angioedema, generalized pain

Nursing Considerations

- Use alfuzosin cautiously in patients who have symptomatic hypotension or who

have had a hypotensive response to other drugs. Orthostatic hypotension (with or without symptoms such as dizziness) may occur within hours after alfuzosin administration.

- Use cautiously in patients with severe renal insufficiency; decreased drug clearance may increase risk of adverse reactions.
- Be aware that alfuzosin shouldn't be used to treat bladder symptoms in women.
- Know that alpha₁ blockers such as alfuzosin may predispose patients to intraoperative floppy iris syndrome during cataract surgery that may require surgical repair.
- Monitor patient for chest pain. If symptoms of angina pectoris occur or worsen, notify prescriber immediately and expect drug to be discontinued.

PATIENT TEACHING

- Stress need to take alfuzosin immediately after a meal because absorption is decreased by 50% if taken on an empty stomach.
- Tell patient not to crush or chew tablets but to swallow them whole.
- Caution patient to avoid hazardous activities until drug's CNS effects are known and also for several hours after taking dose; blood pressure may drop suddenly after use.

alglucerase

Ceredase

Class and Category

Chemical class: Glucocerebrosidase beta-glucosidase

Therapeutic class: Enzyme replacement

Pregnancy category: C

Indications and Dosages

➤ *To treat chronic nonneuropathic Gaucher's disease in patients with moderate to severe anemia, thrombocytopenia with bleeding tendencies, bone disease, or significant hepatomegaly or splenomegaly*

I.V. INFUSION

Adults and children age 2 and over.

Individualized. 2.5 units/kg to 60 units/kg infused over 1 to 2 hr, usually every 2 wk.

DOSAGE ADJUSTMENT Highly individualized based on body size and disease severity. Some patients may need infusion once every other day; others may need it once every 4 wk. Maintenance dosage progressively reduced every 3 to 6 mo to as low as 1 unit/kg.

Route	Onset	Peak	Duration
I.V.	Up to 60 min	Unknown	Variable

Mechanism of Action

Catalyzes hydrolysis of glucocerebroside to glucose and ceramide in membrane lipids. Gaucher's disease results from deficiency of the enzyme beta-glucocerebrosidase and causes the lipid glucocerebroside to accumulate in tissue macrophages.

Contraindications

Hypersensitivity to alglucerase

Adverse Reactions

CNS: Chills, dizziness, fatigue, fever, headache

CV: Transient peripheral edema, vasomotor irritability

EENT: Oral ulcerations

GI: Abdominal discomfort, diarrhea, nausea, vomiting

MS: Backache

Other: I.V. site burning, itching, or swelling

Nursing Considerations

- Before starting alglucerase therapy, expect to give antihistamines if patient is hypersensitive to drug.
- On day of dose, use aseptic technique to dilute alglucerase with normal saline solution to final volume of no more than 200 ml.
- Don't shake drug because doing so could inactivate it.
- Don't use alglucerase if it's discolored or contains precipitate.
- Be aware that drug doesn't contain preservatives. Discard unused portion.
- Infuse drug with in-line I.V. particle filter.

PATIENT TEACHING

- Tell patient that he may experience flulike symptoms with each dose of alglucerase.
- Instruct patient to report headache, hot flashes, nausea, and other adverse reactions.

- Inform patient that alglucerase is derived from pooled human placental tissue and poses a slight risk of viral contamination.
- Advise patient to keep appointments for scheduled doses of alglucerase.

aliskiren

Tekturna

Class and Category

Chemical class: Hemifumarate salt

Therapeutic class: Antihypertensive (direct renin inhibitor)

Pregnancy category: C (first trimester), D (second and third trimester)

Indications and Dosages

↗ *To treat hypertension*

TABLETS

Adults. 150 mg once daily, increased to 300 mg once daily, as needed.

Route	Onset	Peak	Duration
P.O.	Unknown	1–3 hr	Unknown

Mechanism of Action

Inhibits renin secreted by the kidneys in response to decreased blood volume and renal perfusion. Renin cleaves angiotensinogen to form angiotensin I, which is converted to angiotensin II by ACE and non-ACE pathways. Angiotensin II is a powerful vasoconstrictor that induces release of catecholamines from the adrenal medulla and prejunctional nerve endings. It also promotes aldosterone secretion and sodium reabsorption. Together, these actions increase blood pressure. By inhibiting renin release, aliskiren impairs the renin-angiotensin-aldosterone system. Without the vasoconstrictive effect of angiotensin II, blood pressure decreases.

Contraindications

Hypersensitivity to aliskiren or its components; pregnancy; renal impairment, disease, or failure

Interactions

DRUGS

ACE inhibitors (diabetics): Increased risk of hyperkalemia

atorvastatin, cyclosporin, ketoconazole:

Increased aliskiren blood level

furosemide: Decreased blood furosemide levels

irbesartan: Decreased blood aliskiren level

Adverse Reactions

CNS: Dizziness, fatigue, headache, seizures

CV: Hypotension

EENT: Nasopharyngitis

GI: Abdominal pain, diarrhea, dyspepsia, gastroesophageal reflux

GU: Renal calculi

HEME: Decreased hemoglobin and hematocrit

MS: Back pain

RESP: Increased cough, upper respiratory tract infection

SKIN: Rash

Other: Angioedema of head and neck, elevated creatine kinase or uric acid level, gout, hyperkalemia

Nursing Considerations

- Use cautiously in patients with a history of dialysis or who have moderate to severe renal dysfunction; it isn't known whether nephritic syndrome and renovascular hypertension are adverse effects of aliskiren.

- To prevent hypotension, take measures to correct volume or salt depletion from high-dose diuretic therapy before starting aliskiren. If hypotension occurs during aliskiren therapy, place patient in a supine position and give normal saline solution intravenously, as needed and prescribed.

WARNING Watch closely for angioedema of the head or neck. If angioedema occurs, discontinue aliskiren, notify prescriber, and provide supportive therapy until swelling has ceased. If swelling of the tongue, glottis, or larynx is involved, be prepared to give epinephrine solution 1:1,000 (0.3 ml to 0.5 ml), as prescribed, and provide measures to ensure a patent airway. Be aware that patient shouldn't receive aliskiren again.

- Monitor serum potassium level as ordered in patients who are diabetic and also receiving ACE inhibitor therapy because hyperkalemia may occur. Also monitor serum electrolytes, as ordered, especially in patients with severe renal impairment.

PATIENT TEACHING

- Advise patient to avoid high-fat meals

while taking aliskiren because fat decreases drug absorption significantly.

- Instruct patient how to monitor blood pressure to determine effectiveness of aliskiren therapy.
- Explain that decreased blood pressure could lead to light-headedness, especially in the first few days of therapy. Advise patient to change positions slowly and, if light-headedness develops, to notify prescriber. Tell patient to stop taking aliskiren and to notify prescriber if she faints.
- Explain that light-headedness and fainting could also result from dehydration caused by inadequate fluid intake, excessive perspiration, diarrhea, or vomiting.
- Instruct patient to avoid using potassium supplements or potassium salt substitutes and to inform all prescribers about her aliskiren and ACE inhibitor therapy.
- Stress importance of stopping aliskiren and seeking immediate medical attention if patient has swelling of face, extremities, eyes, lips, or tongue or if patient has trouble swallowing or breathing.
- Instruct female patient to notify prescriber immediately if she is or could be pregnant because drug will need to be discontinued and another antihypertensive chosen.

allopurinol

Apo-Allopurinol (CAN), Lopurin, Purinol (CAN), Zylorim

allopurinol sodium

Aloprim

Class and Category

Chemical class: Hypoxanthine derivative, xanthine oxidase inhibitor

Therapeutic class: Antigout

Pregnancy category: C

Indications and Dosages

↗ *To treat gout and hyperuricemia*

TABLETS

Adults. 200 to 600 mg daily in divided doses, depending on disease severity. *Usual:* 200 to 300 mg daily. *Maximum:* 800 mg daily.

↗ *To treat secondary hyperuricemia caused by neoplastic disease*

TABLETS

Children ages 6 to 10. 300 mg daily, adjusted after 48 hr, depending on response to treatment.

Children under age 6. 150 mg daily, adjusted after 48 hr, depending on response to treatment.

↗ *To prevent gout attack*

TABLETS

Adults. 100 mg daily increased by 100 mg/wk until serum uric acid level is 6 mg/dl or less.

↗ *To prevent uric acid nephropathy during vigorous treatment of neoplastic disease*

TABLETS

Adults. 600 to 800 mg daily for 2 to 3 days, then adjusted to keep serum uric acid level within normal limits.

↗ *To treat recurrent calcium oxalate calculi*

TABLETS

Adults. 200 to 300 mg daily as a single dose or in divided doses, adjusted based on 24-hr urine urate level.

DOSAGE ADJUSTMENT For patient with impaired renal function, dosage adjusted to 200 mg daily if creatinine clearance is 10 to 20 ml/min/1.73 m², 100 mg daily if creatinine clearance is 3 to 10 ml/min/1.73 m², or 100 mg every other day if creatinine clearance falls below 3 ml/min/1.73 m².

↗ *To treat increased serum and urine uric acid levels in patients with leukemia, lymphoma, and solid tumors whose cancer chemotherapy has increased those levels and who can't tolerate oral therapy*

I.V. INFUSION

Adults. 200 to 400 mg/m² daily as a single infusion or in equally divided infusions every 6, 8, or 12 hr. *Maximum:* 600 mg daily.

Children. 200 mg/m² daily as a single infusion or in equally divided infusions every 6, 8, or 12 hr.

Route	Onset	Peak	Duration
P.O.	2–3 days	1–3 wk*	1–2 wk

Mechanism of Action

Inhibits uric acid production by inhibiting

* For hyperuricemia; several months for gout attack prevention.

xanthine oxidase, the enzyme that converts hypoxanthine and xanthine to uric acid. Allopurinol is metabolized to oxipurinol, which also inhibits xanthine oxidase.

Incompatibilities

Don't combine I.V. allopurinol in solution with amikacin, amphotericin B, carmustine, cefotaxime sodium, chlorpromazine hydrochloride, cimetidine hydrochloride, clindamycin phosphate, cytarabine, dacarbazine, daunorubicin hydrochloride, diphenhydramine hydrochloride, doxorubicin hydrochloride, doxycycline hyclate, droperidol, floxuridine, gentamicin sulfate, haloperidol lactate, hydroxyzine hydrochloride, idarubicin hydrochloride, imipenem-cilastatin sodium, mechloroethamine hydrochloride, meperidine hydrochloride, metoclopramide hydrochloride, methylprednisolone sodium succinate, minocycline hydrochloride, nalbuphine hydrochloride, netilmicin sulfate, ondansetron hydrochloride, prochlorperazine edisylate, promethazine hydrochloride, sodium bicarbonate, streptozocin, tobramycin sulfate, vinorelbine tartrate.

Contraindications

Hypersensitivity to allopurinol

Interactions

DRUGS

ACE inhibitors: Increased risk of hypersensitivity reactions
amoxicillin, ampicillin: Increased risk of rash
azathioprine, mercaptopurine: Inactivation of these drugs
chlorpropamide: Increased risk of hypoglycemia in patients with renal insufficiency
cyclophosphamide, other cytotoxic drugs: Enhanced bone marrow suppression
dicumarol: Increased half-life and anticoagulant action of dicumarol
thiazide diuretics: Possibly increased risk of allopurinol toxicity
uricosuric agents: Increased urinary excretion of uric acid
vitamin C (large doses): Possibly urine acidification and increased risk of renal calculus formation

Adverse Reactions

CNS: Chills, drowsiness, fever, headache, neuritis, paresthesia, peripheral neuropathy, somnolence

CV: Vasculitis

EENT: Epistaxis, loss of taste

GI: Abdominal pain, diarrhea, dysphagia, elevated liver function test results, gastritis, granulomatous hepatitis, hepatic necrosis, hepatomegaly, nausea, vomiting

GU: Exacerbated renal calculi, renal failure

HEME: Agranulocytosis, aplastic anemia, bone marrow depression, eosinophilia, leukocytosis, leukopenia, thrombocytopenia

MS: Arthralgia, exacerbation of gout, myopathy

SKIN: Alopecia; ecchymosis; jaundice; maculopapular, scaly, or exfoliative rash (sometimes fatal); pruritus; urticaria

Nursing Considerations

- As ordered, obtain baseline CBC and uric acid level, and review results of renal and liver function tests before and during allopurinol therapy.

- Reconstitute and dilute I.V. preparation to a concentration of 6 mg/ml or less.

WARNING Discontinue allopurinol and notify prescriber immediately at first sign of hypersensitivity reaction, such as rash, which may precede more severe reactions.

- To decrease risk of calculus formation, maintain fluid intake of up to 3 L daily and monitor patient for output of 2 L daily. Also, don't give vitamin C.

PATIENT TEACHING

- Advise patient to take allopurinol after meals and to drink at least 10 large glasses of water daily.
- Instruct patient to report unusual bleeding or bruising, fever, chills, gout attack, numbness, and tingling.
- Inform patient that acute gout attacks may occur more often early in allopurinol treatment and that results may not be noticeable for 2 weeks or longer.
- Instruct patient not to drive or perform hazardous tasks if drug causes drowsiness.

almotriptan malate

Axert

Class and Category

Chemical class: Selective 5-hydroxytryptamine₁ (5-HT₁) receptor agonist

Therapeutic class: Antimigraine drug

Pregnancy category: C

Indications and Dosages

↗ *To treat acute migraine*

TABLETS

Adults and adolescents ages 12 to 17.

Initial: 6.25 to 12.5 mg as a single dose, repeated in 2 hr p.r.n. *Maximum:* 2 doses/24 hr or 4 migraine treatments/mo.

DOSE ADJUSTMENT For patient with impaired renal or hepatic function, initial dose reduced to 6.25 mg with maximum daily dose of 12.5 mg.

Mechanism of Action

May stimulate 5-HT₁ receptors on intracranial blood vessels and sensory nerves in trigeminal vascular system. By activating these receptors, almotriptan selectively constricts inflamed and dilated cranial blood vessels and inhibits production of proinflammatory neuropeptides. It also interrupts transmission of pain signals to the brain.

Contraindications

Basilar or hemiplegic migraine; cerebrovascular, peripheral vascular, or ischemic or vasospastic coronary artery disease (CAD); hypersensitivity to almotriptan or its components; hypertension (uncontrolled); use within 24 hours of other serotonin-receptor agonists or ergotamine-containing or ergot-type drugs

Interactions**DRUGS**

ergotamine-containing drugs: Prolonged vasospastic reactions

erythromycin, itraconazole, ketoconazole, ritonavir: Possibly increased blood almotriptan level

MAO inhibitors, verapamil: Increased blood almotriptan level

selective serotonin reuptake inhibitors, such as citalopram, escitalopram, fluoxetine, fluvoxamine, paroxetine, sertraline: Increased risk of serotonin syndrome

serotonin norepinephrine reuptake inhibitors, such as duloxetine, venlafaxine: Increased risk of serotonin syndrome

Adverse Reactions

CNS: Dizziness, headache, paresthesia, seizures, somnolence, syncope

CV: Coronary artery vasospasm, hypertension, ischemia, MI, palpitations, vasodilation, ventricular fibrillation, ventricular tachycardia

EENT: Dry mouth

GI: Nausea

Other: Serotonin syndrome

Nursing Considerations

WARNING Because almotriptan can cause coronary artery vasospasm, monitor patient with CAD for angina. Because it may cause peripheral vasospastic reactions, such as ischemic bowel disease, watch for abdominal pain and bloody diarrhea.

- For patient with risk factors for CAD but no known cardiovascular abnormalities, expect to give first dose of almotriptan in a medical facility.
- In patient with risk factors for CAD, obtain an ECG immediately after first dose of almotriptan, as ordered, because cardiac ischemia can occur without causing clinical symptoms.
- Expect to give a lower dosage to patients with hepatic or renal dysfunction because of impaired drug metabolism or excretion.
- Monitor blood pressure regularly during therapy in patients with hypertension because almotriptan may produce a transient increase in blood pressure.

WARNING Monitor patient for evidence of serotonin syndrome, such as agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. In its most severe form, serotonin syndrome can resemble neuroleptic malignant syndrome, which includes a high fever, muscle rigidity, autonomic instability with possible fluctuations in vital signs, and mental status changes.

- Monitor patients hypersensitive to sulfonamides for hypersensitivity to almotriptan because cross-sensitivity may occur.

PATIENT TEACHING

- Inform patient that almotriptan is used to treat acute migraine and that he shouldn't take it to treat nonmigraine headaches.
- Advise patient to consult prescriber before taking any OTC or prescription drugs.
- Advise patient not to take more than maximum prescribed.
- Caution patient that drug may cause adverse CNS reactions, and advise him to avoid hazardous activities until he knows how drug affects him.
- Instruct patient to seek emergency care

immediately for cardiac symptoms (such as heaviness, pain, pressure, or tightness in chest, jaw, neck, or throat) or if multiple new symptoms develop (such as mental changes, high fever, incoordination, nausea, vomiting, diarrhea) after taking drug.

alosetron hydrochloride

Lotronex

Class and Category

Chemical class: Selective serotonin 5-HT₃ receptor antagonist

Therapeutic class: Antidiarrheal

Pregnancy category: B

Indications and Dosages

↗ *To treat women with severe diarrhea-predominant irritable bowel syndrome (IBS) who haven't responded to conventional therapy*

TABLETS

Adults. *Initial:* 1 mg daily for 4 wk, increased to 1 mg b.i.d. if needed. Discontinued if no response in first 4 wk of therapy or if drug doesn't adequately control symptoms after 4 wk of b.i.d. regimen.

Mechanism of Action

Inhibits activation of 5-HT₃ nonselective cation channels found in enteric neurons in the GI tract, thereby decreasing visceral sensations, colonic transit, and secretions in the GI tract. These changes reduce GI pain and hyperactivity, symptoms that are prominent in diarrhea-predominant IBS.

Contraindications

Administration with fluvoxamine, history of chronic or severe constipation or sequelae from constipation, Crohn's disease, diverticulitis, GI perforation or adhesions, hypercoagulable state, impaired intestinal circulation, intestinal obstruction or stricture, ischemic colitis, thrombophlebitis, toxic megacolon, or ulcerative colitis; hypersensitivity to alosetron or its components; severe hepatic impairment

Interactions

DRUGS

fluvoxamine, ketoconazole: Increased blood alosetron level

cimetidine, clarithromycin, itraconazole, protease inhibitors, quinolones, telithromycin, voriconazole: Possibly increased alosetron level

Adverse Reactions

CNS: Anxiety, fatigue, headache, hypnagogic effects, malaise, temperature regulation disturbances

CV: Tachyarrhythmias

GI: Abdominal or GI discomfort and pain, abdominal distention, constipation (may be severe), diarrhea, dyspepsia, flatulence, GI spasms or lesions, hemorrhoids, hemorrhoidal hemorrhage, hyposalivation, ileus, impaction, ischemic colitis, nausea, obstruction, perforation, regurgitation and reflux, small-bowel mesenteric ischemia, ulceration

GU: Urinary frequency

RESP: Breathing disorders

SKIN: Diaphoresis, rash, urticaria

Other: Nonspecific cramps or pain

Nursing Considerations

- Be aware that only physicians enrolled in GlaxoSmithKline's prescribing program for alosetron should prescribe the drug and only patients who have read and signed the patient-physician agreement can receive the drug. Confirm that the agreement has been signed before therapy starts.
- Use alosetron cautiously in patients with mild to moderate liver dysfunction because alosetron is extensively metabolized in the liver.
- Report all adverse reactions to alosetron to the prescriber and to Prometheus at 1-888-423-5227.

WARNING Monitor patient for constipation, especially if she's elderly or debilitated or takes drugs that decrease GI motility. Also watch for evidence of ischemic colitis, such as rectal bleeding, bloody diarrhea, or new or worsening abdominal pain. Serious adverse GI reactions may occur without warning. If they do, be prepared to stop alosetron therapy immediately. If discontinued for ischemic colitis, drug shouldn't be resumed later; however, a patient who no longer has constipation can resume it, if needed.

- Make sure program stickers required by drug maker are affixed to all prescriptions,

including refills, before giving to patient.

PATIENT TEACHING

- Explain that alosetron therapy can't begin until patient has read the medication guide that outlines drug's risks and benefits and has signed the permission form.
- Instruct patient not to start alosetron if constipated and to notify prescriber.
- Advise patient that serious adverse GI effects may occur without warning. Tell her to stop taking alosetron immediately and to notify prescriber if evidence of ischemic colitis or constipation arises. Tell her to notify prescriber if constipation doesn't resolve after stopping drug.
- Inform patient that alosetron will be stopped after 4 weeks of 1 mg b.i.d. if it doesn't control IBS symptoms.

alpha₁-proteinase inhibitor (human)

Prolastin, Prolastin-C, Zemaira

Class and Category

Chemical class: Plasma protein

Therapeutic class: Enzyme replacement

Pregnancy category: C

Indications and Dosages

➤ *To treat congenital alpha₁-antitrypsin deficiency in patients with signs of pancreatic emphysema (Prolastin); to augment and maintain patients with emphysema who are deficient in alpha₁-proteinase inhibitor*

I.V. INFUSION

Adults. 60 mg/kg infused over 30 min (Prolastin) or 15 min (Prolastin-C, Zemaira) at a rate of at least 0.08 ml/kg/min once weekly.

Mechanism of Action

Replaces the enzyme alpha₁-antitrypsin, which normally inhibits the proteolytic enzyme elastase in patients with alpha₁-antitrypsin deficiency. Without alpha₁-proteinase inhibitor, elastase attacks and destroys alveolar membranes and causes emphysema.

Contraindications

Hypersensitivity to alpha₁-proteinase inhibitor, its components, or other alpha₁-

proteinase products; selective immunoglobulin A (IgA) deficiency in patients with anti-IgA antibodies

Interactions

ACTIVITIES

smoking: Inactivation of alpha₁-proteinase inhibitor

Adverse Reactions

CNS: Asthenia, chills, dizziness, fever, headache, light-headedness, malaise, paresthesia

EENT: Sinusitis

ENDO: Hot flashes

HEME: Mild, transient leukocytosis

RESP: Upper respiratory tract infection, worsening of existing COPD

SKIN: Pruritus, rash

Other: Flulike symptoms, infusion site pain

Nursing Considerations

- Use alpha₁-proteinase inhibitor cautiously in patients at risk for circulatory overload because drug is a colloid solution that increases plasma volume.
- Before reconstituting, remove drug and diluent from refrigerator and let it warm to room temperature.
- To reconstitute, remove caps from vials and clean rubber stoppers with antiseptic. After stoppers are dry, remove protective cover from diluent end of transfer device and insert into center of upright diluent vial. Then remove protective cover from drug end of transfer device, invert diluent vial with attached transfer device, and using minimal force, insert drug end of transfer device into center of rubber stopper of upright drug vial. Make sure flange of transfer device rests on stopper surface so that diluent flows into drug vial.
- During diluent transfer, wet lyophilized cake completely by gently tilting drug vial. Don't let air inlet filter face downward. (Take care not to lose the vacuum because this will prolong drug reconstitution.) Once diluent transfer is complete, pull transfer device along with attached diluent vial out of drug vial and discard. Gently swirl drug vial until powder is completely dissolved. Avoid shaking because this may cause drug to foam and degrade.
- If more than one vial of alpha₁-proteinase inhibitor is required, use aseptic technique to transfer reconstituted solution from

each vial into a sterile I.V. administration container.

- Administer at room temperature within 3 hours of reconstitution as an I.V. infusion, using the large-volume 5-micron conical filter provided. Place filter between distal end of I.V. administration set and infusion set, and infuse at 0.08 ml/kg/min or as determined by patient response and comfort.

WARNING Alpha₁-proteinase inhibitor is made from human plasma and may contain infectious agents, such as viruses. Make sure patient is immunized against hepatitis B before giving drug. If time doesn't allow for antibody formation, give a single dose of hepatitis B immune globulin with hepatitis B vaccine, as prescribed.

- Monitor patient for delayed fever, which may occur up to 12 hours after therapy. Fever usually resolves within 24 hours.

PATIENT TEACHING

- Tell patient to report immediately early evidence of allergic reaction, such as chest tightness, trouble breathing, faintness, hives, wheezing, and any other unusual symptoms.
- Advise patient to notify prescriber about signs or symptoms of viral infection (chills, drowsiness, fever, and runny nose, followed 2 weeks later by joint pain and a rash) after receiving drug.
- Stress importance of receiving weekly doses to maintain an adequate antielastase barrier in the lungs. Explain that treatment must continue for life.
- Warn patient not to smoke.

alprazolam

Apo-Alpraz (CAN), Novo-Alprazol (CAN), Nu-Alpraz, Xanax, Xanax XR

Class, Category, and Schedule

Chemical class: Benzodiazepine

Therapeutic class: Antianxiety drug

Pregnancy category: D

Controlled substance schedule: IV

Indications and Dosages

➤ *To control anxiety disorders, relieve anxiety (short-term therapy), or treat anxiety associated with depression*

TABLETS

Adults. *Initial:* 0.25 to 0.5 mg t.i.d., adjusted to patient's needs. *Maximum:* 4 mg daily in divided doses.

DOSAGE ADJUSTMENT In elderly or debilitated patients or patients with advanced hepatic disease, initial dosage 0.25 mg b.i.d. or t.i.d. and increased gradually, as needed and tolerated.

➤ *To treat panic attack*

ORALLY DISINTEGRATING TABLETS, TABLETS

Adults. *Initial:* 0.5 mg t.i.d., increased every 3 to 4 days by no more than 1 mg daily, based on patient response. *Maximum:* 10 mg daily in divided doses.

E.R. TABLETS

Adults. *Initial:* 0.5 to 1 mg daily in morning, increased every 3 to 4 days by no more than 1 mg daily, based on patient response. *Maximum:* 10 mg daily as single dose in morning.

Mechanism of Action

May increase effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptors in limbic and cortical areas of the CNS. GABA inhibits excitatory stimulation, which helps control emotional behavior. The limbic system contains many benzodiazepine receptors, which may help explain drug's antianxiety effects.

Contraindications

Acute angle-closure glaucoma; hypersensitivity to alprazolam, its components, or other benzodiazepines; itraconazole or ketoconazole therapy

Interactions

DRUGS

antacids: Altered alprazolam absorption rate
cimetidine, disulfiram, fluoxetine, isoniazid, metoprolol, oral contraceptives, propoxyphene, propranolol, valproic acid: Decreased alprazolam elimination and increased effects
CNS depressants: Possibly increased CNS effects of both drugs
digoxin: Possibly increased serum digoxin level, causing digitalis toxicity
itraconazole, ketoconazole: Possibly profoundly inhibited alprazolam metabolism
levodopa: Decreased effects of levodopa
neuromuscular blockers: Possibly potentiated or antagonized effects of these drugs
phenytoin: Possibly increased serum pheny-

toin level, causing phenytoin toxicity
probenecid: Possibly faster onset or prolonged effects of alprazolam
ranitidine: Possibly reduced absorption of alprazolam

ACTIVITIES

alcohol use: Enhanced adverse CNS effects of alprazolam

Adverse Reactions

CNS: Agitation, akathisia, confusion, depression, dizziness, drowsiness, fatigue, hallucinations, headache, insomnia, irritability, lack of coordination, light-headedness, memory loss, nervousness, paresthesia, rigidity, speech problems, syncope, tremor, weakness

CV: Chest pain, edema, hypotension, non-specific ECG changes, palpitations, tachycardia

EENT: Blurred vision, altered salivation, dry mouth, nasal congestion, tinnitus

ENDO: Galactorrhea, gynecomastia, hyperprolactinemia

GI: Abdominal discomfort, anorexia, constipation, diarrhea, elevated liver function test results, hepatitis, hepatic failure, nausea, vomiting

GU: Altered libido, urinary hesitancy

MS: Dysarthria, muscle rigidity and spasms

RESP: Hyperventilation, upper respiratory tract infection

SKIN: Dermatitis, diaphoresis, pruritus, rash, Stevens-Johnson syndrome

Other: Weight gain or loss

Nursing Considerations

- Expect to give a higher dosage if patient's panic attacks occur unexpectedly or during such activities as driving.
- Because use can lead to dependency, expect to reduce dosage gradually when stopping drug. To prevent withdrawal symptoms, don't stop drug abruptly.

PATIENT TEACHING

- Warn against stopping drug abruptly because withdrawal symptoms may occur.
- Instruct patient never to increase prescribed dose because of risk of dependency.
- Urge patient to avoid drinking alcohol during alprazolam therapy.
- Advise patient to avoid driving and activities that require alertness until alprazolam's effects are known.
- Instruct female patient of childbearing age

to notify prescriber immediately if she becomes or might be pregnant. Drug isn't recommended during pregnancy.

alprostadil

Caverject, Edex, Muse

Class and Category

Chemical class: Prostaglandin E₁

Therapeutic class: Anti-impotence drug

Pregnancy category: C

Indications and Dosages

↗ *To treat erectile dysfunction caused by vascular or psychogenic causes or both*

INTRACAVERNOSUS INJECTION (CAVERJECT, EDEX)

Adults. *Initial*: 2.5 mcg. Increased to 5 mcg if partial response or 7.5 mcg if no response, followed by incremental increases of 5 to 10 mcg until erection suitable for intercourse (not exceeding 1-hr duration) is achieved. No more than 2 doses, separated by 1 hr, should be given on a single day during initial titration phase. *Maximum*: 3 doses/wk, separated by 24 hr.

URETHRAL SUPPOSITORY (MUSE)

Adults. *Initial*: 125 to 250 mcg. If no response, dosage increased in increments to 500 or 1,000 mcg until erection suitable for intercourse (not exceeding 1-hr duration) is achieved. *Maximum*: 2 doses/24 hr.

↗ *To treat erectile dysfunction caused by spinal cord injury*

INTRACAVERNOSUS INJECTION (CAVERJECT, EDEX)

Adults. *Initial*: 1.25 mcg. Increased to 2.5 mcg if partial response, then to 5 mcg, and increased in 5-mcg increments until erection suitable for intercourse (not exceeding 1-hr duration) is achieved. No more than 2 doses, separated by 1 hr, should be given on a single day during initial titration phase. *Maximum*: 3 doses/week, separated by 24 hr.

Route	Onset	Peak	Duration
Intra-cavernous	5–20 min	Unknown	60 min
Intra-urethral	5–10 min	Unknown	30–60 min

Contraindications

Anuria, balanitis (inflammation of head of

Mechanism of Action

Alprostadil causes penile erection by increasing blood flow to the penis through relaxation of trabecular smooth muscles and dilation of cavernosal arteries (*upper right*). A naturally occurring prostaglandin, alprostadil interacts with specific membrane-bound receptors in the corpora cavernosa cells of the penis. This action activates intracellular adenylyl cyclase (*lower right*), which in turn converts adenosine triphosphate (ATP) into cyclic adenosine monophosphate (cAMP). Increased intracellular levels of cAMP activate protein kinase, an enzyme that activates other enzymes to initiate a cascade of chemical reactions.

These chemical reactions cause the trabecular smooth muscles to relax and the cavernosal arteries to dilate. Blood flow to the penis is then increased, which distends the penile lacunar spaces and compresses the veins, trapping blood in the penis and causing it to become enlarged and rigid.

penis), cavernosal fibrosis, hypersensitivity to alprostadil or its components, hyperviscosity syndrome, indwelling urethral catheter, leukemia, men for whom sexual activity is contraindicated, multiple myeloma, penile angulation, penile implants, Peyronie's disease, polycythemia, severe hypospadias (urethral opening on underside of penis), sickle cell anemia or trait, tendency to develop venous thrombosis, thrombocytopenia, urethral obstruction or stricture, urethritis

Interactions

DRUGS

anticoagulants: Possibly increased risk of bleeding

cyclosporine: Possibly decreased blood cyclosporine level

Adverse Reactions

CNS: Dizziness, headache, syncope

CV: Hypertension, hypotension, tachycardia, vasodilation

EENT: Nasal congestion, sinusitis

GU: Pelvic pain; penile disorders, including

edema, fibrosis, pain, and rash; priapism; prolonged erection; prostatic pain or enlargement; urethral abrasions; urethral bleeding

MS: Back pain

RESP: Cough, upper respiratory tract infection

Other: Flulike symptoms, injection site bruising or hematoma, needle breakage

Nursing Considerations

- Reconstitute solution with 1 ml diluent, for a concentration of 5, 10, 20, or 40 mcg/ml, depending on vial strength. Gently swirl contents of reconstituted vial. Use reconstituted solution within 24 hours when stored at room temperature. Don't use vials that contain precipitate or discolored solution. Discard unused reconstituted solution.
- Using a ½-inch 27G to 30G needle, inject drug at a 90-degree angle into proximal third of spongy tissue that runs the length of the dorsolateral aspect of penis, avoiding any visible veins. Rotate injection sites by alternating sides of the penis.

- Carefully examine penis for evidence of penile fibrosis. Expect to discontinue treatment if patient develops cavernosal fibrosis, penile angulation, or Peyronie's disease (hardening of the corpora cavernosa, which causes penis to become distorted when erect) during therapy.

WARNING Watch for prolonged erection after giving drug. Notify prescriber, and be prepared to treat patient for priapism if erection lasts longer than 4 hours.

- If patient is receiving an anticoagulant, such as warfarin or heparin, watch for bleeding at injection site because drug may inhibit platelet aggregation.

PATIENT TEACHING

- Inform patient that initial therapy must be performed in the office setting. Teach him how to correctly administer intracavernous injections or urethral suppositories. Inform him that the goal of treatment is to produce an erection that lasts no longer than 1 hour.
- Advise patient to use alprostadil for injection no more than three times/week and to separate doses by 24 hours. Inform patient using urethral suppositories not to exceed two doses in a 24-hour period.
- Tell patient to inform prescriber immediately about nodules or hard tissue in the penis; an erection that persists for more than 4 hours; new or worsened penile pain; or persistent curvature, redness, swelling, or tenderness of the erect penis.
- Inform patient that common adverse reactions include mild to moderate pain immediately after injection and burning after suppository insertion. Also, needle may break. Advise patient to avoid it by following prescriber's instructions exactly and by handling injection device properly. If needle breaks during injection and he can see and grasp broken end, he should remove it and contact prescriber. If he can't see or grasp broken end, he should seek medical care.
- Instruct patient using suppository form to urinate just before inserting suppository and to insert it with applicator supplied with drug. Tell patient to hold penis upright after insertion and to roll it firmly between his hands to distribute drug.
- Tell patient to sit, stand, or walk for 10 minutes after inserting suppository to

- increase blood flow and enhance erection.
- Tell patient to expect an erection 5 to 20 minutes after injecting drug or about 10 minutes after inserting suppository.
- Advise patient not to change dosage without consulting prescriber and to keep scheduled follow-up appointments.
- Warn patient that alprostadil offers no protection from sexually transmitted diseases. Urge him to use a condom to decrease risk of blood-borne disease, because injection can cause minor bleeding at injection site.
- Instruct patient not to reuse or share needles or syringes. Inform him of proper procedure for sharps disposal.
- Warn patient using suppository form not to have sexual intercourse with a pregnant woman unless a condom is used because drug's effect on pregnancy is unknown.
- Advise patient who plans to travel not to check drug with airline baggage or store it in a closed car.

alteplase (tissue plasminogen activator, recombinant)

Activase, Activase rt-PA (CAN)

Class and Category

Chemical class: Purified glycoprotein

Therapeutic class: Thrombolytic

Pregnancy category: C

Indications and Dosages

➤ *To treat acute MI*

ACCELERATED I.V. INFUSION

Adults weighing more than 67 kg (148 lb).

15-mg bolus followed by 50 mg infused over next 30 min and then by 35 mg infused over next 60 min.

Adults weighing 67 kg or less. 15-mg bolus followed by 0.75 mg/kg (up to 50 mg) infused over next 30 min and then 0.5 mg/kg (up to 35 mg) infused over next 60 min.

I.V. INFUSION

Adults weighing more than 65 kg (143 lb).

100 mg infused over 3 hr as follows: 6 to 10 mg by bolus over first 1 to 2 min, 50 to 54 mg over remainder of first hr, 20 mg over second hr, and 20 mg over third hr.

Adults weighing 65 kg or less. 1.25 mg/kg

infused over 3 hr on similar schedule as those weighing more than 65 kg.

➤ **To treat acute ischemic stroke**

To avoid acute bleeding complications, treatment for acute ischemic stroke must begin within 3 hr after onset of stroke symptoms and only after computed tomography or other diagnostic imaging method excludes intracranial hemorrhage.

I.V. INFUSION

Adults. 0.9 mg/kg infused over 60 min, with 10% of total dose given as bolus over first min. *Maximum:* 90 mg.

➤ **To treat pulmonary embolism**

I.V. INFUSION

Adults. 100 mg infused over 2 hr.

Route	Onset	Peak	Duration
I.V.	Immediate	20–120 min	4 hr

Mechanism of Action

Binds to fibrin in a thrombus and converts trapped plasminogen to plasmin. Plasmin breaks down fibrin, fibrinogen, and other clotting factors, which dissolves the thrombus.

Incompatibilities

Don't add other drugs to solution that contains alteplase.

Contraindications

For all indications: Active internal bleeding, arteriovenous malformation or aneurysm, bleeding diathesis, intracranial neoplasm, severe uncontrolled hypertension

For acute MI and pulmonary embolism only: History of stroke, intracranial or intraspinal surgery or trauma in past 2 months

For acute ischemic stroke only: Recent head trauma, recent intracranial surgery, recent stroke, seizure activity at onset of stroke, subarachnoid hemorrhage, suspicion or history of intracranial hemorrhage

Interactions

DRUGS

drugs that alter platelet function, such as abciximab, acetylsalicylic acid, and dipyridamole; heparin; vitamin K antagonists:

Increased risk of bleeding

Adverse Reactions

CNS: Cerebral edema, cerebral herniation, fever, seizure, stroke

CV: Arrhythmias (including bradycardia and electromechanical dissociation), cardiac arrest, cardiac tamponade, cardiogenic shock, cholesterol embolism, coronary thrombolysis, heart failure, hypotension, mitral insufficiency, myocardial reinfarction or rupture, pericardial effusion, pericarditis, venous thrombosis and embolism

EENT: Epistaxis, gingival bleeding, laryngeal edema

GI: GI bleeding, nausea, retroperitoneal bleeding, vomiting

GU: GU bleeding

RESP: Pleural effusion, pulmonary edema, pulmonary reembolization

SKIN: Bleeding at puncture sites, ecchymosis, rash, urticaria

Other: Anaphylaxis

Nursing Considerations

WARNING To avoid acute bleeding complications, treatment for acute ischemic stroke must begin within 3 hr after onset of stroke symptoms and only after computed tomography or other diagnostic imaging method excludes intracranial hemorrhage.

- Immediately before use, reconstitute alteplase with sterile water for injection only. Swirl gently to dissolve powder; don't shake.
- Monitor patient for bleeding, especially at arterial puncture sites.
- Monitor blood pressure and heart rate and rhythm frequently during and after therapy.

WARNING Alteplase therapy may cause arrhythmias from sudden reperfusion of the myocardium. Monitor continuous ECG for arrhythmias during drug therapy.

- Minimize bleeding from noncompressible sites by avoiding internal jugular and subclavian venous puncture sites.
- Discontinue alteplase immediately if serious bleeding occurs.
- After administering alteplase, apply pressure for at least 30 minutes, followed by a pressure dressing.
- Store reconstituted solution at room temperature (about 86° F [30° C]) or refrigerated (36° to 46° F [2.2° to 7.7° C]).

PATIENT TEACHING

- Tell patient to immediately report bleeding, including from the nose or gums.

- Advise patient to limit physical activity during alteplase administration to reduce risk of injury and bleeding.

aluminum carbonate

Basaljel

aluminum hydroxide

AlternaGEL, Alu-Cap, Alugel (CAN), Alu-Tab, Amphojel, Dialume

Class and Category

Chemical: Aluminum salt

Therapeutic: Antacid, phosphate binder

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat hyperacidity associated with gastric hyperacidity, gastritis, hiatal hernia, peptic esophagitis, and peptic ulcers; to prevent phosphate renal calculus formation; to reduce hyperphosphatemia in chronic renal failure*

ALUMINUM CARBONATE CAPSULES, SUSPENSION, TABLETS

Adults. 2 capsules or tablets or 10 ml suspension every 2 hr up to 12 times daily p.r.n.

ALUMINUM HYDROXIDE CAPSULES, SUSPENSION, TABLETS

Adults. 500 to 1,500 mg as capsules or tablets in divided doses 3 to 6 times daily, taken between meals and at bedtime; 5 to 30 ml as suspension, p.r.n., taken between meals and at bedtime.

Route	Onset	Peak	Duration
P.O.	Varies	Unknown	20–40 min*

Mechanism of Action

Neutralizes or reduces gastric acidity, increasing stomach and duodenal alkalinity. Protects stomach and duodenum lining by inhibiting pepsin's proteolytic activity. Binds with phosphate ions in intestine to form insoluble aluminum-phosphate compounds, which lower blood phosphate level.

* If fasting; at least 3 hr if given 1 hr after meals.

Contraindications

Hypersensitivity to aluminum

Interactions

DRUGS

allopurinol, chloroquine, corticosteroids, diflunisal, digoxin, ethambutol, H₂-receptor blockers, iron, isoniazid, penicillamine, phenothiazines, ranitidine, tetracyclines, thyroid hormones, ticlopidine: Decreased effects of these drugs
benzodiazepines: Increased benzodiazepine effects

Adverse Reactions

CNS: Encephalopathy

GI: Constipation, intestinal obstruction, white-speckled stool

MS: Osteomalacia, osteoporosis

Other: Aluminum accumulation in serum, bone, and CNS; aluminum intoxication; electrolyte imbalances

Nursing Considerations

- Don't give aluminum hydroxide within 1 to 2 hours of other oral drugs.
- Know that two 0.6-g aluminum hydroxide tablets can neutralize 16 mEq of acid.
- Monitor patient's serum levels of sodium, phosphate, and other electrolytes, as appropriate.

PATIENT TEACHING

- Instruct patient to chew tablets thoroughly before swallowing and then to drink a full glass of water.
- Warn patient not to take maximum dosage for more than 2 weeks unless prescribed because doing so may cause stomach to secrete excess hydrochloric acid.
- Teach patient to prevent constipation with a high-fiber diet and increased fluid intake (2 to 3 L daily), if appropriate.
- If patient takes other prescription drugs, advise him to notify prescriber about them before taking aluminum because of risk of interactions.
- Advise patient to notify prescriber if symptoms worsen or don't subside.

alvimopan

Entereg

Class and Category

Chemical class: Single stereoisomer

Therapeutic class: Mu opioid receptor antagonist

Pregnancy category: B

Indications and Dosages

➤ *To accelerate GI recovery in hospitalized patients after partial large- or small-bowel resection with primary anastomosis*

CAPSULES

Adults. *Initial:* 12 mg started 30 min to 5 hr before surgery, followed by 12 mg b.i.d. starting the day after surgery for up to 7 days or until discharge. *Maximum:* 24 mg/day with a maximum of 15 doses total.

Route	Onset	Peak	Duration
P.O.	Unknown	2 hr	Unknown

Mechanism of Action

Competitively binds to selective mu opioid receptors in GI tract, antagonizing peripheral effects of opioids on GI motility and secretion without reversing the central analgesic effects of opioid agonists. This action alleviates postoperative ileus by causing bowel function to return more quickly after part of bowel has been removed and an end-to-end anastomosis performed.

Contraindications

Hypersensitivity to alvimopan or its components, severe hepatic or renal impairment, use of opioids for more than 7 consecutive days immediately before alvimopan starts

Interactions

DRUGS

opioids given within previous 7 days at therapeutic doses: Increased sensitivity to alvimopan

Adverse Reactions

GI: Abdominal pain, constipation, diarrhea, dyspepsia, flatulence

GU: Urine retention

HEME: Anemia

MS: Back pain

Other: Hypokalemia

Nursing Considerations

- Don't give alvimopan to patients with severe hepatic or renal impairment or to patients having surgery to correct a complete bowel obstruction.
- Alvimopan is prescribed only for short-

term use with maximum of 15 doses and is only dispensed in hospitals enrolled in Entereg Access Support and Education (E.A.S.E.) program. Closely monitor number of doses given, and expect to stop drug when patient has received 15 doses or is discharged from hospital.

- Monitor patient's serum potassium level closely, as ordered, because drug may cause hypokalemia. Also check patient's hemoglobin level and hematocrit because drug has been associated with anemia.
- Monitor patient with mild to moderate hepatic or renal failure for evidence of high alvimopan levels, such as abdominal pain or cramping, diarrhea, nausea, and vomiting. If present, alert prescriber.
- Monitor Japanese patients closely for possible adverse effects because alvimopan level may be higher in this population.

PATIENT TEACHING

- Explain the need to accurately describe long-term or intermittent use of opioid pain therapy, including any use of opioids in the week before receiving alvimopan. Taking alvimopan after such use may cause serious adverse GI reactions.
- Inform patient that the most common adverse effects of alvimopan are constipation, dyspepsia, and flatulence.
- Tell patient that drug is for in-hospital use only and will not be taken at home.

amantadine hydrochloride (adamantanamine hydrochloride)

Endantadine (CAN), Gen-Amantadine (CAN), Symmetrel

Class and Category

Chemical class: Adamantane derivative

Therapeutic class: Antidyskinetic, antiviral

Pregnancy category: C

Indications and Dosages

➤ *To manage symptoms of primary Parkinson's disease, postencephalitic parkinsonism, arteriosclerotic parkinsonism, and parkinsonism caused by CNS injury from carbon monoxide*

*intoxication***CAPSULES, SYRUP, TABLETS**

Adults. *Initial:* 100 mg b.i.d. *Maximum:* 400 mg daily in divided doses.

↗ *To treat drug-induced extrapyramidal reactions*

CAPSULES, SYRUP, TABLETS

Adults. *Initial:* 100 mg b.i.d. *Maximum:* 300 mg daily in divided doses.

DOSAGE ADJUSTMENT For elderly patients, patients taking high doses of other antidyskinetics, and patients who have a serious medical condition (such as heart failure, epilepsy, or psychosis), initial dosage reduced to 100 mg daily, with gradual titration to 100 mg b.i.d. after 1 to several wk. For patients with impaired renal function, dosage adjusted to 200 mg on day 1 and then to 100 mg daily if creatinine clearance is 30 to 50 ml/min/1.73 m²; to 200 mg on day 1 and then to 100 mg every other day if creatinine clearance is 15 to 29 ml/min/1.73 m²; and to 200 mg every wk if creatinine clearance is less than 15 ml/min/1.73 m² or if patient is receiving hemodialysis.

↗ *To prevent and treat respiratory tract infection caused by influenza A*

CAPSULES, SYRUP, TABLETS

Adults and children age 12 and over.

Initial: 200 mg daily or 100 mg b.i.d.

Maximum: 200 mg daily.

DOSAGE ADJUSTMENT In impaired renal function, if creatinine clearance is 30 to 50 ml/min/1.73 m², 200 mg on day 1 and then 100 mg daily. If clearance is 15 to 29 ml/min/1.73 m², 200 mg on day 1 and then 100 mg every other day. If clearance is less than 15 ml/min/1.73 m² or patient is having hemodialysis, 200 mg every wk.

Children ages 9 to 12. 100 mg every 12 hr.

Maximum: 200 mg daily.

Children ages 1 to 9. 1.5 to 3 mg/kg every 8 hr or 2.2 to 4.4 mg/kg every 12 hr.

Maximum: 150 mg/day.

Route	Onset	Peak	Duration
P.O.	In 48 hr*	Unknown	Unknown

Mechanism of Action

Affects dopamine, a neurotransmitter that is synthesized and released by neurons lead-

* Antidyskinetic action; antiviral action unknown.

ing from substantia nigra to basal ganglia and is essential for normal motor function. In Parkinson's disease, progressive degeneration of these neurons reduces intrasynaptic dopamine. Amantadine may cause dopamine to accumulate in the basal ganglia by increasing dopamine release or by blocking dopamine reuptake into the presynaptic neurons of the CNS. Amantadine also may stimulate dopamine receptors or make postsynaptic receptors more sensitive to dopamine. These actions help control alterations in involuntary muscle movements, such as tremors and rigidity, that are associated with Parkinson's disease.

Amantadine may inhibit influenza A viral replication by blocking uncoating of virus and release of viral nucleic acid into respiratory epithelial cells. It also may interfere with early replication of viruses that have already penetrated cells.

Contraindications

Angle-closure glaucoma, hypersensitivity to amantadine or its components

Interactions**DRUGS**

anticholinergics or other drugs with anticholinergic activity, other antidyskinetics, antihistamines, phenothiazines, tricyclic antidepressants: Possibly increased anticholinergic effects and risk of paralytic ileus

carbidopa-levodopa, levodopa: Increased effectiveness of these drugs

CNS stimulants: Excessive CNS stimulation, possibly causing arrhythmias, insomnia, irritability, nervousness, or seizures

hydrochlorothiazide, triamterene: Possibly decreased amantadine clearance and increased risk of toxicity

live-virus vaccines: Possibly interference with vaccine effectiveness

quinidine, quinine, trimethoprim-sulfamethoxazole: Increased blood amantadine level

ACTIVITIES

alcohol use: Possibly increased risk of CNS effects—including confusion, dizziness, and light-headedness—and orthostatic hypotension

Adverse Reactions

CNS: Agitation, anxiety, confusion, dizziness, drowsiness, fatigue, fever, hallucinations, insomnia, irritability, light-headed-

ness, mental impairment, nervousness, neuroleptic malignant syndrome, nightmares, suicidal ideation, syncope

CV: Arrhythmias, cardiac arrest, orthostatic hypotension, peripheral edema, tachycardia

EENT: Blurred vision; dry mouth, nose, or throat; keratitis; mydriasis

GI: Constipation, diarrhea, dysphagia, nausea

GU: Dysuria, increased libido

HEME: Agranulocytosis, leukopenia, neutropenia

RESP: Acute respiratory failure, pulmonary edema, tachypnea

SKIN: Diaphoresis, livedo reticularis (purplish, netlike rash), pruritus

Other: Anaphylaxis; intense urges to perform certain activities, such as gambling or sexual acts

Nursing Considerations

- Be aware that prophylactic therapy with amantadine should begin as soon as possible after exposure to persons infected with influenza A virus and should continue for 10 days. During an influenza epidemic, expect drug to be given daily throughout the epidemic, which typically lasts 6 to 8 weeks. If patient has previously received inactivated influenza A vaccine, prescriber may discontinue it when sure that patient has developed active immunity against the virus. If patient receives inactivated influenza A vaccine at the same time amantadine therapy starts, expect amantadine to be given for 2 to 3 weeks.
- Expect amantadine therapy to start 24 to 48 hours after the onset of influenza A symptoms and to continue 48 hours after they resolve.
- Monitor patients who have a history of psychiatric illness or substance abuse because amantadine may worsen these conditions. Some patients taking amantadine have attempted suicide or had suicidal ideation.
- If patient has a history of heart failure or peripheral edema, monitor for weight gain and edema because drug may cause redistribution of body fluid.
- Amantadine may increase seizure activity in patients with a history of seizures.

WARNING Monitor patient for evidence of neuroleptic malignant syndrome during

dosage reduction or discontinuation of therapy. These include fever, hypertension or hypotension, involuntary motor activity, mental changes, muscle rigidity, tachycardia, and tachypnea. Be prepared to provide supportive treatment and additional drug therapy, as prescribed.

- Be aware that patients receiving more than 200 mg daily are more likely to experience adverse or toxic reactions.
- Monitor patient for decreased drug effectiveness over time. If therapeutic response declines, expect to increase dosage or discontinue drug temporarily, as ordered.
- Assess patient regularly for skin changes because melanoma risk is higher in those with Parkinson's disease. It isn't clear whether the risk is increased by the disease or by its treatment.

PATIENT TEACHING

- Instruct patient to take amantadine exactly as prescribed and not to stop abruptly. Advise patient to notify prescriber if drug becomes less effective.
- Tell patient to notify prescriber if influenza symptoms don't improve after 2 to 3 days.
- **WARNING** Advise patient or family member to notify prescriber immediately if patient reveals thoughts of suicide.
- Encourage patient to avoid consuming alcohol during amantadine therapy because alcohol may increase the risk of confusion, dizziness, light-headedness, or orthostatic hypotension.
- Advise patient to avoid driving and other activities that require a high level of alertness until he knows how the drug affects him because it may cause blurred vision and mental impairment.
- Advise patient to change positions slowly to minimize effects of orthostatic hypotension.
- Tell patient to use ice chips or sugarless candy or gum to relieve dry mouth.
- Caution patient to resume physical activities gradually as signs and symptoms improve.
- Urge patient to have regular skin examinations by a dermatologist or other qualified health professional.
- Instruct patient to notify prescriber about intense urges, such as for gambling or sex, because dosage may need to be reduced or drug discontinued.

ambenonium chloride

Mytelase

Class and Category

Chemical class: Synthetic quaternary ammonium compound

Therapeutic class: Antimyasthenic, cholinergic

Pregnancy category: C

Indications and Dosages

↗ *To improve muscle strength in patients with myasthenia gravis in whom pyridostigmine or neostigmine are contraindicated*

TABLETS

Adults and adolescents. *Initial:* 5 mg t.i.d. or q.i.d., increased at 1- to 2-day intervals to optimum dosage based on patient response. *Usual:* Highly individualized but usually 5 to 50 mg t.i.d. or q.i.d.

Children. *Initial:* 0.3 mg/kg or 10 mg/m² daily in divided doses t.i.d. or q.i.d.

Maintenance: Up to 1.5 mg/kg or 50 mg/m² daily in divided doses t.i.d. or q.i.d.

Route	Onset	Peak	Duration
P.O.	20–30 min	Unknown	3–8 hr

Mechanism of Action

Attaches to acetylcholinesterase and blocks its breakdown. This action prolongs and exaggerates acetylcholine's effects, producing cholinergic responses, such as miosis, increased intestinal and skeletal muscle tone, bronchoconstriction, bradycardia, and increased salivary and sweat gland secretion.

Contraindications

Hypersensitivity to ambenonium, its components, or anticholinesterases; mechanical intestinal or urinary tract obstruction

Interactions

DRUGS

anesthetics, antiarrhythmics, corticosteroids, magnesium, methocarbamol: Decreased effects of ambenonium
aminoglycosides, anticholinesterase muscle stimulants, depolarizing muscle relaxants, ganglionic blockers, mecamylamine: Increased effects of ambenonium

Adverse Reactions

CNS: Dizziness, drowsiness, headache, loss of consciousness, seizures, syncope

CV: AV block, bradycardia, decreased cardiac output, hypotension

EENT: Dysphonia, increased salivation, laryngospasm

GI: Abdominal cramps, dysphagia, flatulence, increased gastric and intestinal secretions, increased peristalsis, mild diarrhea, nausea, vomiting

GU: Incontinence, urinary frequency or urgency

MS: Arthralgia, dysarthria, fasciculations, muscle spasms, muscle weakness

RESP: Bronchoconstriction, bronchospasm, dyspnea, increased tracheobronchial secretions, lung congestion, respiratory arrest or depression, respiratory muscle paralysis

SKIN: Diaphoresis, flushing, rash, urticaria

Nursing Considerations

- Increase dosage gradually as prescribed to avoid ambenonium buildup and overdose.
- When increasing dosage to optimum level, note when no further increase in muscle strength is observed. Then expect to reduce dosage to previous effective level and to use this as maintenance dosage.
- Expect prescriber to order ephedrine (25 mg per ambenonium dose) or potassium chloride (1 to 2 g per ambenonium dose) to further improve muscle strength.

WARNING Drug has a narrow margin between effectiveness and overdose. If patient receives more than 200 mg daily, watch closely for overdose (cholinergic crisis), such as abdominal cramps, diarrhea, nausea, vomiting, increased salivation, diaphoresis, difficulty swallowing, blurred vision, miosis, hypertension, fasciculations, and voluntary muscle paralysis.

- Assess neuromuscular status to detect progressive or recurrent muscle weakness during long-term ambenonium therapy.
- If patient develops drug resistance in long-term therapy, expect to restore responsiveness by decreasing dosage or briefly stopping drug with close supervision.

PATIENT TEACHING

- Instruct patient to swallow tablet with liquid or food to minimize GI irritation.
- Advise patient to consult prescriber before discontinuing drug—even if symptoms diminish or disappear.

ambrisentan

Letairis

Class and Category

Chemical class: Autocrine and paracrine peptide

Therapeutic class: Endothelin receptor antagonist

Pregnancy category: X

Indications and Dosages

➤ *To treat pulmonary arterial hypertension, improve exercise capacity, and delay worsening in patients with World Health Organization (WHO) class II or III symptoms*

TABLETS

Adults. *Initial:* 5 mg once daily, increased to 10 mg once daily as needed and tolerated.

Route	Onset	Peak	Duration
P.O.	Unknown	2 hr	Unknown

Mechanism of Action

Blocks the action of endothelin-1 (ET-1), a potent autocrine and paracrine peptide in vascular smooth muscle and endothelium of lung tissue. ET-1 levels increase in pulmonary arterial hypertension, and ET-1 may affect its development and progression. Ambrisentan blocks an ET-1 receptor subtype, ETA, that causes vasoconstriction and cell proliferation, decreasing pulmonary artery pressure and cell proliferation and possibly delaying disease progression.

Contraindications

Hypersensitivity to ambrisentan or its components, pregnancy, breast-feeding, moderate to severe hepatic disease

Interactions

DRUGS

cyclosporine A: Possibly increased exposure to ambrisentan

strong CYP3A inhibitors (such as ketoconazole) and CYP2C19 inhibitors (such as omeprazole): Possibly increased plasma ambrisentan level and increased risk of toxicity

FOODS

grapefruit juice: Possibly increased blood ambrisentan level

Adverse Reactions

CNS: Headache

CV: Heart failure, palpitations, peripheral edema

EENT: Nasal congestion, nasopharyngitis, sinusitis

GI: Abdominal pain, constipation, elevated liver enzymes

HEME: Anemia

RESP: Dyspnea

SKIN: Flushing

Other: Angioedema

Nursing Considerations

- Ambrisentan isn't recommended for patients with moderate to severe hepatic impairment. Use it cautiously in patients with mild hepatic impairment.
- Ambrisentan is available only through a restricted distribution program. Patients must be enrolled, meet all conditions of the program, and be re-enrolled annually.
- Before giving ambrisentan for the first time, make sure patient understands its risks, has signed the agreement form, and knows that he'll need to be re-enrolled after 6 months of therapy and then yearly.
- If patient is a woman of childbearing age, obtain a negative pregnancy test before giving ambrisentan and then monthly during therapy. A positive result requires immediately stopping drug because of the risk of serious birth defects.
- Obtain liver enzyme levels, as ordered, before starting ambrisentan therapy and monthly during therapy because drug may significantly increase liver aminotransferase (ALT and AST) levels. If liver enzymes are more than three times the upper limit of normal, expect to not start ambrisentan. If they're somewhat elevated, expect to monitor bilirubin before and monthly during therapy. If liver enzymes become elevated during therapy and evidence of hepatic dysfunction (abdominal pain, fever, jaundice, nausea, vomiting, unusual lethargy or fatigue) develops or patient's bilirubin level exceeds twice the upper limit of normal, notify prescriber and expect to stop ambrisentan therapy.
- Monitor patient's hemoglobin level before starting ambrisentan, again after 1 month of therapy, and periodically thereafter. If level declines significantly, notify prescriber and expect to discontinue drug.

- Assess patient closely for peripheral edema, especially if elderly. If edema becomes pronounced, notify prescriber. Further evaluation will reveal whether it results from ambrisentan or another condition, such as heart failure.
- If patient takes ambrisentan for longer than 12 months, watch for hepatic cirrhosis (abdominal pain, fever, jaundice, nausea, vomiting, or unusual lethargy or fatigue). A similar drug, bosentan, rarely has caused unexplained hepatic cirrhosis after being taken longer than 12 months.

PATIENT TEACHING

- Caution patient not to split, crush, or chew ambrisentan tablets.
- Instruct female patient of childbearing age to use two reliable forms of birth control during therapy unless she has had a tubal ligation or a Copper T 380A or LNG 20 intrauterine device inserted. Explain that she'll need monthly pregnancy test.
- Inform male patient that sperm counts have declined in some men taking drugs similar to ambrisentan, affecting their ability to father children. If this concerns him, suggest that he consult prescriber.
- Stress the need for follow-up visits and tests, such as hemoglobin checks.
- Advise patient to promptly report any signs of liver dysfunction to the prescriber.
- Instruct patient to notify prescriber about fluid retention.

amikacin sulfate

Amikin

Class and Category

Chemical class: Aminoglycoside

Therapeutic class: Antibiotic

Pregnancy category: D

Indications and Dosages

➤ *To treat serious gram-negative bacterial infections (including septicemia; neonatal sepsis; respiratory tract, bone, joint, CNS, skin, soft-tissue, intra-abdominal, burn, and postoperative infections; and serious, complicated, and recurrent UTI) caused by Acinetobacter, Enterobacter, Escherichia coli, Klebsiella, Proteus, Providencia, Pseudomonas, and Serratia; and staphylococcal infec-*

tions when penicillin is contraindicated

I.V. INFUSION, I.M. INJECTION

Adults and children. 15 mg/kg daily in equal doses at equally spaced intervals (7.5 mg/kg every 12 hr or 5 mg/kg every 8 hr) for 7 to 10 days. *Maximum:* 1,500 mg daily.

DOSAGE ADJUSTMENT For patients with impaired renal function, loading dose of 7.5 mg/kg daily; then maintenance dosage based on creatinine clearance and serum creatinine level and given every 12 hr. For morbidly obese patients, dosage not to exceed 1.5 g daily.

Neonates. *Loading dose:* 10 mg/kg.

Maintenance: 7.5 mg/kg every 12 hr for 7 to 10 days.

➤ *To treat uncomplicated UTI*

I.V. INFUSION, I.M. INJECTION

Adults. 250 mg b.i.d. for 7 to 10 days.

Route	Onset	Peak	Duration
I.V.	Immediate	Unknown	Unknown
I.M.	Rapid	Unknown	Unknown

Mechanism of Action

Binds to negatively charged sites on bacteria's outer cell membrane, disrupting cell integrity. Also binds to bacterial ribosomal subunits and inhibits protein synthesis. Both actions lead to cell death.

Incompatibilities

Don't mix or infuse amikacin with other drugs.

Contraindications

Hypersensitivity to amikacin or other aminoglycosides

Interactions**DRUGS**

cephalosporins, enflurane, methoxyflurane,

vancomycin: Increased nephrotoxic effects

general anesthetics: Increased risk of neuromuscular blockade

loop diuretics: Increased risk of ototoxicity

neuromuscular blockers: Possibly increased neuromuscular blockade and prolonged respiratory depression

penicillins: Possibly inactivation of or synergistic effects with amikacin

Adverse Reactions

CNS: Drowsiness, headache, loss of balance, neuromuscular blockade, tremor, vertigo

EENT: Hearing loss, ototoxicity, tinnitus

GI: Nausea, vomiting

GU: Azotemia, dysuria, nephrotoxicity, oliguria or polyuria, proteinuria

MS: Acute muscle paralysis; arthralgia; muscle fatigue, spasms, and weakness

RESP: Apnea

Other: Hyperkalemia

Nursing Considerations

- Expect to obtain results of culture and sensitivity testing before therapy begins.
 - Prepare amikacin I.V. solution by adding contents of 500-mg vial to 100 to 200 mL of sterile diluent. Then infuse drug over 30 to 60 minutes.
 - Give I.M. injection in large muscle mass.
 - Watch for signs of ototoxicity, such as tinnitus and vertigo, especially during high-dosage or prolonged amikacin therapy.
- WARNING** Because amikacin may produce nephrotoxic effects, assess renal function before and daily during therapy, as ordered. To minimize renal tubule irritation, maintain hydration during therapy.
- Be aware that amikacin may exacerbate muscle weakness in such conditions as myasthenia gravis and Parkinson's disease.
 - Measure serum amikacin concentrations as ordered, usually 30 to 90 minutes after injection (for peak concentration) and just before administering next dose (for trough concentration).

PATIENT TEACHING

- Tell patient that daily laboratory tests are necessary during treatment.
- Instruct patient to report ringing in ears, hearing changes, headache, nausea, vomiting, and changes in urination.

amiloride hydrochloride

Midamor

Class and Category

Chemical class: Pyrazine-carbonyl-guanidine

Therapeutic class: Potassium-sparing diuretic

Pregnancy category: B

Indications and Dosages

↗ *As adjunct to thiazide or loop diuretic in*

patient with heart failure or hypertension to correct diuretic-induced hypokalemia or to prevent diuretic-induced hypokalemia that increases the risk of arrhythmias or other complications

TABLETS

Adults. 5 to 10 mg daily as single dose; if hypokalemia persists, increased to 15 mg daily and then 20 mg daily.

Route	Onset	Peak	Duration
P.O.	2 hr	6–10 hr	24 hr

Mechanism of Action

Inhibits sodium reabsorption in distal convoluted tubules and cortical collecting ducts, causing sodium and water loss and enhancing potassium retention.

Contraindications

Hypersensitivity to amiloride; impaired renal function; serum potassium level above 5.5 mEq/L; therapy with another potassium-sparing diuretic, such as spironolactone or triamterene, or a potassium supplement

Interactions

DRUGS

angiotensin II receptor antagonists, captopril, enalapril, lisinopril, potassium products, spironolactone: Increased risk of hyperkalemia

digoxin: Decreased effectiveness of digoxin

lithium: Reduced renal clearance of lithium and increased risk of lithium toxicity

NSAIDs: Reduced diuretic effect of amiloride

sympathomimetics: Possibly reduced antihypertensive effects of amiloride

FOODS

high-potassium food: Increased risk of hyperkalemia

Adverse Reactions

CNS: Confusion, depression, dizziness, drowsiness, encephalopathy, fatigue, headache, insomnia, nervousness, paresthesia, somnolence, tremor, vertigo

CV: Angina, arrhythmias, orthostatic hypotension, palpitations

EENT: Dry mouth, increased intraocular pressure, nasal congestion, tinnitus, vision disturbances

GI: Abdominal pain or fullness, anorexia, appetite changes, constipation, diarrhea, GI

bleeding, heartburn, indigestion, nausea, thirst, vomiting

GU: Bladder spasms, dysuria, impotence, loss of libido, polyuria

HEME: Aplastic anemia, neutropenia

MS: Arthralgia, muscle spasms or weakness

RESP: Cough, dyspnea

SKIN: Alopecia, jaundice, pruritus, rash

Other: Dehydration, hyperchloremia, hyperkalemia, hyponatremia, metabolic acidosis

Nursing Considerations

- Administer amiloride with food to reduce GI upset and early in the day to minimize sleep interference from polyuria.
- Monitor renal function test results, fluid intake and output, and weight. Also monitor serum potassium level to detect hyperkalemia.

WARNING Don't administer amiloride with other potassium-sparing diuretics.

PATIENT TEACHING

- Warn patient to avoid high-potassium food and salt substitutes that contain potassium.
- Advise patient to consult prescriber before taking other drugs, including OTC remedies, especially sympathomimetics.
- Tell patient to report dizziness, trembling, numbness, and muscle weakness or spasms.
- Advise patient to increase fluid and fiber intake to prevent constipation.
- Warn patient to expect reversible hair loss and impotence.

aminocaproic acid

Amicar

Class and Category

Chemical class: Aminohexanoic acid

Therapeutic class: Antifibrinolytic, anti-hemorrhagic

Pregnancy category: C

Indications and Dosages

➤ *To treat excessive bleeding caused by fibrinolysis*

SYRUP, TABLETS

Adults. *Initial:* 5 g in first hour, followed by 1 to 1.25 g/hr to sustain drug plasma level of 0.13 mg/ml. *Maximum:* 30 g daily.

I.V. INJECTION

Adults. 4 to 5 g in 250 ml of diluent over 1 hr followed by continuous infusion of 1 g/hr in 50 ml of diluent. Continue for 8 hr or until bleeding stops.

Route	Onset	Peak	Duration
P.O.	Rapid	Unknown	Unknown
I.V.	Immediate	Unknown	Under 3 hr

Mechanism of Action

Inhibits breakdown of blood clots by interfering with plasminogen activator substances and producing antiplasmin activity.

Contraindications

Hypersensitivity to aminocaproic acid; signs of active intravascular clotting, as in disseminated intravascular coagulation; upper urinary tract bleeding

Interactions

DRUGS

activated prothrombin, prothrombin complex concentrates: Increased risk of thrombosis
estrogens, oral contraceptives: Increased risk of hypercoagulation

Adverse Reactions

CNS: Delirium, dizziness, hallucinations, headache, malaise, stroke, weakness

CV: Bradycardia, cardiomyopathy, elevated serum CK level, hypotension, ischemia, thrombophlebitis

EENT: Nasal congestion, tinnitus

GI: Abdominal cramps and pain, diarrhea, elevated AST level, nausea, vomiting

GU: Elevated BUN level, intrarenal obstruction, renal failure

HEME: Agranulocytosis, leukopenia, thrombocytopenia

MS: Myopathy

RESP: Dyspnea, pulmonary embolism

SKIN: Pruritus, rash

Other: Elevated serum aldolase and potassium levels

Nursing Considerations

- Be aware that patients on oral therapy may need up to 10 tablets during the first hour of treatment and tablets around the clock during continued treatment.
- Mix aminocaproic acid solution with sterile water for injection, normal saline solution, D₅W, or Ringer's solution.

WARNING Avoid rapid I.V. delivery because

it increases risk of hypotension and bradycardia.

- Monitor neurologic status for drug-induced changes. Note that increased clotting may lead to stroke.

PATIENT TEACHING

- Tell patient that he'll be closely monitored during I.V. therapy and will have blood drawn for laboratory tests before, during, and after treatment.
- Advise patient who takes aminocaproic acid at home to report adverse reactions, take drug exactly as prescribed, and keep follow-up appointments with prescriber.

aminoglutethimide

Cytadren

Class and Category

Chemical class: Hormone

Therapeutic class: Adrenal steroid inhibitor

Pregnancy category: D

Indications and Dosages

↗ *To suppress adrenal function in patients with Cushing's syndrome who are waiting for surgery or for whom other treatment can't be used*

TABLETS

Adults. *Initial:* 250 mg every 6 hr. Increased as needed by 250 mg daily every 1 to 2 wk.

Maximum: 2,000 mg daily.

Route	Onset	Peak	Duration
P.O.	3–5 days	Unknown	72 hr

Mechanism of Action

Inhibits the conversion of cholesterol to delta-5-pregnenolone, which is needed to produce certain hormones, including adrenal glucocorticoids, mineralocorticoids, estrogens, and androgens.

Contraindications

Hypersensitivity to aminoglutethimide or glutethimide

Interactions

DRUGS

antidiabetics, dexamethasone, digoxin, med-roxyprogesterone, synthetic glucocorticoids, theophylline, warfarin and other oral anticoagulants: Decreased effects of these drugs

Adverse Reactions

CNS: Dizziness, drowsiness, fever, headache

CV: Hypotension, orthostatic hypotension, tachycardia

ENDO: Adrenal insufficiency, hypothyroidism, masculinization

GI: Anorexia, nausea

SKIN: Hair growth, morbiliform rash, pruritus, urticaria

Nursing Considerations

- Expect to reduce aminoglutethimide dosage or discontinue treatment if extreme drowsiness, severe rash, or excessively low cortisol level occurs.

WARNING Monitor for signs of hypothyroidism, including lethargy, dry skin, and slow pulse. If prescribed, administer thyroid hormone supplement.

- Monitor blood pressure for orthostatic or persistent hypotension.

PATIENT TEACHING

- Teach patient to recognize orthostatic hypotension (dizziness, weakness when moving from sitting to standing position) and to minimize it (as by rising slowly from a supine to an upright position).
- Tell patient to report dizziness, appetite loss, nausea, headache, or severe drowsiness. Warn him to avoid driving if drowsy.
- Instruct patient to take a missed dose as soon as remembered and to evenly space out the day's remaining doses.
- Advise patient that rash, sometimes accompanied by fever, may appear on day 10 of treatment and should subside by day 15 or 16. Tell him to report severe rash or one that doesn't disappear.

aminophylline (theophylline ethylenediamine)

Phyllocontin, Truphylline

Class and Category

Chemical class: Xanthine

Therapeutic class: Bronchodilator

Pregnancy category: C

Indications and Dosages

↗ *To relieve acute bronchospasm*

I.V. INFUSION

Adults and children not currently receiv-

ing theophylline products. *Initial:* 6 mg/kg (equal to 4.7 mg/kg anhydrous theophylline), not to exceed 25 mg/min.

Maintenance: For adults (nonsmokers), 0.7 mg/kg/hr for first 12 hr, then 0.5 mg/kg/hr. For children ages 9 to 16, 1 mg/kg/hr for first 12 hr, then 0.8 mg/kg/hr. For children ages 6 months to 9 years and young adult smokers, 1.2 mg/kg/hr for first 12 hr, then 1 mg/kg/hr.

Adults and children currently receiving theophylline products. *Initial:* If possible, determine the time, amount, administration route, and form of last dose. Loading dose is based on the principle that each 0.63 mg/kg (0.5 mg/kg anhydrous theophylline) given raises serum theophylline level by 1 mcg/ml. Defer loading dose if serum theophylline level can be readily obtained. If this isn't possible and patient has no obvious signs of theophylline toxicity, prescriber may order 3.1 mg/kg (2.5 mg/kg anhydrous theophylline), which may increase serum theophylline level by about 5 mcg/ml. *Maintenance:* For adults (nonsmokers), 0.7 mg/kg/hr for first 12 hr, then 0.5 mg/kg/hr. For children ages 9 to 16, 1 mg/kg/hr for first 12 hr, then 0.8 mg/kg/hr. For children ages 6 months to 9 years and young adult smokers, 1.2 mg/kg/hr for first 12 hr, then 1 mg/kg/hr.

DOSE ADJUSTMENT For elderly patients and those with cor pulmonale, dosage reduced to 0.6 mg/kg for 12 hr, then 0.3 mg/kg. For patients with heart failure and hepatic disease, dosage reduced to 0.5 mg/kg for 12 hr, then 0.1 to 0.2 mg/kg.

➤ *To prevent or treat reversible bronchospasm from asthma, chronic bronchitis, and emphysema and to maintain patent airways*

E.R. TABLETS, ORAL LIQUID, TABLETS, SUPPOSITORIES

Adults and children. *Initial (rapidly absorbed forms):* 16 mg/kg daily or 400 mg daily (whichever is less) in divided doses every 6 to 8 hr. *Maintenance:* Daily dosage increased in increments of 25% every 3 days, as tolerated, until response achieved or maximum dose reached. When maximum dose is reached, dosage adjusted according to peak serum theophylline level. *Initial (E.R. forms):* 12 mg/kg daily or 400 mg daily (whichever is less) in divided doses every 8 to 12 hr. *Maintenance:* Daily

dosage increased in increments of 2 to 3 mg/kg every 3 days. When maximum dose is reached, dosage adjusted according to peak serum theophylline level.

Route	Onset	Peak	Duration
P.O. (E.R.)	Unknown	Unknown	8–12 hr
P.O. (tab)	Unknown	Unknown	6–8 hr
I.V.	Immediate	Unknown	4–8 hr

Mechanism of Action

Inhibits phosphodiesterase enzymes, causing bronchodilation. Normally, these enzymes inactivate cyclic adenosine monophosphate (cAMP) and cyclic guanosine monophosphate (cGMP), which are responsible for bronchial smooth-muscle relaxation. Other mechanisms of action may include translocation of calcium, prostaglandin antagonism, stimulation of catecholamines, inhibition of cGMP metabolism, and adenosine receptor antagonism.

Incompatibilities

Don't add other drugs to prepared bag or bottle of aminophylline. Don't mix aminophylline in same syringe with doxapram. Also avoid administering amiodarone, ciprofloxacin, diltiazem, dobutamine, hydralazine, or ondansetron into the Y-port of a continuous infusion of aminophylline.

Contraindications

Active peptic ulcer disease, hypersensitivity to aminophylline, rectal or lower intestine irritation or infection (suppository form), underlying seizure disorder

Interactions

DRUGS

activated charcoal, aminoglutethimide, barbiturates, ketoconazole, rifampin, sulfipyrazone, sympathomimetics: Decreased serum theophylline level

allopurinol, calcium channel blockers, cimetidine, corticosteroids, disulfiram, ephedrine, influenza virus vaccine, interferon, macrolides, mexiletine, nonselective beta blockers, oral contraceptives, quinolones, thiabendazole: Increased serum theophylline level
benzodiazepines: Antagonized sedative effects of benzodiazepines
beta agonists: Increased effects of aminophylline and beta agonist
carbamazepine, isoniazid, loop diuretics:

Altered serum theophylline level
halothane: Increased risk of cardiotoxicity
*hydantoin*s: Decreased hydantoin level
ketamine: Increased risk of seizures
lithium: Decreased serum lithium level
nondepolarizing muscle relaxants: Reversed neuromuscular blockade
propofol: Antagonized sedative effects of propofol
tetracyclines: Enhanced adverse effects of theophylline

FOODS

all foods: Altered bioavailability and absorption of E.R. form, leading to toxicity
high-carbohydrate, low-protein diet: Decreased theophylline elimination and prolonged aminophylline half-life
low-carbohydrate, high-protein diet; char-broiled beef: Increased theophylline elimination and shortened aminophylline half-life

ACTIVITIES

alcohol abuse: Increased aminophylline effects
smoking (1 or more packs daily): Decreased effects of aminophylline

Adverse Reactions

CNS: Dizziness, fever, headache, insomnia, irritability, restlessness, seizures
CV: Arrhythmias (including sinus tachycardia and life-threatening ventricular arrhythmias), hypotension, palpitations
EENT: Bitter aftertaste
ENDO: Hyperglycemia, syndrome of inappropriate ADH secretion
GI: Anorexia, diarrhea, epigastric pain, heavy feeling in stomach, hematemesis, indigestion, nausea, rectal bleeding or irritation (suppositories), vomiting
GU: Diuresis, proteinuria, urine retention in men with prostate enlargement
MS: Muscle twitching
RESP: Respiratory arrest, tachypnea
SKIN: Alopecia, exfoliative dermatitis, flushing, rash, urticaria

Nursing Considerations

WARNING Because aminophylline has a narrow therapeutic window (10 to 20 mcg/ml), closely monitor serum theophylline level and watch for evidence of toxicity (tachycardia, tachypnea, nausea, vomiting, restlessness, seizures). Keep in mind that acetaminophen, furosemide, phenylbutazone, probenecid, theobromine, coffee, tea, soft drinks, and chocolate can alter serum

theophylline result.

- To determine peak serum theophylline level, draw blood sample 15 to 30 minutes after administering I.V. loading dose.
- Give immediate-release and liquid forms with food to reduce GI upset. Give E.R. form 1 hour before or 2 hours after meals because food can alter drug absorption.

PATIENT TEACHING

- Advise patient to avoid excessive caffeine (in coffee, tea, soft drinks, and chocolate); it can falsely elevate theophylline level.
- Explain that blood tests may be needed to monitor drug's therapeutic effect.

aminosalicylate sodium

(para-aminosalicylate, PAS)

Nemasol Sodium (CAN), PAS

Class and Category

Chemical class: Para-aminobenzoic acid analogue

Therapeutic class: Antitubercular

Pregnancy category: C

Indications and Dosages

➤ To treat tuberculosis as adjunct to isoniazid, streptomycin, or both and in patients with multidrug-resistant tuberculosis or when therapy with rifampin and isoniazid isn't possible because of resistance or intolerance

TABLETS

Adults. 14 to 16 g daily in 2 or 3 divided doses.

Children. 275 to 420 mg/kg daily in 3 or 4 divided doses.

Mechanism of Action

Inhibits incorporation of para-aminobenzoic acid into folic acid and prevents synthesis of folic acid, a compound needed for bacterial growth. Aminosaliclylate sodium is bacteriostatic against *Mycobacterium tuberculosis*, and it delays bacterial resistance to streptomycin and isoniazid.

Contraindications

Hypersensitivity to aminosaliclylate sodium, severe renal disease

Interactions**DRUGS**

digoxin: Decreased serum digoxin level
probenecid: Increased serum aminosaliclylate level
rifampin: Decreased serum rifampin level

Adverse Reactions

CNS: Encephalopathy, fever
CV: Vasculitis
ENDO: Goiter with or without myxedema
GI: Abdominal pain, diarrhea, hepatitis, nausea, vomiting
HEME: Agranulocytosis, hemolytic anemia, leukopenia, thrombocytopenia
SKIN: Jaundice, various types of eruptions
Other: Infectious mononucleosis-like syndrome, Loeffler's syndrome (anorexia, breathlessness, fever, and weight loss)

Nursing Considerations

- Administer aminosaliclylate with food to reduce GI upset.

WARNING Protect drug from water, heat, and sunlight to prevent rapid deterioration. Don't give tablets with brown or purple discoloration—a sign of deterioration.

PATIENT TEACHING

- Teach patient to discard aminosaliclylate that appears brown or purple.
- Instruct patient to take drug with food.

amiodarone hydrochloride

Cordarone, Nexterone, Pacerone

Class and Category

Chemical class: Iodinated benzofuran derivative

Therapeutic class: Class III antiarrhythmic
Pregnancy category: D

Indications and Dosages

➤ To treat life-threatening, recurrent ventricular fibrillation and hemodynamically unstable ventricular tachycardia when these arrhythmias don't respond to other drugs or when patient can't tolerate other drugs

TABLETS

Adults. *Loading*: 800 to 1,600 mg daily in divided doses for 1 to 3 wk. *Maintenance*: 600 to 800 mg daily in divided doses for

1 mo; then if cardiac rhythm is stable, 400 mg daily in 1 or 2 doses. Use lowest possible dose.

I.V. INFUSION

Adults. *Loading*: 150 mg over 10 min (15 mg/min) followed by 360 mg infused over 6 hr (1 mg/min). *Maintenance*: 540 mg infused over 18 hr (0.5 mg/min); then after the first 24 hr, 720 mg infused over 24 hr (0.5 mg/min), continued up to 2 to 3 wk, as needed. Rate may be increased in first 24 hr, if needed, but initial infusion rate shouldn't exceed 30 mg/min. Change to oral form as soon as possible.

➤ To treat breakthrough episodes of ventricular fibrillation or hemodynamically unstable ventricular tachycardia

I.V. INFUSION (NEXTERONE)

Adults. 150 mg mixed in 100 ml D₅W and infused over 10 min (15 mg/min).

Route	Onset	Peak	Duration
P.O.	2 days– 3 wk	1–5 mo	Weeks– months
I.V.	Hours– 3 days	1–3 wk	Weeks– months

Mechanism of Action

Acts on cardiac cell membranes, prolonging repolarization and the refractory period and raising ventricular fibrillation threshold. Drug relaxes vascular smooth muscles, mainly in coronary circulation, and improves myocardial blood flow. It relaxes peripheral vascular smooth muscles, decreasing peripheral vascular resistance and myocardial oxygen consumption.

Incompatibilities

Amiodarone is incompatible with heparin. To prevent precipitation, don't add amiodarone admixed with D₅W to aminophylline 4 mg/ml, cefamandole nafate, cefazolin sodium, or mezlocillin sodium, and don't mix amiodarone 3 mg/ml with sodium bicarbonate. Also, don't use evacuated glass containers for admixing because precipitation may occur.

Contraindications

Bradycardia that causes syncope (unless pacemaker present), cardiogenic shock, hypersensitivity to amiodarone or its components, hypokalemia, hypomagnesemia,

SA node dysfunction, second- and third-degree AV block (unless pacemaker present)

Interactions

DRUGS

anticoagulants: Increased anticoagulant response and possibly serious bleeding
azole antifungals, fluoroquinolones, macrolide antibiotics: Increased risk of prolonged QT interval and life-threatening arrhythmias

beta blockers: Increased serum levels of beta blockers with increased risk of AV block, hypotension, and bradycardia

calcium channel blockers: Increased serum levels of these drugs and increased risk of AV block, bradycardia, and hypotension
cholestyramine, phenytoin, rifampin, St. John's wort: Decreased amiodarone level

cimetidine: Increased amiodarone level
clopidogrel: Increased risk of ineffective inhibition of platelet aggregation

cyclosporine: Increased cyclosporine level
dextromethorphan, methotrexate, phenytoin: Increased serum levels of these drugs and increased risk of toxicity if amiodarone is taken orally for more than 2 weeks

digoxin: Increased serum digoxin level and risk of digitalis toxicity

diltiazem, propranolol, verapamil: Increased risk of hemodynamic and electrophysiologic abnormalities

disopyramide: Increased serum disopyramide level with QT prolongation and increased risk of arrhythmias

fentanyl: Increased serum fentanyl level with increased risk of bradycardia, decreased cardiac output, and hypotension

flecainide: Increased serum flecainide level
HMG-CoA reductase inhibitors such as atorvastatin and simvastatin: Increased risk of myopathy and rhabdomyolysis

hydantoins: Increased serum hydantoin level with long-term use and reduced serum amiodarone level

lidocaine: Increased serum lidocaine level and risk of seizures and bradycardia

lorazepam, trazodone: Increased risk of QT-interval prolongation and torsades de pointes

potassium- and magnesium-depleting drugs: Increased risk of hypokalemia and hypomagnesemia

procainamide: Increased serum procainamide or N-acetylprocainamide level

quinidine: Increased serum quinidine level with risk of life-threatening arrhythmias
ritonavir: Increased serum amiodarone level with increased risk of cardiotoxicity

theophylline: Increased serum theophylline level; increased risk of theophylline toxicity
warfarin: Increased PT and risk of bleeding

FOODS

grapefruit juice: Increased amiodarone level

Adverse Reactions

CNS: Abnormal gait, ataxia, confusion, delirium, demyelinating polyneuropathy, disorientation, dizziness, fatigue, fever, hallucinations, headache, insomnia, involuntary motor activity, lack of coordination, malaise, paresthesia, parkinsonian symptoms, peripheral neuropathy, pseudotumor cerebri, sleep disturbances, tremor

CV: Arrhythmias (including bradycardia, electromechanical dissociation, torsades de pointes, and ventricular tachycardia or fibrillation), cardiac arrest, cardiogenic shock, edema, heart failure, hypotension, vasculitis

EENT: Abnormal salivation, abnormal taste and smell, blurred vision, corneal microdeposits, dry eyes, halo vision, lens opacities, macular degeneration, optic neuritis, optic neuropathy, papilledema, permanent blindness, photophobia, scotoma

ENDO: Hyperthyroidism, hypothyroidism, syndrome of inappropriate ADH secretion, thyroid cancer

GI: Abdominal pain, anorexia, cirrhosis, constipation, diarrhea, elevated liver function test results, hepatitis, nausea, pancreatitis, vomiting

GU: Acute renal failure, decreased libido, epididymitis, impotence

HEME: Agranulocytosis, aplastic or hemolytic anemia, coagulation abnormalities, neutropenia, pancytopenia, spontaneous bruising, thrombocytopenia

MS: Muscle weakness, myopathy, rhabdomyolysis

RESP: Acute respiratory distress syndrome; bronchospasm; eosinophilic pneumonia; infiltrates that lead to dyspnea, cough, hemoptysis, hypoxia, pulmonary fibrosis, pulmonary alveolar hemorrhage, pulmonary interstitial pneumonitis, crackles, and wheezing; pleural effusion; pleuritis; pneumonia; respiratory arrest or failure

SKIN: Alopecia, bluish gray pigmentation, eczema, erythema multiforme, exfoliative

dermatitis, flushing, photosensitivity, pruritus, rash, skin cancer, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylactic shock, angioedema

Nursing Considerations

- If patient has an implantable cardiac device, have it checked, as ordered, at the start of and during amiodarone therapy because drug may affect pacing or defibrillating thresholds.
- Parenteral amiodarone may be diluted in D₅W or normal saline solution and given in polyvinyl chloride (PVC), polyolefin, or glass containers.
- Use an in-line filter during I.V. administration of amiodarone. Also use a central venous catheter whenever possible. A central venous catheter is required when infusion rate exceeds 2 mg/ml because drug may cause peripheral vein phlebitis at higher rates. Cordarone I.V. must be given by volumetric infusion pump.
- Monitor amiodarone I.V. infusion closely because loading doses at higher concentrations and rates may cause hepatocellular necrosis, acute renal failure, and death.
- Although maintenance therapy usually is needed for only up to 96 hours, infusion of up to 0.5 mg/minute may be continued for 2 to 3 weeks regardless of patient's age, renal function, or left ventricular function.

WARNING Amiodarone may cause or worsen pulmonary disorders that may develop days to weeks after therapy and progress to respiratory failure or even death. Expect to obtain chest x-ray and pulmonary function tests before therapy starts and then chest x-ray and follow-up exams every 3 to 6 months during therapy.

- Monitor vital signs and oxygen level often during and after giving amiodarone. Keep emergency equipment and drugs nearby.

WARNING Monitor continuous ECG; check for increased PR and QRS intervals, arrhythmias, and heart rate below 60 beats/min because amiodarone toxicity may cause or worsen arrhythmias.

- Monitor serum amiodarone level, which normally ranges from 1.0 to 2.5 mcg/ml.
- Assess liver enzyme and thyroid hormone levels; drug inhibits conversion of T₄ to T₃ and may cause drug-induced hyperthyroidism, thyrotoxicosis, and new or worsened arrhythmias. If new signs of arrhyth-

mia occur, notify prescriber at once.

PATIENT TEACHING

- Explain that patient will need frequent monitoring and laboratory tests during treatment.
- Advise patient to report swollen hands and feet, wheezing, dyspnea, cough, nausea, vomiting, dark urine, fatigue, yellow skin or sclerae, stomach pain, light-headedness, fainting, or a rapid, slow, pounding, or irregular heartbeat.
- Instruct patient to report abnormal bleeding or bruising.
- Advise patient to avoid corneal refractive laser surgery while taking drug.

amitriptyline hydrochloride

Apo-amitriptyline (CAN), Endep, Levate (CAN), Novotriptyn (CAN)

Class and Category

Chemical class: Tertiary amine

Therapeutic class: Tricyclic antidepressant

Pregnancy category: D

Indications and Dosages

↗ *To relieve depression, especially when accompanied by anxiety and insomnia*

TABLETS

Adults and children over age 12. *Outpatient:* 75 mg daily in divided doses, increased to 150 mg daily, if needed. *Inpatient:* 100 mg daily, gradually increased to 300 mg daily, if needed. *Maintenance:* 40 to 100 mg daily at bedtime.

DOSAGE ADJUSTMENT Maintenance dosage reduced to 10 mg t.i.d. plus 20 mg at bedtime for adolescent and elderly patients.

Route	Onset	Peak	Duration
P.O.	14–21	Unknown	Unknown days

Contraindications

Acute recovery phase after MI, hypersensitivity to amitriptyline, MAO inhibitor therapy within 14 days

Interactions

DRUGS

anticholinergics, epinephrine, norepineph-

Mechanism of Action

Normally, when an impulse reaches adrenergic nerves, the nerves release serotonin and norepinephrine from their storage sites. Some serotonin and norepinephrine reaches receptor sites on target tissues. Most is taken back into the nerves and stored by the reuptake mechanism, as

shown below on the left.

Amitriptyline blocks serotonin and norepinephrine reuptake by adrenergic nerves. By doing so, it raises serotonin and norepinephrine levels at nerve synapses. This action may elevate mood and reduce depression.

rine: Increased effects of these drugs

barbiturates: Decreased amitriptyline level

carbamazepine: Decreased serum amitriptyline level and increased serum carbamazepine level, which increases therapeutic and toxic effects of carbamazepine

cimetidine, disulfiram, fluoxetine, fluvoxamine, haloperidol, H₂-receptor antagonists, methylphenidate, oral contraceptives, paroxetine, phenothiazines, sertraline: Increased serum amitriptyline level

cisapride: Possibly prolonged QT interval and increased risk of arrhythmias

clonidine, guanethidine, and other antihypertensives: Decreased antihypertensive effects

dicumarol: Increased anticoagulant effect

levodopa: Decreased levodopa absorption; sympathetic hyperactivity, sinus tachycardia, hypertension, agitation

MAO inhibitors: Possibly seizures and death

thyroid replacement drugs: Arrhythmias and increased antidepressant effects

ACTIVITIES

alcohol use: Enhanced CNS depression

smoking: Decreased amitriptyline effects

Adverse Reactions

CNS: Anxiety, ataxia, coma, chills, delusions, disorientation, drowsiness, extrapyramidal reactions, fatigue, fever, headache,

insomnia, nightmares, peripheral neuropathy, suicidal ideation, tremor

CV: Arrhythmias (including prolonged AV conduction, heart block, and tachycardia), cardiomyopathy, hypertension, MI, nonspecific ECG changes, orthostatic hypotension, palpitations

EENT: Abnormal taste, black tongue, blurred vision, dry mouth, increased salivation, nasal congestion, tinnitus

ENDO: Gynecomastia, increased or decreased blood glucose level, increased prolactin level, syndrome of inappropriate ADH secretion

GI: Abdominal cramps, constipation, diarrhea, flatulence, ileus, increased appetite, nausea, vomiting

GU: Impotence, libido changes, menstrual irregularities, testicular swelling, urinary hesitancy, urine retention

HEME: Agranulocytosis, bone marrow depression, eosinophilia, leukopenia, thrombocytopenia

SKIN: Alopecia, flushing, purpura

Other: Weight gain

Nursing Considerations

- Because of amitriptyline's atropine-like effects, use caution if patient has a history

of seizures, urine retention, or angle-closure glaucoma.

WARNING Don't give an MAO inhibitor within 14 days of amitriptyline because of the risk of seizures and death.

- Closely monitor patient with CV disorder because amitriptyline may cause arrhythmias, such as sinus tachycardia.
- Watch patients closely (especially children, adolescents, and young adults), for suicidal tendencies, particularly when therapy starts and dosage changes. Depression may worsen temporarily during these times.
- Monitor blood pressure for hypotension or hypertension.
- Stay alert for behavior changes, such as hallucinations and decreased interest in personal appearance. Be aware that psychosis may develop in schizophrenic patients, and symptoms may increase in paranoid patients.
- Abrupt withdrawal after long use may cause nausea, headache, vertigo, and nightmares.

PATIENT TEACHING

- Instruct patient to take amitriptyline at bedtime to avoid daytime drowsiness.
- Instruct patient to avoid using alcohol or OTC drugs that contain alcohol during amitriptyline therapy because alcohol enhances CNS depressant effects.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.

amlodipine besylate

Norvasc

Class and Category

Chemical class: Dihydropyridine

Therapeutic class: Antianginal, antihypertensive

Pregnancy category: C

Indications and Dosages

➤ *To control hypertension*

TABLETS

Adults. *Initial:* 5 mg daily, increased gradually over 10 to 14 days, as needed.

Maximum: 10 mg daily.

DOSAGE ADJUSTMENT Initially 2.5 mg daily

for elderly patients or patients with impaired hepatic function. Increased gradually over 7 to 14 days based on response.

➤ *To treat chronic stable angina and Prinzmetal's (variant) angina*

TABLETS

Adults. 5 to 10 mg daily.

DOSAGE ADJUSTMENT 5 mg daily for elderly patients and those with impaired hepatic function.

Route	Onset	Peak	Duration
P.O.	Unknown	6–12 hr	24 hr

Mechanism of Action

Binds to dihydropyridine and nondihydropyridine cell membrane receptor sites on myocardial and vascular smooth-muscle cells and inhibits influx of extracellular calcium ions across slow calcium channels. This decreases intracellular calcium level, inhibiting smooth-muscle cell contractions and relaxing coronary and vascular smooth muscles, decreasing peripheral vascular resistance, and reducing systolic and diastolic blood pressure. Decreased peripheral vascular resistance also decreases myocardial workload, oxygen demand, and possibly angina. Also, by inhibiting coronary artery muscle cell contractions and restoring blood flow, drug may relieve Prinzmetal's angina.

Contraindications

Hypersensitivity to amlodipine or its components

Interactions

DRUGS

beta blockers: Possibly excessive hypotension
fentanyl: Increased risk of severe hypotension and increased fluid volume requirements during surgery

Adverse Reactions

CNS: Anxiety, dizziness, fatigue, headache, lethargy, light-headedness, paresthesia, somnolence, syncope, tremor
CV: Arrhythmias, hypotension, palpitations, peripheral edema
EENT: Dry mouth, pharyngitis
ENDO: Hot flashes
GI: Abdominal cramps, abdominal pain, constipation, diarrhea, esophagitis, indigestion, nausea

GU: Decreased libido, impotence, urinary frequency

MS: Myalgia

RESP: Dyspnea

SKIN: Dermatitis, flushing, rash

Other: Weight loss

Nursing Considerations

- Use amlodipine cautiously in patients with heart block, heart failure, impaired renal function, hepatic disorder, or severe aortic stenosis.
- Monitor blood pressure while adjusting dosage, especially in patients with heart failure or severe aortic stenosis.

PATIENT TEACHING

- Tell patient to take missed dose as soon as remembered and next dose in 24 hours.
- Tell patient to immediately notify prescriber of dizziness, arm or leg swelling, difficulty breathing, hives, or rash.
- Suggest taking amlodipine with food to reduce GI upset.
- Advise patient to routinely have blood pressure checked for possible hypotension.

ammonium chloride

Class and Category

Chemical class: Ammonium ion

Therapeutic class: Acidifier

Pregnancy category: C

Indications and Dosages

↗ *To treat hypochloremia and metabolic alkalosis*

I.V. INFUSION

Adults. Individualized based on serum bicarbonate level. *Usual:* 100 to 200 mEq added to 500 or 1,000 ml of normal saline solution, infused at 5 ml/min or less (about 3 hr for an infusion of 1,000 ml).

Route	Onset	Peak	Duration
I.V.	1–3 min	3–6 hr	Unknown

Mechanism of Action

Is converted to urea and hydrochloric acid in the liver. During conversion, drug breaks into ammonium and chloride ions, and hydrogen ions are released. They enter the blood and extracellular fluid, where hydrogen reacts with bicarbonate ions to form

water and carbon dioxide. This process decreases bicarbonate ions and increases chloride ions in blood and extracellular fluid, which decreases blood and urine pH and corrects alkalosis.

Incompatibilities

Don't mix I.V. ammonium chloride with codeine, levorphanol, or methadone.

Contraindications

Hypersensitivity to ammonium chloride or its components, markedly impaired renal or hepatic function, metabolic alkalosis caused by vomiting of hydrochloric acid and accompanied by sodium loss caused by sodium bicarbonate excretion in urine

Interactions

DRUGS

amphetamines, salicylates, sulfonyleureas, tricyclic antidepressants: Decreased therapeutic blood level of ammonium
chlorpropamide: Increased ammonium effects

Adverse Reactions

CNS: Fever, headache

CV: Phlebitis or thrombosis extending from injection site

GI: Indigestion, nausea, severe hepatic dysfunction, vomiting

RESP: Hyperventilation

SKIN: Extravasation

Other: Injection site infection, irritation, or pain; hypovolemia; severe metabolic acidosis (with large doses)

Nursing Considerations

- Before use, warm ammonium chloride solution to room temperature to dissolve crystals by placing infusion in warm water.
- During I.V. use, keep sodium bicarbonate or sodium lactate nearby to treat overdose.
- Infuse ammonium chloride slowly to avoid I.V. site pain and irritation.

WARNING Monitor patient for ammonia toxicity (arrhythmias, such as bradycardia; coma; irregular breathing; pallor; retching; seizures; diaphoresis; and twitching).

- Watch for signs of metabolic acidosis, such as increased respirations, increased serum pH, restlessness, and diaphoresis.
- Monitor serum bicarbonate level, urinalysis results, and renal and liver function test results as appropriate.

PATIENT TEACHING

- Tell patient to eat potassium-rich foods,

such as bananas, oranges, cantaloupe, spinach, dried fruit, and potatoes, during therapy.

amobarbital sodium

Amytal, Novamobarb (CAN)

Class, Category, and Schedule

Chemical class: Barbiturate

Therapeutic class: Anticonvulsant, sedative-hypnotic

Pregnancy category: D

Controlled substance schedule: II

Indications and Dosages

↗ *To produce preanesthesia sedation*

CAPSULES, ELIXIR, TABLETS

Adults. 200 mg 1 to 2 hr before surgery.

Children. 2 to 6 mg/kg up to a maximum of 100 mg/dose.

↗ *To produce sedation*

CAPSULES, ELIXIR, TABLETS, I.V. OR I.M.

INJECTION

Adults. 30 to 50 mg (may range from 15 to 120 mg) b.i.d. or t.i.d. *Maximum I.V.:* 1,000 mg/dose. *Maximum I.M.:* 500 mg/dose.

Children over age 6. 2 mg/kg daily in four divided doses.

↗ *To treat insomnia*

CAPSULES, ELIXIR, TABLETS

Adults. 65 to 200 mg at bedtime for up to 2 wk.

↗ *To induce a hypnotic state*

CAPSULES, ELIXIR, TABLETS, I.V. OR I.M.

INJECTION

Adults. 65 to 200 mg/dose. *Maximum I.V.:* 1,000 mg/dose. *Maximum I.M.:* 500 mg/dose

Children up to age 6. 2 to 3 mg/kg I.M. per dose.

↗ *To manage seizures*

I.V. OR I.M. INJECTION

Use I.V. route only when other routes aren't appropriate. For I.V. injection, use I.M. dose and inject slowly at 50 mg/min or less to prevent sudden respiratory depression, apnea, laryngospasm, or hypotension.

Adults. *Usual:* 65 to 500 mg to a maximum of 1,000 mg. Dosage for acute seizures is determined by response; 200- to 500-mg doses are typically needed to control seizures.

Children age 6 and over. 65 to 500 mg I.V.

Children up to age 6. 3 to 5 mg/kg/dose.

Route	Onset	Peak	Duration
P.O.*	60 min	Unknown	10–12 hr
I.V.	Unknown	Unknown	10–12 hr
I.M.	Unknown	Unknown	10–12 hr

Mechanism of Action

Nonselectively acts on the CNS to depress the sensory cortex, decrease motor activity, alter cerebellar function, and produce drowsiness, sedation, and hypnosis. Appears to reduce wakefulness and alertness by acting in the thalamus, where it depresses the reticular activating system and interferes with impulse transmission from the periphery to the cortex. Produces CNS depressant effects ranging from mild sedation and anxiety reduction to anesthesia and coma, depending on the dose, route, and individual patient's response.

Incompatibilities

Don't mix amobarbital in solution with other drugs.

Contraindications

Alcoholism, history of porphyria, history of sedative or barbiturate addiction, hypersensitivity to barbiturates, renal or hepatic disease, severe respiratory disease, sleep apnea, suicidal tendency, uncontrolled pain

Interactions

DRUGS

acetaminophen: Increased blood acetaminophen level and risk of hepatotoxicity
antihistamines, CNS depressants, phenothiazines, tranquilizers: Increased CNS depression

beta blockers, carbamazepine, clonazepam, corticosteroids, digitoxin, doxycycline, estrogens, griseofulvin, metronidazole, oral anticoagulants, oral contraceptives, phenylbutazones, quinidine, theophyllines, tricyclic antidepressants: Decreased blood levels and effects of these drugs

chloramphenicol: Inhibited amobarbital metabolism; enhanced chloramphenicol metabolism

MAO inhibitors: Increased serum level and sedative effects of amobarbital

* For capsules, elixir, and tablets.

methoxyflurane: Increased nephrotoxicity
phenytoin: Altered effects of phenytoin
rifampin: Decreased serum level and effects of amobarbital

valproic acid: Increased amobarbital effects

ACTIVITIES

alcohol use: Increased serum level of amobarbital and additive CNS depressant effects

Adverse Reactions

CNS: Agitation, anxiety, ataxia, CNS depression, confusion, dizziness, hallucinations, hangover, headache, hyperkinesia, insomnia, nightmares, nervousness, paradoxical stimulation, permanent neurologic deficit (with injection near nerve), psychiatric disturbance, somnolence, syncope, vertigo

CV: Bradycardia, hypotension, shock

EENT: Laryngospasm

GI: Constipation, diarrhea, epigastric pain, nausea, vomiting

RESP: Apnea, bronchospasm, hypoventilation, respiratory depression

SKIN: Exfoliative dermatitis, rash, Stevens-Johnson syndrome, urticaria

Other: Angioedema, gangrene of arm or leg from accidental injection into artery, injection site tissue damage and necrosis, physical and psychological dependence, potentially fatal withdrawal syndrome, tolerance

Nursing Considerations

- Use amobarbital cautiously in patients with cardiac disease, debilitation, diabetes mellitus, fever, hyperthyroidism, severe anemia, shock, status asthmaticus, or uremia.
- Administer by deep I.M. injection, preferably in large muscle.

WARNING To prevent tissue damage and necrosis at I.M. injection site, don't give more than 5 ml of this highly alkaline drug at any one site. Know that accidental arterial injection may cause gangrene of the arm or leg.

- During I.V. administration, closely monitor blood pressure, pulse, and respirations. Keep emergency equipment and drugs nearby in case respiratory depression occurs.

WARNING Use I.V. route only when other routes aren't appropriate.

WARNING Don't administer solution after 30 minutes of exposure to air. Solution

quickly becomes unstable because amobarbital sodium hydrolyzes in solution.

- To prevent withdrawal symptoms, such as diaphoresis, insomnia, irritability, nightmares, and tremors, expect to taper amobarbital dosage gradually after long-term use, especially for epileptic patients.

PATIENT TEACHING

- Advise patient to use caution when driving or doing tasks that require alertness.
- Instruct patient not to use alcohol or other CNS depressants (unless prescribed) because they increase amobarbital's effects.
- Warn patient not to stop taking drug abruptly; withdrawal symptoms can occur.
- Instruct patient to report severe dizziness, persistent drowsiness, rash, or skin lesions.
- Explain that drug effects, such as drowsiness, may be less pronounced after a few days and when drug is taken with food.

amoxapine

Asendin

Class and Category

Chemical class: Dibenzoxazepine derivative

Therapeutic class: Tricyclic antidepressant

Pregnancy category: C

Indications and Dosages

↗ To relieve depression, including endogenous (long-term) depression and depression associated with anxiety and agitation

TABLETS

Adults and children age 16 and over.

Initial: 50 mg b.i.d. or t.i.d., increased to 100 mg b.i.d. or t.i.d. by end of first wk, if tolerated. *Maintenance*: If 300-mg daily dose is ineffective after 2-wk trial period, dosage increased to a maximum of 400 mg daily in divided doses. Inpatients may receive up to a maximum of 600 mg daily in divided doses. When effective dose is achieved, a single dose may be given at bedtime, not to exceed 300 mg.

DOSAGE ADJUSTMENT For elderly patients.

Initial: 25 mg b.i.d. or t.i.d., increased to 50 mg b.i.d. or t.i.d. by end of first wk. *Maintenance*: 100 to 150 mg daily in divided doses, carefully increased to 300 mg daily as tolerated. When effective dose is

achieved, a single dose may be given at bedtime, not to exceed 300 mg.

Route	Onset	Peak	Duration
P.O.	2–3 wk	Unknown	Unknown

Mechanism of Action

Blocks serotonin and norepinephrine reuptake by adrenergic nerves, thus raising serotonin and norepinephrine levels at nerve synapses. This action may elevate mood and reduce depression.

Normally, when an impulse reaches adrenergic nerves, they release serotonin and norepinephrine from their storage sites. Some serotonin and norepinephrine reach receptor sites on target tissues. The majority is taken back into the nerves and stored by the reuptake mechanism.

Contraindications

Acute recovery phase after MI, hypersensitivity to amoxapine or its components, MAO inhibitor therapy within 14 days

Interactions

DRUGS

anticholinergics, epinephrine, norepinephrine: Increased effects of these drugs

barbiturates: Decreased amoxapine level

carbamazepine: Decreased serum amoxapine level; increased serum carbamazepine level, increasing its therapeutic and toxic effects

cimetidine, disulfiram, fluoxetine, fluvoxamine, haloperidol, H₂-receptor antagonists, methylphenidate, oral contraceptives, paroxetine, phenothiazines, sertraline: Increased blood amoxapine level

clonidine, guanethidine, other antihypertensives: Decreased antihypertensive effects

dicumarol: Increased anticoagulant effect

levodopa: Decreased levodopa absorption; agitation, hypertension, sinus tachycardia, sympathetic hyperactivity

MAO inhibitors: Possibly seizures and death
thyroid replacement drugs: Arrhythmias and increased antidepressant effects

ACTIVITIES

alcohol use: Increased CNS depression

smoking: Decreased amoxapine effects

Adverse Reactions

CNS: Agitation, anxiety, ataxia, chills, confusion, dizziness, drowsiness, excitement,

extrapyramidal reactions, fatigue, fever, headache, insomnia, nervousness, nightmares, paresthesia, restlessness, sedation, seizures, stroke, syncope, tremor, weakness
CV: Atrial arrhythmias, heart block, heart failure, hypertension, hypotension, MI, palpitations, tachycardia

EENT: Blurred vision, dry mouth, increased salivation, nasal congestion, taste perversion, tinnitus

ENDO: Gynecomastia, increased or decreased blood glucose level, increased prolactin level, syndrome of inappropriate ADH secretion

GI: Anorexia, constipation, diarrhea, elevated liver function test results, flatulence, increased appetite, nausea, vomiting

GU: Impotence, libido changes, menstrual irregularities, testicular swelling, urinary hesitancy, urine retention

HEME: Agranulocytosis, leukopenia

SKIN: Diaphoresis, flushing, photosensitivity, pruritus, rash

Other: Weight gain or loss; withdrawal symptoms, such as headache, nausea, nightmares, and vertigo

Nursing Considerations

WARNING Don't give an MAO inhibitor within 14 days of amoxapine.

- To avoid withdrawal, don't stop drug abruptly.
- Watch patients closely (especially children, adolescents, and young adults), for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times.

PATIENT TEACHING

- Advise patient to take amoxapine at bedtime if daytime sedation occurs.
- Caution patient that stopping amoxapine abruptly may cause withdrawal symptoms.
- Urge patient to avoid alcohol because it can potentiate amoxapine's effects.
- Tell patient to report adverse effects of amoxapine.
- Instruct patient to take drug with food to prevent GI upset.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.

amoxicillin trihydrate (amoxycillin)

Amoxil, Apo-Amoxi (CAN), DisperMox, Moxatag, Novamoxin (CAN), Nu-Amoxi (CAN), Polymox, Trimox, Wymox

Class and Category

Chemical class: Aminopenicillin

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat ear, nose, throat, GU tract, skin, and soft-tissue infections caused by susceptible gram-positive and gram-negative organisms*

CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, PEDIATRIC DROPS, POWDER OR TABLETS FOR ORAL SUSPENSION, TABLETS

Adults and children weighing 20 kg (44 lb) or more. 250 mg every 8 hr; for severe infections, 500 mg every 8 hr or 875 mg every 12 hr.

Children age 12 wk and over weighing less than 20 kg. 20 mg/kg daily in divided doses every 8 hr; for severe infections, 40 to 45 mg/kg/day in divided doses every 8 hr.

Children under age 12 wk. 30 mg/kg/day in divided doses every 12 hr.

➤ *To treat tonsillitis or pharyngitis caused by Streptococcus pyogenes*

E.R. TABLETS (MOXATAG)

Adults and children age 12 and over.

775 mg once daily for 10 days, taken within 1 hr of finishing a meal.

➤ *To treat lower respiratory tract infections caused by susceptible gram-positive and gram-negative organisms*

CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, PEDIATRIC DROPS, POWDER OR TABLETS FOR ORAL SUSPENSION, TABLETS

Adults and children weighing 20 kg or more. 875 mg every 12 hr; for severe infections, 500 mg every 8 hr.

Children age 12 wk and over weighing less than 20 kg. 40 to 45 mg/kg daily in divided doses every 8 hr.

Children under age 12 wk. 30 mg/kg daily in divided doses every 12 hr.

➤ *To treat gonorrhea and acute uncomplicated anogenital and urethral infections*

caused by susceptible strains of gram-positive and gram-negative organisms

CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, POWDER OR TABLETS FOR ORAL SUSPENSION, TABLETS

Adults and postpubertal children. 3 g as a single dose.

Prepubertal children age 2 and over.

50 mg/kg of amoxicillin plus 25 mg/kg of pro-benedicid as a single dose.

➤ *As adjunct to eradicate Helicobacter pylori to reduce risk of duodenal ulcer recurrence*

CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, POWDER OR TABLETS FOR ORAL SUSPENSION, TABLETS

Adults. 1 g every 12 hr with 500 mg of clarithromycin every 12 hr and 30 mg of lansoprazole every 12 hr for 14 days. Or, 1 g every 8 hr with 30 mg of lansoprazole every 8 hr for 14 days.

➤ *To prevent bacterial endocarditis before dental, oral, or upper respiratory tract procedures*

CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, POWDER OR TABLETS FOR ORAL SUSPENSION, TABLETS

Adults and children weighing 20 kg or more. 2 g 1 hr before procedure.

Children weighing less than 20 kg. 50 mg/kg 1 hr before procedure.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	6–8 hr

Mechanism of Action

Kills bacteria by binding to and inactivating penicillin-binding proteins on the inner bacterial cell wall, weakening the bacterial cell wall and causing lysis.

Contraindications

Hypersensitivity to amoxicillin or its components

Interactions

DRUGS

allopurinol: Increased risk of rash
chloramphenicol, erythromycins, sulfonamides, tetracyclines: Reduced bactericidal effect of amoxicillin
methotrexate: Increased risk of methotrexate toxicity
oral contraceptives with estrogen: Possibly

reduced effectiveness of contraceptive *probenecid*: Increased amoxicillin effects

Adverse Reactions

CNS: Agitation, anxiety, behavior changes, confusion, dizziness, insomnia, reversible hyperactivity, seizures

CV: Hypersensitivity vasculitis

EENT: Black, hairy tongue; mucocutaneous candidiasis; tooth discoloration

GI: Diarrhea, diarrhea related to *Clostridium difficile*, elevated liver enzymes, hemorrhagic or pseudomembranous colitis, jaundice, hepatic dysfunction, nausea, vomiting

GU: Crystalluria, vaginal mycosis

HEME: Agranulocytosis, anemia (including hemolytic anemia), eosinophilia, granulocytosis, leukopenia, thrombocytopenia, thrombocytopenic purpura

SKIN: Erythema multiforme, erythematous maculopapular rash, generalized exanthematous pustulosis, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Allergic reaction, anaphylaxis, serum sicknesslike reaction (such as arthralgia, arthritis, fever, myalgia, rash, and urticaria)

Nursing Considerations

- Patients with mononucleosis shouldn't receive amoxicillin because this class of drugs may cause an erythematous rash.
- Use drug cautiously in patients with hepatic impairment. Monitor hepatic and renal function and CBC, as ordered, in patients on prolonged therapy. Also use cautiously in breast-feeding and elderly patients.
- Expect to start therapy before culture and sensitivity test results are known.
- Be aware that chewable tablets and tablets for oral suspension contain phenylalanine.
- Don't confuse amoxicillin tablets with amoxicillin tablets for oral suspension (DisperMox). They're not interchangeable.

WARNING If allergic reaction occurs, stop amoxicillin immediately and provide emergency care as indicated and ordered.

- Monitor patient closely for diarrhea, which may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber, expect to withhold amoxicillin, and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- Expect treatment that lasts at least 10 days for hemolytic streptococci infections.

- Monitor patient for superinfection. If it occurs, expect to discontinue drug and provide treatment as ordered.

PATIENT TEACHING

- Tell patient to refrigerate reconstituted suspension and to shake well before each use.
- When amoxicillin suspension is prescribed for a child, instruct parents to place it directly on child's tongue to swallow. If this doesn't work, tell parents to mix dose of suspension with formula or cold drink (milk, fruit juice, ginger ale, water) and have child drink it immediately.
- Instruct patient using DisperMox tablets to place one tablet and about 2 teaspoonfuls of water in a glass, drink entire mixture, add more water to the glass, and drink again to ensure delivery of full dose.
- Tell patient to chew or crush chewable tablets and not to swallow them whole.
- To prevent infection from recurring, urge patient to take amoxicillin for full length of time prescribed, even if he feels better.
- Teach patient to report adverse reactions and notify prescriber if infection worsens or doesn't improve after 72 hours.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and may be serious, requiring prompt treatment.

amphetamine sulfate

dexamphetamine sulfate

Liquadd

Class, Category, and Schedule

Chemical class: Sympathomimetic amine

Therapeutic class: CNS stimulant

Pregnancy category: C

Controlled substance schedule: II

Indications and Dosages

↗ To treat attention deficit hyperactivity disorder (ADHD)

ORAL SOLUTION (LIQUADD)

Children ages 3 to 6. *Initial:* 2.5 mg daily.

Increased by 2.5 mg daily at 1-wk intervals until desired response occurs.

Children age 6 and over. *Initial:* 5 mg daily or b.i.d. Increased by 5 mg daily at 1-wk intervals until desired response occurs.

TABLETS

Children age 6 and over. *Initial:* 5 mg daily or b.i.d. Increased by 5 mg daily at 1-wk intervals until desired response occurs.

Usual: 0.1 to 0.5 mg/kg daily.

Children ages 3 to 5. *Initial:* 2.5 mg daily. Increased by 2.5 mg daily at 1-wk intervals until desired response occurs. *Usual:* 0.1 to 0.5 mg/kg daily.

➤ *To treat narcolepsy*

ORAL SOLUTION (LIQUADD)

Adults and children age 12 and over. *Initial:* 10 mg daily. Increased by 10 mg daily at 1-wk intervals until desired response occurs.

Children ages 6 to 12. *Initial:* 2.5 mg b.i.d. Increased by 5 mg daily at 1-wk intervals until desired response occurs.

TABLETS

Adults and children age 12 and over. *Initial:* 10 mg daily. Increased by 10 mg daily at 1-wk intervals until desired response occurs.

Children ages 6 to 12. *Initial:* 2.5 mg b.i.d. Increased by 5 mg daily at 1-wk intervals until desired response occurs or adult dosage is reached to a maximum of 60 mg daily.

Mechanism of Action

May produce its CNS stimulant effects by facilitating release and blocking reuptake of norepinephrine at adrenergic nerve terminals and by direct stimulation of alpha and beta receptors in the peripheral nervous system. It also releases and blocks reuptake of dopamine in limbic regions of the brain. The drug's main action appears to be in the cerebral cortex and, possibly, the reticular activating system. These actions cause decreased motor restlessness, increased alertness, and diminished drowsiness and fatigue. Its peripheral actions include increased blood pressure and mild bronchodilation and respiratory stimulation.

Contraindications

Advanced arteriosclerosis, agitation (for narcolepsy treatment), glaucoma, history of drug abuse, hypersensitivity or idiosyncratic reaction to sympathomimetic amines, hyperthyroidism, MAO inhibitor therapy

within 14 days, moderate to severe hypertension, symptomatic cardiovascular disease

Interactions

DRUGS

adrenergic blockers: Inhibited adrenergic blockade

acetazolamide, alkalinizers (such as sodium bicarbonate), some thiazides: Increased blood level and effects of amphetamine

antihistamines: Possibly reduced sedation from antihistamine

antihypertensives: Possibly decreased antihypertensive effects

chlorpromazine: Inhibited CNS stimulant effects of amphetamine

ethosuximide: Possibly delayed ethosuximide absorption

GI acidifiers (such as ascorbic acid), reserpine: Decreased amphetamine absorption

guanethidine: Decreased antihypertensive effect and decreased amphetamine absorption

haloperidol: Decreased CNS stimulation

lithium carbonate: Possibly decreased anorectic and stimulant effects of amphetamine

MAO inhibitors: Potentiated effects of amphetamine; possibly hypertensive crisis

meperidine: Increased analgesia

methenamine: Increased urine excretion and decreased effects of amphetamine

norepinephrine: Possibly increased adrenergic effect of norepinephrine

phenobarbital, phenytoin: Synergistic anti-convulsant action

propoxyphene: Increased CNS stimulation, potentially fatal seizures

tricyclic antidepressants: Possibly enhanced antidepressant effects and decreased effects of amphetamine

urinary acidifiers (such as ammonium chloride and sodium acid phosphate): Increased amphetamine excretion and decreased amphetamine blood level and effects

veratrum alkaloids: Decreased hypotensive effect

FOODS

acidic fruit juices: Decreased amphetamine absorption

Adverse Reactions

CNS: Anxiety, dizziness, dyskinesia, dysphoria, euphoria, exacerbation of motor and phonic tics and Tourette's syndrome, hallu-

cinations, headache, insomnia, overstimulation, paranoia, psychotic episodes, restlessness, tremor

CV: Cardiomyopathy, hypertension, palpitations, tachycardia

EENT: Dry mouth, unpleasant taste

GI: Anorexia, constipation, diarrhea

GU: Impotence, libido changes

SKIN: Urticaria

Other: Weight loss

Nursing Considerations

- Keep in mind that when symptoms of ADHD occur with acute stress reactions, treatment with amphetamines usually isn't indicated.

WARNING To prevent hypertensive crisis, don't give amphetamine during or for up to 14 days after MAO therapy.

- Give first dose when patient awakens and additional doses at 4- to 6-hour intervals.
- Be aware that 5 ml of oral solution contains 5 mg of dexamphetamine.
- If patient has bothersome adverse reactions, such as insomnia and anorexia, expect to decrease dosage. To minimize insomnia, administer drug earlier in day.
- Be alert for evidence of long-term amphetamine abuse, such as severe dermatoses, marked insomnia, irritability, hyperactivity, and personality changes. If patient suddenly stops drug after long-term, high-dose regimen, watch for extreme fatigue and depression.

PATIENT TEACHING

- Instruct breast-feeding patient to avoid breast-feeding during amphetamine therapy because drug is excreted in breast milk.
- Teach patient to take first dose on awakening and subsequent doses at 4- to 6-hour intervals. Tell him not to take last dose late in evening because insomnia may occur.
- Inform patient or caregiver that each 5 ml of oral solution contains 5 mg of dexamphetamine. Advise patient to use a calibrated measuring device for accurate dose.
- Urge patient to avoid hazardous activities until drug's effects are known.
- Advise patient not to take amphetamine with acidic fruit juice because doing so decreases drug absorption.
- Explain drug's abuse potential, and caution against altering dosage unless prescribed.

amphotericin B

Amphocin, Fungizone Intravenous

amphotericin B cholesteryl sulfate complex

Amphotec

amphotericin B lipid complex

Abelcet

amphotericin B liposomal complex

AmBisome

Class and Category

Chemical class: Amphoteric polyene macrolide

Therapeutic class: Antifungal

Pregnancy category: B (I.V.); C (oral suspension)

Indications and Dosages

↗ To treat severe fungal infections, using amphotericin B

I.V. INFUSION

Adults and adolescents. *Initial:* 1-mg test dose in 20 ml of D₅W infused over 20 to 30 min; if test dose is tolerated, then 0.25 to 0.3 mg/kg daily prepared as a 0.1 mg/ml infusion, given over 2 to 6 hr. Increased in 5- to 10-mg increments up to 50 mg daily, based on patient tolerance and infection severity, not to exceed a total daily dose of 1.5 mg/kg. *Maximum:* 50 mg daily infused over 2 to 6 hr.

Children. *Initial:* 0.25 mg/kg daily in D₅W infused over 6 hr; then increased in 0.125- to 0.25-mg/kg increments daily or every other day as tolerated. *Maximum:* 1 mg/kg or 30 mg/m² of body surface daily.

↗ To treat oral candidiasis, using amphotericin B

ORAL SUSPENSION

Adults and children. 1 ml (100 mg) q.i.d. for 14 days.

↗ To treat aspergillosis, using amphotericin B cholesteryl sulfate complex

I.V. INFUSION

Adults and children. Test dose of 1.6 to 8.3 mg in 10 ml of D₅W infused over 15 to 30 min; if test dose is tolerated, then 3 to 4 mg/kg once daily infused at 1 mg/kg/hr.

↗ *To treat invasive amphotericin B-resistant fungal infections, using amphotericin B lipid complex*

I.V. INFUSION

Adults and children. 5 mg/kg daily infused at 2.5 mg/kg/hr.

↗ *To treat severe aspergillosis, candidiasis, or cryptococcosis, using amphotericin B liposomal complex*

I.V. INFUSION

Adults and children. 3 to 5 mg/kg daily infused over 2 hr. Infusion time may be decreased to 1 hr if tolerated or increased if patient experiences discomfort.

↗ *To treat leishmaniasis, using amphotericin B liposomal complex*

I.V. INFUSION

Immunocompetent adults and children.

3 mg/kg daily on days 1 through 5 and on days 14 and 21, infused over 2 hr. Infusion time may be decreased to 1 hr if tolerated or increased if patient has discomfort.

Immunocompromised adults and children.

4 mg/kg daily on days 1 through 5 and days 10, 17, 24, 31, and 38 infused over 2 hr. Infusion time may be decreased to 1 hr if tolerated or increased if patient has discomfort.

↗ *To treat presumed fungal infections in patients with febrile neutropenia, using amphotericin B lipid complex*

I.V. INFUSION

Adults and children. 3 mg/kg daily infused over 2 hr. Infusion time may be decreased to 1 hr if tolerated or increased if patient has discomfort.

Route	Onset	Peak	Duration
I.V.	Immediate	Unknown	Unknown

Mechanism of Action

Binds to sterols in fungal cell plasma membranes, which changes membrane permeability and allows loss of potassium and small molecules from cells. This action results in cell impairment or death.

Incompatibilities

Don't reconstitute amphotericin B with diluents other than those recommended

because solutions with sodium chloride or bacteriostatic agents (such as benzyl alcohol) may cause drug precipitation.

Contraindications

Hypersensitivity to amphotericin B or its components

Interactions**DRUGS**

antineoplastics: Increased risk of bronchospasm, hypotension, and nephrotoxicity

corticosteroids, corticotropin: Increased risk of hypokalemia and cardiac dysfunction

cyclosporine, nephrotoxic drugs: Increased risk of nephrotoxicity

digitalis glycosides: Possibly hypokalemia and more severe digitalis toxicity

flucytosine: Possibly increased flucytosine toxicity

leukocyte transfusion: Possibly dyspnea, hypoxemia, and pulmonary infiltrates

skeletal muscle relaxants: Possibly hypokalemia and increased muscle relaxation

zidovudine: Possibly myelotoxicity and nephrotoxicity

Adverse Reactions

CNS: Fever, headache, shaking chills, tiredness, weakness

CV: Chest pain, hypotension, irregular heartbeat

EENT: Difficulty swallowing, pharyngitis

GI: Abdominal pain, anorexia, diarrhea, hepatic failure, indigestion, nausea, vomiting

GU: Decreased or increased urine output, impaired renal function

HEME: Anemia, leukopenia, thrombocytopenia, unusual bleeding or bruising

MS: Arthralgia, muscle spasms, myalgia

RESP: Apnea, dyspnea, hypoxia, pulmonary edema, tachypnea

SKIN: Flushing, jaundice, maculopapular rash, pruritus and redness especially around ears, urticaria

Other: Anaphylaxis, hypocalcemia, hypokalemia, hypomagnesemia, infusion site pain and thrombophlebitis

Nursing Considerations

- To prepare amphotericin B, add 10 ml of sterile water for injection without a bacteriostatic agent to vial containing 50 mg of amphotericin B. For I.V. infusion, dilute solution containing 5 mg/ml to 0.1 mg/ml

by adding 1 ml (5 mg) of solution to 49 ml of D₅W with a pH above 4.2.

- Before using D₅W to dilute amphotericin B solution, determine the injection's pH aseptically. If pH is below 4.2, follow manufacturer's instructions for buffering it.
- Because reconstituted amphotericin B is a colloidal suspension, avoid using in-line membrane filter or use one with a mean pore diameter of more than 1 micron to prevent significant drug removal.
- To prepare amphotericin B cholesteryl sulfate complex, reconstitute with sterile water for injection. Using a sterile syringe and 20G needle, rapidly add 10 or 20 ml sterile water for injection to a 50- or 100-mg vial, respectively, to obtain a solution containing 5 mg of amphotericin B per milliliter. Shake gently by hand, rotating vial until solids are dissolved; fluid may be clear or opalescent. For infusion, further dilute reconstituted solution to about 0.6 mg/ml. Don't filter solution or use an in-line filter. Flush existing line with D₅W or use a separate line.
- To prepare amphotericin B lipid complex, shake vial gently until you see no yellow sediment. Using an 18G needle, withdraw prescribed dose from required number of vials into one or more 20-ml syringes. Replace needle with 5-micron filter needle supplied with each vial. Empty syringe contents into bag of D₅W so that final concentration is 1 mg/ml. Expect to use a concentration of 2 mg/ml for children and patients with cardiovascular disease. Before infusion, shake bag until contents are mixed thoroughly. Flush existing line with D₅W, or use a separate line. Don't use an in-line filter. If infusion exceeds 2 hours, shake infusion bag every 2 hours.
- To prepare amphotericin B liposomal complex, add 12 ml sterile water for injection (without bacteriostatic agent) to each 50-mg vial to achieve a concentration of 4 mg amphotericin B per milliliter. Immediately shake vial vigorously for at least 30 seconds until all particles completely disperse. Withdraw prescribed dose of amphotericin B liposomal complex suspension. Then use a 5-micron filter to inject it into D₅W to provide a final concentration of 1 to 2 mg/ml. Expect to use a lower concentration (0.2 to 0.5 mg/ml)

for infants and young children. Flush existing line with D₅W, or use a separate line. You may use an in-line filter with a mean pore diameter of at least 1 micron.

- To help minimize fever and shaking chills, expect to give an antipyretic, antihistamine, meperidine, or corticosteroid just before infusing amphotericin B.
- Before giving amphotericin B oral suspension, shake well. Drop suspension on tongue with calibrated dropper. Then tell patient to swish suspension in mouth for as long as possible before swallowing. If drug must be swabbed on, use a nonabsorbent swab.
- Give amphotericin B oral suspension between meals to permit prolonged contact with oral lesions.
- Assess I.V. insertion site regularly to detect extravasation of amphotericin B, which may cause severe local irritation. To minimize local thrombophlebitis, plan to add heparin to infusion or expect to administer amphotericin on alternate days, which also may help prevent anorexia. Alternate-day dose shouldn't exceed 1.5 mg/kg.
- Monitor renal function because of the risk of renal impairment. Plan to obtain serum creatinine level every other day while amphotericin B dosage is increasing and then at least twice weekly during therapy. If serum creatinine or BUN level increases significantly, expect to stop amphotericin B until renal function improves. Know that a cumulative dose of more than 4 g may cause irreversible renal dysfunction.
- Expect to monitor CBC and platelet count weekly during therapy to detect adverse hematologic effects. Also monitor serum calcium, magnesium, and potassium levels twice weekly to detect abnormalities.
- Use reconstituted amphotericin B within 24 hours if stored at room temperature, 1 week if refrigerated. Use reconstituted amphotericin B cholesteryl sulfate complex within 24 hours. Use amphotericin B lipid complex within 6 hours if stored at room temperature, 48 hours if refrigerated. Use diluted amphotericin B liposomal complex within 24 hours if refrigerated, but begin infusion within 6 hours.

PATIENT TEACHING

- Instruct patient to shake bottle of oral suspension well before each dose; to drop

suspension directly on his tongue using calibrated dropper; and then to swish suspension in his mouth for as long as possible before swallowing. If prescriber orders drug to be swabbed onto oral lesions, tell patient to use nonabsorbent swab. Instruct him to take drug four times a day (between meals and at bedtime).

- Tell patient to notify prescriber if he develops local irritation, if existing symptoms worsen or return, or if new symptoms arise.

ampicillin

Apo-Ampi (CAN), Novo-Ampicillin (CAN), Nu-Ampi (CAN), Omnipen

ampicillin sodium

Ampicin (CAN), Omnipen-N, Polycillin-N, Totacillin-N

ampicillin trihydrate

D-Amp, Omnipen, Penbritin (CAN), Polycillin, Principen-250, Principen-500, Totacillin

Class and Category

Chemical class: Semisynthetic aminopenicillin

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

- ↗ *To treat GI infections and genitourinary infections (other than gonorrhea) caused by susceptible strains of Shigella, Salmonella typhi and other species, Escherichia coli, Proteus mirabilis, and enterococci*

CAPSULES, ORAL SUSPENSION, I.V. INFUSION, I.M. INJECTION

Adults and children weighing 20 kg (44 lb) or more. 500 mg P.O. every 6 hr or 250 to 500 mg I.V. or I.M. every 6 hr.

Children weighing less than 20 kg. 50 to 100 mg/kg daily in divided doses P.O. every 6 hr or 12.5 mg/kg I.V. or I.M. every 6 hr.

- ↗ *To treat gonorrhea caused by susceptible strains of non-penicillinase-producing Neisseria gonorrhoeae*

CAPSULES, ORAL SUSPENSION

Adults and children. 3.5 g as a single dose

with 1 g of probenecid.

I.V. INFUSION, I.M. INJECTION

Adults and children weighing 45 kg (99 lb) or more. 500 mg every 6 hr.

Children weighing less than 40 kg (88 lb). 50 mg/kg daily in divided doses every 6 to 8 hr.

- ↗ *To treat respiratory tract infections caused by susceptible strains of non-penicillinase-producing Haemophilus influenzae, staphylococci, and streptococci, including Streptococcus pneumoniae*

CAPSULES, ORAL SUSPENSION, I.V. INFUSION, I.M. INJECTION

Adults and children weighing 40 kg or more. 250 to 500 mg I.V. or I.M. every 6 to 8 hr.

Adults and children weighing 20 kg or more. 250 mg P.O. every 6 hr.

Children weighing less than 40 kg. 25 to 50 mg/kg daily I.V. or I.M. in divided doses every 6 to 8 hr.

Children weighing less than 20 kg. 50 mg/kg daily P.O. in divided doses every 6 or 8 hr or 12.5 mg/kg I.V. or I.M. every 6 hr.

- ↗ *To treat septicemia*

I.V. INFUSION, I.M. INJECTION

Adults. 8 to 14 g I.V. daily in divided doses every 3 to 4 hr for at least 3 days; then I.M.

Children. 150 to 200 mg/kg daily I.V. in divided doses every 3 to 4 hr for at least 3 days; then I.M.

- ↗ *To prevent bacterial endocarditis from dental, oral, or upper respiratory tract procedures*

I.V. INFUSION, I.M. INJECTION

Adults. 2 g within 30 min of procedure

Children. 50 mg/kg within 30 min of procedure

- ↗ *To treat bacterial meningitis caused by susceptible strains of Neisseria meningitidis*

I.V. INFUSION, I.M. INJECTION

Adults. 8 to 14 g daily or 150 to 200 mg/kg daily I.V. in equally divided doses every 3 to 4 hr for at least 3 days; then I.M. at same dosage and schedule.

Children. 100 to 200 mg/kg daily I.V. in equally divided doses every 3 to 4 hr for at least 3 days; then I.M. at same dosage and schedule.

- ↗ *To treat listeriosis*

I.V. INFUSION, I.M. INJECTION

Adults and children weighing 20 kg or more. 50 mg/kg every 6 hr.
Children weighing less than 20 kg. 12.5 mg/kg every 6 hr.

Route	Onset	Peak	Duration
I.V.	Immediate	Unknown	Unknown

Mechanism of Action

Inhibits bacterial cell wall synthesis. The rigid, cross-linked cell wall is assembled in several steps. Ampicillin exerts its effects on susceptible bacteria in the final stage of the cross-linking process by binding with and inactivating penicillin-binding proteins (enzymes responsible for linking the cell wall strands). This action causes bacterial cell lysis and death.

Incompatibilities

Don't mix ampicillin and any aminoglycoside in the same I.V. bag, bottle, or tubing; otherwise, both drugs will be inactivated. If patient must receive both drugs, administer them in separate sites at least 1 hour apart.

Contraindications

Hypersensitivity to any penicillin, infection caused by penicillinase-producing organism

Interactions

DRUGS

allopurinol: Increased risk of rash, particularly in hyperuricemic patient

aminoglycosides: Possibly inactivated action of aminoglycoside and ampicillin when given together

heparin, oral anticoagulants: Increased risk of bleeding

oral contraceptives: Possibly reduced contraceptive effectiveness and breakthrough bleeding

probenecid: Possibly increased serum ampicillin level and ampicillin toxicity

tetracyclines: Possibly impaired action of ampicillin

Adverse Reactions

CNS: Chills, fatigue, fever, headache, malaise

CV: Chest pain, edema, thrombophlebitis

EENT: Epistaxis, glossitis, laryngeal stridor, mucocutaneous candidiasis, stomatitis, throat tightness

GI: Abdominal distention, diarrhea, diarrhea related to *Clostridium difficile*, entero-

colitis, flatulence, gastritis, nausea, pseudomembranous colitis, vomiting
GU: Dysuria, urine retention, vaginal candidiasis

HEME: Agranulocytosis, anemia, eosinophilia, leukopenia, thrombocytopenia, thrombocytopenic purpura

SKIN: Erythema multiforme; erythematous, mildly pruritic maculopapular rash or other types of rash; exfoliative dermatitis; pruritus; urticaria

Other: Anaphylaxis, facial edema, injection site pain

Nursing Considerations

- Avoid giving ampicillin to patients with mononucleosis because of increased risk of rash.
- Expect to give ampicillin for 48 to 72 hours after patient becomes asymptomatic. For streptococcal infection, expect to give ampicillin for at least 10 days after cultures show streptococcal eradication to reduce risk of rheumatic fever or glomerulonephritis.
- To dilute ampicillin for I.M. use, add (depending on manufacturer) 1.2 ml of sterile water or bacteriostatic water for injection to each 125-mg vial, 1 ml of diluent to each 250-mg vial, 1.8 ml of diluent to each 500-mg vial, 3.5 ml of diluent to each 1-g vial, or 6.8 ml of diluent to each 2-g vial.
- To dilute ampicillin for intermittent infusion, add 5 ml of sterile water or bacteriostatic water for injection to each 125-, 250-, or 500-mg vial or 7.4 to 10 ml of diluent to each 1- or 2-g vial. Infuse in suitable diluent at less than 30 mg/ml.

WARNING Infuse I.V. solution for 3 to 5 minutes for each 125 or 500 mg or 10 to 15 minutes for each 1 or 2 g. More rapid infusion may cause seizures.

- Monitor patient closely for anaphylaxis, which may be life-threatening. Patients at greatest risk are those with a history of multiple allergies, hypersensitivity to cephalosporins, or a history of asthma, hay fever, or urticaria.

WARNING In an anaphylactic reaction, stop drug, notify prescriber immediately, and provide immediate treatment with epinephrine, airway management, oxygen, and I.V. corticosteroids, as needed.

- Notify prescriber if patient has evidence of

superinfection; expect to stop drug and provide appropriate treatment.

- If long-term or high-dose ampicillin therapy is required, closely monitor results of renal and liver function tests and CBCs.
- Monitor patient closely for diarrhea, which may be pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold ampicillin and administer fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

PATIENT TEACHING

- Stress the importance of taking the full course of ampicillin exactly as prescribed.
- Tell patient to take dose with 8 oz of water 30 minutes before or 2 hours after meals.
- Instruct patient to shake suspension well before each use, keep bottle tightly closed between uses, and discard unused portion after 14 days if refrigerated or 7 days if stored at room temperature.
- Review signs of allergic reaction; if they occur, tell patient to hold next ampicillin dose and contact prescriber immediately.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools may occur 2 or more months after antibiotic therapy and may be serious, requiring prompt treatment.

amyl nitrite

Class and Category

Chemical class: Nitrite ester

Therapeutic class: Antianginal

Pregnancy category: C

Indications and Dosages

↗ *To treat acute attacks of angina pectoris*

CRUSHABLE AMPULES

Adults. 1 ampule (0.18 or 0.3 ml) inhaled and repeated in 3 to 5 min, if needed.

Route	Onset	Peak	Duration
Inhalation	10–30 sec	Unknown	3–5 min

Mechanism of Action

After inhalation, is absorbed by pulmonary alveoli, which causes relaxation of vascular smooth-muscle cells, dilation of large coro-

nary blood vessels, decreased systemic vascular resistance, decreased venous return to the heart, reduced afterload, decreased cardiac output, and subsequent relief of angina.

Contraindications

Hypersensitivity to amyl nitrite, its components, or nitrates

Interactions

DRUGS

aspirin: Increased serum level and action of amyl nitrite

calcium channel blockers: Possibly severe symptomatic hypotension

sildenafil: Increased risk of hypotension

sympathomimetics: Possibly decreased antianginal effects and severe hypotension and tachycardia

ACTIVITIES

alcohol use: Increased risk of severe hypotension and cardiovascular collapse

Adverse Reactions

CNS: Dizziness, headache, restlessness, syncope, weakness

CV: Orthostatic hypotension, tachycardia

GI: Fecal incontinence, nausea, vomiting

GU: Urinary incontinence

HEME: Hemolytic anemia, methemoglobinemia

SKIN: Face and neck flushing, pallor, rash

Nursing Considerations

- Use amyl nitrite cautiously in elderly patients and patients with cerebral hemorrhage, glaucoma, hyperthyroidism, recent head trauma or MI, or severe anemia.
- Monitor blood pressure during and after drug administration. Also monitor cardiac function periodically in patients who use amyl nitrite regularly.

WARNING Stop drug and notify prescriber if evidence of overdose, such as bluish lips, fingernails, or palms; dizziness; fainting; extreme pressure in head; dyspnea; unusual tiredness or weakness; a weak or fast heartbeat; or increased methemoglobin level. Cyanosis may occur when methemoglobin level reaches 1.5 g/dl. More pronounced signs occur at 20 to 50 g/dl.

- Expect to treat overdose with high-flow oxygen and I.V. methylene blue. If hypotension is severe, place patient head down. If he needs a vasopressor, avoid epinephrine; it may cause severe hypotension.

PATIENT TEACHING

- Advise patient to store amyl nitrate in a tight container, protected from light.
 - Tell patient to crush ampule between finger and thumb, hold it to nostrils, and inhale 1 to 6 times.
 - Instruct patient to remain seated or supine during administration and to rise slowly afterward to prevent dizziness.
 - Inform patient that relief usually occurs in 1 to 5 minutes. If pain continues, he should repeat dose. If pain continues after another 5 minutes, he should seek emergency help.
 - Urge patient not to use any more drug than prescribed because of possible overdose.
- WARNING** Caution patient that drug is flammable and must be kept from flame and heat.
- Inform patient that amyl nitrite commonly causes headaches. Tell him to notify prescriber if they're severe or bothersome.

anagrelide hydrochloride

Agrylin

Class and Category

Chemical class: Imidazoquinazolinone

Therapeutic class: Platelet count–reducing agent

Pregnancy category: C

Indications and Dosages

➤ *To treat essential thrombocythemia*

CAPSULES

Adults. 0.5 mg q.i.d. or 1 mg b.i.d. for 1 wk; then adjusted to lowest dose that keeps platelet count below 600,000/mm³ or within normal range. Shouldn't be increased by more than 0.5 mg daily in any 1 wk.

Maximum: 10 mg daily or 2.5 mg in a single dose.

DOSE ADJUSTMENT For patients with moderate hepatic impairment, 0.5 mg daily for at least 1 wk, increased as needed by no more than 0.5 mg daily in any 1-wk period.

Mechanism of Action

May decrease megakaryocyte hypermaturation (bone marrow cells from which platelets form), reducing platelet count. Higher

doses may inhibit platelet aggregation.

Route	Onset	Peak	Duration
P.O.	7–14 days	Unknown	Up to 4 days

Contraindications

Hypersensitivity to anagrelide, severe hepatic impairment

Interactions**DRUGS**

amrinone, cilostazol, enoximone, milrinone, olprinone: Increased effects of these drugs; possible risk of increased adverse effects
aspirin: Possibly increased risk of bleeding
sucralfate: Possibly interference with anagrelide absorption

Adverse Reactions

CNS: Amnesia, asthenia, chills, confusion, depression, dizziness, fever, headache, insomnia, malaise, nervousness, paresthesia, seizures, somnolence, stroke, syncope, weakness

CV: Angina, arrhythmias, edema, heart failure, hypertension, MI, orthostatic hypotension, palpitations, tachycardia, vasodilation

EENT: Amblyopia, diplopia, epistaxis, rhinitis, sinusitis, stomatitis, tinnitus, vision or visual field abnormality

GI: Abdominal pain, anorexia, constipation, diarrhea, elevated liver function test results, eructation, flatulence, gastric and duodenal ulceration, gastritis, GI hemorrhage, hepatotoxicity, indigestion, melena, nausea, pancreatitis, vomiting

GU: Dysuria, hematuria, renal failure

HEME: Anemia, hemorrhage, thrombocytopenia

MS: Arthralgia, back pain, leg cramps, myalgia, neck pain

RESP: Allergic alveolitis, asthma, bronchitis, dyspnea, eosinophilic pneumonia, interstitial pneumonitis, lung infiltrations, pneumonia

SKIN: Alopecia, ecchymosis, photosensitivity, pruritus, rash, urticaria

Other: Dehydration, flulike symptoms, generalized body pain, lymphadenoma

Nursing Considerations

- Use anagrelide cautiously in patients with heart disease because it may cause cardiovascular problems, such as heart failure.

Use drug cautiously in patients with renal insufficiency (serum creatinine level 2 mg/dl or more) or hepatic dysfunction (liver function tests more than 1.5 times normal) because of the increased risk of nephrotoxicity and hepatotoxicity.

- Determine whether patient takes aspirin before starting anagrelide therapy and, if so, monitor patient closely because bleeding risk may be higher when aspirin and anagrelide are taken concurrently.
- To assess efficacy and prevent thrombocytopenia, expect to monitor platelet count every 2 days for first week, then at least weekly until reaching lowest effective dose.
- While platelet count is declining (usually during first 2 weeks of therapy), assess WBC count and hemoglobin, AST, ALT, creatinine, and BUN levels to detect abnormalities.
- Monitor blood pressure to detect orthostatic hypotension.

PATIENT TEACHING

- Stress need to return for laboratory tests, such as platelet counts, to monitor anagrelide's effectiveness and adjust its dosage.
- Tell patient to keep drug bottle tightly capped and to protect drug from light.
- Urge patient to ask prescriber before taking aspirin or aspirin-containing products.

anakinra

Kineret

Class and Category

Chemical class: Recombinant human interleukin-1 receptor antagonist
Therapeutic class: Antirheumatic
Pregnancy category: B

Indications and Dosages

➤ *To reduce signs and symptoms and slow structural damage in moderate to severe active rheumatoid arthritis in patients who have not responded to disease-modifying antirheumatics*

SUBCUTANEOUS INJECTION

Adults. 100 mg daily.

DOSE ADJUSTMENT Interval reduced to every other day in severe renal insufficiency or end-stage renal disease (creatinine clearance less than 30 ml/min/1.73 m²).

Mechanism of Action

Inhibits the binding of interleukin-1 (IL-1) to its type 1 receptor; blocking its activity. Inflammatory stimuli prompt T cells to release IL-1, a mediator of inflammation, pain, and stiffness in rheumatoid arthritis.

Contraindications

Active infection; hypersensitivity to anakinra, its components, or *Escherichia coli*-derived proteins

Interactions

DRUGS

etanercept, infliximab, and other drugs that block tumor necrosis factor: Increased risk of serious infection

live-virus vaccines Possibly decreased antibody response to vaccine, potential for infection with live virus

Adverse Reactions

CNS: Headache

EENT: Sinusitis

GI: Abdominal pain, diarrhea, nausea

HEME: Neutropenia

MS: Bone and joint infections

RESP: Pneumonia, upper respiratory tract infection

Skin: Cellulitis

Other: Flulike symptoms; hypersensitivity reaction; injection site ecchymosis, erythema, inflammation, pain, and pruritus; malignancies; positive results for anti-anakinra antibodies; serious infections

Nursing Considerations

- Expect to obtain baseline neutrophil count before therapy and to monitor neutrophil count every month for 3 months and every 3 months for up to 1 year.
- Discard solution if it contains particles or is discolored. Use prefilled syringe and needles to administer drug. Don't shake syringe; allow time for solution to clear if it becomes foamy.
- Give drug about the same time each day.

WARNING Anakinra isn't recommended for patients with active infections. Monitor patient for evidence of infection, such as fever, chills, sore throat, and mouth sores, before and during therapy because drug increases the risk of infections, such as cellulitis, pneumonia, and bone and joint infections. Notify prescriber if signs are present. Patients with asthma and those

receiving etanercept or infliximab are at increased risk for serious infections. Expect anakinra to be stopped if serious infection develops.

- Be aware that live-virus vaccines shouldn't be given to patients receiving anakinra because drug decreases immune response.
- Monitor patients with impaired renal function for signs of anakinra toxicity; they're at increased risk because drug is excreted primarily by the kidneys.
- Store anakinra at 2° to 8° C (36° to 46° F). Protect from freezing and light.

PATIENT TEACHING

- Teach proper injection technique if patient will self-administer drug. Make sure patient understands the process and can correctly prepare and inject doses.
- Instruct patient to rotate injection sites among thighs, stomach, and upper arms and to avoid areas that are tender, hard, red, or bruised. Advise him to make sure that each injection site is at least 1 inch away from the previous site.
- Urge patient to discard used needles and syringes in a puncture-resistant container and not to reuse them. Instruct him to return container to prescriber for disposal.
- Review evidence of allergic reaction, including rash and shortness of breath.
- Urge patient to immediately report signs of infection, such as cough, fever, chills, dyspnea, or headache, to prescriber.

anastrozole

Arimidex

Class and Category

Chemical class: Nonsteroidal selective aromatase inhibitor

Therapeutic class: Antineoplastic

Pregnancy category: D

Indications and Dosages

➤ *To treat postmenopausal women with unknown or positive hormone receptor and locally advanced or metastatic breast cancer, and those with advanced breast cancer that progresses after tamoxifen therapy; as adjunct to treat early breast cancer in postmenopausal women with positive hormone receptor*

TABLETS

Adult women. 1 mg daily.

Contraindications

Hypersensitivity to anastrozole or its components, pregnancy, premenopausal women

Adverse Reactions

CNS: Asthenia, depression, dizziness, headache, hypertonionia, insomnia, lethargy, paresthesia

CV: Angina, MI

EENT: Dry mouth, pharyngitis

ENDO: Hot flashes, weight gain

CV: Chest pain, hypertension, peripheral edema, thromboembolic disease, vasodilation

GI: Abdominal or pelvic pain, anorexia, increased appetite, constipation, diarrhea, nausea, vomiting

GU: Leukorrhage; vaginal bleeding, dryness, or hemorrhage

MS: Back or bone pain

RESP: Increased cough, dyspnea

SKIN: Diaphoresis, rash, urticaria

Other: Anaphylaxis, angioedema, flulike symptoms, pain, tumor flare

Nursing Considerations

- Assess patient for evidence of thromboembolic events during anastrozole therapy, such as shortness of breath, leg pain, and altered mental status.
- Assess patient for evidence of ischemic cardiovascular disorders, such as angina and MI, especially in women with ischemic heart disease.
- Store drug in a tightly closed container at room temperature.

PATIENT TEACHING

- Urge patient to report menopausal status accurately because drug is contraindicated and ineffective in premenopausal women.
- Inform patient about possible dizziness and lethargy, and advise her to avoid potentially hazardous activities until drug's CNS effects are known.
- Urge patient to tell prescriber about leg pain or calf swelling, which may indicate a blood clot.
- Advise patient to consume adequate calcium and to follow an exercise program; drug may reduce bone mineral density.
- Urge patient taking anastrozole to comply with follow-up appointments.

Mechanism of Action

Anastrozole treats certain breast cancers in postmenopausal women by inhibiting the enzyme aromatase, as shown in the illustrations below, thus preventing production of estrone and estradiol. This is

how, in women with breast tumors that contain estrogen receptors, anastrozole prevents the stimulatory effects of estrogen on tumor growth.

anisindione

Miradon

Class and Category

Chemical class: Indanedione derivative

Therapeutic class: Anticoagulant

Pregnancy category: X

Indications and Dosages

➤ *To prevent and treat venous thrombosis, atrial fibrillation with embolization, and pulmonary embolism; as adjunct to treat coronary artery occlusion, usually in patients who can't tolerate coumarin anticoagulants*

TABLETS

Adults. *Initial:* 300 mg on day 1; then 200 mg on day 2, and 100 mg on day 3.

Maintenance: 25 to 250 mg daily.

Route	Onset	Peak	Duration
P.O.	In 6 hr	48–72 hr	1–3 days

Mechanism of Action

Interferes with the liver's ability to synthesize vitamin K–dependent clotting factors, which results in the depletion of clotting factors II (prothrombin), VII, IX, and X. By depleting levels of vitamin K–dependent

clotting factors that are needed to form a stable fibrin clot, anisindione interferes with the clotting cascade and prevents coagulation.

Contraindications

Ascorbic acid deficiency; blood dyscrasias; continuous small-intestine drainage tube; diverticulitis; emaciation; GI, GU, or respiratory tract bleeding; hemophilia; hemorrhagic tendency; history of warfarin-induced necrosis; hypersensitivity to anisindione or its components; leukemia; major recent surgery; malnutrition; pericardial effusion; pericarditis; polyarthritis; pregnancy; prostatectomy; recent spinal puncture, percutaneous invasive procedure, diagnostic testing, or insertion of intrauterine device; recent or possible CNS or eye surgery; severe renal or hepatic disease; severe uncontrolled diabetes; severe uncontrolled malignant hypertension; subacute bacterial endocarditis; thrombocytopenic pur-pura; visceral carcinomas; ulcerative colitis

Interactions

DRUGS

abciximab, acetaminophen, allopurinol, alteplase, amiodarone, amitriptyline, amoxapine, androgens, aspirin, beta blockers, cephalosporins, chloral hydrate, chloram-

phenicol, chlorpropamide, cimetidine, cisapride, clofibrate, clomipramine, corticosteroids, co-trimoxazole, cyclophosphamide, danazol, desipramine, dextrothyroxine, diclofenac, diflunisal, disulfiram, doxepin, erythromycin, etodolac, fluconazole, fluroxymesterone, fosphenytoin, gemfibrozil, glucagon, hydantoin, ifosfamide, influenza virus vaccines, imipramine, indomethacin, isoniazid, itraconazole, ketoconazole, ketolorac, lepirudin, loop diuretics, lovastatin, low-molecular-weight heparins, meclizine, mefenamic acid, methyltestosterone, metronidazole, miconazole, moricizine, nabumetone, naproxen, nalidixic acid, neomycin, nortriptyline, NSAIDs, omeprazole, oxandrolone, penicillins, phenylbutazones, phenytoin, piroxicam, propafenone, propoxyphene, protriptyline, quinidine, quinine, quinolones, reteplase, salicylates, stanozolol, streptokinase, sulfamethoxazole, sulfipyrazone, sulindac, tamoxifen, testosterone, thioamines, thyroid hormones, tomentin, urokinase: Increased anticoagulant effects aminoglutethimide, ascorbic acid, barbiturates, carbamazepine, cholestyramine, corticosteroids, dicloxacillin, estrogen, ethanol, ethchlorvynol, etretinate, glutethimide, griseofulvin, nafcillin, oral contraceptives, rifampin, spironolactone, sucralfate, thiazide diuretics, thiopurines, trazodone, vitamin K: Decreased anticoagulant effects aminoglycosides, mineral oil, tetracycline, vitamin E: Interference with vitamin K, leading to increased anticoagulant effects

FOODS

enteral products and foods high in vitamin K, such as dark green leafy vegetables:

Interference with anticoagulant effects

ACTIVITIES

alcohol use: Possibly increased or decreased anticoagulation

Adverse Reactions

CNS: Fever, headache

EENT: Blurred vision, mouth ulcers, pharyngitis

GI: Abdominal cramps, diarrhea, hepatic dysfunction, hepatitis, nausea, steatorrhea

GU: Albuminuria, anuria, priapism, red-orange urine, renal tubular necrosis

HEME: Agranulocytosis, anemia, atypical mononuclear cells, eosinophilia, hemorrhage, leukocytosis, leukopenia, RBC aplasia, thrombocytopenia

SKIN: Alopecia, exfoliative dermatitis, jaundice, necrosis of the skin and tissues evidenced by gangrene and purple toes, urticaria

Nursing Considerations

• Watch for PT to become prolonged 6 hours after anisindione administration, although maximum therapeutic effects may take 48 to 72 hours to appear.

WARNING Watch for signs of overanticoagulation, such as microscopic hematuria, excessive menstrual bleeding, melena, petechiae, and bleeding from superficial trauma, such as tooth brushing or shaving.

• Monitor INR, CBC, fecal occult blood test, and urinalysis results for signs of overanticoagulation.

PATIENT TEACHING

• Advise patient to avoid alcohol, salicylates, and drastic changes in his intake of vitamin K-rich food.

• Instruct patient to promptly report pregnancy to prescriber.

• Provide patient with a list of foods rich in vitamin K. Advise him to eat consistent daily amounts of vitamin K.

• Urge patient to consult prescriber before having dental work or elective surgery.

• Tell patient to immediately report unusual bleeding, bruising, red or red-orange urine, red or tarry black stools, diarrhea, bleeding from gums or nose, or excessive bleeding from minor cuts or scratches.

anistreplase

(anisoylated plasminogen-streptokinase activator complex)

Eminase

Class and Category

Chemical class: p-Anisoylated derivative of the Lys-plasminogen-streptokinase activator complex

Therapeutic class: Thrombolytic enzyme

Pregnancy category: C

Indications and Dosages

↗ To treat acute MI, lyse thrombi that are

obstructing coronary arteries, reduce infarct size, improve ventricular function after acute MI, reduce mortality from acute MI

I.V. INFUSION

Adults. 30 units injected over 2 to 5 min.

Route	Onset	Peak	Duration
I.V.	Immediate	20 min– 2 hr	4–6 hr

Mechanism of Action

Indirectly promotes conversion of plasminogen to plasmin, an enzyme that breaks down fibrin clots, fibrinogen, and other plasma proteins, including procoagulant factors V and VIII.

Incompatibilities

Don't add other drugs to anistreplase solution or infuse other drugs through same I.V. line.

Contraindications

Active internal bleeding, arteriovenous malformation or aneurysm, bleeding diathesis, history of stroke, hypersensitivity to anistreplase or streptokinase, intracranial neoplasm, intracranial or intraspinal surgery or trauma within past 2 months, severe uncontrolled hypertension

Interactions

DRUGS

aspirin, dipyridamole, and other drugs that alter platelet function; heparin; vitamin K antagonists: Possibly increased risk of bleeding if administered before anistreplase

Adverse Reactions

CNS: Dizziness, fever, headache, intracranial hemorrhage

CV: Ankle edema, arrhythmias (especially accelerated idioventricular rhythm, conduction disorders, premature ventricular beats, sinus bradycardia, ventricular fibrillation, ventricular tachycardia), hypotension, vasculitis

EENT: Epistaxis

GI: Abdominal pain or swelling, constipation, GI bleeding, nausea, vomiting

GU: Hematuria, proteinuria, vaginal bleeding

HEME: Bleeding tendency, eosinophilia, mild to severe hemorrhage

MS: Arthralgia, back pain, joint stiffness, myalgia

RESP: Bronchospasm, dyspnea, hemoptysis

SKIN: Flushing, pruritus, rash, urticaria

Other: Anaphylaxis (rare), angioedema

Nursing Considerations

- Use anistreplase cautiously in patients with acute pericarditis; cerebrovascular disease; hemorrhagic ophthalmic conditions; history of major surgery, GI or GU bleeding, or trauma within past 10 days; hypertension; mitral stenosis with atrial fibrillation; pregnancy; septic thrombophlebitis; severe hepatic or renal disease; or subacute bacterial endocarditis.
- Reconstitute anistreplase by slowly directing 5 ml of sterile water for injection USP or sodium chloride for injection against side of vial. Then gently roll vial to mix dry powder and fluid and minimize foaming. Don't shake vial. The resulting solution should be colorless to pale yellow and transparent.
- Before administering, inspect solution for particles and discoloration. If present, discard and reconstitute drug from a new vial. Then withdraw entire contents of vial. Don't dilute reconstituted solution further or add it to I.V. fluid. Don't add other drugs to vial or syringe that contains anistreplase. Discard drug if not given within 30 minutes after reconstitution.
- For maximum effectiveness, expect to administer anistreplase as soon as possible after onset of MI symptoms.
- Closely monitor all puncture sites, such as catheter insertion and needle puncture sites, for bleeding.
- Don't give I.M. injections, and avoid handling patient unnecessarily during anistreplase therapy. Perform venipuncture only when necessary.
- If an arterial puncture is needed after anistreplase administration, use an arm vessel that allows easy manual compression. Apply a pressure dressing afterward, and check puncture site often for bleeding.
- Use continuous cardiac monitoring because arrhythmias may occur during reperfusion. Keep antiarrhythmics on hand during anistreplase therapy, and manage arrhythmias using facility policy.
- Keep epinephrine nearby for anaphylaxis.
- Know that anistreplase may be less effective if given more than 5 days after anistreplase or streptokinase administration. This

occurs because patient may have developed antistreptokinase antibodies, which makes him more resistant to the drug and drug therapy less effective. Elevated serum antistreptokinase antibody levels and reduced drug effectiveness can persist for 5 days to 12 months.

- Closely monitor blood coagulation test results. The drug markedly decreases plasminogen and fibrinogen levels and increases thrombin time, APTT, and PT.

PATIENT TEACHING

- Instruct patient to report adverse reactions immediately, especially bleeding, dizziness, and chest pain.

antihemophilic factor (recombinant), plasma/albumin-free method (rAHF-PFM)

Advate, Kogenate FS, Xyntha

antihemophilic factor (human)

Alphanate

antihemophilic factor—von Willebrand factor complex (human, dried, pasteurized)

Humate-P

Class and Category

Chemical class: Recombinant protein

Therapeutic class: Antihemophilic factor

Pregnancy category: C

Indications and Dosages

- ↗ *To prevent and control bleeding episodes in patients with hemophilia A and factor VIII inhibitors not exceeding 10 Bethesda Units/ml*

I.V. INJECTION

Adults and children. Highly individualized.

For early hemarthrosis, muscle bleeding episode, or mild oral bleeding episode: Dose given to achieve peak post-infusion factor VIII activity in blood (determined by multiplying dose given/kg body weight by 2) 20% to 40% of normal with infusions every 12 to 24 hr for 1 to 3 days until bleeding episode resolved. *For more extensive hemarthrosis, muscle bleeding episode, or hematoma:* Dose given to achieve peak post-infusion factor VIII activity in blood 30% to 60% of normal with infusions every 12 to 24 hr for 3 or more days until pain and disability are resolved. *For life-threatening bleeding episodes:* Dose given to achieve peak postinfusion factor VIII activity in blood 60% to 100% with infusions every 8 to 24 hr until bleeding episode stops.

- ↗ *To prevent and control perioperative bleeding in patients with hemophilia A*

I.V. INJECTION

Adults and children. Highly individualized.

For minor surgery, including tooth extraction: Dose given to achieve peak postinfusion factor VIII activity in blood (determined by multiplying dose given/kg body weight by 2) between 60% and 100% of normal, given as a single bolus infusion within 1 hr of operation, with optional additional dose every 12 to 24 hr, as needed. *For major surgery:* Dose given to achieve peak postinfusion factor VIII activity in blood 80% to 100% before and after surgery with infusions every 8 to 24 hr.

I.V. INJECTION (KOGENATE FS)

Adults and children. Highly individualized

based on this formula: Body weight (kg) × desired factor VIII rise (international units/dL or % of normal) × 0.5 (international units/kg per international units/dL). *For minor surgery, including tooth extraction:* 15 to 30 international units/kg to achieve desired factor VIII rise to 30% to 60% of normal with injections repeated every 12 to 24 hr until bleeding has resolved. *For major surgery:* 50 international units/kg preoperatively to achieve a desired factor VIII rise to 100% of normal with dosage repeated 6 to 12 hr after initial dose as needed, and for 10 to 14 days thereafter, as needed, until healing is complete.

I.V. INFUSION (XYNTHA)

Adults and children. Highly individualized based on this formula: Body weight (kg) \times desired factor VIII rise (international units/dL or % of normal) \times 0.5 (international units/kg per international units/dL). *For minor surgery, including tooth extraction:* Desired factor VIII rise is 30% to 60% of normal with infusions every 12 to 24 hr for 3 to 4 days or until adequate local hemostasis is achieved (for tooth extraction, a single infusion plus oral antifibrinolytic therapy within 1 hr may be sufficient). *For major surgery:* Desired factor VIII rise is 60% to 100% of normal with infusions every 8 to 24 hr until adequate local hemostasis and wound healing are achieved.

➤ *To prevent or treat bleeding in hemophilia A*

I.V. INJECTION (HUMATE-P)

Adults. Highly individualized. *For mild hemorrhage, such as early joint or muscle bleed or severe epistaxis:* Loading dose of 15 international units/kg to achieve factor VIII:C plasma level about 30% of normal, with half the loading dose repeated once or twice daily for 1 to 2 days as needed. *For moderate hemorrhage, such as advanced joint or muscle bleed; neck, tongue, or pharyngeal hematoma without airway compromise; tooth extraction; or severe abdominal pain:* Loading dose of 25 international units/kg to achieve factor VIII:C plasma level about 50% of normal, followed by 15 international units/kg every 8 to 12 hr for first 1 to 2 days to maintain factor VIII:C plasma level at 30% of normal, and then 15 international units/kg once or twice daily for total of up to 7 days or until adequate wound healing. *For life-threatening hemorrhage, as may occur in major surgery; GI bleeding; neck, tongue, or pharyngeal hematoma with potential for airway compromise; intracranial, intra-abdominal, or intrathoracic bleeding; or fractures:* Loading dose of 40 to 50 international units/kg, followed by 20 to 25 international units/kg every 8 hr to maintain factor VIII:C plasma level at 80% to 100% of normal for 7 days, followed by 20 to 25 international units/kg once or twice daily for another 7 days to maintain factor VIII:C level at 30% to 50% of normal.

I.V. INJECTION (KOGENATE FS)

Adults and children. Highly individualized

based on this formula: Body weight (kg) \times desired factor VIII rise (international units/dL or % of normal) \times 0.5 (international units/kg per international units/dL). *For early hemarthrosis or minor muscle or oral bleeds:* 10 to 20 international units/kg to achieve desired factor VIII rise of 20% to 40% of normal, dosage repeated, if needed. *For moderate bleeding into muscles, mild head trauma, or bleeding into oral cavity:* 15 to 30 international units/kg to achieve desired factor VIII rise of 30% to 60% of normal with injections every 12 to 24 hr until bleeding has resolved. *For major GI bleeding; intracranial, intra-abdominal or intrathoracic bleeding; or fractures:* Initial dose of 40 to 50 international units/kg followed by repeat dose of 20 to 25 international units/kg to achieve desired factor VIII rise of 60% to 100% of normal with injections of 20 to 25 international units/kg repeated every 8 to 24 hr until bleeding has resolved.

I.V. INFUSION (XYNTHA)

Adults and children. Highly individualized based on this formula: Body weight (kg) \times desired factor VIII rise (international units/dL or % of normal) \times 0.5 (international units/kg per international units/dL). *For early hemarthrosis or minor muscle or oral bleeds:* Desired factor VIII rise is 20% to 40% of normal with infusions every 12 to 24 hr for at least 1 day, depending on the severity of the bleeding episode. *For moderate bleeding into muscles, mild head trauma, or bleeding into the oral cavity:* Desired factor VIII rise is 30% to 60% of normal with infusions every 12 to 24 hr for 3 to 4 days or until adequate local hemostasis is achieved. *For major GI bleeding; intracranial, intra-abdominal, or intrathoracic bleeding; or fractures:* Desired factor VIII rise is 60% to 100% of normal with infusions every 8 to 24 hr until bleeding has resolved.

➤ *To treat spontaneous and trauma-induced bleeding episodes and prevent excessive bleeding during and after surgery in patients with von Willebrand disease when use of desmopressin is inadequate*

I.V. INJECTION (HUMATE-P)

Adults and children. 40 to 80 international units/kg every 8 to 12 hr as needed.

↗ *To prevent excessive bleeding during and after surgery in patients with von Willebrand disease*

I.V. INJECTION (HUMATE-P)

Adults and children. Highly individualized. *For emergency surgery:* Loading dose of 50 to 60 international units/kg, followed by half the loading dose every 6 to 12 hr as needed. *For preplanned surgery:* Individualized loading dose based on patient need 1 to 2 hr before surgery, followed by half the loading dose every 6 to 12 hr for at least 12 hr (oral surgery), 48 hr (minor surgery), or 72 hr (major surgery).

Route	Onset	Peak	Duration
I.V.	Immediate	5 min	Unknown

Mechanism of Action

Provides supplemental factor VIII, the coagulation factor required for blood to clot that's missing in patients with hemophilia A and diminished in patients with factor VIII inhibitors. After blood clots, bleeding stops.

Contraindications

Life-threatening, immediate hypersensitivity reactions, including anaphylaxis, experienced with prior administration of drug or exposure to mouse or hamster proteins

Adverse Reactions

CNS: Dizziness, fever, headache, rigidity

CV: Chest pain, hypotension

EENT: Taste perversion

ENDO: Hot flashes

GI: Abdominal pain, diarrhea, nausea, vomiting

HEME: Bleeding tendency, decreased coagulation factor VIII, decreased hematocrit, hematoma, hemolytic anemia

MS: Joint swelling, lower limb edema

RESP: Dyspnea, shortness of breath

SKIN: Diaphoresis, pruritus, rash, urticaria

Other: Anaphylaxis, angioedema, catheter-related infection, injection site reactions

Nursing Considerations

- Check to confirm that clotting defect is factor VIII deficiency (Kogenate FS or Xyntha only) or von Willebrand disease (Humate-P only) before giving antihemophilic factor (recombinant) because drug isn't effective in treating other coagulation

factor deficiencies.

- Reconstitute Advate or Alphanate using sterile water for injection. Bring both drug and diluent to room temperature; then clean stoppers with antiseptic solution and let dry. Remove protective covering from one end of double-ended needle and insert through center of diluent stopper. Remove protective covering from other end of double-ended needle. Invert diluent bottle over upright drug bottle; then rapidly insert free end of needle through drug stopper at center. The vacuum in bottle will draw in the diluent. Then disconnect the two bottles by removing needle from diluent bottle stopper, and remove the needle from drug bottle. Swirl gently until all drug is dissolved. Avoid shaking to prevent foaming and degradation of drug. Administer in a separate line within 3 hours of reconstitution.
- Reconstitute Humate-P, Kogenate FS, and Xyntha according to manufacturer instructions in package insert.
- Take patient's pulse before and periodically during drug administration. If pulse rate increases significantly, reduce administration rate or temporarily halt injection to let pulse rate return to preadministration level before resuming administration.
- To administer Advate or Alphanate, use only plastic material because protein in drug will adhere to glass. Attach filter needle to syringe and draw back plunger to draw air into syringe. Insert needle into reconstituted drug vial. Inject air into bottle and then withdraw drug from vial. Remove and discard filter needle from syringe, attach a suitable needle, and inject I.V. bolus at no more than 10 ml/min over no more than 5 minutes.
- To give Humate-P, slowly inject I.V. bolus at no more than 4 ml/min using a venipuncture or other suitable I.V. injection set.
- To give Kogenate FS, check patient's pulse; then slowly inject intravenously over 1 to 15 minutes, checking pulse rate throughout administration. If pulse rises significantly, slow administration or temporarily stop delivery to let pulse rate return to normal; then continue administration.
- To administer Xyntha, slowly infuse intravenously over several minutes at a rate comfortable for the patient. Don't infuse

in tubing or container that contains other drugs.

- Monitor patient's plasma factor VIII levels (and von Willebrand factor: Ristocetin cofactor if patient has von Willebrand disease) during and after treatment to ensure adequate levels have been reached and are being maintained, as ordered.
- Monitor patient for anaphylaxis, and have emergency equipment nearby.
- After giving drug, monitor patient for formation of neutralizing antibodies to factor VIII, a known complication in hemophilia A treatment that may cause continued bleeding. Obtain laboratory analysis to detect neutralizing antibodies, as ordered.
- Watch for hemolysis when giving large doses to patients with blood types A, B, and AB.

PATIENT TEACHING

- Teach patient and caregivers how to administer antihemophilic factor (recombinant) at home in an emergency.
- Explain that drug may be stored in the refrigerator or at room temperature but that it shouldn't be exposed to temperatures above 77° F (25° C) or below freezing because they may alter effectiveness.
- Instruct patient to stop drug and seek emergency help immediately if he has an acute allergic reaction, such as hives, chest tightness, wheezing, low blood pressure, or fainting, during or after administration.

antithrombin III, human

(AT-III, heparin co-factor I)

ATnativ, Thrombate III

Class and Category

Chemical class: Alpha₂-globulin
Therapeutic class: Anticoagulant,
antithrombotic
Pregnancy category: C

Indications and Dosages

- ↗ *To treat patients with hereditary antithrombin III (AT-III) deficiency who are undergoing surgery or obstetric procedures or who have thromboembolism*

I.V. INJECTION

Adults and children. *Initial:* Individualized (based on weight, degree of AT-III deficiency, and desired level of AT-III to be achieved) sufficient to increase AT-III activity to 120% of normal, given at 50 to 100 international units/min. *Maintenance:* Individualized dosage sufficient to keep AT-III activity at 80% or more of normal, administered every 24 hr, continued for 2 to 8 days, depending on the patient's condition and history and prescriber's judgment. A pregnant, immobilized, or postsurgical patient may need more prolonged therapy.

Route	Onset	Peak	Duration
I.V.	Immediate	Unknown	4 days

Mechanism of Action

Inhibits blood coagulation by inactivating thrombin; activated forms of factors IX, X, XI, and XII; and plasmin.

Interactions

DRUGS

heparin: Enhanced anticoagulant effect

Adverse Reactions

CNS: Chills, dizziness, fever, light-headedness

CV: Chest pain or tightness, hypotension, vasodilation

EENT: Unpleasant taste

GI: Abdominal cramps, bowel fullness, nausea

GU: Diuresis

HEME: Hematoma

RESP: Dyspnea

SKIN: Oozing lesions, urticaria

Nursing Considerations

- Reconstitute AT-III with 10 ml sterile water for injection (provided by manufacturer) or alternate solution, such as normal saline solution or D₅W injection. Don't shake vial during reconstitution. Let solution come to room temperature before administration. If desired, dilute reconstituted solution further, using same diluent.

WARNING Don't use diluent that contains benzyl alcohol to reconstitute drug for a neonate. It can cause a fatal toxic syndrome with metabolic acidosis, CNS depression, respiratory problems, renal failure, hypotension, seizures, and

intracranial hemorrhage.

- Don't refrigerate reconstituted solution. Use within 3 hours; discard unused portion.
- Administer AT-III alone. Don't mix it with other drugs or solutions.
- If after 30 minutes the initial dose doesn't increase AT-III activity to 120% of normal, expect prescriber to increase dosage.
- If patient requires a dosage increase, monitor AT-III activity more often and expect to adjust dosage accordingly.
- To avoid bleeding, anticipate a reduction in heparin dosage during AT-III therapy.
- If mild adverse reactions occur, decrease infusion rate, as prescribed. If severe reactions occur, discontinue infusion, as prescribed, until they subside.
- Evaluate serum AT-III level twice daily until dosage is stabilized. After that, evaluate level once daily, just before a dose.

PATIENT TEACHING

- Tell patient that blood will be drawn periodically to guide dosage adjustments.

apomorphine hydrochloride

Apokyn

Class and Category

Chemical class: Nonergoline dopamine agonist

Therapeutic class: Hypomobility antiparkinsonian

Pregnancy category: C

Indications and Dosages

↗ *To treat hypomobility "off" episodes (end-of-dose wearing off and unpredictable on/off episodes) in advanced Parkinson's disease*

SUBCUTANEOUS INJECTION

Adults. *Initial:* 0.2 ml (2 mg) p.r.n. adjusted as needed in 0.1-ml (1-mg) increments every few days. *Maximum:* 0.6 ml (6 mg).

DOSAGE ADJUSTMENT For patients who tolerate 0.2 ml (2 mg) but have no response, a 0.4-ml (4-mg) dose may be given under medical supervision, with standing and supine blood pressure checked every 20 min for 1 hr at the next observed "off" period, as long as it is at least 2 hr after the initial 0.2-ml (2-mg) test dose. If tolerated, a dose

0.1 ml (1 mg) lower may be given p.r.n. and increased in 0.1-ml (1-mg) increments every few days as needed to a maximum dose of 0.6 ml (6 mg).

If patient doesn't tolerate a 0.4-ml (4-mg) test dose, a 0.3-ml (3-mg) test dose may be given under medical supervision, with standing and supine blood pressure checked every 20 min for 1 hr at the next observed "off" period, as long as it is at least 2 hr after the initial 0.4-ml (4-mg) test dose. If tolerated, a 0.2-ml (2-mg) dose can be started p.r.n. and increased to no more than 0.3 ml (3 mg) if needed after a few days.

For patients with mild to moderate renal impairment, the initial dose should be reduced to 0.1 ml (1 mg).

Route	Onset	Peak	Duration
SubQ	10–60 min	Unknown	Unknown

Mechanism of Action

May stimulate postsynaptic dopamine D₂ receptors in the caudate-putamen of the brain. As a result, apomorphine improves motor function and activity levels in patients with Parkinson's disease.

Contraindications

Concurrent use of 5-HT₃ antagonists, such as alosetron, dolasetron, granisetron, ondansetron, and palonosetron; hypersensitivity to apomorphine or its components, including sodium metabisulfite

Interactions**DRUGS**

5-HT₃ antagonists: Increased risk of profound hypotension and loss of consciousness

antihypertensives, vasodilators: Increased risk of serious adverse reactions, such as hypotension, MI, and bone or joint injuries
dopamine antagonists (such as butyrophenones, metoclopramide, phenothiazines, thioxanthenes): Decreased apomorphine effectiveness

drugs that prolong QT interval: Increased risk of torsades de pointes

entacapone, tolcapone: Increased risk of tachycardia, hypertension, and arrhythmias

ACTIVITIES

alcohol use: Increased risk of hypotension

Adverse Reactions

CNS: Aggravated Parkinson's disease, anxiety, confusion, depression, dizziness, drowsiness, dyskinesia, euphoria, fatigue, hallucinations, headache, insomnia, somnolence, weakness, yawning

CV: Angina, chest pain, congestive heart failure, edema, MI, orthostatic hypotension, prolonged QT interval

EENT: Rhinorrhea

GI: Constipation, diarrhea, nausea, vomiting

GU: UTI

MS: Arthralgia, back or limb pain

RESP: Dyspnea, pneumonia, tachypnea

SKIN: Contact dermatitis, diaphoresis, ecchymosis, flushing, pallor

Other: Dehydration; injection site bruising, granuloma, or pruritus; intense urges to perform certain activities, such as gambling and sexual acts

Nursing Considerations

- Use apomorphine cautiously in patients with hepatic or renal insufficiency.
- An antiemetic, such as trimethobenzamide 300 mg t.i.d., should be started 3 days before apomorphine starts and continue for at least the first 2 months of therapy. Apomorphine may cause severe nausea and vomiting, even with an antiemetic.
- Monitor patient's blood pressure closely because drug can cause severe orthostatic hypotension.
- Give a 0.2-ml (2-mg) test dose of apomorphine, as prescribed, and then check patient's supine and standing blood pressure 20, 40, and 60 minutes later.
- Monitor patient closely if he has an increased risk of prolonged QT interval, as from hypokalemia, hypomagnesemia, bradycardia, use of certain drugs, or genetic predisposition. QT-interval prolongation may lead to torsades de pointes.
- Monitor patient for evidence of apomorphine abuse. Although rare, drug may cause psychosexual stimulation and increased libido, which may cause patient to use it more often than needed for reducing Parkinson's disease symptoms.
- Assess patient regularly for skin changes because melanoma risk is higher in those with Parkinson's disease. It isn't clear whether the risk is increased by the disease or by its treatment.

PATIENT TEACHING

- Explain that an antiemetic will be prescribed starting 3 days before first apomorphine dose. Urge patient to take the antiemetic exactly as prescribed. Explain that it will be needed for 2 months or longer during apomorphine therapy.
- Explain that a test dose will determine response and drug's effects on blood pressure before patient goes home with drug.
- Teach patient how to use dosing pen and how to give drug subcutaneously.
- Emphasize that apomorphine doses are expressed as milliliters, not milligrams. Tell patient to draw up each dose carefully to reduce the chance of dosage error.
- Instruct patient to rotate injection sites in a systematic manner.
- Stress importance of taking apomorphine only as prescribed because serious adverse reactions may occur.
- Advise patient to avoid hazardous activities until drug's CNS effects are known. In particular, caution patient that apomorphine increases the risk of falling asleep suddenly, without feeling sleepy.
- Urge patient to have regular skin examinations by a dermatologist or other qualified health professional.
- Instruct patient to notify prescriber about intense urges, such as for gambling or sex, because dosage may need to be reduced or drug discontinued.

aprepitant

Emend

fosaprepitant dimeglumine

Emend for Injection

Class and Category

Chemical class: Substance P/neurokinin 1 (NK1) receptor antagonist

Therapeutic class: Antiemetic

Pregnancy category: B

Indications and Dosages

- ↗ *To prevent acute and delayed nausea and vomiting associated with highly emetogenic chemotherapy, including high-dose cisplatin*

CAPSULES

Adults. 125 mg 1 hr before chemotherapy treatment, followed by 80 mg daily in morning on next 2 days.

I.V. INFUSION

Adults. 115 mg 30 min before chemotherapy begins (day 1 only).

↗ *To prevent postoperative nausea and vomiting*

CAPSULES

Adults. 40 mg within 3 hr before induction of anesthesia

Route	Onset	Peak	Duration
P.O., I.V.	Unknown	4 hr	Unknown

Mechanism of Action

Crosses the blood–brain barrier to occupy brain NK1 receptors, which prevents nerve transmission of signals that cause nausea and vomiting.

Contraindications

Hypersensitivity to aprepitant, polysorbate 80, or their components; use of astemizole, cisapride, pimozide, or terfenadine

Interactions**DRUGS**

carbamazepine, phenytoin, rifampin:

Possibly decreased blood aprepitant level
corticosteroids: Increased blood corticosteroid level

CYP2C9 metabolizers (such as phenytoin, tolbutamide, and warfarin): Decreased blood level and effectiveness of CYP2C9 metabolizers

CYP3A4 inhibitors (such as clarithromycin, diltiazem, itraconazole, ketoconazole, nefazodone, nelfinavir, and troleandomycin): Increased blood aprepitant level

CYP3A4 substrates (such as astemizole, benzodiazepines, cisapride, docetaxel, etoposide, ifosfamide, imatinib, irinotecan, paclitaxel, pimozone, terfenadine, vinblastine, vincristine, and vinorelbine): Increased level of CYP3A4 substrates, resulting in possibly serious or life-threatening adverse reactions

oral contraceptives: Possibly decreased effectiveness of oral contraceptives

paroxetine: Possibly decreased blood level of both drugs

Adverse Reactions

CNS: Anxiety, asthenia, confusion, depres-

sion, dizziness, fatigue, fever, headache, insomnia, malaise, peripheral or sensory neuropathy, somnolence

CV: Deep vein thrombosis, edema, hypertension, hypotension, tachycardia

EENT: Increased salivation, mucous membrane alteration, nasal discharge, pharyngitis, stomatitis, taste perversion, tinnitus, vocal disturbance

ENDO: Hot flashes, hyperglycemia

GI: Abdominal pain, anorexia, constipation, diarrhea, dysphagia, elevated liver function test results, epigastric discomfort, flatulence, gastritis, gastroesophageal reflux, heartburn, hiccups, nausea, obstipation, vomiting

GU: Dysuria, elevated BUN and serum creatinine levels, hematuria, leukocyturia, renal insufficiency

HEME: Anemia, febrile neutropenia, leukocytosis, thrombocytopenia

MS: Muscle weakness, myalgia, pelvic pain

RESP: Cough, dyspnea, non–small-cell lung carcinoma, pneumonitis, pulmonary embolism, respiratory insufficiency, respiratory tract infection

SKIN: Alopecia, diaphoresis, flushing, pruritus, rash, urticaria

Other: Anaphylaxis, angioedema, dehydration, hypokalemia, hyponatremia, infusion site pain or induration, malignant neoplasm, septic shock, weight loss

Nursing Considerations

- Use caution when giving aprepitant to patients with severe hepatic insufficiency because drug's effects on such patients aren't known.
- For maximum antiemetic effects, expect to administer aprepitant with dexamethasone and a 5-HT₃ antagonist, such as dolasetron, granisetron, or ondansetron.
- Drug is given intravenously only as the first dose 30 minutes before chemotherapy. Later doses are given orally.
- To reconstitute parental aprepitant, inject 5 ml normal saline for injection along vial wall to prevent foaming. Swirl vial gently. Withdraw contents from vial and add to an infusion bag containing 110 ml normal saline solution. Gently invert the bag two or three times. Administer over 15 minutes. Reconstituted solution may be stored at room temperature for 24 hours.

PATIENT TEACHING

- Instruct patient to take 125-mg dose of oral aprepitant 1 hour before chemotherapy, 80-mg dose in the morning for 2 days after chemotherapy, or 40-mg dose within 3 hours before induction of anesthesia.
- Tell female patients taking oral contraceptives to use an alternative or backup method of contraception during aprepitant therapy and for 1 month after last dose because drug reduces effectiveness of oral contraceptives.
- Tell patient taking warfarin to have clotting status monitored closely for 2 weeks after first aprepitant dose, especially every 7 to 10 days during each chemotherapy cycle in which the drug is used.
- Caution patient to inform prescriber of any drugs he's taking, including OTC drugs and herbal preparations, because they may interact with aprepitant.

arformoterol

Brovana

Class and Category

Chemical class: Selective beta₂-adrenergic agonist, sympathomimetic

Therapeutic class: Bronchodilator

Pregnancy category: C

Indications and Dosages

➤ *To provide maintenance treatment of bronchoconstriction in patients with COPD, including chronic bronchitis and emphysema*

INHALATION SOLUTION

Adults. 15 mcg (contents of one 2-ml vial) b.i.d. (morning and evening) via nebulization. Do not exceed 30 mcg daily.

Mechanism of Action

Attaches to beta₂ receptors on bronchial cell membranes, stimulating the intracellular enzyme adenylate cyclase to convert adenosine triphosphate to cyclic adenosine monophosphate (cAMP). The resulting increase in intracellular cAMP level relaxes bronchial smooth-muscle cells, stabilizes mast cells, and inhibits histamine release.

Contraindications

Hypersensitivity to arformoterol, racemic

formoterol, or its components; acute bronchospasm; symptoms of COPD

Interactions**DRUGS**

beta blockers: Decreased effectiveness of either drug

corticosteroids, methylxanthines such as aminophylline or theophylline, non-potassium-sparing (such as loop and thiazide)

diuretics: Increased risk of hypokalemia
drugs known to prolong the QT interval, MAO inhibitors, tricyclic antidepressants: Increased risk of life-threatening ventricular arrhythmias

thyroid hormones: Increased risk of coronary insufficiency

Adverse Reactions

CNS: Agitation, asthenia, circumoral paresthesia, fatigue, fever, headache, hypokinesia, insomnia, malaise, nervousness, paralysis, somnolence, stroke, tremor

CV: Angina, arrhythmias, atrial flutter, chest pain, congestive heart failure, dizziness, heart block, hyperlipemia, hypertension, hypertension, MI, palpitations, peripheral edema, prolonged QT interval

EENT: Abnormal vision, dry mouth, glaucoma, herpes simplex or zoster, oral candidiasis, rectal hemorrhage, sinusitis, voice alteration

ENDO: Hyperglycemia, hypoglycemia

GI: Constipation, diarrhea, gastritis, melena, nausea, pelvic pain, retroperitoneal hemorrhage, vomiting

GU: Cystitis, hematuria, nocturia, PSA elevation, pyuria, renal calculi

HEME: Leukocytosis

MS: Arthralgia, arthritis, back pain, leg or muscle cramps, neck rigidity

RESP: Bronchitis, bronchospasm, COPD, pulmonary congestion

SKIN: Discoloration, dryness, hypertrophy, photosensitivity, rash, urticaria

Other: Anaphylaxis, angioedema, dehydration, flulike syndrome, gout, hyperkalemia, hypokalemia, metabolic acidosis

Nursing Considerations

- Use cautiously in patients with cardiovascular disorders, especially insufficiency, cardiac arrhythmias, and hypertension; convulsive disorders; thyrotoxicosis; and unusual sensitivity to sympathomimetic

amines because arformoterol may cause significant adverse effects.

- Arformoterol shouldn't be used to relieve bronchospasm quickly because of its prolonged onset of action. Patients already taking the drug twice daily shouldn't take additional doses for exercise-induced bronchospasm.
- Arformoterol shouldn't be used with other inhaled, long-acting beta₂-agonists or with other medications containing long-acting beta₂-agonists.

WARNING Asthma-related deaths may increase in patients receiving salmeterol, a drug in the same class as arformoterol. Monitor patient closely, and notify prescriber immediately of any changes in patient's respiratory status.

- Watch for arrhythmias and changes in heart rate or blood pressure after use in patients with cardiovascular disorders because of drug's beta-adrenergic effects.

WARNING Stop arformoterol immediately and notify prescriber if patient develops paradoxical bronchospasm or an allergic reaction.

- Monitor patient's blood glucose level, especially if diabetic, and plasma potassium level, as ordered, because arformoterol may cause significant changes.

PATIENT TEACHING

- Advise patient to take doses 12 hours apart, morning and evening, for optimum effect. Caution against using drug more than every 12 hours.
- Teach patient to self-administer drug with a standard jet nebulizer connected to an air compressor and to use vial immediately after removing from foil package.
- Caution patient not to swallow solution.
- Tell patient to return unused vials to pouch and store arformoterol in the refrigerator.
- Instruct patient taking inhaled, short-acting beta₂-agonists on a regular basis to discontinue regular use of these drugs and to use them only for symptomatic relief of acute respiratory symptoms.
- Instruct patient to notify prescriber if he needs four or more oral inhalations of rapid-acting inhaled bronchodilator a day for 2 or more consecutive days, or if he uses more than one canister of rapid-acting bronchodilator in an 8-week period.

argatroban

Acova

Class and Category

Chemical class: N2-substituted derivative of arginine

Therapeutic class: Anticoagulant

Pregnancy category: B

Indications and Dosages

↗ *To prevent or treat thrombosis in patients with heparin-induced thrombocytopenia (HIT)*

I.V. INFUSION

Adults. 2 mcg/kg/min as a continuous infusion. *Maximum:* 10 mcg/kg/min.

DOSAGE ADJUSTMENT Dosage adjusted as prescribed to maintain patient's APTT at 1.5 to 3 times the initial baseline value, not to exceed 100 sec. Initial dosage reduced to 0.5 mcg/kg/min for patients with moderate hepatic impairment.

↗ *To prevent or treat thrombosis in patients with or at risk for HIT when undergoing percutaneous coronary intervention (PCI)*

I.V. INFUSION

Adults. *Initial:* 350 mcg/kg over 3 to 5 min followed by continuous infusion of 25 mcg/kg/min.

DOSAGE ADJUSTMENT Dosage adjusted as prescribed to keep activated clotting time (ACT) at 300 to 450 sec. If ACT is less than 300 sec, give additional I.V. bolus dose of 150 mcg/kg and increase infusion to 30 mcg/kg/min; if ACT exceeds 450 sec, reduce dosage to 15 mcg/kg/min. For dissection, impending abrupt closure, thrombus formation during PCI, or inability to reach or keep ACT above 300 sec, give additional bolus dose of 150 mcg/kg and increase infusion to 40 mcg/kg/min.

Route	Onset	Peak	Duration
I.V.	Immediate	3–4 hr	Unknown

Mechanism of Action

Forms a tight bond with thrombin, neutralizing this enzyme's actions, even when the enzyme is trapped within clots. Thrombin causes fibrinogen to convert to fibrin, which is essential for clot formation.

Contraindications

Active major bleeding, hypersensitivity to argatroban or its components

Interactions

DRUGS

alteplase, antineoplastic drugs, antiplatelets, antithymocyte globulin, heparin, NSAIDs, reteplase, salicylates, streptokinase, strontium chloride Sr 89, warfarin: Increased risk of bleeding

porfimer: Possibly decreased efficacy of porfimer photodynamic therapy

Adverse Reactions

CNS: Cerebrovascular bleeding, fever, headache

CV: Atrial fibrillation, cardiac arrest, hypotension, unstable angina, ventricular tachycardia

GI: Abdominal pain, anorexia, diarrhea, elevated liver function test results, GI bleeding, melena, nausea, vomiting

GU: Elevated BUN and serum creatinine levels, hematuria (microscopic), UTI

HEME: Hypoprothrombinemia, unusual bleeding or bruising

RESP: Cough, dyspnea, hemoptysis, pneumonia

SKIN: Bleeding at puncture site, rash

Other: Sepsis

Nursing Considerations

WARNING Argatroban isn't recommended for PCI patients with significant hepatic disease or AST/ALT levels three times or more the upper limits of normal.

- Reconstitute drug to 1 mg/ml before giving.
- Protect solution from direct sunlight.

WARNING Monitor patients with thrombocytopenia or those receiving daily doses of salicylates greater than 6 g for signs and symptoms of bleeding because they're at increased risk of bleeding from hypoprothrombinemia.

WARNING Expect to perform blood coagulation tests before and 2 hours after start of therapy because of the major risk of bleeding associated with argatroban. Be aware that coagulopathy must be ruled out before therapy starts. When giving drug to a patient undergoing PCI, expect to check ACT 5 to 10 minutes after each bolus and each infusion rate change and every 20 to 30 minutes during the PCI.

- Monitor the following patients for signs

and symptoms of bleeding because they're at increased risk during argatroban therapy: women with active menstruation; patients with vascular or organ abnormalities, such as severe uncontrolled hypertension, advanced renal disease, infective endocarditis, dissecting aortic aneurysm, diverticulitis, hemophilia, hepatic disease (especially if associated with a deficiency of vitamin K–dependent clotting factors), inflammatory bowel disease, or peptic ulcer disease; and those who have recently had a stroke, major surgery (including eye, brain, or spinal cord surgery), large vessel puncture or organ biopsy, lumbar puncture, spinal anesthesia, or major bleeding (including intracranial, GI, intraocular, retroperitoneal, or pulmonary bleeding).

- Whenever possible, avoid I.M. injections in patients receiving argatroban to decrease the risk of bleeding.
- Thrombin times may not be helpful for monitoring argatroban activity because the drug affects all thrombin-dependent coagulation tests.
- Expect dosage to be tapered before stopping to prevent the risk of rebound hypercoagulopathy; drug's effects last only a short time once drug is discontinued.

PATIENT TEACHING

- Inform patient that argatroban is a blood thinner that's given in the hospital by infusion into a vein. If he needs long-term anticoagulation, he'll be switched to another drug before discharge.
- Advise patient to immediately report unusual or unexplained bleeding, such as blood in urine, easy bruising, nosebleeds, tarry stools, and vaginal bleeding.
- Instruct patient to avoid injury while receiving argatroban. For example, suggest that he brush his teeth gently, using a soft-bristled toothbrush, and take special care when flossing.

aripiprazole

Abilify, Abilify Discmelt

Class and Category

Chemical class: Dihydrocarbotyryl

Therapeutic class: Atypical antipsychotic

Pregnancy category: C

Indications and Dosages

↗ *To treat acute schizophrenia; to maintain stability in patients with schizophrenia*

ORAL SOLUTION, ORALLY DISINTEGRATING

TABLETS, TABLETS

Adults. *Initial:* 10 or 15 mg daily. Increased to 30 mg daily, as needed, with dosage adjustments at 2-wk intervals. *Maintenance:* 15 mg daily.

↗ *To treat acute manic and mixed episodes in bipolar I disorder with or without psychotic features; to maintain stability in patients with bipolar I disorder; as adjunct with lithium or valproate in patients with bipolar I disorder*

ORAL SOLUTION, ORALLY DISINTEGRATING

TABLETS, TABLETS

Adults. *Initial:* 15 mg daily, increased to 30 mg daily, as needed. *Maintenance:* 15 to 30 mg daily. *Maximum:* 30 mg daily.

Children ages 10 to 17. *Initial:* 2 mg daily, increased after 2 days to 5 mg daily and then after 2 days to 10 mg daily. Increased in 5-mg increments, as needed, at 2-wk intervals. *Maintenance:* Lowest dose possible to maintain remission. *Maximum:* 30 mg daily.

↗ *As adjunct to treat depression in patients already taking an antidepressant*

ORAL SOLUTION, ORALLY DISINTEGRATING

TABLETS, TABLETS

Adults. *Initial:* 2 to 5 mg daily, with dosage increased to 5 mg daily at 1-wk intervals.

↗ *To treat agitation in schizophrenia or bipolar mania*

I.M. INJECTION

Adults. *Initial:* Depending on severity of agitation, 5.25 to 15 mg. May be repeated 2 or more hr later, as needed. *Maximum:* 30 mg daily.

↗ *To treat irritability associated with autistic disorder*

ORAL SOLUTION, ORALLY DISINTEGRATING

TABLETS, TABLETS

Children. *Initial:* 2 mg daily, with dosage increased after 1 wk to 5 mg daily and then after 1 wk to 10 mg daily and then after 1 wk to 15 mg daily, as needed.

DOSAGE ADJUSTMENT Dosage reduced to half normal amount when given with clarithromycin, fluoxetine, itraconazole, ketoconazole, paroxetine, or quinidine. Dosage doubled when given with carbamazepine.

Mechanism of Action

May produce antipsychotic effects through partial agonist and antagonist actions.

Aripiprazole acts as a partial agonist at dopamine (especially D₂) receptors and serotonin (especially 5-HT_{1A}) receptors. The drug acts as an antagonist at 5-HT_{2A} serotonin receptor sites.

Contraindications

Breast-feeding, hypersensitivity to aripiprazole or its components

Interactions

DRUGS

anticholinergics: Increased risk for potentially fatal elevation of body temperature
carbamazepine and other CYP3A4 inducers: Possibly increased clearance and decreased blood level of aripiprazole

clarithromycin, fluoxetine, paroxetine, quinidine, and other CYP2D6 inhibitors; ketoconazole and other CYP3A4 inhibitors:

Possibly inhibited aripiprazole elimination and increased blood level

CNS depressants: Increased CNS depression

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Abnormal gait, agitation, akathisia, anxiety, asthenia, cognitive and motor impairment, confusion, delusions, depression, dizziness, dream disturbances, dystonia, extrapyramidal reactions, fatigue, fever, hallucinations, headache, hostility, insomnia, intracranial hemorrhage, lethargy, light-headedness, mania, nervousness, neuroleptic malignant syndrome, paranoia, restlessness, schizophrenic reaction, seizures, somnolence, stroke (elderly), suicidal ideation, tardive dyskinesia, transient ischemic attack (elderly), tremor

CV: Arrhythmias, bradycardia, cardiopulmonary arrest, chest pain, circulatory collapse, deep vein thrombosis, elevated serum CK levels, heart failure, hypertension, MI, orthostatic hypotension, peripheral edema, prolonged QT interval, tachycardia

EENT: Blurred vision, conjunctivitis, dry mouth, hepatitis, increased salivation, laryngospasm, nasopharyngitis, oropharyngeal spasm, pharyngitis, rhinitis, sinusitis

ENDO: Hyperglycemia

GI: Abdominal discomfort, constipation, decreased appetite, diarrhea, difficulty swal-

lowing, GI bleeding, indigestion, jaundice, nausea, vomiting

GU: Renal failure, urinary incontinence

HEME: Agranulocytosis, anemia, leukopenia, neutropenia, thrombocytopenia

MS: Arthralgia, elevated blood CK level, muscle spasms, musculoskeletal pain, myalgia, neck and limb rigidity, rhabdomyolysis

RESP: Apnea, aspiration, asthma, cough, dyspnea, pneumonia, pulmonary edema or embolism, respiratory failure

SKIN: Diaphoresis, dry skin, ecchymosis, pruritus, rash, ulceration, urticaria

Other: Anaphylaxis, angioedema, dehydration, flulike symptoms, heat stroke, weight gain

Nursing Considerations

- Aripiprazole shouldn't be used to treat dementia-related psychosis in the elderly because of an increased risk of death.
- Use cautiously in patients with CV disease, cerebrovascular disease, or conditions that would predispose them to hypotension. Also use cautiously in those with a history of seizures or with conditions that lower the seizure threshold, such as Alzheimer's disease.
- Also use cautiously in elderly patients because of increased risk of serious adverse cerebrovascular effects, such as stroke and transient ischemic attack.
- Oral solution may be given on a milligram-per-milligram basis in place of tablets up to 25 mg. For example, if patient needs 30 mg of tablet and is switched to oral solution, expect to give 25 mg of solution.
- Inject parenteral form slowly, deep into the muscle, and never I.V. or subcutaneously.
- Monitor patient for difficulty swallowing or excessive somnolence, which could predispose to accidental injury or aspiration.

WARNING Aripiprazole rarely may cause neuroleptic malignant syndrome, tardive dyskinesia, and seizures. Monitor patient closely throughout therapy, and take safety precautions as needed.

- Monitor patient's blood glucose level routinely; risk of hyperglycemia may increase.
- Watch patients closely (especially children, adolescents, and young adults) for suicidal tendencies, particularly when therapy starts and dosage changes, because depres-

sion may worsen temporarily during these times.

- Monitor patient's CBC, as ordered, because serious adverse hematologic reactions may occur, such as agranulocytosis, leukopenia, and neutropenia. Assess more often during first few months of therapy if patient has a history of drug-induced leukopenia or neutropenia or a significantly low WBC count. If abnormalities occur during therapy, watch for fever or other signs of infection, notify prescriber and, if severe, expect drug to be stopped.

PATIENT TEACHING

- Instruct patient prescribed orally disintegrating tablets to open the blister pack only when ready to take the tablet. Tell him to peel back the foil and not to push tablet through the foil because doing so could damage the tablet. Tell him to place the tablet on his tongue without breaking it and let it dissolve. If needed, he may take a drink.
- Advise patient to get up slowly from a lying or sitting position during aripiprazole therapy to minimize orthostatic hypotension.
- Urge patient to avoid alcohol during aripiprazole therapy.
- Instruct patient to avoid hazardous activities until drug's effects are known.
- Urge patient to avoid activities that raise body temperature suddenly, such as strenuous exercise and exposure to extreme heat, and to compensate for situations that cause dehydration, such as vomiting or diarrhea.
- Instruct patient to inform all prescribers of any drugs he's taking, including OTC drugs, because of risk of interactions.
- Advise female patient of childbearing age to notify prescriber if she intends to become or suspects that she is pregnant during therapy.
- Instruct diabetic patient taking the oral solution to monitor blood glucose levels closely because each milliliter of solution contains 400 mg of sucrose and 200 mg of fructose.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.

armodafinil

Nuvigil

Class and Category

Chemical class: Diphenylmethyl sulfinylacetamide

Therapeutic class: CNS stimulant

Pregnancy category: C

Indications and Dosages

↗ *To treat narcolepsy or as adjunct to standard therapy for excessive daytime sleepiness in obstructive sleep apnea/hypopnea syndrome*

TABLETS

Adults. 150 or 250 mg once daily in the morning.

↗ *To improve daytime wakefulness in patients with excessive sleepiness from circadian rhythm disruption (shift-work sleep disorder)*

TABLETS

Adults. 150 mg once daily about 1 hr before start of work shift.

DOSAGE ADJUSTMENT Decreased dosage recommended for patients who are elderly, have severe hepatic impairment, or take steroidal contraceptives.

Route	Onset	Peak	Duration
P.O.	Unknown	2 hr (fasting) 4–6 hr (with food)	Unknown

Mechanism of Action

May produce CNS-stimulant effects by binding to dopamine transporter in the brain and inhibiting dopamine reuptake in limbic regions. These actions increase alertness and reduce drowsiness and fatigue.

Contraindications

Hypersensitivity to armodafinil, modafinil, or their components

Interactions

DRUGS

amitriptyline, citalopram, clomipramine, diazepam, imipramine, propranolol, tolbamate, topiramate: Possibly prolonged elimination time and increased blood levels of these drugs

barbiturates (such as phenobarbital, primidone), dexamethasone, rifabutin, rifampin: Possibly decreased blood level and effectiveness of armodafinil

carbamazepine: Possibly decreased armodafinil effectiveness and decreased blood carbamazepine level

cimetidine, clarithromycin, erythromycin, fluconazole, fluoxetine, fluvoxamine, itraconazole, ketoconazole, nefazodone, sertraline: Possibly inhibited metabolism, decreased clearance, and increased blood level of armodafinil

clozapine: Possibly increased levels of clozapine caused by decreased secondary hepatic metabolism

contraceptive-containing implants or devices: Possibly contraceptive failure

cyclosporine: Possibly decreased blood cyclosporine level and increased risk of organ transplant rejection

dextroamphetamine, methylphenidate: Possibly 1-hr delay in armodafinil absorption when these drugs are given together

fosphenytoin, mephenytoin, phenytoin: Possibly decreased effectiveness of armodafinil, increased blood phenytoin level, and increased risk of phenytoin toxicity

midazolam, triazolam: Possibly decreased effectiveness of triazolam or midazolam
oral contraceptives: Possibly decreased effectiveness of oral contraceptive
theophylline: Possibly decreased blood level and effectiveness of theophylline
warfarin: Possibly decreased warfarin metabolism and increased risk of bleeding

FOODS

alcohol use: Possibly adverse CNS effects
all foods: 2- to 4-hr delay for armodafinil to reach peak levels and possibly delayed onset of action

caffeine: Increased CNS stimulation

grapefruit juice: Possibly decreased armodafinil metabolism

Adverse Reactions

CNS: Agitation, anxiety, attention disturbance, depression, dizziness, fatigue, fever, headache (including migraine), insomnia, nervousness, paresthesia, suicidal ideation, thirst, tremor

CV: Increased heart rate, palpitations

EENT: Dry mouth

GI: Abdominal pain (upper), anorexia, con-

stipation, decreased appetite, diarrhea, dyspepsia, loose stools, nausea, vomiting

GU: Polyuria

RESP: Dyspnea

SKIN: Contact dermatitis, hyperhidrosis, rash

Other: Angioedema, flulike illness

Nursing Considerations

- Armodafinil shouldn't be given to patients with mitral valve prolapse syndrome or a history of left ventricular hypertrophy because drug may cause ischemic changes.

WARNING If patient has a history of alcoholism, stimulant abuse, or other substance abuse, ensure compliance with armodafinil therapy. Watch for signs of misuse or abuse, including frequent prescription refill requests, increased frequency of dosing, and drug-seeking behavior. Also watch for evidence of excessive armodafinil use, including agitation, anxiety, diarrhea, nausea, nervousness, palpitations, sleep disturbances, and tremor.

- Be aware that armodafinil, like other CNS stimulants, may alter mood, perception, thinking, judgment, feelings, and motor skills and may produce signs that patient needs sleep.
- If giving drug to patient with a history of psychosis, emotional instability, or psychological illness with psychotic features, be prepared for baseline behavioral assessment or frequent clinical observation.

PATIENT TEACHING

- Inform patient that armodafinil can help, but not cure, narcolepsy and that drug's full effects may not be seen right away.
- Advise patient to avoid taking armodafinil within 2 hours of eating because food may delay time to peak drug effect and onset of action. If patient drinks grapefruit juice, encourage him to drink a consistent amount daily.
- Inform patient that drug can affect his concentration and ability to function and can hide signs of fatigue. Urge him not to drive or perform activities that require mental alertness until drug's full CNS effects are known.
- Because alcohol may decrease alertness, advise patient to avoid it with armodafinil.
- Encourage a regular sleeping pattern.
- Caution patient to avoid excessive intake of foods, beverages, and OTC drugs that

contain caffeine because caffeine may lead to increased CNS stimulation.

- Inform woman that armodafinil can decrease effectiveness of certain contraceptives, including birth control pills and implantable hormonal contraceptives. If she uses such contraceptives, urge her to use an alternate birth control method during armodafinil therapy and for up to 1 month after it stops.
- Advise patient to keep follow-up appointments with prescriber so that her progress can be monitored.

asenapine

Saphris

Class and Category

Chemical: Dibenzo-oxepino pyrrole

Therapeutic: Second-generation antipsychotic, atypical antipsychotic

Pregnancy category: C

Indications and Dosages

↗ *To treat schizophrenia*

SUBLINGUAL TABLETS

Adults. 5 mg twice daily.

↗ *To treat manic or mixed episodes associated with bipolar I disorder*

SUBLINGUAL TABLETS

Adults. 10 mg twice daily.

DOSAGE ADJUSTMENT Dosage may be decreased to 5 mg twice daily if adverse reactions occur.

Route	Onset	Peak	Duration
P.O.	Unknown	30–90 min	Unknown

Mechanism of Action

May produce antipsychotic effects through antagonist actions at dopamine receptors, especially D₂, and serotonin receptors, especially 5-HT_{2A}.

Contraindications

Hypersensitivity to asenapine or its components

Interactions

DRUGS

antihypertensives, CNS depressants: Possibly enhanced effects

class I A and III antiarrhythmics, gatifloxacin, moxifloxacin, other antipsychotic

drugs: Increased risk of prolonged QT interval

paroxetine: Possibly increased paroxetine effect

ACTIVITIES

alcohol use: Possibly enhanced effect

Adverse Reactions

CNS: Akathisia, anxiety, depression, dizziness, dystonia, dyskinesia, extrapyramidal symptoms, fatigue, gait disturbance, hyperkinesias, insomnia, irritability, masked facies, parkinsonism, seizures, somnolence, syncope, tardive dyskinesia, torticollis, tremor

CV: Hypertension, orthostatic hypotension, prolonged QT interval

EENT: Blepharospasm, dry mouth, oral hypoesthesia, salivary hypersecretion, toothache

ENDO: Hyperglycemia, hyperprolactinemia

GI: Constipation, dyspepsia, increased appetite, stomach discomfort, vomiting

HEME: Anemia, leukopenia, neutropenia, thrombocytopenia

MS: Arthralgia, extremity pain, muscle rigidity

Other: Hyponatremia, weight gain

Nursing Considerations

- Asenapine should be avoided in patients with a history of cardiac arrhythmias; conditions that might prolong the QT interval, such as bradycardia, hypokalemia, or hypomagnesemia; or congenital QT-interval prolongation because of increased risk of torsades de pointes or sudden death.
- Asenapine shouldn't be used for dementia-related psychosis in elderly patients because of an increased risk of death.
- Use cautiously in patients with mild to moderate hepatic impairment. Asenapine isn't recommended in patients with severe hepatic impairment (Child-Pugh Class C).
- Use cautiously in patients with a history of seizures or who have conditions that may lower the seizure threshold, such as Alzheimer's dementia, because drug increases risk of seizures in these patients.
- Monitor patients with diabetes mellitus for increased blood glucose levels.

WARNING Asenapine rarely may cause neuroleptic malignant syndrome or tardive dyskinesia. Monitor patient closely throughout therapy, and take safety pre-

cautions as needed. Expect to stop drug if any of these adverse effects occur.

- Monitor patient's CBC regularly, as ordered. Notify prescriber of any change because drug may need to be stopped.
- Monitor patient for trouble swallowing or excessive somnolence, which could predispose him to injury or aspiration.

PATIENT TEACHING

- Tell patient to remove tablet from package only when ready to take it and to use dry hands. Tell him to firmly press and hold thumb button, and then pull out tablet pack from case. Then, he should peel back the colored tab, being careful not to push tablet through the tab because doing so could damage tablet. Instruct patient to place tablet under his tongue and let it dissolve completely. Tell him to then slide tablet pack back into case until it clicks.
- Caution patient not to crush, chew or swallow tablets.
- Advise him not to eat or drink for at least 10 minutes after taking asenapine.
- Urge patient to avoid alcohol while taking asenapine.
- Instruct diabetic patient taking asenapine to monitor blood glucose levels closely because hyperglycemia may occur.
- Advise patient to get up slowly from lying or sitting position during asenapine therapy to minimize orthostatic hypotension.
- Caution patient to avoid hazardous activities until drug's effects are known.
- Urge patient to avoid activities that raise body temperature suddenly, such as strenuous exercise and exposure to extreme heat, and to compensate for situations that cause dehydration, such as vomiting or diarrhea.

aspirin

(acetylsalicylic acid, ASA)

Ancasal (CAN), Apo-As (CAN), Apo-ASEN (CAN), Arthrinol (CAN), Arthrisin (CAN), Aspergum, Aspirin, Atria S.R. (CAN), Bayer, Easprin, Ecotrin, Ecotrin Maximum Strength, 8-Hour Bayer Time Release, Empirin, Genprin, Maximum Bayer, Norwich Extra-

Strength, Novasen (CAN), Sal-Adult (CAN), Sal-Infant (CAN), St. Joseph Children's, Supasa (CAN), Therapy Bayer, ZORprin

Class and Category

Chemical class: Salicylate

Therapeutic class: Anti-inflammatory, antiplatelet, antipyretic, nonopioid analgesic

Pregnancy category: D

Indications and Dosages

↗ *To relieve mild pain or fever*

CHEWABLE TABLETS, CHEWING GUM, CONTROLLED-RELEASE TABLETS, ENTERIC-COATED TABLETS, SOLUTION, TABLETS, TIMED-RELEASE TABLETS, SUPPOSITORIES

Adults and adolescents. 325 to 650 mg every 4 hr, p.r.n., or 500 mg every 3 hr, p.r.n., or 1,000 mg every 6 hr, p.r.n.

Children ages 2 to 14. 10 to 15 mg/kg/dose every 4 hr, p.r.n., up to 80 mg/kg daily.

↗ *To relieve mild to moderate pain from inflammation, as in rheumatoid arthritis and osteoarthritis*

CHEWABLE TABLETS, CHEWING GUM, CONTROLLED-RELEASE TABLETS, ENTERIC-COATED TABLETS, SOLUTION, TABLETS, TIMED-RELEASE TABLETS, SUPPOSITORIES

Adults and adolescents. 3.2 to 6 g daily in divided doses. *Maximum:* 6 g daily.

Children. 10 to 15 mg/kg daily, up to 80 mg/kg daily, in divided doses every 4 to 6 hr.

↗ *To treat juvenile rheumatoid arthritis*

CHEWABLE TABLETS, CHEWING GUM, CONTROLLED-RELEASE TABLETS, ENTERIC-COATED TABLETS, SOLUTION, TABLETS, TIMED-RELEASE TABLETS, SUPPOSITORIES

Children. 60 to 110 mg/kg daily in divided doses every 6 to 8 hr.

↗ *To treat acute rheumatic fever*

CHEWABLE TABLETS, CHEWING GUM, CONTROLLED-RELEASE TABLETS, ENTERIC-COATED TABLETS, SOLUTION, TABLETS, TIMED-RELEASE TABLETS, SUPPOSITORIES

Adults and adolescents. 5 to 8 g daily in divided doses.

Children. *Initial:* 100 mg/kg daily in divided doses for first 2 wk. *Maintenance:* 75 mg/kg/day in divided doses for next 4 to 6 wk.

↗ *To reduce the risk of recurrent transient ischemic attacks or stroke in men*

CHEWABLE TABLETS, CHEWING GUM, CONTROLLED-

RELEASE TABLETS, ENTERIC-COATED TABLETS, SOLUTION, TABLETS, TIMED-RELEASE TABLETS, SUPPOSITORIES

Adults. 650 mg b.i.d. or 325 mg q.i.d.

↗ *To reduce the severity of or prevent acute MI*

CHEWABLE TABLETS, CHEWING GUM, CONTROLLED-RELEASE TABLETS, ENTERIC-COATED TABLETS, SOLUTION, TABLETS, TIMED-RELEASE TABLETS, SUPPOSITORIES

Adults. *Initial:* 160 to 162.5 mg (half of a 325-mg tablet or two 80- or 81-mg tablets) as soon as MI is suspected. *Maintenance:* 160 to 162.5 mg daily for 30 days.

↗ *To reduce risk of MI in patients with previous MI or unstable angina*

CHEWABLE TABLETS, CHEWING GUM, CONTROLLED-RELEASE TABLETS, ENTERIC-COATED TABLETS, SOLUTION, TABLETS, TIMED-RELEASE TABLETS, SUPPOSITORIES

Adults. 325 mg daily.

Route	Onset	Peak	Duration
P.O.	Rapid	Unknown	1–4 hr
(chewable tablets)			
P.O.	5–30	1–4 hr	4–6 hr
(controlled-min release)			
P.O.	5–30	Unknown	1–4 hr
(enteric-coated)	min		
P.O.	5–30	15–40	1–4 hr
(solution)	min	min	
P.O.	15–30	1–2 hr	4–6 hr
(tablets)	min		
P.O.	5–30	1–4 hr	4–6 hr
(timed-release)	min		
P.R.	Unknown	Unknown	4–6 hr

Mechanism of Action

Blocks the activity of cyclooxygenase, the enzyme needed for prostaglandin synthesis. Prostaglandins, important mediators in the inflammatory response, cause local vasodilation with swelling and pain. With blocking of cyclooxygenase and inhibition of prostaglandins, inflammatory symptoms subside. Pain is also relieved because prostaglandins play a role in pain transmission from the periphery to the spinal cord.

Aspirin inhibits platelet aggregation by interfering with production of thromboxane A₂, a substance that stimulates platelet aggregation. Aspirin acts on the heat-regulating center in the hypothalamus and causes peripheral vasodilation, diaphoresis, and heat loss.

Contraindications

Allergy to tartrazine dye, asthma, bleeding problems (such as hemophilia), hypersensitivity to aspirin or its components, peptic ulcer disease

Interactions

DRUGS

ACE inhibitors: Decreased antihypertensive effect

activated charcoal: Decreased aspirin absorption

antacids, urine alkalinizers: Decreased aspirin effectiveness

anticoagulants: Increased risk of bleeding; prolonged bleeding time

carbonic anhydrase inhibitors: Salicylism

corticosteroids: Increased excretion and decreased blood level of aspirin

heparin: Increased risk of bleeding

ibuprofen: Possibly reduced cardioprotective and stroke preventive effects of aspirin

methotrexate: Increased blood level and decreased excretion of methotrexate, causing toxicity

nizatidine: Increased blood aspirin level

NSAIDs: Possibly decreased blood NSAID level and increased risk of adverse GI effects

sulfonylureas: Possibly enhanced effect of sulfonylureas with large doses of aspirin

urine acidifiers (such as ammonium chloride, ascorbic acid): Decreased aspirin excretion

vancomycin: Increased risk of ototoxicity

ACTIVITIES

alcohol use: Increased risk of ulcers

Adverse Reactions

CNS: Confusion, CNS depression

EENT: Hearing loss, tinnitus

GI: Diarrhea, GI bleeding, heartburn, hepatotoxicity, nausea, stomach pain, vomiting

HEME: Decreased blood iron level, leukopenia, prolonged bleeding time, shortened life span of RBCs, thrombocytopenia

SKIN: Ecchymosis, rash, urticaria

Other: Angioedema, Reye's syndrome, salicylism (dizziness, tinnitus, difficulty hear-

ing, vomiting, diarrhea, confusion, CNS depression, diaphoresis, headache, hyperventilation, and lassitude) with regular use of large doses

Nursing Considerations

- Don't crush timed-release or controlled-release aspirin tablets unless directed.
- Ask about tinnitus. This reaction usually occurs when blood aspirin level reaches or exceeds maximum for therapeutic effect.

PATIENT TEACHING

WARNING Advise parents not to give aspirin to a child or adolescent with chickenpox or flu symptoms because of risk of Reye's syndrome (rare life-threatening reaction characterized by vomiting, lethargy, delirium, and coma). Tell them to consult prescriber for alternative drugs.

- Advise adult patient taking low-dose aspirin not to also take ibuprofen because it may reduce the cardioprotective and stroke preventive effects of aspirin.
- Instruct patient to take aspirin with food or after meals because it may cause GI upset if taken on an empty stomach.
- Advise patient with tartrazine allergy not to take aspirin.
- Tell patient to consult prescriber before taking aspirin with any prescription drug for blood disorder, diabetes, gout, or arthritis.
- Tell patient not to use aspirin if it has a strong vinegar-like odor.

atenolol

Apo-Atenol (CAN), **Novo-Atenol** (CAN), **Tenormin**

Class and Category

Chemical class: Beta-adrenergic blocker (beta₁ and at high doses beta₂)

Therapeutic class: Antianginal, antihypertensive

Pregnancy category: D

Indications and Dosages

↗ *To treat angina pectoris and control hypertension*

TABLETS

Adults. 50 mg daily increased, p.r.n., after 1 to 2 wk to 100 mg daily.

↗ *To treat acute MI*

TABLETS, I.V. INFUSION

Adults. *Initial:* 5 mg I.V. over 5 min followed by 5 mg I.V. 10 min later. After another 10 min, 50 mg given and followed by another 50 mg in 12 hr. *Maintenance:* 50 mg P.O. b.i.d. or 100 mg P.O. daily for 6 to 9 days or until discharged from hospital. **DOSAGE ADJUSTMENT** Dosage reduced to 50 mg daily P.O. for renally impaired patients and for elderly, renally impaired patients with creatinine clearance of 15 to 35 ml/min/1.73 m². Dosage reduced to 25 mg daily P.O. for renally impaired patients and for elderly, renally impaired patients with creatinine clearance less than 15 ml/min/1.73 m².

Route	Onset	Peak	Duration
P.O.	1 hr	2–4 hr	24 hr
I.V.	Immediate	5 min	12 hr

Mechanism of Action

Inhibits stimulation of beta₁-receptor sites, located mainly in the heart, decreasing cardiac excitability, cardiac output, and myocardial oxygen demand. Atenolol also acts to decrease release of renin from the kidneys, aiding in reducing blood pressure. At high doses, it inhibits stimulation of beta₂ receptors in the lungs, which may cause bronchoconstriction.

Contraindications

Cardiogenic shock, heart block greater than first degree, hypersensitivity to beta blockers, overt heart failure, sinus bradycardia

Interactions**DRUGS**

amiodarone: Additive atenolol effects *calcium channel blockers, such as verapamil and diltiazem:* Possibly symptomatic bradycardia and conduction abnormalities *catecholamine-depleting drugs, such as reserpine:* Additive antihypertensive effect *clonidine:* Rebound hypertension *disopyramide:* Increased risk of severe bradycardia, asystole, and heart failure

Adverse Reactions

CNS: Depression, disorientation, dizziness, drowsiness, emotional lability, fatigue, fever, lethargy, light-headedness, short-term memory loss, vertigo

CV: Arrhythmias, including bradycardia

and heart block; cardiogenic shock; cold arms and legs; heart failure; mesenteric artery thrombosis; mitral insufficiency; myocardial reinfarction; orthostatic hypotension; Raynaud's phenomenon **EENT:** Dry eyes, laryngospasm, pharyngitis **GI:** Diarrhea, ischemic colitis, nausea **GU:** Renal failure **HEME:** Agranulocytosis **MS:** Leg pain **RESP:** Bronchospasm, dyspnea, pulmonary emboli, respiratory distress, wheezing **SKIN:** Erythematous rash **Other:** Allergic reaction

Nursing Considerations

- Use atenolol cautiously in patients with heart failure controlled by digitalis glycosides or diuretics, patients with conduction abnormalities or left ventricular dysfunction who take verapamil or diltiazem, patients with arterial circulatory disorders, and patients with impaired renal function.
- Use atenolol cautiously in diabetic patients because it may mask tachycardia caused by hypoglycemia. Unlike other beta-adrenergic blockers, it doesn't mask other signs of hypoglycemia, cause hypoglycemia, or delay the return of blood glucose to a normal level.
- At first sign of heart failure, expect patient to receive a digitalis glycoside, a diuretic, or both and to be monitored closely. If failure continues, expect to stop atenolol.
- Closely monitor patient with hyperthyroidism because atenolol may mask some signs of thyrotoxicosis. Abrupt withdrawal of atenolol may precipitate thyrotoxicosis.
- If patient also receives clonidine, expect to stop atenolol several days before gradually withdrawing clonidine. Then expect to restart atenolol therapy several days after clonidine has been discontinued.
- During I.V. atenolol therapy, monitor vital signs and cardiac rhythm closely.
- Discard parenteral mixture with atenolol if it isn't used within 48 hours.
- Stop atenolol and notify prescriber if patient develops bradycardia, hypotension, or other serious adverse reaction.

PATIENT TEACHING

- Instruct patient not to stop taking atenolol abruptly. Otherwise, angina may worsen, and an MI or arrhythmia may occur.

- While patient is being weaned from atenolol, tell him to perform minimal physical activity to prevent chest pain.
- Instruct patient to take a missed dose as soon as possible. However, if it's within 8 hours of the next scheduled dose, tell him to skip the missed dose and return to his regular schedule.
- Explain that atenolol may alter serum glucose level and mask hypoglycemia.
- Inform the patient that he may experience fatigue and reduced tolerance to exercise and that he should notify his prescriber if this interferes with his normal lifestyle.

atomoxetine hydrochloride

Strattera

Class and Category

Chemical class: Selective norepinephrine reuptake inhibitor

Therapeutic class: Anti-ADHD agent

Pregnancy category: C

Indications and Dosages

↗ *To treat attention deficit hyperactivity disorder (ADHD)*

CAPSULES

Adults and children weighing 70 kg

(154 lb) or less. *Initial:* 0.5 mg/kg daily, increased after at least 3 days to 1.2 mg/kg daily given either as a single dose in the morning or in evenly divided doses morning and late afternoon or early evening, as needed. *Maximum:* 1.4 mg/kg or 100 mg daily, whichever is less.

Adults and children weighing more than 70 kg.

Initial: 40 mg daily, increased after at least 3 days to 80 mg daily given either as a single dose in the morning or in evenly divided doses morning and late afternoon or early evening. After 2 to 4 additional wk, dosage may be increased to 100 mg daily if optimal response hasn't been achieved. *Maximum:* 100 mg daily.

DOSAGE ADJUSTMENT For patients with moderate (Child-Pugh Class B) hepatic impairment, dosage reduced by 50%. For patients with severe (Child-Pugh Class C) hepatic impairment, dosage reduced by 75%. For patients weighing 70 kg or less

and taking strong CYP2D6 inhibitors, such as paroxetine, fluoxetine, or quinidine, initial dosage of 0.5 mg/kg daily should be increased to 1.2 mg/kg daily only if symptoms fail to improve after 4 wk. For patients weighing more than 70 kg and taking strong CYP2D6 inhibitors, initial dosage of 40 mg daily should be increased to 80 mg daily only if symptoms fail to improve after 4 wk.

Mechanism of Action

Selectively inhibits presynaptic norepinephrine transport in the nervous system to increase attention span and produce a calming effect.

Contraindications

Angle-closure glaucoma, hypersensitivity to atomoxetine or its components, use within 14 days of MAO inhibitor therapy

Interactions

DRUGS

albuterol and other beta₂ agonists: May potentiate action of albuterol and other beta₂ agonists on cardiovascular system
CYP2D6 inhibitors (such as fluoxetine, paroxetine, and quinidine): Increased blood atomoxetine level

MAO inhibitors: Possibly induced hypertensive crisis

pressor agents: Possibly altered blood pressure

Adverse Reactions

CNS: Aggressiveness, anxiety, chills, crying, depression, dizziness, early morning awakening, fatigue, headache, hostility, insomnia, irritability, lethargy, mood changes, paresthesia, peripheral coldness, pyrexia, rigors, sedation, seizures, sleep disturbance, somnolence, stroke, suicidal ideation (children and adolescents), syncope, tremor, unusual dreams

CV: Chest pain, hypotension, orthostatic hypotension, MI, palpitations, QT-interval prolongation, Raynaud's phenomenon, tachycardia

EENT: Conjunctivitis, dry mouth, ear infection, mydriasis, nasal congestion, nasopharyngitis, pharyngitis, rhinorrhea, sinus congestion

ENDO: Hot flashes

GI: Abdominal pain (upper), anorexia, constipation, diarrhea, elevated liver function

test results, flatulence, gastroenteritis (viral), indigestion, nausea, severe hepatic dysfunction, vomiting

GU: Decreased libido, dysmenorrhea, dysuria, ejaculation disorders, erectile dysfunction, impotence, male pelvic pain, menstrual irregularities, orgasm abnormality, priapism, prostatitis, urinary hesitancy, urine retention

MS: Arthralgia, back pain, myalgia

RESP: Cough, upper respiratory tract infection

SKIN: Dermatitis, diaphoresis, pruritus, rash, urticaria

Other: Angioedema, influenza, weight loss

Nursing Considerations

- Use atomoxetine cautiously in patients with cerebrovascular or CV disease (especially hypertension or tachycardia) because drug may increase blood pressure and heart rate. Also use cautiously in those prone to orthostatic hypotension and those with serious structural cardiac abnormalities, cardiomyopathy, serious heart rhythm abnormalities, or other serious cardiac problems because drug may increase risk of sudden death from these conditions.

WARNING Monitor children and adolescents closely for evidence of suicidal thinking and behavior as well as for psychotic or manic symptoms such as hallucinations, delusional thinking, or mania because atomoxetine increases the risk of suicidal ideation and the onset of psychotic or manic symptoms in these age-groups.

- Obtain baseline blood pressure and heart rate before starting therapy. Monitor patient's vital signs after dosage increases and periodically during therapy.
- Monitor patient closely for allergic reactions. If these occur, notify prescriber.
- Monitor child's or adolescent's growth and weight. Expect to interrupt therapy, as prescribed, if patient isn't growing or gaining weight appropriately.
- Monitor patient's liver function studies, as ordered. Notify prescriber immediately if enzyme levels are elevated or patient has evidence of hepatic dysfunction (jaundice, dark urine, pruritus, right-upper-quadrant tenderness, or unexplained flulike symptoms). Expect to stop drug permanently.

PATIENT TEACHING

- Caution patient not to open capsules. If a capsule opens, urge patient to promptly wash his hands and any surface drug touches. If drug gets in his eyes, tell him to flush immediately with water and seek medical care.

- Instruct patient or parent to immediately report to prescriber any adverse reactions to atomoxetine therapy, such as facial swelling, itching, or rash.

WARNING Urge parents to watch their child or adolescent closely for evidence of abnormal thinking or behavior or increased aggression or hostility. Stress need to notify prescriber about unusual changes.

- Urge patient to tell prescriber immediately about yellowing of his skin or eyes, itching, right upper abdominal pain, dark urine, or flulike symptoms. Also tell patient to notify prescriber immediately if he experiences exertional chest pain, unexplained syncope, or other symptoms suggestive of heart disease.

- Caution patient to assume sitting or standing position slowly because of drug's potential effect on blood pressure.

- Urge male patient to seek immediate medical attention for a penile erection that becomes prolonged or painful.

- Advise patient to report urinary hesitancy or urine retention to prescriber.

- Remind patient of the importance of alerting all prescribers to any OTC drugs, dietary supplements, or herbal remedies he's taking.

- Caution patient to avoid hazardous activities until drug's CNS effects are known.

- Reassure patient or parent that drug doesn't cause physical or psychological dependence.

- Instruct patient or parent to monitor weight during therapy.

atorvastatin calcium

Lipitor

Class and Category

Chemical class: Synthetically derived fermentation product

Therapeutic class: Antihyperlipidemic,

HMG-CoA reductase inhibitor

Pregnancy category: X

Indications and Dosages

➤ *To control lipid levels as adjunct to diet in primary (heterozygous familial and nonfamilial) hypercholesterolemia and mixed dyslipidemia*

TABLETS

Adults. *Initial:* 10 or 20 mg once daily; then increased according to lipid level.

Maintenance: 10 to 80 mg once daily.

DOSAGE ADJUSTMENT Initial dose may be increased to 40 mg once daily for patients who need cholesterol level reduced more than 45%.

➤ *To control lipid levels in homozygous familial hypercholesterolemia*

TABLETS

Adults. 10 to 80 mg daily.

➤ *To control lipid levels in pediatric heterozygous familial hypercholesterolemia*

TABLETS

Adolescents and children ages 10 to 17.

Initial: 10 mg daily, adjusted at intervals of 4 wk or more, as needed. *Maximum:* 20 mg daily.

➤ *To reduce debilitating cardiovascular events such as stroke and MI in patients with multiple risk factors but without known coronary artery disease*

TABLETS

Adults. 10 mg once daily.

Mechanism of Action

Reduces plasma cholesterol and lipoprotein levels by inhibiting HMG-CoA reductase and cholesterol synthesis in the liver and by increasing the number of LDL receptors on liver cells to enhance LDL uptake and breakdown.

Contraindications

Active hepatic disease, hypersensitivity to atorvastatin or its components, unexplained persistent rise in serum transaminase level

Interactions

DRUGS

amlodipine, cimetidine, clarithromycin, diltiazem, erythromycin, itraconazole, ritonavir with saquinavir: Increased atorvastatin level
antacid, colestipol, efavirenz, rifampin: Possibly decreased blood atorvastatin level
azole antifungals, clarithromycin, cyclosporine, erythromycin, fibric acid deriva-

tives, lopinavir with ritonavir, niacin (at dosage used for lipid modification), nicotinic acid, ritonavir with saquinavir: Increased risk of severe myopathy or rhabdomyolysis
cyclosporine: Increased atorvastatin bioavailability and risk of adverse reactions
digoxin: Possibly increased blood digoxin level, causing toxicity
oral contraceptives (such as ethinyl estradiol and norethindrone): Increased hormone level

FOODS

grapefruit juice (more than 1.2 L daily):

Increased blood atorvastatin level

Adverse Reactions

CNS: Abnormal dreams, amnesia, asthenia, emotional lability, facial paralysis, fever, headache, hyperkinesia, lack of coordination, malaise, paresthesia, peripheral neuropathy, somnolence, syncope, weakness
CV: Arrhythmias, elevated serum CK level, orthostatic hypotension, palpitations, phlebitis, vasodilation
EENT: Amblyopia, altered refraction, dry eyes, dry mouth, epistaxis, eye hemorrhage, gingival hemorrhage, glaucoma, glossitis, hearing loss, lip swelling, loss of taste, pharyngitis, sinusitis, stomatitis, taste perversion, tinnitus

ENDO: Hyperglycemia or hypoglycemia

GI: Abdominal or biliary pain, anorexia, colitis, constipation, diarrhea, duodenal or stomach ulcers, dysphagia, eructation, esophagitis, flatulence, gastroenteritis, hepatic failure, hepatitis, increased appetite, indigestion, melena, pancreatitis, rectal hemorrhage, tenesmus, vomiting
GU: Abnormal ejaculation; cystitis; decreased libido; dysuria; epididymitis; hematuria; impotence; nephritis; nocturia; renal calculi; urinary frequency, incontinence, or urgency; urine retention; vaginal hemorrhage

HEME: Anemia, thrombocytopenia

MS: Arthralgia, back pain, bursitis, gout, leg cramps, myalgia, myasthenia gravis, myositis, neck rigidity, tendon contracture, tenosynovitis, torticollis

RESP: Dyspnea, pneumonia

SKIN: Acne, alopecia, contact dermatitis, diaphoresis, dry skin, ecchymosis, eczema, jaundice, petechiae, photosensitivity, pruritus, rash, seborrhea, ulceration, urticaria

Other: Allergic reaction, facial or generalized edema, flulike symptoms, infection, lymphadenopathy, weight gain

Nursing Considerations

- Atorvastatin is used in patients with homozygous familial hypercholesterolemia as an adjunct to other lipid-lowering treatments or alone only if other treatments aren't available.
- Atorvastatin may be used with colestipol or cholestyramine for additive antihyperlipidemic effects.
- Expect atorvastatin to be used in patients without obvious coronary artery disease (CAD) but with multiple risk factors (such as age 55 or over, smoker, history of hypertension or low HDL level, or family history of early CAD). Drug is used to reduce risk of MI, angina, and adverse effects of revascularization procedures.
- Also expect drug to be used in patients with type 2 diabetes who have no obvious CAD but multiple risk factors, such as retinopathy, albuminuria, smoking, or hypertension. Drug is used in these patients to reduce risk of MI and stroke.
- Expect liver function tests to be performed before atorvastatin therapy starts, after 6 and 12 weeks, with each dosage increase, and every 6 months thereafter.
- Expect to measure lipid levels 2 to 4 weeks after therapy starts, to adjust dosage as directed, and to repeat periodically until lipid levels are within desired range.

PATIENT TEACHING

- Stress that atorvastatin is an adjunct to—not a substitute for—low-cholesterol diet.
- Tell patient to take drug at the same time each day to maintain its effects.
- Instruct patient to take a missed dose as soon as possible. If it's almost time for his next dose, he should skip the missed dose. Tell him not to double the dose.
- Instruct patient to consult prescriber before taking OTC niacin because of increased risk of rhabdomyolysis.
- Advise patient to notify prescriber immediately if he develops unexplained muscle pain, tenderness, or weakness, especially if accompanied by fatigue or fever.
- Be aware that atorvastatin is expensive. Reinforce the benefits of therapy, and urge patient to comply if possible.

atovaquone

Mepron

Class and Category

Chemical class: Hydroxy-1,4-naphthoquinone

Therapeutic class: Antiprotozoal

Pregnancy category: C

Indications and Dosages

↗ *To prevent Pneumocystis jiroveci (formerly carinii) pneumonia in patients who can't tolerate co-trimoxazole*

SUSPENSION, TABLETS

Adults and adolescents. 750 mg (5 ml)

b.i.d. with meals for 21 days.

↗ *To treat mild to moderate P. jiroveci pneumonia in patients who can't tolerate co-trimoxazole*

SUSPENSION, TABLETS

Adults and adolescents. 750 mg (5 ml)

b.i.d. with meals for 21 days. *Maximum:*

1,500 mg/day.

Mechanism of Action

May destroy *P. jiroveci* organisms by inhibiting the enzymes needed to synthesize nucleic acid and adenosine triphosphate.

Contraindications

Hypersensitivity to atovaquone or its components

Interactions

DRUGS

rifabutin, rifampin: Possibly decreased blood atovaquone level

Adverse Reactions

CNS: Fever, headache, insomnia

EENT: Rhinitis, throat tightness, vortex keratopathy

GI: Abdominal pain, diarrhea, elevated liver enzyme levels, hepatitis, hepatic failure, nausea, pancreatitis, vomiting

GU: Acute renal dysfunction

HEME: Anemia, thrombocytopenia

RESP: Bronchospasm, cough, dyspnea

SKIN: Desquamation, erythema multiforme, Stevens-Johnson syndrome, rash, urticaria

Other: Allergic reaction, angioedema, methemoglobinemia

Nursing Considerations

- Use atovaquone cautiously in patient with

severe hepatic impairment because, although rare, serious adverse reactions affecting liver function may occur.

- Monitor blood test results because atovaquone may decrease serum sodium and hemoglobin levels and neutrophil count and may increase AST, ALT, alkaline phosphatase, and serum amylase levels.
- Crush atovaquone tablets, if needed.
- Don't use tablets and oral suspension interchangeably; they aren't bioequivalent.

PATIENT TEACHING

- Instruct patient to take atovaquone with meals for maximum effectiveness.
- Instruct patient to take a missed dose as soon as possible. If it's almost time for the next dose, tell him to skip the missed dose. Tell him not to double the next dose.
- Tell patient to notify prescriber if his condition doesn't improve in a few days or if he develops signs of an allergic reaction, such as fever or rash.

atracurium besylate

Tracrium

Class and Category

Chemical class: Biquaternary ammonium ester

Therapeutic class: Skeletal muscle relaxant

Pregnancy category: C

Indications and Dosages

↗ *To facilitate endotracheal intubation and induce skeletal muscle relaxation for surgery or mechanical ventilation as adjunct to anesthesia*

I.V. INFUSION OR INJECTION

Adults and children age 2 or over. *Initial:* 0.4 to 0.5 mg/kg by I.V. bolus for nearly complete neuromuscular blockade.

Maintenance: 0.08 to 0.10 mg/kg 20 to 45 min after initial dose during prolonged surgery. Maintenance doses may be given every 15 to 25 min for patients under balanced anesthesia. For patients having extended surgical procedures, after an initial I.V. bolus, an infusion of 9 to 10 mcg/kg/min may be needed to counteract the spontaneous return of neuromuscular function and thereafter 5 to 10 mcg/kg/min as a constant infusion.

Children ages 1 month to 2 years having halothane anesthesia. *Initial:* 0.3 to 0.4 mg/kg. Frequent maintenance doses may be needed.

Route	Onset	Peak	Duration
I.V.	2–2.5 min	3–5 min	35–70 min

Mechanism of Action

Inhibits nerve impulse transmission by competing with acetylcholine for cholinergic receptors on motor end plate.

Incompatibilities

Don't mix atracurium in same syringe or give it through same I.V. needle as an alkaline solution, such as a barbiturate injection. Don't mix atracurium with lactated Ringer's injection.

Contraindications

Hypersensitivity to atracurium, its components, or benzyl alcohol

Interactions

DRUGS

aminoglycosides, enflurane, furosemide, halothane, isoflurane, lithium, magnesium salts, polymyxin antibiotics, procainamide, quinidine, thiazide diuretics: Possibly enhanced or prolonged atracurium effects
opioid analgesics: Possibly additive histamine release and increased risk and severity of bradycardia and hypotension

Adverse Reactions

CNS: Seizures

CV: Bradycardia, hypertension, hypotension, tachycardia

MS: Inadequate or prolonged neuromuscular blockade

RESP: Apnea, bronchospasm, dyspnea, laryngospasm, wheezing

SKIN: Flushing, rash, urticaria

Other: Anaphylaxis, injection site reaction

Nursing Considerations

- Use atracurium cautiously in patients with hypotension, and monitor blood pressure closely.
- Watch closely for adverse reactions, especially those related to histamine release. Atracurium is more likely than other neuromuscular blockers to cause skin flushing.
- Anticipate using lower doses for patients with neuromuscular disease, severe elec-

trolyte disorders, or carcinomatosis because of risk of enhanced neuromuscular blockade and difficulties with reversal.

- Keep atropine nearby to treat atracurium-induced bradycardia.
- For I.V. infusion, dilute atracurium with normal saline solution, D₅W, or dextrose 5% in normal saline solution. To prepare a solution that yields 200 mcg/ml atracurium, add 2 ml atracurium to 98 ml diluent. To prepare a solution that yields 500 mcg/ml, add 5 ml atracurium to 95 ml diluent.
- Refrigerate solution or store at room temperature for up to 24 hours.

PATIENT TEACHING

- Explain atracurium's purpose and administration during anesthesia. Keep in mind that the patient can still hear.

atropine

AtroPen

atropine sulfate

Class and Category

Chemical class: Belladonna alkaloid

Therapeutic class: Anticholinergic, anti-muscarinic

Pregnancy category: C

Indications and Dosages

↗ *To reduce respiratory tract secretions related to anesthesia*

TABLETS (ATROPINE SULFATE)

Adults. 0.4 to 0.6 mg preoperatively.

Children. 0.01 mg/kg up to total of 0.4 mg preoperatively and repeated every 4 to 6 hr, p.r.n.

I.V., I.M., OR SUBCUTANEOUS INJECTION

Adults. 0.4 to 0.6 mg preoperatively.

Children. 0.01 mg/kg up to total of 0.4 mg preoperatively and repeated every 4 to 6 hr, p.r.n.

↗ *To correct bradycardia*

I.V. INJECTION (ATROPINE SULFATE)

Adults. 0.4 to 1 mg. If no response to first dose, repeat once after 5 min.

Children. 0.01 to 0.02 mg/kg with a minimum dose of 0.1 mg and a maximum dose of 0.5 mg. If no response to first dose, repeat once after 5 min.

↗ *To treat cholinesterase inhibitor (such as*

neostigmine, pilocarpine, and methacholine) toxicity

I.V. INJECTION (ATROPINE SULFATE)

Adults. 2 to 4 mg. Then 2 mg every 5 to 10 min until muscarinic signs (bradycardia, vasodilation, and pupil dilation) disappear or signs of atropine intoxication develop.

I.V. OR I.M. INJECTION (ATROPINE SULFATE)

Children. 1 mg. Then 0.5 to 1 mg every 5 to 10 min until muscarinic signs disappear or signs of atropine intoxication develop.

↗ *To treat mushroom (muscarine) toxicity*

I.V. OR I.M. INJECTION (ATROPINE SULFATE)

Adults. 1 to 2 mg every hr until respiratory signs and symptoms subside.

↗ *To treat pesticide (organophosphate) toxicity*

I.V. OR I.M. INJECTION (ATROPINE SULFATE)

Adults. 1 to 2 mg, repeated in 20 to 30 min as soon as cyanosis has cleared. Then continued until definite improvement is maintained, possibly for 2 or more days.

↗ *To treat known or suspected exposure to chemical nerve agent or insecticide*

I.M. INJECTION (ATROPEN)

Adults and children weighing over 41 kg (90 lb) with two or more mild symptoms. 2 mg. If severe symptoms develop after injection, two or more 2-mg injections given in rapid succession 10 min after initial injection.

Adults and children weighing over 41 kg who are unconscious or have other severe symptoms. 2 mg given immediately 3 times in rapid succession.

Children weighing 18 to 41 kg (40 to 90 lb) with two or more mild symptoms. 1 mg. If severe symptoms develop after injection, two more 1-mg injections given in rapid succession 10 min after initial injection.

Children weighing 18 to 41 kg who are unconscious or exhibit any other severe symptoms. 1 mg given immediately 3 times in rapid succession.

Children weighing 7 to 18 kg (15 to 40 lb) with two or more mild symptoms. 0.5 mg. If severe symptoms develop after injection, two more 0.5-mg injections given in rapid succession 10 min after initial injection.

Children weighing 7 to 18 kg who are unconscious or exhibit any other severe symptoms. 0.5 mg given immediately 3 times in rapid succession.

Mechanism of Action

Inhibits acetylcholine's muscarinic action at the neuroeffector junctions of smooth muscles, cardiac muscles, exocrine glands, SA and AV nodes, and the urinary bladder. In small doses, atropine inhibits salivary and bronchial secretions and diaphoresis. In moderate doses, it increases impulse conduction through the AV node and increases heart rate. In large doses, it decreases GI and urinary tract motility and gastric acid secretion.

Route	Onset	Peak	Duration
P.O.	30–120 min	1–2 hr	4–6 hr
I.V.	Immediate	2–4 min	Brief
I.M.	5–40 min	20–60 min	Brief
SubQ	Unknown	Unknown	Brief

Contraindications

Angle-closure glaucoma, asthma, GI obstructive disease (achalasia, pyloric obstruction, pyloroduodenal stenosis), hepatic disease, hypersensitivity to atropine or its components, ileus, intestinal atony, myasthenia gravis, myocardial ischemia, obstructive uropathy, renal disease, severe ulcerative colitis, tachycardia, toxic megacolon, unstable cardiovascular status in acute hemorrhage

Interactions

DRUGS

adsorbent antidiarrheals, antacids: Decreased atropine absorption
amantadine, anticholinergics, antidiyskinetics, glutethimide, meperidine, muscle relaxants, phenothiazines, tricyclic antidepressants and other drugs with anticholinergic properties, including antiarrhythmics (disopyramide, procainamide, quinidine), antihistamines, buclizine, meclizine: Increased atropine effects
antimyasthenics: Reduced intestinal motility
cyclopropane: Risk of ventricular arrhythmias
haloperidol: Decreased antipsychotic effect
ketoconazole: Decreased ketoconazole absorption
metoclopramide: Decreased effect on GI motility
opioid analgesics: Increased risk of ileus,

severe constipation, and urine retention
potassium chloride, especially wax-matrix forms: Possibly GI ulcers
urinary alkalinizers (calcium or magnesium antacids, carbonic anhydrase inhibitors, citrates, sodium bicarbonate): Delayed excretion, increased risk of adverse atropine effects

Adverse Reactions

CNS: Agitation, amnesia, anxiety, ataxia, Babinski's or Chaddock's reflex, behavioral changes, CNS stimulation (at high doses), coma, confusion, decreased concentration, decreased tendon reflexes, delirium, dizziness, drowsiness, fever, hallucinations, headache, hyperreflexia, insomnia, lethargy, mania, mental disorders, nervousness, paranoia, restlessness, seizures, somnolence, stupor, syncope, vertigo, weakness

CV: Arrhythmias, bradycardia (at low doses), cardiac dilation, chest pain, hypertension, hypotension, left ventricular failure, MI, palpitations, tachycardia (at high doses), weak or impalpable peripheral pulses

EENT: Acute angle-closure glaucoma, altered taste, blepharitis, blindness, blurred vision, conjunctivitis, cyclophoria, cycloplegia, decreased visual acuity or accommodation, dry eyes or conjunctiva, dry mucous membranes, dry mouth, eye irritation, eyelid crusting, heterophoria, increased intraocular pressure, keratoconjunctivitis, lacrimation, laryngitis, laryngospasm, mydriasis, nasal congestion, oral lesions, photophobia, pupils poorly reactive to light, strabismus, tongue chewing

GI: Abdominal distention, abdominal pain, bloating, constipation, decreased bowel sounds or food absorption, delayed gastric emptying, dysphagia, heartburn, ileus, nausea, vomiting

GU: Bladder distention, enuresis, impotence, urinary hesitancy, urinary urgency, urine retention

MS: Dysarthria, hypertonia, muscle twitching

RESP: Bradypnea, dyspnea, inspiratory stridor, pulmonary edema, respiratory failure, shallow breathing, subcostal recession, tachypnea

SKIN: Cold skin, cyanosis, decreased sweating, dermatitis, flushing, rash, urticaria

Other: Anaphylaxis, dehydration, injection site reaction, polydipsia, sensations of warmth

Nursing Considerations

WARNING For patient prescribed AtroPen for suspected nerve gas or insecticide exposure, dosage is determined by severity of symptoms. Mild symptoms include blurred vision, miosis, excessive unexplained teary eyes or runny nose, increased salivation, chest tightness, difficulty breathing, tremors, muscle twitching, nausea, vomiting, unexplained wheezing or coughing, acute onset of stomach cramps, tachycardia, and bradycardia. Severe symptoms include confusion or other strange behavior, severe difficulty breathing, extreme secretions from airway or lungs, severe muscle twitching and general weakness, involuntary urination and defecation, seizures, and unconsciousness.

- Avoid using high-dose atropine sulfate in patients with ulcerative colitis because of risk of toxic megacolon or in patients with hiatal hernia and reflux esophagitis because of risk of esophagitis
- AtroPen has no absolute contraindications when used to treat life-threatening nerve gas or insecticide exposure.

WARNING Assess for symptoms of toxic doses of atropine, such as excitement, agitation, drowsiness, and confusion, which are likely to affect elderly patients even with low doses. If symptoms occur, take safety precautions to prevent injury.

- Assess bowel and bladder elimination. Notify prescriber of diarrhea, constipation, urinary hesitancy, or urine retention.

PATIENT TEACHING

- For patient prescribed an AtroPen to carry because of risk of nerve gas or insecticide exposure, explain when and how to self-administer the drug.
- Instruct patient to take atropine sulfate 30 to 60 minutes before meals.
- Advise patient to notify prescriber if he has persistent or severe diarrhea, constipation, or difficulty urinating.

auranofin

Ridaura

Class and Category

Chemical class: Gold salt

Therapeutic class: Anti-inflammatory

Pregnancy category: C

Indications and Dosages

➤ To treat active rheumatoid arthritis that's unresponsive to NSAIDs

CAPSULES

Adults. *Initial:* 6 mg daily or 3 mg b.i.d. *Maintenance:* Up to 9 mg daily after 3 mo of treatment, if needed.

Children age 6 and over. *Initial:* 0.1 mg/kg daily. *Maintenance:* 0.15 mg/kg daily.

Maximum: 0.2 mg/kg daily.

DOSAGE ADJUSTMENT Drug discontinued if therapeutic response isn't adequate after 3 mo at 9 mg daily.

Route	Onset	Peak	Duration
P.O.	3–6 mo	1–2 hr	Up to 26 days

Mechanism of Action

Decreases rheumatoid factor and humoral antibody (immunoglobulin) levels. Although exact anti-inflammatory action is unknown, drug may suppress the increased phagocytic activity of macrophages and polymorphonuclear leukocytes that occurs with rheumatoid arthritis and thereby inhibit release of destructive enzymes that cause joint inflammation.

Contraindications

Agranulocytosis, blood dyscrasias, bone marrow aplasia, colitis, eczema, exfoliative dermatitis, hepatic disease, history of gold or heavy metal toxicity, hypersensitivity to auranofin, marked hypertension, necrotizing enterocolitis, pulmonary fibrosis, recent radiation therapy, renal disease, severe debilitation, systemic lupus erythematosus, uncontrolled diabetes mellitus, uncontrolled heart failure, urticaria, youth (under age 6)

Interactions

DRUGS

phenytoin: Possibly increased phenytoin level

Adverse Reactions

CNS: Confusion, dizziness, EEG abnormalities, hallucinations, seizures

EENT: Gingivitis, glossitis, iritis or corneal ulcers from gold deposits in ocular tissue, metallic taste, stomatitis

GI: Abdominal cramps, anorexia, constipation, diarrhea, enterocolitis, flatulence, indigestion, melena, nausea, vomiting

GU: Hematuria, elevated BUN and serum

creatinine levels, proteinuria, vaginitis

HEME: Agranulocytosis, aplastic anemia, eosinophilia, leukopenia, neutropenia, thrombocytopenia

RESP: Cough, dyspnea, fibrosis, interstitial pneumonitis

SKIN: Alopecia, dermatitis, exfoliative dermatitis, jaundice, photosensitivity, pruritus, rash, urticaria

Nursing Considerations

- Monitor blood and urine tests for signs of gold toxicity during auranofin therapy.

WARNING Gold toxicity may occur during treatment or several months afterward. It usually occurs with a cumulative dose of 400 to 800 mg and may cause decreased hemoglobin level, WBC count less than 4,000/mm³, granulocyte count less than 1,500/mm³, platelet count less than 150,000/mm³, severe diarrhea, stomatitis, hematuria, proteinuria, rash, and pruritus.

- Monitor fluid intake and output imbalance. If urine output decreases, assess BUN and serum creatinine levels for signs of renal impairment.

- Notify prescriber about possible allergic reaction (dermatitis, rash, pruritus). Drug may need to be discontinued.

PATIENT TEACHING

vAdvise patient that diarrhea is common but that he should notify prescriber immediately if it becomes severe.

- Tell patient to take drug exactly as prescribed and to have monthly blood tests.
- Inform patient that drug may take 3 to 4 months to reach a therapeutic level.
- Urge patient to report skin problems, fatigue, or stomatitis (possible blood dyscrasias).
- Tell patient to report blood in stool or urine, easy bruising, and bleeding gums.

azathioprine

Imuran

azathioprine sodium

Imuran

Class and Category

Chemical class: Purine analogue

Therapeutic class: Antimetabolite, immunosuppressant

Pregnancy category: D

Indications and Dosages

↗ *To prevent kidney rejection after transplantation*

TABLETS, I.V. INFUSION

Adults and children. *Initial:* 3 to 5 mg/kg daily P.O. or I.V. as a single dose on, or 1 to 3 days before, day of transplantation, followed by 3 to 5 mg/kg daily I.V. after surgery until P.O. dose is tolerated.

Maintenance: 1 to 3 mg/kg daily P.O.

DOSAGE ADJUSTMENT Dosage reduced for patients with oliguria (as from tubular necrosis) after transplantation because drug or metabolite excretion may be delayed.

↗ *To treat refractory rheumatoid arthritis*

TABLETS

Adults. *Initial:* 1 mg/kg (50 to 100 mg) daily as a single dose or b.i.d. for 6 to 8 wk.

Maintenance: If initial therapy doesn't produce therapeutic effects or serious adverse effects, dosage increased every 4 wk by 0.5 mg/kg up to 2.5 mg/kg. Optimal dosage is 2 to 2.5 mg/kg daily.

DOSAGE ADJUSTMENT Dosage reduced to 25% to 33% of usual dosage for patients who also take allopurinol.

Route	Onset	Peak	Duration
P.O., I.V.	4–8 wk	Unknown	Several days

Mechanism of Action

May prevent proliferation and differentiation of activated B and T cells by interfering with purine (protein) and nucleic acid (DNA and RNA) synthesis.

Contraindications

Hypersensitivity to azathioprine

Interactions

DRUGS

ACE inhibitors and drugs that affect bone marrow and cell development in bone marrow, such as co-trimoxazole: Possibly severe leukopenia

allopurinol: Possibly increased therapeutic and adverse effects of azathioprine

anticoagulants: Possibly decreased anticoagulant action

cyclosporine: Possibly decreased plasma

cyclosporine level

methotrexate: Possibly increased plasma level of azathioprine's metabolite, 6-mercaptopurine, which can lead to cell death
nondepolarizing neuromuscular blockers: Possibly decreased or reversed action of neuromuscular blocker

Adverse Reactions

CNS: Fever, malaise

GI: Abdominal pain, diarrhea, hepatotoxicity (elevated liver function test results), nausea, pancreatitis, steatorrhea, vomiting

HEME: Leukopenia, macrocytic anemia, pancytopenia, thrombocytopenia

MS: Arthralgia, myalgia

SKIN: Alopecia, rash

RESP: Reversible interstitial pneumonitis

Other: Infection, lymphomas and other neoplasms, negative nitrogen balance

Nursing Considerations

- Before I.V. use, add 20 ml sterile water for injection to azathioprine vial and swirl until clear solution forms. Resulting drug concentration is 100 mg and can be diluted further as prescribed. Calculate infusion rate based on final volume to be infused. Then give over 30 to 60 minutes or as prescribed (5 minutes to 8 hours).
- Obtain results of baseline laboratory tests, including WBC, RBC, and platelet counts. Expect to monitor results once a week during first month of therapy, twice a month during second and third months, and once a month or more thereafter.
- Hematologic reactions typically are dose-related and may occur late in therapy, especially in patients with transplant rejection.

WARNING If WBC count decreases rapidly or remains significantly and consistently low, expect to reduce dosage or discontinue azathioprine.

- Periodically monitor liver function test results for early signs of hepatotoxicity.
- If patient develops thrombocytopenia, take bleeding precautions, such as avoiding I.M. injections and venipunctures, applying ice to areas of trauma, and checking I.V. infusion sites every 2 hours for bleeding.
- If patient also receives an oral anticoagulant, monitor his PT.
- Azathioprine therapy increases risk of

viral, fungal, bacterial, and protozoal infections. Watch for evidence of infection, such as fever, chills, sore throat, and mouth sores. Expect to administer aggressive antibiotic, antiviral, or other drug therapy and reduce azathioprine dosage.

- Minimize the risk of infection. If patient has severe leukopenia, take neutropenic precautions, such as placing him in a private room and limiting visitors.
- Rheumatoid arthritis requires at least 12 weeks of azathioprine therapy. During this time, continue other pain-relief measures, such as rest, physical therapy, and other drugs, such as salicylates and corticosteroids.
- If oral azathioprine causes GI upset, give it in divided doses or with meals.
- Expect to use lowest possible maintenance dosage for rheumatoid arthritis, reducing it gradually in 0.5-mg/kg (about 25-mg) increments at 4-week intervals.
- Drug can be stopped abruptly, but its effects may persist several days.

PATIENT TEACHING

- Advise patient to take oral drug with food or meals to minimize GI upset.

WARNING Teach patient to recognize and report signs of infection, such as sore throat and fever.

- Teach patient how to reduce the risk of bleeding and falling.

azelastine hydrochloride

Astelin

Class and Category

Chemical class: Phthalazinone derivative

Therapeutic class: Antihistamine,

H₁-receptor antagonist

Pregnancy category: C

Indications and Dosages

↗ *To treat symptoms of seasonal rhinitis (rhinorrhea, sneezing, and nasal itching)*

NASAL SPRAY

Adults and children age 12 and over.

2 sprays in each nostril b.i.d.

Mechanism of Action

Binds nonselectively to central and periph-

eral H₁ receptors, preventing histamine from reaching its site of action, which reduces or prevents most of histamine's physiologic effects. By blocking histamine at its site of action, azelastine inhibits respiratory, vascular, and GI smooth-muscle contraction; decreases capillary permeability, which reduces wheals, flares, and itching; and decreases salivary and lacrimal gland secretions.

Route	Onset	Peak	Duration
Nasal	In 3 hr	Unknown	12 hr

Contraindications

Hypersensitivity to azelastine or its components

Interactions

DRUGS

cimetidine, ketoconazole: Possibly increased blood azelastine level

CNS depressants: Possibly increased sedative effects and reduced mental alertness

ACTIVITIES

alcohol use: Possibly increased sedative effects and reduced mental alertness

Adverse Reactions

CNS: Dizziness, fatigue, headache, somnolence

CV: Atrial fibrillation, palpitations

EENT: Bitter taste, dry mouth, epistaxis, nasal burning, paroxysmal sneezing, pharyngitis, rhinitis

GI: Nausea

Other: Weight gain

Nursing Considerations

- Assess for changes in alertness, and take safety precautions, if needed.

PATIENT TEACHING

- Teach patient how to use azelastine nasal spray properly to achieve maximum therapeutic effects.
- Before patient's first use of nasal spray, instruct him to prime pump by placing his thumb on base and his index and middle fingers on shoulder area of bottle and then pressing thumb firmly and quickly against bottle four times or until fine mist appears.
- If patient hasn't used spray in more than 3 days, instruct him to reprime pump with two sprays or until fine mist appears.
- Advise patient to clear nostrils gently, if

needed, before using spray.

- Teach patient to inhale deeply after each spray and then exhale through his mouth and tilt his head back so drug can spread over nasopharynx.
- Advise patient to store bottle upright and tightly closed.

WARNING Emphasize that patient must consult prescriber before taking any OTC drug, such as cough syrup or a cold remedy, because of the risk of extreme CNS depression.

- Inform patient that decreased alertness may occur. Advise him to avoid hazardous activities or those that require alertness, such as driving or operating machinery, until drug's effects are known.

azithromycin

Zithromax, Zmax

Class and Category

Chemical class: Azalide (subclass of macrolide)

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ *To treat mild community-acquired pneumonia, otitis media, pharyngitis, tonsillitis, and uncomplicated skin and soft-tissue infections*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults. 500 mg as a single dose on day 1, followed by 250 mg daily on days 2 through 5.

Children age 6 months or over with acute otitis media or community-acquired pneumonia. 10 mg/kg as a single dose (not to exceed 500 mg daily) on day 1, followed by 5 mg/kg (not to exceed 250 mg daily) daily on days 2 through 5. Or, for acute otitis media, 30 mg/kg of oral suspension as a single dose or 10 mg/kg daily for 3 days.

Children age 12 or over with pharyngitis or tonsillitis. 12 mg/kg (not to exceed 500 mg daily) as single dose daily for 5 days.

↗ *To treat mild to moderate acute bacterial exacerbations of COPD*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults. 500 mg daily for 3 days. Or, 500 mg as single dose on day 1, followed by 250 mg

daily on days 2 through 5.

➤ *To treat community-acquired pneumonia*

CAPSULES, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults and adolescents age 16 or over.

500 mg I.V. as a single dose daily for at least 2 days, followed by 500 mg P.O. as a single dose daily until patient completes 7 to 10 days of therapy.

➤ *To treat community-acquired pneumonia caused by Chlamydomphila pneumoniae, Haemophilus influenzae, Mycoplasma pneumoniae, or Streptococcus pneumoniae*

E.R. ORAL SOLUTION (ZMAX)

Adults. 2 g as a single dose on an empty stomach.

➤ *To treat chancroid caused by Haemophilus ducreyi; gonococcal pharyngitis; urethritis, cervicitis, or other infections caused by Chlamydia trachomatis*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults. 1 g as a one-time dose.

Children age 8 or over and children under age 8 weighing 45 kg (99 lb) or more (with infections caused by C. trachomatis). 1 g as a one-time dose.

➤ *To treat urethritis or cervicitis caused by Neisseria gonorrhoeae*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults. 2 g as a one-time dose.

➤ *To prevent Mycobacterium avium complex in patients with advanced HIV infection*

CAPSULES, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults. 1.2 g once weekly, as indicated.

➤ *To treat pelvic inflammatory disease*

CAPSULES, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults. 500 mg I.V. as a single dose daily for 1 to 2 days, followed by 250 mg P.O. as a single dose daily until patient completes 7 days of therapy.

➤ *To treat acute bacterial sinusitis*

ORAL SUSPENSION, TABLETS

Adults. 500 mg daily for 3 days.

Children. 10 mg/kg daily for 3 days.

➤ *To treat acute bacterial sinusitis caused by H. influenzae, Moraxella catarrhalis, or S. pneumoniae*

E.R. ORAL SOLUTION (ZMAX)

Adults. 2 g as a single dose on an empty stomach.

Route	Onset	Peak	Duration
P.O.	Varies	Unknown	Unknown

Mechanism of Action

Binds to a ribosomal subunit of susceptible bacteria, blocking peptide translocation and inhibiting RNA-dependent protein synthesis. Drug concentrates in phagocytes, macrophages, and fibroblasts, which release it slowly and may help move it to infection sites.

Incompatibilities

Don't add I.V. substances, additives, or drugs to azithromycin I.V. solution, and don't infuse through the same I.V. line.

Contraindications

Hypersensitivity to azithromycin, erythromycin, ketolide antibiotics, or other macrolide antibiotics

Interactions

DRUGS

antacids that contain aluminum or magnesium: Possibly decreased peak blood azithromycin level, but extent of absorption is unchanged

carbamazepine, cyclosporine, phenytoin, terfenadine (drugs metabolized by P-450 cytochrome system): Possibly increased blood levels of these drugs

digoxin: Possibly increased blood digoxin level

dihydroergotamine, ergotamine: Possibly severe peripheral vasospasm and abnormal sensations (acute ergot toxicity)

HMG-CoA reductase inhibitors: Increased risk of severe myopathy or rhabdomyolysis

pimozide: Possibly sudden death

oral anticoagulants: Possibly potentiated effects of oral anticoagulants

theophylline: Possibly increased blood theophylline level

triazolam: Possibly decreased excretion and increased therapeutic effects of triazolam

warfarin: Possibly increased anticoagulation

FOODS

food: Dramatically increased absorption rate of azithromycin

Adverse Reactions

CNS: Aggressiveness, agitation, anxiety,

asthenia, dizziness, fatigue, headache, hyperaesthesia, malaise, nervousness, paresthesia, seizures, somnolence, syncope, vertigo

CV: Chest pain, edema, elevated serum CK level, hypotension, palpitations, prolonged QT interval, torsades de pointes, ventricular tachycardia

EENT: Hearing loss, mucocutaneous candidiasis, perversion or loss of taste or smell, tinnitus

ENDO: Hyperglycemia

GI: Abdominal pain, anorexia, cholestatic jaundice, constipation, diarrhea, dyspepsia, elevated liver function test results, flatulence, hepatic necrosis or failure, hepatitis, nausea, pancreatitis, pseudomembranous colitis, vomiting

GU: Acute renal failure, elevated BUN and serum creatinine levels, nephritis, vaginal candidiasis

HEME: Leukopenia, neutropenia, thrombocytopenia

MS: Arthralgia

SKIN: Erythema multiforme, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Allergic reaction, anaphylaxis, angioedema, elevated serum phosphorus level, hyperkalemia, infusion site reaction (such as pain and redness), new or worsening myasthenia syndrome, superinfection

Nursing Considerations

- Obtain culture and sensitivity test results, if possible, before starting therapy.
- Use azithromycin cautiously in patients with hepatic dysfunction (drug is metabolized in the liver) or renal dysfunction (effects are unknown in this group).
- Give azithromycin capsules 1 hour before or 2 to 3 hours after food. Give tablets or suspension without regard to food.

WARNING Don't give azithromycin by I.V. bolus or I.M. injection because it may cause erythema, pain, swelling, tenderness, or other reaction at the site. Infuse it over 60 minutes or longer, as prescribed (typically 1 mg/ml over 3 hours or 2 mg/ml over 1 hour.)

- If hepatic function is impaired, monitor liver function studies because drug is eliminated mainly by the liver.
- Assess patient for bacterial or fungal superinfection, which may occur with prolonged or repeated therapy. If it occurs,

expect to give another antibiotic or antifungal.

- Monitor bowel elimination; if needed, obtain stool culture to rule out pseudomembranous colitis. If it occurs, expect to stop azithromycin and give fluid, electrolytes, and antibiotics effective with *Clostridium difficile*.

PATIENT TEACHING

- Tell patient to take azithromycin capsules 1 hour before or 2 to 3 hours after food. Instruct patient to take tablets or suspension without regard to food.

WARNING Urge patient to consult prescriber before taking OTC drugs, including antacids. If they're prescribed, tell patient to take azithromycin 1 hour before or 2 to 3 hours after taking antacids.

- Tell patient to immediately report signs and symptoms of allergic reaction (such as rash, itching, hives, chest tightness, and trouble breathing).
- Warn patient that abdominal pain and loose, watery stools may occur. If diarrhea persists or becomes severe, urge him to contact prescriber and replace fluids.
- Because azithromycin may destroy normal flora, teach patient to watch for and immediately report signs of superinfection, such as white patches in the mouth.

aztreonam

Azactam

Class and Category

Chemical class: Monobactam

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ *To treat infections of the urinary tract, lower respiratory tract, skin, soft tissue, female reproductive tract; intra-abdominal infections; septicemia; and surgical abscesses caused by susceptible strains of gram-negative bacteria*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 0.5 to 2 g every 8 to 12 hr to maximum of 8 g daily. For life-threatening systemic infection, 2 g every 6 to 8 hr to maximum of 8 g daily.

Children ages 9 months to 16 years.

30 mg/kg every 6 to 8 hr up to 120 mg/kg

daily; 50 mg/kg every 4 to 6 hr (for *Pseudomonas aeruginosa*).

DOSE ADJUSTMENT If creatinine clearance is 10 to 30 ml/min/1.73 m², initial dose is 1 to 2 g; then 50% of usual dose at usual interval. If creatinine clearance is less than 10 ml/min/1.73 m², initial dose is 500 mg to 2 g; then 25% of the usual dose every 6, 8, or 12 hr.

Route	Onset	Peak	Duration
I.V. infusion	Immediate	Immediate	Unknown
I.V. injection	Immediate	Immediate	Unknown
I.M.	Variable	60 min	Unknown

Mechanism of Action

Inhibits bacterial cell wall synthesis in susceptible aerobic gram-negative bacteria. These bacteria assemble rigid, cross-linked cell walls in several steps. Aztreonam affects the final cross-linking step by inactivating penicillin-binding protein 3 (the enzyme that links cell wall strands), which causes cell lysis and death.

Incompatibilities

Don't mix aztreonam in same I.V. solution as cephadrine, metronidazole, or nafcillin sodium. Don't mix it in same I.M. injection solution as local anesthetic.

Contraindications

Hypersensitivity to aztreonam or its components

Interactions

DRUGS

aminoglycosides (prolonged or high-dose therapy): Increased risk of nephrotoxicity and ototoxicity

cefotixin, *imipenem*: Possibly antagonized action of aztreonam

furosemide, *probenecid*: Possibly increased blood aztreonam level

Adverse Reactions

CNS: Confusion, dizziness, fever, headache, insomnia, malaise, paresthesia, seizures, vertigo

CV: Chest pain, hypotension, transient ECG changes

EENT: Altered taste, diplopia, halitosis, mouth ulcers, mucocutaneous candidiasis,

nasal congestion, sneezing, tinnitus, tongue numbness

GI: Abdominal cramps, diarrhea, elevated liver function test results, GI bleeding, hepatitis, nausea, pseudomembranous colitis, vomiting

GU: Breast tenderness, elevated serum creatinine level, vaginal candidiasis

HEME: Anemia, eosinophilia, leukocytosis, neutropenia, pancytopenia, positive Coombs' test, prolonged PT and APTT, thrombocytopenia, thrombocytosis

MS: Myalgia

RESP: Bronchospasm, dyspnea, wheezing

SKIN: Diaphoresis, erythema multiforme, exfoliative dermatitis, flushing, jaundice, petechiae, pruritus, purpura, rash, toxic epidermal necrolysis, urticaria

Other: Allergic reaction; injection site pain, phlebitis, swelling, or thrombophlebitis

Nursing Considerations

- Obtain culture and sensitivity test results, if possible, before starting aztreonam therapy. If patient is acutely ill, expect to begin therapy before results are available.
- Keep in mind that other antimicrobials may be used with aztreonam in seriously ill patients at risk for gram-positive infection.
- Expect to use I.V. route for patients who need single doses over 1 g and those with life-threatening systemic infections, such as septicemia or peritonitis.
- To reconstitute aztreonam for I.V. bolus injection, use sterile water for injection.
- Immediately after adding diluent to vial, shake it vigorously to mix. After obtaining correct dose, discard unused solution.
- Reconstituted solution may turn light pink on standing at room temperature. This doesn't affect drug potency.
- Give I.V. bolus injection directly into I.V. tubing over 3 to 5 minutes.

WARNING When preparing aztreonam for I.V. infusion, use at least 50 ml of appropriate infusion solution per gram of aztreonam. Further dilute drug in I.V. solution, such as normal saline solution, D₅W, dextrose 5% in normal saline solution, lactated Ringer's solution, or Ringer's solution.

- Know that I.V. infusion may be administered over 20 to 60 minutes.
- Flush I.V. tubing with solution, such as

normal saline solution, before and after administering I.V. infusion to reduce risk of incompatibilities.

- If prescribed, mix aztreonam in same I.V. solution with other antibiotics (such as ampicillin sodium, cefazolin sodium, clindamycin phosphate, gentamicin sulfate, or tobramycin sulfate), or mix it with cloxacillin sodium and vancomycin hydrochloride in peritoneal dialysis solution.
- Prepare solution for I.M. injection using sterile or bacteriostatic water or sodium chloride for injection. Administer injection deep into large muscle, such as in dorsogluteal or ventrogluteal area.
- Assess for signs of bacterial or fungal superinfection, which may occur with prolonged or repeated therapy. If superinfection occurs, treat it as prescribed.
- Monitor bowel elimination; if needed, obtain stool culture to rule out pseudomembranous colitis. If it occurs, expect to discontinue aztreonam and administer fluid, electrolytes, and antibiotics effective against *Clostridium difficile*.
- Evaluate patient's renal and liver function test results, as ordered, if patient has renal or hepatic impairment.
- Monitor renal function if patient is receiving an aminoglycoside because of the increased risk of nephrotoxicity.

PATIENT TEACHING

- Stress the need to take full course of aztreonam exactly as prescribed, even if patient feels better before finishing it.
- Teach patient to recognize and immediately report signs and symptoms of allergic reactions, such as chest tightness, difficulty breathing, hives, itching, and rash.
- Warn patient that abdominal pain and loose, watery stools may occur 2 months or more after aztreonam therapy stops. If diarrhea persists or becomes severe, urge him to contact prescriber and replace fluids.
- Because aztreonam may destroy normal flora, teach patient to watch for and immediately report signs of superinfection, such as white patches in mouth.

B

bacampicillin hydrochloride

Penglobe (CAN), Spectrobid

Class and Category

Chemical class: Aminopenicillin

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat upper respiratory tract infections (including otitis media) caused by streptococci, pneumococci, non-penicillinase-producing staphylococci, and Haemophilus influenzae; UTI caused by Escherichia coli, Proteus mirabilis, or Streptococcus faecalis; skin and soft-tissue infections caused by streptococci and susceptible staphylococci*

TABLETS

Adults. 400 mg every 12 hr; 800 mg every 12 hr for severe infections and those caused by less susceptible organisms.

Children weighing 25 kg (55 lb) or more.

25 mg/kg daily in divided doses every 12 hr; 50 mg/kg daily in divided doses every 12 hr for severe infections and those caused by less susceptible organisms.

➤ *To treat lower respiratory tract infections caused by streptococci, pneumococci, non-penicillinase-producing staphylococci, and H. influenzae*

TABLETS

Adults. 800 mg every 12 hr.

Children weighing 25 kg or more. 50 mg/kg/day in divided doses every 12 hr.

➤ *To treat uncomplicated gonorrhea caused by Neisseria gonorrhoeae*

TABLETS

Adults. 1.6 g plus 1 g of probenecid as a single dose.

Route	Onset	Peak	Duration
P.O.	Variable	Unknown	12 hr

Mechanism of Action

Inhibits bacterial cell wall synthesis in sus-

ceptible bacteria. These bacteria assemble rigid, cross-linked cell walls in several steps. Bacampicillin, which undergoes hydrolysis to ampicillin, affects final stage of cross-linking by binding with and inactivating penicillin-binding protein (enzyme responsible for linking cell wall strands). This action inhibits bacterial cell wall synthesis and causes cell lysis and death.

Contraindications

Cholestatic jaundice and hepatic dysfunction associated with amoxicillin and clavulanate potassium; hypersensitivity to penicillins, cephalosporins, imipenem and cilastatin, or beta-lactamase inhibitors, such as piperacillin and tazobactam

Interactions

DRUGS

allopurinol: Increased risk of rash from bacampicillin use

beta-adrenergic blockers: Increased risk of anaphylaxis

disulfiram: Possibly disulfiram reaction when administered together

oral contraceptives: Possibly reduced effectiveness of oral contraceptives, contraceptive failure, and breakthrough bleeding

tetracyclines: Possibly impaired bactericidal effects of bacampicillin

Adverse Reactions

CNS: Anxiety, confusion, depression, fatigue, fever, hallucinations, lethargy, malaise, neuromuscular irritability, seizures, stroke, syncope

CV: Hypotension, palpitations, periarteritis nodosa, pulmonary hypertension, tachycardia, vascular collapse

EENT: Altered taste, black “hairy” tongue, blurred vision, glossitis, laryngospasm, mouth soreness, mucocutaneous candidiasis, stomatitis, taste disorders

GI: Abdominal cramps or pain, anorexia, diarrhea, enterocolitis, epigastric distress, elevated liver function test results, gastritis, nausea, pseudomembranous colitis, vomiting

GU: Elevated BUN and serum creatinine levels, hematuria, impotence, interstitial nephritis, neurogenic bladder, priapism, renal failure, vaginal candidiasis

HEME: Agranulocytosis, anemia, bone marrow depression, decreased hemoglobin level and hematocrit, eosinophilia, leukope-

nia, neutropenia, prolonged PT, thrombocytopenia, thrombocytopenic purpura

MS: Arthralgia, arthritis exacerbation

RESP: Bronchospasm

SKIN: Exfoliative dermatitis, rash, urticaria

Other: Allergic reaction, lymphadenopathy, serum sickness

Nursing Considerations

- Obtain culture and sensitivity test results, if possible, before starting therapy. Expect to start drug before results are available.
- Expect to continue treatment for at least 48 hours after symptoms resolve or culture detects no signs of infection.

WARNING Expect to give bacampicillin for 10 days to treat infection caused by group A beta-hemolytic streptococci to prevent development of acute rheumatic fever or acute glomerulonephritis.

- Assess patient for bacterial or fungal superinfection, which may occur with prolonged or repeated therapy. If it occurs, expect to administer another antibiotic or antifungal drug.
- Monitor bowel elimination; if needed, obtain stool culture to rule out pseudomembranous colitis. If this adverse reaction occurs, expect to discontinue bacampicillin and give fluid, electrolytes, and antibiotics effective against *Clostridium difficile*.

PATIENT TEACHING

- Teach patient to recognize and immediately report signs of allergic reaction, including rash, itching, hives, chest tightness, and difficulty breathing.
- Warn that abdominal pain and loose, watery stools may occur. If diarrhea persists or becomes severe, urge him to contact prescriber and drink plenty of fluids.
- Because bacampicillin may destroy normal flora, teach patient to watch for and immediately report signs of superinfection, such as white patches in mouth and vaginal itching and discharge.

bacitracin

Baci-IM

Class and Category

Chemical class: Bacillus subtilis derivative (polypeptide)

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

➤ To treat pneumonia and empyema caused by susceptible staphylococci

I.M. INJECTION

Infants weighing more than 2.5 kg (5.5 lb).

1,000 units/kg daily in 2 or 3 divided doses.

Infants weighing less than 2.5 kg. 900 units/kg daily in 2 or 3 divided doses.

Route	Onset	Peak	Duration
I.M.	Rapid	Unknown	About 6 hr

Mechanism of Action

Interferes with bacterial cell wall synthesis by binding with isoprenyl pyrophosphate (a lipid-carrying molecule that transports substances out of bacterial cells to help build new cell walls), forming an unusable complex in bacterial cells. This weakens cell walls and causes lysis and death. Bacitracin is considered bacteriostatic and bactericidal.

Incompatibilities

Don't dilute bacitracin with a solution that contains parabens.

Contraindications

Hypersensitivity or toxic reaction to bacitracin

Interactions

DRUGS

aminoglycosides: Increased risk of respiratory paralysis and renal dysfunction

nondepolarizing neuromuscular blockers:

Possibly increased neuromuscular blockade

Adverse Reactions

GI: Nausea, vomiting

GU: Albuminuria, azotemia, cylindrical mucus casts in urine, nephrotoxicity

SKIN: Rash

Other: Injection site pain, superinfection

Nursing Considerations

- Obtain culture and sensitivity test results before therapy begins, if possible. Be prepared to start bacitracin therapy before results are available.

WARNING Use parenteral bacitracin for I.M. injection only.

- For I.M. solution of 5,000 units/ml, reconstitute 50,000 units bacitracin powder with 9.8 ml sodium chloride for injection

- that contains 2% procaine hydrochloride.
- Administer I.M. injection into upper outer quadrant of buttocks, alternating between right and left sides. To prevent pain at injection site, avoid giving multiple injections in same site.
 - During therapy, compare daily results of renal function tests with baseline results, as appropriate.
 - Assess urine output often (hourly, if needed), and replace fluids orally and parenterally to maintain adequate renal function.
- WARNING** Because of increased risk of nephrotoxicity, avoid concurrent use of other nephrotoxic drugs, such as streptomycin, kanamycin, polymyxin B, and neomycin.
- Assess infant for signs of superinfection, especially white patches in mouth and perineum. If superinfection develops, plan to treat with appropriate antibiotics.

PATIENT TEACHING

- Advise parents that daily blood tests are needed to assess infant's renal function.
- Encourage parents to provide oral fluids to promote renal function. Teach them how to record infant's fluid intake.
- Instruct parents to report signs or symptoms of superinfection, such as white patches in mouth or perineal area and bright red diaper rash.

baclofen

Apo-Baclofen (CAN), Lioresal, Lioresal Intrathecal, Novo-Baclofen (CAN)

Class and Category

Chemical class: Gamma-aminobutyric acid (GABA) chlorophenyl derivative

Therapeutic class: Skeletal muscle relaxant, spasmolytic

Pregnancy category: C

Indications and Dosages

➤ *To relieve symptoms of spasticity caused by multiple sclerosis (particularly flexor spasms and pain, clonus, and muscle rigidity) and spasticity from spinal cord injury or disease and brain injury*

TABLETS

Adults and children age 12 and over. 5 mg t.i.d. for 3 days; then 10 mg t.i.d. for 3 days; then 15 mg t.i.d. for 3 days; then 20 mg

t.i.d. for 3 days; then increased if needed up to 80 mg daily. Usual dosage ranges from 40 to 80 mg daily.

➤ *To relieve severe symptoms of spasticity of spinal cord origin when symptoms don't respond to oral drug or when oral drug causes severe adverse CNS effects*

INTRATHECAL BOLUS, INTRATHECAL INFUSION

Adults. *For screening before implantable pump insertion:* 50 mcg in 1 ml sterile preservative-free sodium chloride for injection as bolus injection into intrathecal space over 1 min or more. After 4 to 8 hr, if symptoms don't improve as much as desired, second bolus of 75 mcg in 1.5 ml of sterile preservative-free sodium chloride for injection, injected after 24 hr, followed by third bolus of 100-mcg/2 ml dilution injected after another 24 hr, if needed. *After implantable pump insertion:* Effective screening dose doubled and infused over 24 hr. Or effective screening dose (if it provided desired effects for more than 12 hr) infused over 24 hr.

For spasticity of spinal cord origin after implantable pump insertion: After first 24 hr, daily dose increased by 10% to 30% once every 24 hr until desired effects achieved.

For spasticity of cerebral origin after implantable pump insertion: Daily dose increased by 5% to 15% once every 24 hr until desired effects achieved.

For long-term maintenance therapy in spasticity of spinal cord origin: 12 to 2,003 mcg/day (usual dose 300 to 800 mcg daily).

Lowest possible therapeutic dose should be used. If adverse effects occur, daily dose may be decreased by 10% to 20%. During periodic pump refills, daily dose may be increased by 10% up to 40% to control symptoms adequately.

For long-term maintenance therapy in spasticity of cerebral origin: 90 to 703 mcg daily (usual) but ranging from 22 to 1,400 mcg/day. If adverse effects occur, daily dose may be decreased by 10% to 20%. During periodic pump refills, daily dose may be increased by 5% to 20% to control symptoms adequately.

Children. *For screening before implantable pump insertion:* 1 ml of 50-mcg/ml dilution or 1 ml of 25-mcg/ml dilution (if child is very young) as bolus injection into intrathecal space over 1 min or more. After

4 to 8 hr, if symptoms don't improve as desired, second bolus of 75 mcg in 1.5 ml of sterile preservative-free sodium chloride for injection, injected after 24 hr, followed by third bolus of 100-mcg/2 ml dilution, injected after another 24 hr, if needed.

After implantable pump insertion: Daily dose increased by 5% to 15% once every 24 hr until desired effect is achieved.

For maintenance therapy: In children over age 12—90 to 703 mcg daily (usual), ranging from 22 to 1,400 mcg daily. In children under age 12—274 mcg daily (average), ranging from 24 to 1,199 mcg daily.

DOSE ADJUSTMENT Dosage reduced for patients with renal impairment because drug is excreted primarily unchanged by kidneys.

Route	Onset	Peak	Duration
P.O.	Hours–weeks	Unknown	Unknown
Intrathecal bolus injection	30–60 min	About 4 hr	4–8 hr
Intrathecal infusion	6–8 hr	24–48 hr	Unknown

Mechanism of Action

May inhibit transmission of monosynaptic and polysynaptic impulses, similar to effects of gamma-aminobutyric acid (GABA). Baclofen may work in the spinal cord at the afferent spinal end of upper motor neurons, where it hyperpolarizes nerve fibers and inhibits impulse transmission. This reduces excess muscle activity caused by muscle hypertonia, spasms, and spasticity.

Contraindications

Hypersensitivity to baclofen; treatment of skeletal muscle spasm resulting from rheumatic disorders, cerebral palsy, Parkinson's disease, or stroke (oral form only)

Interactions

DRUGS

CNS depressants: Possibly increased CNS depression

epidural morphine: Possibly hypotension and dyspnea

ACTIVITIES

alcohol use: Possibly increased CNS depression

Adverse Reactions

CNS: Abnormal gait, anxiety, ataxia, chills, coma, confusion, depression, dizziness, drowsiness, dystonia, emotional lability, euphoria, excitement, fatigue, fever, hallucinations, headache, hypertonia, hypothermia, hypotonia, impaired concentration, insomnia, lack of coordination, lethargy, memory loss, paresthesia, personality disorder, seizures, somnolence, stroke, syncope, tremor, weakness

CV: Bradycardia, chest pain, chest tightness, deep vein thrombosis, hypertension, orthostatic hypotension, palpitations, peripheral edema

EENT: Amblyopia, blurred vision, diplopia, dry mouth, miosis, mydriasis, nasal congestion, nystagmus, photophobia, ptosis, rhinitis, slurred speech, strabismus, taste loss, tinnitus

ENDO: Hyperglycemia

GI: Abdominal pain, anorexia, constipation, dysphagia, elevated liver function test results, flatulence, ileus, indigestion, nausea, vomiting

GU: Albuminuria, bladder spasms, dysuria, enuresis, hematuria, impotence, renal failure, sexual dysfunction, urinary frequency, urinary incontinence, urine retention

HEME: Anemia

MS: Muscle twitching

RESP: Aspiration pneumonia, pulmonary embolism, respiratory depression

SKIN: Alopecia, diaphoresis, facial edema, flushing, pruritus, rash, urticaria, wound dehiscence

Other: Dehydration, infection at pump implantation site, weight loss

Nursing Considerations

- Expect to start baclofen therapy at a low dose and gradually increase until desired effects are achieved.

WARNING Before screening dose is given, expect prescriber to make sure patient is free of infection to prevent systemic infection from interfering with patient's response. Before implantable pump insertion, also expect prescriber to make sure patient is free of infection to reduce risk of complications and interference with determining most appropriate dose.

- Use baclofen cautiously in patients with a history of autonomic dysreflexia. Nociceptor stimulation may precipitate

autonomic dysreflexia. Be aware that abrupt withdrawal of intrathecal infusion may produce symptoms similar to autonomic dysreflexia, high fever, life-threatening complications such as multiple organ-system failure, and death.

WARNING Never give intrathecal form of baclofen by I.V., I.M., or subcutaneous routes.

- Assess for signs of effectiveness, such as relief of spasms, pain, and muscle rigidity.
- Because CNS depression can occur, take precautions to prevent injury. Also take precautions for patients who use spasticity to maintain locomotion or upright posture and balance. Relief of spasticity may increase risk of falls and injury.

WARNING Because continuous intrathecal infusion increases risk of life-threatening CNS depression, keep emergency equipment nearby.

- Expect baclofen to be discontinued slowly; hallucinations and seizures may occur with abrupt withdrawal.

PATIENT TEACHING

- Teach patient how to care for and operate programmable implanted pump. Have her demonstrate all procedures.
- Advise against stopping baclofen abruptly. Stress the importance of keeping follow-up appointments for intrathecal infusion.
- Instruct patient to avoid driving and other activities that require mental alertness, coordination, or physical dexterity until baclofen's effects are known.
- Urge patient to contact prescriber before taking OTC drugs, such as cough syrups and cold remedies, which may increase risk of sedation.
- Urge patient to notify prescriber if spasticity increases or drug is no longer effective.

balsalazide disodium

Colazal

Class and Category

Chemical class: Prodrug of 5-aminosalicylic acid (5-ASA)

Therapeutic class: Anti-inflammatory

Pregnancy category: B

Indications and Dosages

➤ *To treat mildly to moderately active ulcerative colitis*

CAPSULES

Adults. 2.25 g t.i.d. for 8 wk. *Maximum:* 6.75 g daily for 12 wk.

Children ages 5 to 17. 750 mg or 2.25 g t.i.d. for up to 8 wk.

Mechanism of Action

After it has been metabolized to 5-ASA, balsalazide may reduce inflammation by inhibiting the enzyme cyclooxygenase and decreasing production of arachidonic acid metabolites, which may be increased in patients with inflammatory bowel disease.

Cyclooxygenase is needed to form prostaglandin from arachidonic acid. Prostaglandin mediates inflammatory activity and produces signs and symptoms of inflammation. By inhibiting prostaglandin synthesis, balsalazide may reduce signs and symptoms of inflammation in inflammatory bowel disease.

Balsalazide also interferes with leukotriene synthesis and inhibits the enzyme lipoxigenase. These substances are involved in the inflammatory response.

Contraindications

Hypersensitivity to balsalazide, salicylates, or their components

Adverse Reactions

CNS: Fatigue, fever, headache, insomnia

CV: Myocarditis, pericarditis, vasculitis

EENT: Dry mouth, nasopharyngitis, pharyngitis, rhinitis, stomatitis

GI: Abdominal cramps or pain, anorexia, cirrhosis, constipation, diarrhea, dyspepsia, elevated liver enzyme levels, exacerbation of colitis, flatulence, hepatotoxicity, jaundice, nausea, pancreatitis, vomiting

GU: Dysmenorrhea, interstitial nephritis, renal failure, UTI

MS: Arthralgia, myalgia

RESP: Alveolitis, cough, flulike syndrome, pleural effusion, pneumonia, respiratory tract infection

SKIN: Alopecia, pruritus

Nursing Considerations

WARNING Monitor patients who are sensitive to sulfasalazine or olsalazine for possible cross-sensitivity to balsalazide.

- Monitor patients with pyloric stenosis for

decreased or delayed drug effects due to prolonged gastric retention of balsalazide capsules.

- Monitor patient for possible exacerbation of colitis symptoms.

PATIENT TEACHING

- Inform patient that balsalazide is used to reduce bowel inflammation and pain in ulcerative colitis and to minimize recurring inflammation.
- Instruct patient to swallow capsules whole, with a full glass of water, and not to crush or chew them.
- Advise patient to notify prescriber of any other drugs she may be taking, including OTC drugs, nutritional supplements, and herbal products, because they may interact with balsalazide.
- Instruct patient to notify prescriber immediately if colitis symptoms worsen.
- Inform patient that she can expect some improvement in symptoms in 3 to 21 days but that optimal results may take up to 6 weeks of treatment.

basiliximab

Simulect

Class and Category

Chemical class: Chimeric (murine or human) monoclonal antibody

Therapeutic class: Immunosuppressant

Pregnancy category: B

Indications and Dosages

➤ *To prevent acute rejection in kidney transplantation*

I.V. INFUSION OR INJECTION

Adults and adolescents over age 15. 20 mg within 2 hr before transplantation; then 20 mg 4 days after transplantation.

Children and adolescents ages 2 to 15. 12 mg/m² within 2 hr before transplantation; then 12 mg/m² 4 days after transplantation. *Maximum:* 20 mg/dose.

Route	Onset	Peak	Duration
I.V.	Unknown	Unknown	22–50 days

Mechanism of Action

Initiates immunosuppression by blocking interleukin-2 receptors located on the sur-

face of activated T cells. Normally, interleukin-2 is released by stimulated T lymphocytes, causing activation and differentiation of other T lymphocytes responsible for cell-mediated immunity.

Incompatibilities

Don't add or infuse any other drugs simultaneously through same I.V. line.

Contraindications

Hypersensitivity to basiliximab or its components

Adverse Reactions

CNS: Asthenia, dizziness, fever, headache, insomnia, tremor

CV: Hypertension, peripheral edema

EENT: Oral candidiasis, pharyngitis, rhinitis

ENDO: Hyperglycemia

GI: Abdominal pain, constipation, diarrhea, indigestion, nausea, vomiting

GU: Dysuria, increased urinary nitrogen level, UTI

HEME: Anemia

MS: Back pain, leg pain

RESP: Cough, dyspnea, upper respiratory tract infection

SKIN: Acne

Other: Hypercholesterolemia, hyperkalemia, hyperuricemia, hypocalcemia, hypokalemia, hypophosphatemia, impaired wound healing, injection site reaction, metabolic acidosis, weight gain

Nursing Considerations

- To reconstitute basiliximab, add 5 ml sterile water for injection to powder and shake vial gently to dissolve. Further dilute with normal saline solution or D₅W for infusion to a volume of 50 ml. Gently invert infusion bag to avoid foaming; don't shake. Drug should appear clear to opalescent and colorless.
- Give reconstituted drug I.V. over 20 to 30 minutes or as bolus dose directly through central or peripheral I.V. line. Be aware that bolus dose may cause nausea, vomiting, and a localized injection-site reaction, including pain.
- Expect drug to be given as adjunct to cyclosporine and corticosteroids.
- Don't store drug at room temperature for longer than 4 hours; don't refrigerate for longer than 24 hours.

WARNING Patient may develop hypersensitivity reactions (anaphylaxis, bronchospasm, dyspnea, hypotension, pruritus, rash, respiratory failure, sneezing, tachycardia, urticaria, wheezing) on initial exposure or following re-exposure after several months. Notify prescriber immediately if such reactions occur.

PATIENT TEACHING

- Inform patient that second dose of basiliximab will be given 4 days after transplantation and that she may also receive cyclosporine and corticosteroid therapy.
- Inform patient that because of drug’s immunosuppressant effects, she may experience slower wound healing and be more susceptible to upper respiratory tract infections.

beclomethasone dipropionate

Beclodisk (CAN), Beclovent Rotacaps (CAN), Beconase, Beconase AQ, QVAR, Vancenase, Vanceril

Class and Category

Chemical class: Synthetic glucocorticoid
Therapeutic class: Antiasthmatic, anti-inflammatory
Pregnancy category: C

Indications and Dosages

➤ *To control and prevent symptoms in patients with chronic asthma and those who also require oral corticosteroids*

INHALATION AEROSOL (84 MCG)

Adults and children age 12 and over.

Initial: 2 inhalations (168 mcg) b.i.d. For patients with severe asthma, 6 to 8 inhalations (504 to 672 mcg) daily with dosage reduced based on patient response.

Maximum: 10 inhalations (840 mcg) daily.

Children ages 6 to 12. *Initial:* 2 inhalations (168 mcg) b.i.d. *Maximum:* 5 inhalations (420 mcg) daily.

INHALATION AEROSOL (42 MCG)

Adults and children age 12 and over.

Initial: 2 inhalations (84 mcg) t.i.d. or q.i.d. or 4 inhalations (168 mcg) b.i.d. For patients with severe asthma, 12 to 16 inhalations (504 to 672 mcg) daily with dosage reduced based on patient response.

Maximum: 20 inhalations (840 mcg) daily.
Children ages 6 to 12. *Initial:* 1 or 2 inhalations (42 mcg or 84 mcg) t.i.d. or q.i.d. or 4 inhalations (168 mcg) b.i.d. with dosage reduced based on patient response.

Maximum: 10 inhalations (420 mcg) daily.

INHALATION AEROSOL (40 MCG, 80 MCG [QVAR])

Adults and adolescents. *Initial for patients previously taking bronchodilators alone:* 1 to 2 inhalations (40 to 80 mcg) b.i.d., depending on strength used. *Maximum:* 4 to 8 inhalations (320 mcg) b.i.d., depending on strength used. *Initial for patients previously taking inhaled corticosteroids:* 1 to 4 inhalations (160 mcg) b.i.d., depending on strength used. *Maximum:* 4 to 8 inhalations (320 mcg) b.i.d., depending on strength used.

Children ages 5 to 11. 1 inhalation (40 mcg) b.i.d. *Maximum:* 1 to 2 inhalations (80 mcg) b.i.d., depending on strength used.

➤ *To relieve symptoms of seasonal or perennial allergic and nonallergic (vasomotor) rhinitis and prevent nasal polyps from recurring after surgical removal*

NASAL INHALATION AEROSOL

Adults and children age 12 and over.

Initial: 1 inhalation (42 mcg) in each nostril b.i.d. to q.i.d. for total dose of 168 to 336 mcg daily. *Maintenance:* 1 inhalation (42 mcg) in each nostril t.i.d. for total dose of 252 mcg daily.

Children ages 6 to 12. 1 inhalation (42 mcg) in each nostril t.i.d. for total dose of 252 mcg daily.

NASAL SPRAY

Adults and children age 12 and over. 1 or 2 inhalations (42 or 84 mcg) in each nostril b.i.d. for total dose of 168 or 336 mcg daily.

Mechanism of Action

May decrease number and activity of cells involved in the inflammatory response of asthma, allergies, and rhinitis, such as mast cells, eosinophils, basophils, lymphocytes, macrophages, and neutrophils. Also may inhibit production or secretion of chemical mediators, such as histamine, eicosanoids, leukotrienes, and cytokines. May produce direct smooth-muscle cell relaxation and decrease airway hyperresponsiveness.

Contraindications

Hypersensitivity to beclomethasone’s ingre-

dients, infrequent oral corticosteroid treatment, primary treatment of status asthmaticus or other acute asthma attack, relief of acute bronchospasm or of asthma controlled by bronchodilators or other nonsteroidal drugs, treatment of nonasthmatic bronchitis

Adverse Reactions

CNS: Depression, fatigue, fever, headache, insomnia, light-headedness

CV: Chest pain, tachycardia

EENT: Cataracts, dry mouth, dysphonia, earache, epistaxis, glaucoma, hoarseness, lacrimation, nasal congestion, nose and throat dryness and irritation, oral candidiasis, pharyngitis, rhinorrhea, sinusitis, sneezing, unpleasant smell and taste

ENDO: Adrenal insufficiency, cushingoid symptoms

GI: Diarrhea, indigestion, nausea, rectal hemorrhage

GU: Dysmenorrhea, UTI

MS: Arthralgia, growth suppression in children (nasal aerosol)

RESP: Bronchitis, bronchospasm, chest congestion, cough, pulmonary infiltrates, upper respiratory tract infection, wheezing

SKIN: Acne, eczema, pruritus, rash, skin discoloration, urticaria

Other: Angioedema, flulike symptoms, lymphadenopathy, weight gain

Nursing Considerations

- If patient also takes an oral corticosteroid, expect to taper dosage slowly (by decreasing daily dosage or taking drug every other day) about 1 week after beclomethasone therapy begins. Expect dosage reductions of more than 2.5 mg daily.

WARNING When gradually switching patient from oral corticosteroid to inhaled beclomethasone, watch for signs of life-threatening adrenal insufficiency, such as fatigue, lassitude, weakness, nausea, vomiting, and hypotension, during transition period and when exposed to trauma, surgery, infection, or other stressor. If signs occur, notify prescriber immediately.

- Expect to resume oral corticosteroid during a stressful period or severe asthma attack.
- Because beclomethasone may be absorbed systemically, watch for signs of adrenal insufficiency during periods of stress.

- If patient has acute asthma attack or increased wheezing after receiving beclomethasone, give fast-acting bronchodilator, as prescribed. Expect to discontinue beclomethasone.
- Assess for signs of candidiasis, such as thick white plaques or coating on tongue and sides of mouth. If present, notify prescriber and expect to reduce dose or frequency or to stop beclomethasone. Also anticipate treatment with antifungal drug.
- When administering beclomethasone nasal spray, periodically assess nasal discharge for color or consistency changes, which may indicate infection.
- Monitor the growth of children receiving beclomethasone nasally.

PATIENT TEACHING

- Advise patient not to abruptly stop taking beclomethasone because adrenal insufficiency may occur. Urge her to notify prescriber if she develops signs of adrenal insufficiency, such as nausea, fatigue, anorexia, dyspnea, hypotension, fever, malaise, dizziness, and fainting.
- Before patient uses nasal spray for first time, instruct her to prime pump by placing her thumb on its base and her index and middle fingers on its shoulder area and then pressing her thumb firmly and quickly against the bottle several times or until fine mist appears. Before patient uses nasal inhalation canister for first time, instruct her to shake it and check that it's working properly by spraying it once in the air while looking for fine mist.
- Teach patient to inhale deeply after each nasal spray or inhalation, exhaling through mouth and tilting head back to let drug spread over the nasopharynx.
- Teach patient how to properly use oral inhalation aerosol, shaking canister well before using. If patient has trouble using device and coordinating inhalation with it, suggest using a spacer device.
- If two inhalations are prescribed, advise patient to wait a minute between them.
- If patient uses an inhaled bronchodilator with beclomethasone oral inhalation, tell her to use bronchodilator first, wait 5 minutes, and then use beclomethasone.

WARNING Warn patient that beclomethasone isn't intended to relieve acute bronchospasm. Urge patient to notify pre-

scriber if asthma symptoms don't respond.

- Advise patient to wear medical identification that states need for supplemental oral corticosteroids during stress or severe asthma attack. Inform patient that prescriber may order high-dose oral corticosteroid therapy.

WARNING Caution patient to avoid exposure to chickenpox and measles because drug may cause immunosuppression. If she's exposed to these disorders, urge her to notify prescriber immediately.

belladonna alkaloids

Class and Category

Chemical class: Tertiary amine

Therapeutic class: GI anticholinergic

Pregnancy category: C

Indications and Dosages

➤ *To treat peptic ulcer disease, functional digestive disorders (including spastic, mucous, and ulcerative colitis), diarrhea, diverticulitis, pancreatitis, dysmenorrhea, nocturnal enuresis, idiopathic and postencephalitic parkinsonism, motion sickness, and nausea and vomiting of pregnancy*

TABLETS

Adults. 0.25 to 0.5 mg t.i.d.

Children over age 6. 0.125 to 0.25 mg t.i.d.

TINCTURE

Adults. 0.6 to 1 ml t.i.d. or q.i.d.

Children. 0.03 ml/kg (0.8 ml/m²) t.i.d.

Route	Onset	Peak	Duration
P.O.	1–2 hr	Unknown	4 hr

Mechanism of Action

Inhibits acetylcholine's muscarinic actions at postganglionic parasympathetic receptor sites, including smooth muscles, secretory glands, and CNS. These actions relax smooth muscles and diminish GI, GU, and biliary tract secretions.

Contraindications

Hepatic disease, hypersensitivity to anticholinergic drugs or scopolamine, ileus, myasthenia gravis, myocardial ischemia, narrow-

angle glaucoma, obstructive condition of GI or GU tract, renal disease, severe ulcerative colitis, tachycardia, toxic megacolon, unstable cardiovascular status in acute hemorrhage

Interactions

DRUGS

amantadine: Increased adverse anticholinergic effects

atenolol, digoxin: Possibly increased therapeutic and adverse effects of these drugs

phenothiazines: Possibly decreased phenothiazine effectiveness and increased adverse effects of belladonna alkaloids

tricyclic antidepressants: Possibly increased adverse anticholinergic effects

Adverse Reactions

CNS: CNS stimulation (with high doses), confusion, dizziness, drowsiness, headache, insomnia, nervousness, weakness

CV: Bradycardia, palpitations, tachycardia

EENT: Altered taste, blurred vision, dry mouth, increased intraocular pressure, mydriasis, nasal congestion, photophobia

GI: Bloating, constipation, dysphagia, heartburn, ileus, nausea, vomiting

GU: Impotence, urinary hesitancy, urine retention

SKIN: Decreased sweating, flushing, urticaria

Other: Anaphylaxis

Nursing Considerations

- Avoid using high doses of belladonna alkaloids in ulcerative colitis because they may inhibit intestinal motility and precipitate or aggravate toxic megacolon. Also avoid high doses in hiatal hernia and reflux esophagitis because they may aggravate esophagitis.
- Use belladonna alkaloids cautiously in patients with allergies, arrhythmias, asthma, autonomic neuropathy, coronary artery disease, debilitating chronic lung disease, heart failure, hypertension, hyperthyroidism, and prostatic hypertrophy.
- Give drug 30 to 60 minutes before a meal.

WARNING Monitor patient for excitement, agitation, drowsiness, and confusion.

Elderly patients are more sensitive to the effects of the drug, even small doses, and are more likely to develop adverse reactions. Dosage may need to be decreased.

- Take safety precautions to protect patient

from injury from falling.

PATIENT TEACHING

- Instruct patient to take belladonna alkaloids 30 to 60 minutes before eating.
- Tell patient to notify prescriber if she has persistent or severe diarrhea, constipation, or difficulty urinating.
- Caution patient to avoid driving and similar activities until the effects of belladonna alkaloids are known.

WARNING Urge patient to avoid extreme heat and humidity because heatstroke could occur.

benazepril hydrochloride

Lotensin

Class and Category

Chemical class: Ethylester of benazeprilat

Therapeutic class: Antihypertensive

Pregnancy category: D

Indications and Dosages

↗ *To control hypertension alone or with a thiazide diuretic*

TABLETS

Adults who don't receive a diuretic. *Initial:* 10 mg daily. *Maintenance:* 20 to 40 mg daily as a single dose or in two divided doses.

Adults who receive a diuretic. 5 mg daily.

DOSAGE ADJUSTMENT Initial dosage of 5 mg/day for patients with impaired renal function and creatinine clearance less than 30 ml/min/1.73 m²; then increased gradually until blood pressure is controlled or dosage reaches maximum of 40 mg daily.

TABLETS, SUSPENSION

Children age 6 and over with glomerular filtration rate of 30 ml/min/1.73 m² or higher. *Initial:* 0.2 mg/kg daily. *Maximum:* 0.6 mg/kg daily or 40 mg daily.

Route	Onset	Peak	Duration
P.O.	1 hr	2–4 hr	24 hr

Mechanism of Action

May reduce blood pressure by affecting renin-angiotensin-aldosterone system. By inhibiting angiotensin-converting enzyme, benazepril:

- prevents conversion of angiotensin I to angiotensin II, a potent vasoconstrictor that also stimulates aldosterone release.
- may inhibit renal and vascular production of angiotensin II.
- decreases serum angiotensin II level and increases serum renin activity. This decreases aldosterone secretion, slightly increasing serum potassium level and fluid loss.
- decreases vascular tone and blood pressure.
- inhibits aldosterone release, which reduces sodium and water resorption, increases their excretion, and reduces blood pressure.

Contraindications

History of angioedema, hypersensitivity to benazepril or other ACE inhibitor

Interactions

DRUGS

antacids: Possibly decreased bioavailability of benazepril; separate doses by 2 hours

antidiabetics (oral): Possibly increased risk of hypoglycemia

capsaicin: Possibly induction or exacerbation of ACE cough caused by benazepril

digoxin: Increased serum digoxin level

diuretics: Possibly excessive hypotension

indomethacin: Reduced hypotensive effects of benazepril

lithium: Increased serum lithium level and risk of lithium toxicity

phenothiazines: Possibly increased therapeutic and adverse effects of benazepril

potassium preparations, potassium-sparing diuretics: Possibly increased serum potassium level

sodium aurothiomalate: Increased risk of nitritoid reactions, such as facial flushing, nausea, vomiting, and hypotension

Adverse Reactions

CNS: Anxiety, asthenia, dizziness, drowsiness, fatigue, headache, hypertonia, insomnia, nervousness, paresthesia, sleep disturbance, somnolence, syncope, weakness
CV: Angina, ECG changes, hypotension, orthostatic hypotension, palpitations, peripheral edema

EENT: Sinusitis

ENDO: Hyperglycemia

GI: Abdominal pain, constipation, elevated liver function test results, gastritis, melena, nausea, pancreatitis, small bowel angio-

edema, vomiting

GU: Decreased libido, elevated BUN and serum creatinine levels, impotence, nephrotic syndrome, proteinuria, renal insufficiency, UTI

HEME: Agranulocytosis, decreased hemoglobin level, leukopenia, neutropenia, thrombocytopenia

MS: Arthralgia, arthritis, myalgia

RESP: ACE cough, asthma, bronchitis, bronchospasm, dyspnea

SKIN: Dermatitis, diaphoresis, flushing, photosensitivity, pruritus, rash

Other: Anaphylaxis, angioedema, hyperkalemia, hyponatremia

Nursing Considerations

- Evaluate blood pressure with patient lying down, sitting, and standing before starting benazepril and then every 4 to 8 hours, as appropriate, to monitor effectiveness.
- Monitor urine output and BUN and serum creatinine levels, as needed, before therapy.

WARNING Be alert for angioedema, especially after first dose. If it extends to larynx and patient has laryngeal stridor or signs of airway obstruction, prepare to give epinephrine subcutaneously immediately, as prescribed, and discontinue benazepril.

- Monitor WBC count periodically to detect neutropenia and agranulocytosis.
- Check serum potassium and other electrolyte levels to detect electrolyte imbalances.
- To prevent injury caused by orthostatic hypotension, take safety precautions, such as having patient change positions slowly and sit on edge of bed before arising.

PATIENT TEACHING

- Teach patient how to monitor blood pressure, if appropriate, and how to recognize signs of hypertension and hypotension.

WARNING Strongly urge patient to contact prescriber before using any OTC salt substitutes, which may contain potassium, or potassium supplements. These substances increase the risk of hyperkalemia.

- Explain that a persistent dry cough may develop and may not subside unless benazepril is stopped. If cough becomes bothersome or interferes with sleep or activities, tell her to notify prescriber.

WARNING Instruct patient to contact pre-

scriber immediately if she has signs of angioedema, such as swelling of the face, eyes, lips, or tongue.

- Caution patient to avoid sudden position changes and to rise slowly from sitting or lying to minimize orthostatic hypotension.

WARNING Advise patient to stop benazepril and notify prescriber as soon as possible if she experiences syncope.

WARNING Caution women of childbearing age to use reliable contraception and to notify prescriber immediately if pregnancy is suspected. Benazepril may cause fetal harm and should be discontinued.

benzonatate

Benzonatate Softgels, Tessalon Perles

Class and Category

Chemical class: Para-aminobenzoic acid (tetracaine-like)

Therapeutic class: Nonnarcotic antitussive

Pregnancy category: C

Indications and Dosages

➤ *To relieve cough*

CAPSULES

Adults and children over age 10. 100 mg t.i.d. up to 600 mg daily.

Route	Onset	Peak	Duration
P.O.	15–20 min	Unknown	3–8 hr

Mechanism of Action

Anesthetizes stretch receptors in respiratory tract, lung tissue, and pleura, interfering with their activity and reducing cough reflex at its source. In usual doses, benzonatate doesn't inhibit respiratory center.

Contraindications

Hypersensitivity to benzonatate or related compounds

Adverse Reactions

CNS: Confusion, hallucinations, headache, mild dizziness, sedation

CV: Cardiogenic shock, chest numbness

EENT: Burning eyes, laryngospasm, nasal congestion

GI: Constipation, GI upset, nausea

RESP: Bronchospasm

SKIN: Pruritus, rash

Nursing Considerations

• Assess type and frequency of cough. Don't try to suppress cough with benzonatate if cough has therapeutic benefit, such as to move secretions and improve airflow.

WARNING Don't break or crush capsules or let patient chew or dissolve them in her mouth. Releasing drug in the mouth may anesthetize mouth and throat, causing risk of choking. Also don't let patient suck or chew capsule to prevent severe hypersensitivity reaction.

PATIENT TEACHING

- Instruct patient to swallow capsules whole and not to chew, suck, or open them.
- Warn patient that mild dizziness and sedation may occur. Teach her to take safety measures, and encourage her to avoid activities that require mental alertness until benzonatate's effects are known.

benzquinamide hydrochloride

Emete-Con

Class and Category

Chemical class: Benzoquinolizine amide

Therapeutic class: Antiemetic

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat nausea and vomiting related to anesthesia or surgery*

I.V. OR I.M. INJECTION

Adults. 50 mg or 0.5 to 1 mg/kg I.M., repeated in 1 hr, then every 3 to 4 hr, p.r.n. Or 25 mg or 0.2 to 0.4 mg/kg by slow infusion (1 ml every 0.5 to 1 min) as a single dose. Then, I.M. doses begin.

↗ *To prevent nausea and vomiting related to anesthesia and surgery*

I.M. INJECTION

Adults. 50 mg or 0.5 to 1 mg/kg 15 min before emergence from anesthesia.

Route	Onset	Peak	Duration
I.V., I.M.	15 min	Unknown	Unknown

Mechanism of Action

Exhibits antiemetic, antihistaminic, mild cholinergic, and sedative effects by unknown mechanism.

Contraindications

Hypersensitivity to benzquinamide or its components

Interactions

DRUGS

vasopressors: Increased hypertensive effects

Adverse Reactions

CNS: Chills, dizziness, drowsiness, excitement, fatigue, fever, headache, insomnia, nervousness, restlessness, tremor, weakness
CV: Atrial fibrillation, hypertension, hypotension, premature atrial or ventricular contractions

EENT: Blurred vision, dry mouth, increased salivation

GI: Anorexia, hiccups, nausea

MS: Muscle twitching

SKIN: Diaphoresis, flushing, rash, urticaria

Nursing Considerations

WARNING Avoid I.V. route in patients with cardiovascular disease because sudden blood pressure increases and transient arrhythmias may occur. Use I.V. route only for patients without cardiovascular disease who aren't receiving a preanesthetic or cardiovascular drug.

- Administer benzquinamide I.M. into large, well-developed muscle. Avoid using deltoid muscle unless it's well developed.
- Take safety precautions to reduce the risk of injury from CNS depression.

PATIENT TEACHING

- Advise patient to stay in bed and call for assistance to reduce risk of injury.
- Tell patient to report whether nausea and vomiting have been relieved.

benztropine mesylate

Apo-Benztropine (CAN), Cogentin, PMS Benztropine (CAN)

Class and Category

Chemical class: Tertiary amine

Therapeutic class: Antiparkinsonian, central-acting anticholinergic

Pregnancy category: C

Indications and Dosages

↗ *As adjunct, to treat all forms of Parkinson's disease*

TABLETS, I.M. OR I.V. INJECTION

Adults with Parkinson's disease. 1 to 2 mg daily (usual dose) with a range of 0.5 to 6 mg daily.

Adults with idiopathic Parkinson's disease. *Initial:* 0.5 to 1 mg at bedtime.

Maximum: 4 to 6 mg daily.

Adults with postencephalitic Parkinson's disease. 2 mg daily in one or more doses; may begin with 0.5 mg at bedtime and increase as needed.

↗ *To control extrapyramidal symptoms (except tardive dyskinesia) caused by phenothiazines and other neuroleptics*

TABLETS, I.M. OR I.V. INJECTION

Adults. 1 to 4 mg once or twice daily.

↗ *To treat acute dystonic reactions*

TABLETS, I.M. OR I.V. INJECTION

Adults. *Initial:* 1 to 2 ml (1 to 2 mg total dose) I.V. or I.M. *Maintenance:* 1 to 2 mg P.O. b.i.d. to prevent recurrence.

Route	Onset	Peak	Duration
P.O.	1–2 hr	Unknown	24 hr
I.V., I.M	15 min	Unknown	24 hr

Mechanism of Action

Blocks acetylcholine's action at cholinergic receptor sites. This restores the brain's normal dopamine and acetylcholine balance, which relaxes muscle movement and decreases drooling, rigidity, and tremor. Benztropine also may inhibit dopamine reuptake and storage, which prolongs dopamine's action.

Contraindications

Achalasia, bladder neck obstruction, glaucoma, hypersensitivity to benztropine mesylate or its components, megacolon, myasthenia gravis, prostatic hypertrophy, pyloric or duodenal obstruction, stenosing peptic ulcer

Interactions**DRUGS**

amantadine: Possibly increased adverse anticholinergic effects

digoxin: Possibly increased digoxin level

haloperidol: Possibly increased schizophrenic symptoms, decreased serum haloperidol level, and development of tardive dyskinesia

levodopa: Possibly decreased levodopa effectiveness

phenothiazines: Possibly reduced phenothiazine effects and increased psychiatric symptoms

Adverse Reactions

CNS: Agitation, confusion, delirium, delusions, depression, disorientation, dizziness, drowsiness, euphoria, excitement, fever, hallucinations, headache, light-headedness, listlessness, memory loss, nervousness, paranoia, psychosis, weakness

CV: Hypotension, mild bradycardia, orthostatic hypotension, palpitations, tachycardia

EENT: Blurred vision, diplopia, dry mouth, increased intraocular pressure, mydriasis, narrow-angle glaucoma, suppurative parotitis

GI: Constipation, duodenal ulcer, epigastric distress, ileus, nausea, vomiting

GU: Dysuria, urinary hesitancy, urine retention

MS: Muscle spasms, muscle weakness

SKIN: Decreased sweating, dermatoses, flushing, rash, urticaria

Nursing Considerations

- Expect to administer I.V. or I.M. benztropine when patient needs more rapid response than oral drug can provide. Be aware that I.M. route is commonly used because it provides effects in about the same time as I.V. route. Watch for improvement a few minutes after administration. If Parkinsonian symptoms reappear, expect to repeat dose.
- Therapy typically begins with a low dose followed by gradual increases of 0.5 mg every 5 or 6 days because benztropine has a cumulative action.
- Assess muscle rigidity and tremor at baseline. Then monitor them often for improvement, which indicates drug's effectiveness.
- Give drug before or after meals based on patient's need and response. If patient has increased salivary secretions, expect to administer benztropine after meals. If patient has dry mouth, plan to give drug before meals unless nausea develops.

WARNING When giving drug to patient with drug-induced extrapyramidal reactions, watch for worsening psychiatric symptoms.

- High-dose benztropine therapy may cause weakness and inability to move specific muscle groups. If this occurs, expect to

reduce benztropine dosage.

PATIENT TEACHING

- Warn patient that drug has a cumulative effect, increasing risk of adverse reactions and overdose.
- Caution against driving and similar activities until benztropine's effects are known because it may cause blurred vision, dizziness, or drowsiness.

WARNING Because benztropine decreases sweating, urge patient to avoid extremely hot or humid conditions to reduce risk of heatstroke and severe hyperthermia. This is especially important for elderly patients and those who abuse alcohol or have chronic illness or CNS disease.

- Stress need for periodic eye examinations and intraocular pressure measurements because drug may cause narrow-angle glaucoma and increase intraocular pressure.

bepridil hydrochloride

Vascor

Class and Category

Chemical class: Calcium channel blocker, diarylammopropylamine derivative

Therapeutic class: Antianginal

Pregnancy category: C

Indications and Dosages

↗ *To treat chronic stable angina in patients who don't respond to or can't tolerate other antianginal drugs*

TABLETS

Adults. *Initial:* 200 mg daily for 10 days followed by dosage increases, depending on patient's response (ability to perform daily activities, length of QT interval, heart rate, and frequency and severity of angina attacks). *Maintenance:* 300 to 400 mg daily (maximum).

Route	Onset	Peak	Duration
P.O.	Unknown	8 days	Unknown

Mechanism of Action

Inhibits calcium movement into coronary and vascular smooth-muscle cells by blocking slow calcium channels in their membranes. This decreases intracellular calcium

level, which inhibits smooth-muscle cell contractions and causes:

- relaxation of coronary and vascular smooth muscles, decreased peripheral vascular resistance, and reduced systolic and diastolic blood pressure, which decrease myocardial oxygen demand
- depression of impulse formation (automaticity) and conduction velocity.

Bepridil also inhibits fast inward sodium channels, reducing speed and degree of action potential and increasing its duration in cardiac muscle.

Contraindications

Congenital prolonged QT interval, history of serious ventricular arrhythmias, hypersensitivity to bepridil, hypotension (systolic pressure below 90 mm Hg), sick sinus syndrome and second- or third-degree AV block unless artificial pacemaker in place, uncompensated cardiac insufficiency, use of other drugs that prolong QT interval

Interactions

DRUGS

antiarrhythmics, such as quinidine and procainamide, with actions similar to bepridil's:

Exaggerated and prolonged QT interval
beta blockers: Possibly increased depression of myocardial contractility and AV conduction

digoxin: Possibly increased serum digoxin level

fentanyl: Severe hypotension and increased need for fluid

nitrates: Additive hypotensive effect

tricyclic antidepressants: Exaggerated and prolonged QT interval

Adverse Reactions

CNS: Amnesia, anxiety, asthenia, depression, dizziness, drowsiness, fever, hallucinations, headache, insomnia, nervousness, paranoia, paresthesia, psychosis, syncope, tremor, vertigo

CV: Edema, hypertension, palpitations, premature ventricular contractions, prolonged QT interval, sinus bradycardia or tachycardia, torsades de pointes, vasodilation, ventricular fibrillation, ventricular tachycardia

EENT: Altered taste, blurred vision, dry mouth, pharyngitis, rhinitis, tinnitus

GI: Abdominal cramps or discomfort, anorexia, appetite increase, constipation, diar-

rhea, flatulence, gastritis, nausea

GU: Decreased libido, impotence

HEME: Agranulocytosis, leukopenia, neutropenia

MS: Arthritis, myalgia

RESP: Cough, dyspnea, respiratory tract infection

SKIN: Dermatitis, diaphoresis, rash

Other: Flulike symptoms

Nursing Considerations

- Use bepridil cautiously in patients with heart failure because it can induce new arrhythmias and may worsen heart failure.
- Because bepridil is metabolized by the liver and its metabolites are excreted in urine, monitor results of liver function studies as well as BUN and serum electrolyte and creatinine levels as appropriate.
- Assess patient's heart rate and rhythm to obtain baseline. Then monitor frequently during therapy. Also, monitor serial 12-lead ECG tracings. Be aware that bepridil can induce new arrhythmias, including ventricular tachycardia and fibrillation (which are more difficult to convert), torsades de pointes, and prolonged QT intervals.

WARNING Be alert for QT intervals that exceed 0.52 second. If this occurs, expect to reduce bepridil dose or discontinue drug.

- Monitor WBC count to detect agranulocytosis, which may warrant stopping bepridil therapy.

WARNING Be aware that bepridil shouldn't be discontinued abruptly. Instead, gradually taper dosage as prescribed to prevent increased frequency and duration of chest pain as increased calcium moves into cells, causing coronary artery spasm.

- Monitor blood pressure often if patient takes a nitrate or beta blocker. Assess for hypotension.
- Monitor serum electrolyte levels. Especially note decreased potassium level, which may worsen existing arrhythmias or induce new ones.

PATIENT TEACHING

- Advise patient to avoid driving and other activities that require alertness and coordination until bepridil's CNS effects are known.

betamethasone

Celestone

betamethasone

acetate-

betamethasone

sodium phosphate

Celestone Soluspan

betamethasone

sodium phosphate

Betnesol (CAN), Celestone Phosphate, Selestoject

Class and Category

Chemical class: Synthetic glucocorticoid

Therapeutic class: Anti-inflammatory

Pregnancy category: C

Indications and Dosages

↗ *To treat conditions with severe inflammation and conditions requiring immunosuppression*

SYRUP, TABLETS (BETAMETHASONE)

Adults. 0.6 to 7.2 mg daily.

I.M. INJECTION (BETAMETHASONE ACETATE-BETAMETHASONE SODIUM PHOSPHATE)

Adults. 0.5 to 9 mg I.M. daily, or one-third to one-half of P.O. dose every 12 hr.

I.M. OR I.V. INJECTION (BETAMETHASONE SODIUM PHOSPHATE)

Adults. *Initial:* Variable (given in emergency situations or when oral therapy isn't possible). *Maximum:* 9 mg daily.

↗ *To treat bursitis, gouty arthritis, osteoarthritis, periostitis of cuboid, peritendinitis, rheumatoid arthritis, skin lesions, tenosynovitis*

INTRA-ARTICULAR, INTRABURSAL, OR INTRADERMAL INJECTION (BETAMETHASONE ACETATE-BETAMETHASONE SODIUM PHOSPHATE)

Adults with bursitis, peritendinitis, or tenosynovitis. 1 ml by intrabursal or intra-articular injection. Three or four injections given every 1 to 2 wk.

Adults with osteoarthritis or rheumatoid arthritis. 0.5 to 2 ml, based on joint size.

Adults with foot bursitis. 0.25 to 0.5 ml every 3 to 7 days.

Adults with foot tenosynovitis or periostitis of cuboid. 0.5 ml every 3 to 7 days.

Adults with acute gouty arthritis. 0.5 to 1 ml every 3 to 7 days.

Adults with skin lesions. 0.2 ml/cm² intradermally, up to 1 ml weekly.

DOSE ADJUSTMENT Dosage reduced for elderly patients and accompanied by periodic monitoring of blood pressure and blood glucose and electrolyte levels.

Route	Onset	Peak	Duration
P.O.	Unknown	1–2 hr	3.25 days
I.V., I.M.*	Rapid	Unknown	Unknown
I.M.†	1–3 hr	Unknown	1 wk
Other‡	Unknown	Unknown	1–2 wk‡

Mechanism of Action

Binds to intracellular glucocorticoid receptors and suppresses inflammatory and immune responses by:

- inhibiting neutrophil and monocyte accumulation at inflammation site and suppressing their phagocytic and bactericidal activity
- stabilizing lysosomal membranes
- suppressing antigen response of macrophages and helper T cells
- inhibiting synthesis of inflammatory response mediators, such as cytokines, interleukins, and prostaglandins.

Contraindications

Idiopathic thrombocytopenic purpura (I.M. injection), live virus vaccination, systemic fungal infection

Interactions

DRUGS

anticholinesterase drugs: Possibly antagonized anticholinesterase effects in myasthenia gravis

barbiturates: Possibly decreased effects of betamethasone

cyclosporine: Possibly increased risk of cyclosporine toxicity

digitalis glycosides: Possibly increased risk of digitalis toxicity

* Sodium phosphate.

† Acetate-sodium phosphate.

‡ For intra-arterial or intrasynovial injection; 1 week for intralesional injection in soft tissue.

estrogens: Possibly decreased excretion of betamethasone

hydantoins, rifampin: Possibly increased excretion and decreased therapeutic effects of betamethasone

isoniazid: Possibly decreased serum isoniazid level

ketoconazole: Possibly decreased excretion of betamethasone

oral anticoagulants: Possibly increased or decreased action of anticoagulants, requiring adjusted anticoagulant dosage

oral contraceptives: Possibly increased half-life and concentration and decreased excretion of betamethasone

potassium-wasting diuretics: Increased risk of hypokalemia

salicylates: Possibly decreased serum level and therapeutic effects of salicylates

somatrem: Possibly inhibition of somatrem's growth-promoting effects

theophyllines: Possibly changes in both drugs' effects

Adverse Reactions

CNS: Fatigue, headache, increased intracranial pressure with papilledema, insomnia, malaise, neuritis, paresthesia, seizures, steroid psychosis, syncope, vertigo

CV: Arrhythmias, ECG changes, fat embolism, heart failure, hypertension, thromboembolism, thrombophlebitis

EENT: Cataracts, exophthalmos, glaucoma, increased intraocular pressure

ENDO: Cushingoid symptoms (buffalo hump, central obesity, decreased carbohydrate tolerance, fat pad enlargement, moon face), fluid retention, growth suppression in children, hyperglycemia, masked signs of infection, negative nitrogen balance, secondary adrenocortical and pituitary unresponsiveness (in times of stress)

GI: Abdominal distention, increased appetite, nausea, pancreatitis, peptic ulcer possibly with perforation, ulcerative esophagitis, vomiting

GU: Amenorrhea, glycosuria, menstrual irregularities

HEME: Leukocytosis

MS: Aseptic necrosis of femoral and humeral heads, loss of muscle mass, muscle weakness, osteoporosis, spontaneous pathologic and vertebral compression fractures, tendon rupture

SKIN: Acneiform lesions, allergic dermatitis, ecchymosis, facial erythema, hirsutism, impaired wound healing, increased sweating, petechiae, lupuslike lesions, purpura, subcutaneous fat atrophy, thin and fragile skin, urticaria

Other: Angioedema, hypocalcemia, hypokalemia, sodium retention, suppressed reaction to skin tests, weight gain

Nursing Considerations

- Expect prescriber to order baseline ophthalmologic examination before starting therapy because prolonged betamethasone use may lead to increased intraocular pressure, glaucoma, and optic nerve damage. Use betamethasone cautiously in patients with ocular herpes simplex because corneal perforation may occur.
- Determine if latent or active amebiasis has been ruled out in patients who have spent time in the tropics or who have unexplained diarrhea before betamethasone therapy starts because drug may worsen it.

WARNING Give betamethasone with extreme care in patients with known or suspected *Strongyloides* (threadworm) infestation because corticosteroids such as betamethasone may result in immunosuppression, *Strongyloides* hyperinfection and dissemination, and widespread larval migration, resulting in severe enterocolitis and potentially life-threatening gram-negative septicemia.

- Assess for signs of infection before administering betamethasone because drug may mask those signs. Because drug may cause immunosuppression, new infection may develop during therapy. If so, expect to administer appropriate antibiotic.
- Review serum electrolyte levels, as ordered, before starting therapy. Monitor these levels often during therapy to detect imbalances. Sodium and water retention and potassium and calcium depletion may occur with high-dose betamethasone therapy. If so, expect to restrict sodium intake and provide potassium and calcium supplements.
- Because betamethasone is linked to peptic ulcer formation, expect to administer it with an antacid or H₂-receptor blocker.

WARNING Monitor ECG tracings for arrhythmias, and evaluate patient for ana-

phylactic reactions, such as angioedema and seizures, which have been associated with rapid I.V. administration of high-dose corticosteroids.

WARNING During long-term betamethasone therapy, assess for signs of adrenal suppression and insufficiency (fatigue, hypotension, lassitude, nausea, vomiting, and weakness) when patient is exposed to stress. If she exhibits these signs, notify prescriber at once.

- Watch for signs of steroid psychosis, such as delirium, clouded sensorium, euphoria, insomnia, mood swings, personality changes, and severe depression, which may develop 15 to 30 days after therapy begins. Expect to stop therapy. If this isn't possible, expect to give psychotropic drugs.
- Rotate I.M. injection sites. To prevent muscle atrophy, avoid subcutaneous injection, injection in deltoid site, and repeated I.M. injections into same site.
- Administer oral betamethasone before 9 a.m., if appropriate, to mimic body's natural release of corticosteroids.
- After intra-articular injection, assess joint for marked increase in pain, local swelling, and more restricted movement. If patient also develops fever and malaise, suspect septic arthritis and notify prescriber immediately. Expect to assist with joint fluid aspiration to confirm septic arthritis.
- Monitor patient for cushingoid signs and symptoms, such as moon face, buffalo hump, central obesity, striae, acne, ecchymosis, and weight gain. Notify prescriber if you detect these symptoms.
- Expect to slowly taper oral betamethasone dosage to prevent adrenal insufficiency.

PATIENT TEACHING

- Instruct patient to take betamethasone with food if GI upset occurs.
- Review signs of adrenal insufficiency and possible need for dosage increases during stress. Advise patient to notify prescriber immediately if signs of insufficiency occur or if she's exposed to stress.
- Instruct patient to avoid exposure to infections because drug can cause immunosuppression. Also teach patient to recognize and immediately report signs of infection.
- After intra-articular use, advise patient not to overuse joint and to continue other treatments such as physical therapy.

betaxolol hydrochloride

Kerlone

Class and Category

Chemical class: Selective beta₁-adrenergic blocker

Therapeutic class: Antihypertensive

Pregnancy category: C

Indications and Dosages

↗ *To treat hypertension alone or with other antihypertensives*

TABLETS

Adults. *Initial:* 10 mg daily. If no response in 7 to 14 days, then 20 mg daily.

DOSAGE ADJUSTMENT For elderly patients and patients who have renal failure or are undergoing hemodialysis, initial dosage reduced to 5 mg daily. If desired response isn't achieved, dosage increased by 5-mg increments every 2 wk up to 20 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	3–4 hr	Unknown

Mechanism of Action

Inhibits stimulation of beta₁-adrenergic receptor sites, primarily in the heart. This decreases myocardial excitability, cardiac output, and myocardial oxygen demand. It also decreases renin release from the kidneys, which helps reduce blood pressure.

Contraindications

Cardiogenic shock, heart failure unless caused by tachyarrhythmia or overt heart failure, hypersensitivity to betaxolol, second- or third-degree heart block, sinus bradycardia

Interactions

DRUGS

aluminum salts, barbiturates, calcium salts, cholestyramine, colestipol, NSAIDs, penicillins, rifampin, salicylates, sulfonpyrazone: Decreased therapeutic and adverse effects of betaxolol

amiodarone, beta blockers, digoxin:

Increased risk of additive systemic beta blockade, especially bradycardia

calcium channel blockers: Possibly increased therapeutic and adverse effects of betaxolol

ciprofloxacin, other quinolones: Possibly increased bioavailability of betaxolol, increasing the drug's pharmacologic effect

clonidine: Possibly severe hypertension when both drugs (or just clonidine) are simultaneously withdrawn

disopyramide: Possibly severe bradycardia, asystole, and heart failure

epinephrine: Possibly severe hypertension followed by bradycardia

ergot alkaloids: Possibly peripheral ischemia and gangrene

flecainide: Possibly increased therapeutic and adverse effects of both drugs

lidocaine: Possibly increased risk of lidocaine toxicity

nondepolarizing neuromuscular blockers: Possibly increased or decreased neuromuscular blockade

oral contraceptives: Possibly increased bioavailability and plasma level of betaxolol, increasing pharmacologic effect

prazosin: Possibly increased orthostatic hypotension

quinidine: Possibly increased effects of betaxolol

sulfonylureas: Possibly masking of hypoglycemic symptoms

Adverse Reactions

CNS: Amnesia, anxiety, behavior changes, confusion, depression, dizziness, emotional lability, fatigue, fever, hallucinations, headache, insomnia, lethargy, malaise, mood changes, nightmares, paresthesia, peripheral neuropathy, sedation, stroke, syncope, tremor, vertigo

CV: Arrhythmias, including asystole, bradycardia, heart block, and torsades de pointes; cardiogenic shock; chest pain; claudication; heart failure; hypercholesterolemia; hyperlipidemia; hypotension; mitral insufficiency; MI; orthostatic hypotension; peripheral vascular insufficiency; Raynaud's phenomenon; renal and mesenteric artery thrombosis

EENT: Altered taste, blurred vision, burning eyes, conjunctivitis, dry eyes, dry mouth, earache, eye irritation, eye pain or pressure, increased salivation, laryngospasm, mouth ulcers, nasal stuffiness, pharyngitis, ptosis, rhinitis, sinusitis, tinnitus

ENDO: Breast pain (women), hyperglycemia, hypoglycemia

GI: Acute pancreatitis, anorexia, bloating, constipation, diarrhea, elevated liver func-

tion test results, epigastric pain, flatulence, gastritis, heartburn, hepatomegaly, increased appetite, indigestion, nausea, vomiting

GU: Decreased libido, dysuria, impotence, nocturia, Peyronie's disease, prostatitis, renal colic, renal failure, urinary frequency, urine retention, UTI

HEME: Agranulocytosis, eosinophilia, leukopenia, thrombocytopenia

MS: Arthralgia, arthritis, gout, muscle spasms or twitching, myalgia, neck pain, tendinitis

RESP: Bronchial obstruction, bronchitis, bronchospasm, cough, pulmonary embolus, respiratory distress, upper respiratory tract infection, wheezing

SKIN: Acne, aggravation of psoriasis, diaphoresis, dry skin, eczema, erythema, exfoliative dermatitis, flushing, increased pigmentation, pallor, photophobia, pruritus, rash

Other: Acidosis, facial edema, hyperkalemia, hyperuricemia, lupus erythematosus, lymphadenopathy, positive ANA titer, weight gain

Nursing Considerations

- Betaxolol shouldn't be given to patients with untreated pheochromocytoma.
- Use drug cautiously in peripheral vascular disease. Assess color, temperature, and pulses in arms and legs, and ask about numbness, tingling and pain.
- Check blood pressure with patient lying, sitting, and standing before starting betaxolol therapy and periodically throughout the day to detect changes.
- Review renal function test results before and during therapy.
- Closely monitor diabetic patient for hypoglycemia because betaxolol may mask tachycardia, but not dizziness and diaphoresis. Be aware that betaxolol may mask tachycardia and blood pressure changes associated with hyperthyroidism.

WARNING Avoid abrupt withdrawal of betaxolol, which can worsen or cause thyroid storm. Expect to withdraw drug gradually and monitor patient closely.

- Expect to taper betaxolol over 2 weeks to prevent MI, ventricular arrhythmias, and possibly death from catecholamine hypersensitivity caused by beta blocker therapy.
- If systolic pressure falls below 90 mm Hg,

expect to discontinue drug and prepare for hemodynamic monitoring.

- Take precautions to prevent injury from falls caused by orthostatic hypotension.

PATIENT TEACHING

- Teach patient how to check her blood pressure, if appropriate. Also discuss signs and symptoms of hypertension and hypotension.
- Advise patient to avoid sudden position changes and to rise slowly from a sitting or lying position to minimize the effects of orthostatic hypotension.
- Advise patient to avoid driving and activities that require mental alertness until drug's CNS effects are known.
- Counsel patient to consult prescriber before using an OTC product, such as a cold remedy or nasal decongestant.

bethanechol chloride

Duvoid, PMS-Bethanechol Chloride (CAN), Urabeth, Urecholine

Class and Category

Chemical class: Synthetic choline ester

Therapeutic class: Cholinergic, parasympathomimetic

Pregnancy category: C

Indications and Dosages

➤ *To treat postoperative and postpartal urine retention and retention caused by neurogenic atony of bladder*

TABLETS

Adults. 10 to 50 mg t.i.d. or q.i.d. *To determine minimum effective dose:* 5 to 10 mg repeated every hr until response is obtained or maximum of 50 mg is reached.

SUBCUTANEOUS INJECTION

Adults. 2.5 to 5 mg t.i.d. or q.i.d. *To determine minimum effective dose:* 2.5 mg repeated every 15 to 30 min until response is obtained or maximum of four doses is reached. Minimum effective dose may be repeated t.i.d. or q.i.d., p.r.n.

Mechanism of Action

Acts directly on muscarinic receptors of the parasympathetic nervous system, increasing detrusor muscle tone in the bladder and

allowing contraction strong enough to start voiding. Like natural neurotransmitter acetylcholine, bethanechol stimulates gastric motility, increases gastric tone, and enhances peristalsis.

Route	Onset	Peak	Duration
P.O.	30–90 min	60 min	6 hr
SubQ	5–15 min	15–30 min	2 hr

Contraindications

Acute inflammatory lesions of GI tract, atrioventricular conduction defects, bronchial asthma, coronary artery disease, epilepsy, hypersensitivity to bethanechol or its components, hypertension, hyperthyroidism, hypotension, marked vagotonia, mechanical obstruction of GI or GU tract, Parkinson's disease, peptic ulcer disease, peritonitis, pronounced bradycardia, questionable integrity of GI or GU mucosa, spastic GI disorders, vasomotor instability

Interactions

DRUGS

cholinergic drugs: Possibly increased effects of bethanechol

ganglionic blockers: Possibly severe hypotension, usually first manifested by severe adverse GI reactions

procainamide, quinidine: Possibly decreased effects of bethanechol

Adverse Reactions

CNS: Headache, malaise

CV: Hypotension with reflex tachycardia, vasomotor response

EENT: Excessive salivation, lacrimation, miosis

GI: Abdominal cramps, colicky pain, diarrhea, eructation, nausea, vomiting

GU: Urinary urgency

RESP: Asthma attack, bronchoconstriction

Nursing Considerations

- Assess urine elimination before starting bethanechol therapy.

WARNING Be aware that patient must have functioning urinary sphincter because a sphincter that doesn't relax when bladder contracts can push urine upward into renal pelvis and cause reflux infection.

- Give oral bethanechol 1 hour before or 2 hours after meals to reduce risk of nausea and vomiting.

WARNING Don't give bethanechol I.M. or I.V. because of risk of cholinergic overstimulation, which can cause abdominal cramps, bloody diarrhea, hypotension, shock, or sudden cardiac arrest. Always keep atropine nearby during subcutaneous administration.

PATIENT TEACHING

- Advise patient to take bethanechol on an empty stomach 1 hour before or 2 hours after meals to reduce risk of nausea and vomiting.

biperiden hydrochloride

Akineton

biperiden lactate

Akineton Lactate

Class and Category

Chemical class: Tertiary amine

Therapeutic class: Anticholinergic, antidyskinetic

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat all forms of Parkinson's disease*

TABLETS

Adults. 2 mg t.i.d. or q.i.d up to 16 mg daily.

↗ *To control extrapyramidal symptoms (except tardive dyskinesia) caused by phenothiazines and other neuroleptic drugs*

TABLETS

Adults. 2 mg one to three times daily.

I.V. OR I.M. INJECTION

Adults. 2 mg repeated every 30 min until symptoms resolve or maximum of four consecutive doses in 24 hr is reached.

Route	Onset	Peak	Duration
I.V.	15 min	Unknown	1–8 hr
I.M.	10–30 min	Unknown	Unknown

Mechanism of Action

Blocks acetylcholine's action at cholinergic receptor sites. This action restores the brain's normal dopamine and acetylcholine

balance, which relaxes muscle movement and decreases rigidity and tremors. Biperiden also may inhibit dopamine reuptake and storage, which prolongs dopamine's action.

Contraindications

Achalasia, bladder neck obstruction, hypersensitivity to biperiden, myasthenia gravis, narrow-angle glaucoma, prostatic hypertrophy, pyloric or duodenal obstruction, stenosing peptic ulcer, toxic megacolon

Interactions

DRUGS

amantadine: Possibly increased adverse anticholinergic effects

digoxin: Possibly increased serum digoxin level

haloperidol: Possibly increased schizophrenic symptoms, decreased serum haloperidol level, and development of tardive dyskinesia

levodopa: Possibly decreased levodopa effectiveness

phenothiazines: Possibly reduced phenothiazine effects and increased psychiatric symptoms

Adverse Reactions

CNS: Agitation, confusion, delirium, delusions, depression, disorientation, dizziness, drowsiness, euphoria, excitement, fever, hallucinations, headache, light-headedness, listlessness, memory loss, nervousness, paranoia, psychosis, weakness

CV: Hypotension, mild bradycardia, orthostatic hypotension, palpitations, tachycardia

EENT: Blurred vision, diplopia, dry mouth, increased intraocular pressure, mydriasis, narrow-angle glaucoma, suppurative parotitis

GI: Constipation, duodenal ulcer, epigastric distress, ileus, nausea, vomiting

GU: Dysuria, urinary hesitancy, urine retention

MS: Muscle spasms, muscle weakness

SKIN: Decreased sweating, dermatosis, flushing, rash, urticaria

Nursing Considerations

- Expect to give I.V. or I.M. biperiden when patient needs more rapid response than oral drug can provide.
- Assess muscle rigidity and tremor as baseline. Then check them often for improve-

ment, indicating biperiden's effectiveness.

WARNING When giving biperiden to patient with drug-induced extrapyramidal reactions, be alert for worsening of psychiatric symptoms.

PATIENT TEACHING

- Caution patient to avoid driving and other activities that require alertness until biperiden's CNS effects are known.

WARNING Because biperiden decreases sweating, urge patient to avoid extremely hot and humid conditions to reduce risk of heatstroke and severe hyperthermia. This is especially important for elderly patients and those who abuse alcohol or have chronic illness or CNS disease.

- Emphasize the need for periodic eye examinations and intraocular pressure measurement because biperiden may cause narrow-angle glaucoma and increase intraocular pressure.

bisoprolol fumarate

Zebeta

Class and Category

Chemical class: Selective beta₁-adrenergic blocker

Therapeutic class: Antihypertensive

Pregnancy category: C

Indications and Dosages

↗ *To treat hypertension, alone or with other antihypertensives*

TABLETS

Adults. 5 mg daily, increased to 10 to 20 mg daily if blood pressure doesn't respond to lower dosage.

DOSAGE ADJUSTMENT Dosage reduced to 2.5 mg daily initially and then increased gradually for patients with impaired renal function and creatinine clearance less than 40 ml/min/1.73 m² or who have impaired hepatic function, as from cirrhosis or hepatitis.

Mechanism of Action

Inhibits stimulation of beta₁-receptors primarily in the heart, which decreases cardiac excitability, cardiac output, and myocardial oxygen demand. Bisoprolol also decreases renin release from kidneys, which helps reduce blood pressure.

Contraindications

Cardiogenic shock, heart failure unless caused by tachyarrhythmia, overt heart failure, second- or third-degree heart block, sinus bradycardia

Interactions

DRUGS

aluminum salts, barbiturates, calcium salts, cholestyramine, colestipol, NSAIDs, penicillins, rifampin, salicylates, sulfapyrazone:

Possibly decreased therapeutic and adverse effects of bisoprolol

beta blockers, digoxin: Increased risk of bradycardia

calcium channel blockers: Possibly increased therapeutic and adverse effects of bisoprolol

ciprofloxacin, quinolones: Possibly increased bioavailability of bisoprolol

clonidine: Possibly severe hypertension from withdrawal of clonidine or both drugs

epinephrine: Possibly hypertension followed by bradycardia

ergot alkaloids: Possibly peripheral ischemia and gangrene

flecainide: Possibly increased therapeutic and adverse effects of either drug

lidocaine: Possibly increased risk of lidocaine toxicity

oral contraceptives: Possibly increased bioavailability and plasma level of bisoprolol

prazosin: Possibly increased orthostatic hypotension

quinidine: Possibly increased bisoprolol effects

sulfonylureas: Possibly masking of hypoglycemic symptoms

Adverse Reactions

CNS: Anxiety, confusion, depression, dizziness, emotional lability, fatigue, fever, hallucinations, headache, insomnia, malaise, nightmares, paresthesia, sleep disturbances, syncope, tremor, unsteadiness, vertigo

CV: Bradycardia, heart block, and other arrhythmias; chest pain; claudication; cold arms and legs; edema; heart failure; hypercholesterolemia; hyperlipidemia; hypotension; MI; orthostatic hypotension; palpitations; peripheral vascular insufficiency; renal and mesenteric artery thrombosis

EENT: Altered taste, blurred vision, dry mouth, eye pain or pressure, hearing loss, increased salivation, laryngospasm, pharyngitis, rhinitis, sinusitis, tinnitus

GI: Constipation, diarrhea, epigastric pain, gastritis, indigestion, ischemic colitis, nausea, vomiting

GU: Cystitis, decreased libido, impotence, Peyronie's disease, renal colic

HEME: Agranulocytosis, eosinophilia, leukopenia, thrombocytopenia, thrombocytopenic purpura

MS: Arthralgia, gout, muscle twitching, neck pain

RESP: Asthma, bronchitis, bronchospasm, cough, dyspnea, respiratory distress, upper respiratory tract infection

SKIN: Alopecia, dermatitis, diaphoresis, eczema, exfoliative dermatitis, flushing, pruritus, psoriasis, rash

Other: Angioedema, hyperkalemia, hyperuricemia, weight gain

Nursing Considerations

- Administer bisoprolol cautiously in patients with peripheral vascular disease because reduced cardiac output can cause or worsen arterial insufficiency. Assess patient's arms and legs for changes in color, temperature, and pulses; ask about numbness, tingling, and pain.
- Measure blood pressure with patient lying, sitting, and standing before starting bisoprolol and then every 4 to 8 hours, as appropriate, to evaluate effectiveness.
- If patient has diabetes, monitor closely for signs of hypoglycemia, which drug may mask.
- If patient has hyperthyroidism, watch for tachycardia and hypertension, which may be masked by bisoprolol.

WARNING Keep in mind that abrupt withdrawal of bisoprolol may cause or worsen thyroid storm. During drug withdrawal, monitor patient closely.

- Expect to stop bisoprolol over 1 to 2 weeks to prevent MI, ventricular arrhythmias, and, possibly, death from catecholamine hypersensitivity caused by beta blocker therapy.
- If systolic blood pressure falls to less than 90 mm Hg, expect to discontinue drug. Prepare for hemodynamic monitoring, if needed.

WARNING If patient is scheduled for surgery with general anesthesia, expect to discontinue bisoprolol about 48 hours beforehand to reduce risk of excessive myocardial depression during anesthesia.

PATIENT TEACHING

- Teach patient how to monitor her blood pressure, if appropriate, and to recognize signs of hypertension and hypotension.
- Instruct patient to avoid sudden position changes and to rise slowly from a sitting or lying position to minimize the effects of orthostatic hypotension.
- Advise patient to avoid driving and other activities that require mental alertness until bisoprolol's CNS effects are known.
- Instruct patient to contact prescriber before using any OTC product, such as a cold remedy or nasal decongestant.

bitolterol mesylate

Tornalate

Class and Category*Chemical class:* Acid ester of colterol*Therapeutic class:* Bronchodilator, sympathomimetic*Pregnancy category:* C**Indications and Dosages**

↗ *To prevent and treat asthma and other conditions associated with reversible bronchospasm, such as emphysema and chronic bronchitis*

INTERMITTENT AEROSOL SOLUTION

Adults and children age 12 and over. 1 mg bitolterol diluted in 0.5 ml normal saline solution and inhaled over 10 to 15 min t.i.d. *Maximum:* 8 mg daily.

CONTINUOUS AEROSOL SOLUTION

Adults and children age 12 and over. 2.5 mg bitolterol diluted in 1.25 ml normal saline solution and inhaled over 10 to 15 min t.i.d. *Maximum:* 14 mg daily.

METERED-DOSE INHALER

Adults and children age 12 and over. *To treat acute bronchospasm:* 2 inhalations over 1 to 3 min and, if needed, a third inhalation. *To prevent bronchospasm:* 2 inhalations every 8 hr, not to exceed 3 inhalations every 6 hr or 2 inhalations every 4 hr.

Mechanism of Action

Is hydrolyzed to active agent colterol (a long-acting agent that primarily affects beta₂-adrenergic receptors). Then it attaches to beta₂ receptors on bronchial cell membranes. This action stimulates the

intracellular enzyme adenylate cyclase to convert adenosine triphosphate to cyclic adenosine monophosphate (cAMP). An increased intracellular level of cAMP relaxes bronchial smooth-muscle cells, stabilizes mast cells, and inhibits histamine release.

Route	Onset	Peak	Duration
Aerosol,	2–3 min	30–60 min	6–8 hr
inhalation			
Metered-	3–5 min	30–120 min	4–8 hr
dose			
inhalation			

Incompatibilities

Don't mix bitolterol in inhalation solution with cromolyn sodium or acetylcysteine.

Contraindications

Hypersensitivity to bitolterol or ingredients

Interactions**DRUGS**

beta blockers: Possibly inhibition of bronchodilating effect of bitolterol
epinephrine, other sympathomimetic drugs: Possibly additive effects of either drug
MAO inhibitors, tricyclic antidepressants: Possibly potentiation of bitolterol's action on cardiovascular system

Adverse Reactions

CNS: Dizziness, fatigue, headache, hyperkinesia, insomnia, light-headedness, nervousness, paresthesia, somnolence, tremor, vertigo

CV: Chest pain, hypertension, irregular pulse, palpitations, tachycardia, transient ECG changes

EENT: Mouth and throat irritation, rhinitis

GI: Elevated liver function test results, nausea

HEME: Decreased hemoglobin level, hematocrit, and WBC count

RESP: Bronchospasm, cough

Nursing Considerations

- Assess respiratory rate, rhythm, and depth and breath sounds before, during, and after bitolterol therapy. Expect improved air movement and improvement in abnormal breath sounds.
- Because beta-adrenergic bronchodilators can significantly increase blood pressure and pulse rate, monitor them often.

- Expect therapy to begin with lowest effective dose because higher doses or more frequent use may reduce effectiveness and cause paradoxical reactions or overdose.

PATIENT TEACHING

- Teach patient how to properly use and care for aerosol nebulizer or metered-dose inhaler. Before patient uses aerosol nebulizer, advise her to look for slight bubbling in solution-filled chamber and fine mist when nebulizer is turned on. Before patient uses inhaler for first time, instruct her to make sure it's working properly by spraying it once in the air and looking for fine mist.
- Teach patient to mix nebulizer solution immediately before use. Afterward, she should clean nebulizer and solution chamber according to manufacturer's recommendations.

WARNING Advise patient not to use more than the recommended dosage of bitolterol; excessive use of sympathomimetic drugs may be fatal.

- Tell patient to wait 1 to 3 minutes between metered-dose inhalations.

bivalirudin

Angiomax

Class and Category

Chemical class: Hirudin analogue

Therapeutic class: Anticoagulant

Pregnancy category: B

Indications and Dosages

➤ *As adjunct to provide anticoagulation and prevent thrombosis in patients with unstable angina who are having percutaneous transluminal coronary angioplasty or percutaneous coronary intervention*

I.V. INFUSION

Adults. *Initial:* Immediately before angioplasty, 0.75-mg/kg bolus; then 1.75 mg/kg/hr as continuous infusion for duration of procedure. Five min after bolus dose and with continuous infusion running, another 0.3-mg/kg dose may be given if needed. After procedure, 1.75 mg/kg/hr may be given for 4 hr by continuous infusion, followed by 0.2 mg/kg/hr for up to 20 hr if needed.

DOSAGE ADJUSTMENT Infusion dosage possibly reduced to 1 mg/kg/hr for patients with severe renal impairment (glomerular filtration rate of 10 to 29 ml/min) and to 0.25 mg/kg/hr for patients having dialysis.

Route	Onset	Peak	Duration
I.V.	Immediate	Unknown	1 hr after end of infusion

Mechanism of Action

Selectively binds to thrombin, including thrombin trapped in established clots. Without thrombin, fibrinogen can't convert to fibrin and clots can't form.

Incompatibilities

Don't mix other drugs in same I.V. line before or during bivalirudin administration. Mixing with alteplase, amiodarone, amphotericin B, chlorpromazine HCL, diazepam, prochlorperazine edisylate, reteplase, streptokinase, or vancomycin HCL can result in haze, particulate formation, or precipitation.

Contraindications

Active major bleeding, hypersensitivity to bivalirudin or its components

Interactions

DRUGS

alteplase, antineoplastics, antithymocyte globulin, heparin, NSAIDs, platelet inhibitors, reteplase, streptokinase, strontium chloride Sr 89, warfarin: Risk of bleeding
porfimer: Possibly decreased efficacy of porfimer photodynamic therapy
salicylates: Increased risk of hypoprothrombinemia and bleeding

Adverse Reactions

CNS: Headache, intracranial hemorrhage
CV: Hypotension, thrombosis (with gamma brachytherapy)
EENT: Epistaxis, gingival bleeding
GI: Abdominal cramps, diarrhea, GI or retroperitoneal bleeding, nausea, vomiting
GU: Hematuria, vaginal bleeding
MS: Back pain
RESP: Hemoptysis, hemothorax
SKIN: Ecchymosis
Other: Injection site bleeding, hematoma, pain

Nursing Considerations

- To reconstitute bivalirudin, add 5 ml sterile water for injection to 250-mg vial and swirl gently until dissolved. For initial infusion, dilute reconstituted vial in 50 ml D₅W or normal saline solution to yield 5 mg/ml.
- For subsequent low-rate infusion, further dilute reconstituted drug in 500 ml D₅W or normal saline solution to final concentration of 0.5 mg/ml.
- Expect to give 300 to 325 mg of aspirin P.O. daily during bivalirudin therapy.

WARNING Monitor blood coagulation tests before and regularly during therapy; bleeding is a major bivalirudin risk.

WARNING Monitor patient often for bleeding because there's no antidote for bivalirudin. If life-threatening bleeding occurs, notify prescriber immediately, stop drug, and monitor APTT and other coagulation tests as ordered. Blood transfusions may be needed. Patients with increased bleeding risk include menstruating women; patients with vascular or organ abnormalities, such as severe uncontrolled hypertension, advanced renal disease, infective endocarditis, dissecting aortic aneurysm, diverticulitis, hemophilia, hepatic disease (especially from deficient vitamin K–dependent clotting factors), inflammatory bowel disease, or peptic ulcer disease; and those with recent stroke, major surgery (including eye, brain, or spinal cord), large vessel or lumbar puncture, organ biopsy, spinal anesthesia, or major bleeding (including intracranial, GI, intraocular, retroperitoneal, or pulmonary bleeding).

- If patient is receiving gamma brachytherapy, watch closely for evidence of thrombosis (weak or absent pulse, pallor, pain); use of bivalirudin may increase the risk in these patients.
- If possible, avoid I.M. injections of any kind to decrease the risk of bleeding.
- Discard any unused portion of drug.

PATIENT TEACHING

- Inform patient that bivalirudin is a blood thinner administered only in the hospital.
- Urge patient to check her skin for bruising or red spots and to immediately report back or stomach pain, trouble breathing, dizziness, fainting, and unusual bleeding

(black, tarry stool; blood in urine; coughing blood; heavy menses; nosebleeds). Drug may need to be stopped.

- Encourage patient to reduce the risk of injury while receiving bivalirudin, such as by brushing her teeth gently with a soft-bristled toothbrush.
- Caution patient not to take anti-inflammatories, such as ibuprofen, naproxen, ketoprofen, aspirin, and aspirin-like products, or other blood thinners, such as warfarin, while receiving bivalirudin unless directed.

bosentan

Tracleer

Class and Category

Chemical class: Endothelin receptor antagonist, pyrimidine derivative

Therapeutic class: Antihypertensive

Pregnancy category: X

Indications and Dosages

➤ *To treat pulmonary arterial hypertension in patients with World Health Organization class III or IV symptoms, to improve exercise ability, and to slow worsening of clinical condition*

TABLETS

Adults. *Initial:* 62.5 mg b.i.d., morning and evening for 4 wk. *Maintenance:* 125 mg b.i.d., morning and evening.

DOSAGE ADJUSTMENT For adults weighing less than 40 kg (88 lb), maintenance dosage is 62.5 mg b.i.d. morning and evening. For patients who have already received ritonavir for 10 days or more, initial dosage is 62.5 mg once daily or once every other day.

Contraindications

Hypersensitivity to bosentan or its components, concurrent use of cyclosporine or glyburide, pregnancy

Interactions

DRUGS

atorvastatin, lovastatin, simvastatin:

Decreased level and efficacy of these drugs
cyclosporine, ritonavir: Markedly increased blood bosentan level

glyburide: Increased liver enzyme and possibly glucose levels; possibly decreased blood

Mechanism of Action

Bosentan is an endothelin (ET) receptor antagonist that inhibits the effects of ET, a potent vasoconstrictor. ET, a neurohormone produced by endothelial cells that line blood vessels, normally increases during cardiovascular stress. Patients with pulmonary arterial hypertension have an abnormal increase in serum ET level.

ET binds with its receptors, ETA and ETB, which are located on endothelial and vascular smooth-muscle cells. When ET

binds with these receptors, it causes vasoconstriction, as shown below left, and such long-term effects as fibrosis and hypertrophy. By binding to ETA and ETB receptors, as shown below right, bosentan blocks the vasoconstrictive effects of ET, causing pulmonary artery vasodilation and decreased pulmonary artery pressure. As a result, the patient experiences increased exercise tolerance and decreased breathlessness.

level of both drugs (and of other oral antidiabetics metabolized by CYP2C9 or CYP3A4)

hormonal contraceptives (oral, injected, implanted): Possibly decreased effects of these drugs

ketonazole and other CYP3A4 inhibitors:

Increased bosentan blood level and effects
rifampicin: Possibly decreased blood bosentan level

tacrolimus: Possibly marked increase in blood bosentan level

warfarin: Increased elimination and decreased blood level of warfarin

Adverse Reactions

CNS: Fatigue, headache

CV: Edema, hypotension, palpitations

EENT: Nasopharyngitis

GI: Elevated liver function test results, hepatic injury, indigestion, liver failure

GU: Decreased sperm count

HEME: Decreased hemoglobin level and hematocrit, thrombocytopenia

SKIN: Flushing, pruritus, rash

Other: Hypersensitivity

Nursing Considerations

- Before giving bosentan, obtain baseline hemoglobin level and liver function test results, as ordered.

WARNING Because bosentan use may cause major birth defects, make sure female patient of childbearing age has had a negative pregnancy test before giving drug.

WARNING Bosentan may cause risk of serious hepatic injury. Assess patient for evidence of hepatic dysfunction, including abdominal pain, fatigue, fever, jaundice, nausea, and vomiting. Monitor liver function test results every month, as ordered.

- Expect dosage to be adjusted or drug stopped if liver function test results become elevated. Expect treatment to be stopped if bilirubin level increases to twice the upper limit of normal (or higher) or if clinical symptoms occur in conjunction with liver function test elevations. Bosentan probably won't be prescribed for patients with moderate to severe hepatic dysfunction or for those with liver function test levels higher than three times the

upper limit of normal.

- Monitor hemoglobin level 1 and 3 months after start of therapy and every 3 months thereafter, as ordered.
- Monitor patient's response to drug, and evaluate her activity tolerance.

PATIENT TEACHING

WARNING Because major birth defects are associated with bosentan, caution female patient of childbearing age to have a urine or serum pregnancy test monthly during bosentan therapy to verify that she isn't pregnant. Advise her to notify prescriber immediately if she has a late or missed menstrual period. Instruct her to use a reliable nonhormonal method of contraception because bosentan may decrease effectiveness of hormonal contraceptives.

- Urge patient to immediately report evidence of hepatic dysfunction, including yellow skin or eyes, fever, nausea, vomiting, fatigue, and abdominal pain.
- Stress the importance of keeping appointments for follow-up testing so that drug's effects can be evaluated.
- Inform patient that bosentan is dispensed only by a special access program set up by the drug's manufacturer and isn't available from commercial pharmacies. Advise patient to allow for adequate delivery time when refilling prescription so that she doesn't run out of drug. Instruct her to review the medication guide that comes with each renewed prescription.
- Explain to man that drug may reduce sperm count. Urge him to consult prescriber if he has concerns about fertility.

bretylium tosylate

Bretylate (CAN), Bretlyol

Class and Category

Chemical class: Bromobenzyl quaternary ammonium compound

Therapeutic class: Class III antiarrhythmic

Pregnancy category: C

Indications and Dosages

➤ To prevent and treat ventricular fibrillation and treat life-threatening ventricular arrhythmias that don't respond to first-line antiarrhythmics, such as lidocaine

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults with immediate life-threatening ventricular arrhythmias. *Initial:* 5 mg/kg, undiluted, by rapid I.V. injection; if ventricular fibrillation persists, 10 mg/kg repeated as often as needed. *Continuous suppression:* 1 to 2 mg/min or 5 to 10 mg/kg of diluted I.V. solution infused over at least 8 min every 6 hr.

Adults with other ventricular arrhythmias. *Initial:* 5 to 10 mg/kg of diluted I.V. solution infused over at least 8 min, repeated every 1 to 2 hr if arrhythmia continues; or 5 to 10 mg/kg undiluted I.M. injection, repeated every 1 to 2 hr if arrhythmia continues. *Maintenance:* 5 to 10 mg/kg diluted I.V. solution infused over at least 8 min every 6 hours, 1 to 2 mg/min infused continuously, or 5 to 10 mg/kg undiluted I.M. injection every 6 to 8 hr.

DOSAGE ADJUSTMENT Interval between dosages increased for patients with impaired renal function because bretylium is excreted mainly by kidneys.

Children with acute ventricular fibrillation. 5 mg/kg I.V. given over 8 to 10 min, followed by 10 mg/kg every 15 to 30 min up to total dose of 30 mg/kg. *Maintenance:* 5 to 10 mg/kg every 6 hr.

Children with other ventricular arrhythmias. 5 to 10 mg/kg every 6 hr.

Route	Onset	Peak	Duration
I.V.	5–10 min*	6–9 hr	6–24 hr
I.M.	20–60 min*	6–9 hr	6–24 hr

Contraindications

Digitalis toxicity, hypersensitivity to bretylium

Interactions

DRUGS

catecholamines (such as dopamine and norepinephrine): Increased vasopressor effects of catecholamines

digoxin: Possibly worsened digitalis toxicity

Adverse Reactions

CNS: Anxiety, confusion, dizziness, emotional lability, fever, lethargy, light-headedness, paranoia, psychosis, syncope, vertigo

* For suppression of ventricular fibrillation; 20 to 120 min for suppression of ventricular tachycardia.

Mechanism of Action

Bretylium prolongs the repolarization phase of the action potential and lengthens the effective refractory period, which helps terminate reentry arrhythmias. The drug also acts on adrenergic nerve terminals initially causing early release of norepinephrine, which increases heart rate and blood pressure. Then it blocks release of norepinephrine, as shown below. This reduces heart rate and blood pressure. Bretylium also increases the ventricular threshold, making the ventricular myocardium less responsive to ectopic impulses and preventing ventricular fibrillation.

CV: Angina, arrhythmias (including bradycardia and more frequent PVCs), hypotension, orthostatic hypotension, transient hypertension

EENT: Mild conjunctivitis, nasal stuffiness

GI: Abdominal pain, diarrhea, hiccups, nausea, vomiting

GU: Renal impairment

RESP: Dyspnea

SKIN: Diaphoresis, erythematous macular rash, flushing

Other: Injection site pain

Nursing Considerations

WARNING Use bretylium cautiously in patients with severe aortic stenosis or pulmonary hypertension because hypotension may occur.

- For I.V. infusion, dilute bretylium and administer at 1 to 2 mg/min.
- Dilute bretylium in compatible I.V. solution, such as D₅W, dextrose 5% in normal

saline solution, dextrose 5% in lactated Ringer's solution, normal saline solution, 5% sodium bicarbonate, 20% mannitol, 1/6 molar sodium lactate, lactated Ringer's solution, calcium chloride in D₅W, and potassium chloride in D₅W.

WARNING Patient may experience hypotension while supine. Have her remain supine until tolerance develops. If supine systolic blood pressure falls below 75 mm Hg, expect to give dopamine or norepinephrine and monitor blood pressure closely because vasopressor effects are increased when these drugs are given together.

- Be alert for transient hypertension and increased frequency of arrhythmias because bretylium initially triggers release of norepinephrine. Monitor patient's ECG tracings and blood pressure continuously, and notify prescriber of changes.
- Monitor blood bretylium level. Notify prescriber if level falls outside therapeutic range of 0.5 to 1.5 mcg/ml.

PATIENT TEACHING

- Advise patient to immediately report chest pain or pressure, pain at I.V. site, or rash.
- Warn patient that she may feel dizzy or light-headed even when lying down. Tell her to stay supine and ask for help when trying to move or sit up. Tell her that this sensation usually subsides in a few days.

bromocriptine mesylate

Alti-Bromocriptine (CAN), Apo-Bromocriptine (CAN), Cycloset, Parlodel, Parlodel SnapTabs

Class and Category

Chemical class: Ergot alkaloid derivative

Therapeutic class: Antidiabetic, antidyskinetic, antihyperprolactinemic, dopamine-receptor agonist, growth hormone suppressant, infertility therapy adjunct

Pregnancy category: B

Indications and Dosages

➤ To treat amenorrhea, galactorrhea, male hypogonadism, and infertility from hyperprolactinemia

CAPSULES, TABLETS

Adults. *Initial:* 1.25 to 2.5 mg at bedtime

with snack. Increased by 2.5 mg every 3 to 7 days as needed to a total daily dose of 5 to 7.5 mg given in divided doses with snacks. *Maintenance:* 2.5 mg b.i.d. or t.i.d. with meals.

➤ *To treat prolactin-secreting adenoma*
CAPSULES, TABLETS

Adults and adolescents age 15 and over.

Initial: 1.25 mg b.i.d. or t.i.d. with meals. Increased gradually over several weeks, if needed, to 10 to 20 mg daily in divided doses with meals. Some patients may need higher doses. *Maintenance:* 2.5 to 20 mg daily in divided doses with meals.

➤ *To treat Parkinson's disease*

CAPSULES, TABLETS

Adults. *Initial:* 1.25 mg at bedtime with snack or b.i.d. with meals. Increased by 2.5 mg every 14 to 28 days, if needed.

Maintenance: 2.5 to 40 mg daily in divided doses with meals.

➤ *To treat acromegaly*

CAPSULES, TABLETS

Adults and children age 15 and over.

Initial: 1.25 to 2.5 mg at bedtime with snack for 3 days. Then increased by 1.25 to 2.5 mg every 3 to 7 days, if needed, up to 30 mg daily. *Maintenance:* Usually 10 to 30 mg daily at bedtime with snack or in divided doses with meals.

➤ *To control blood glucose level in type 2 diabetes mellitus, with diet and exercise*

TABLETS

Adults. *Initial:* 0.8 mg once daily within 2 hr after waking up in morning. Increased weekly in increments of 0.8 mg, as needed. *Maximum:* 4.8 mg daily.

Route	Onset	Peak	Duration
P.O.*	2 hr	8 hr	24 hr
P.O.†	30–90 min	2 hr	Unknown
P.O.‡	1–2 hr	4–8 wk	4–8 hr

Mechanism of Action

Inhibits release of prolactin and growth hormone from the anterior pituitary gland, thus restoring testicular or ovarian function and suppressing lactation. Bromocriptine

* For amenorrhea, galactorrhea, male hypogonadism, infertility from hyperprolactinemia, and prolactin-secreting adenoma.

† For Parkinson's disease.

‡ For acromegaly.

decreases dopamine turnover in the CNS, depleting dopamine or blocking its receptors in the brain, alleviating dyskinesia.

Contraindications

Breast-feeding; hypersensitivity to bromocriptine, other ergot alkaloids, or their components; ketoacidosis; severe ischemic heart disease or peripheral vascular disease; syncopal migraine; type 1 diabetes mellitus

Interactions

DRUGS

antihypertensives: Increased hypotensive effects

clarithromycin, erythromycin, troleandomycin: Increased risk of bromocriptine toxicity
CYP3A4 inhibitors: Increased bromocriptine level

CYP3A4 inducers: Decreased bromocriptine level

dopamine receptor antagonists, including neuroleptic drugs (such as butyrophenones, phenothiazines, or thioxanthenes), metoclopramide: Possibly decreased effectiveness of both drugs

ergot alkaloids or derivatives: Increased risk of hypertension

haloperidol, loxapine, MAO inhibitors, methyldopa, metoclopramide, molindone, phenothiazines, pimozide, reserpine, risperidone, thioxanthenes: Increased serum prolactin level, decreased bromocriptine effectiveness

levodopa: Additive effects requiring reduced levodopa dose

ritonavir: Increased bromocriptine level

sympathomimetic drugs: Possibly increased risk of hypertension and tachycardia

ACTIVITIES

alcohol use: Possibly disulfiram-like reaction

Adverse Reactions

CNS: Asthenia, confusion, dizziness, drowsiness, fatigue, hallucinations, headache, light-headedness, syncope

CV: Hypertension, hypotension, orthostatic hypotension, pericarditis, pericardial effusion, Raynaud's phenomenon

EENT: Amblyopia, dry mouth, nasal congestion, rhinitis, sinusitis

ENDO: Hypoglycemia

GI: Abdominal cramps, anorexia, constipation, diarrhea, GI bleeding, indigestion, nausea, vomiting

RESP: Pleural effusion or thickening, pul-

monary fibrosis

Other: Intense impulse to gamble

Nursing Considerations

- Use bromocriptine cautiously if patient has a history of psychosis or cardiovascular disease, especially after MI with residual arrhythmia. In severe psychotic disorder, bromocriptine isn't recommended because it may worsen the disorder or reduce the effects of drugs used to treat it.
- Expect to perform a pregnancy test every 4 weeks during the amenorrheic period. Once menses resume, test whenever a period is missed, as ordered.
- Plan to withhold bromocriptine if patient becomes pregnant.
- If rapidly expanding adenoma needs continued therapy, watch closely for hypertensive crisis.
- Bromocriptine shouldn't be given postpartum if patient has a history of coronary artery disease or other severe cardiovascular problem unless risk of withdrawing drug is greater than risk of use. If so, monitor closely for signs and symptoms of CV dysfunction, such as chest pain.
- Expect to give drug with levodopa if patient is being treated for Parkinson's disease.
- Assess for hypotension when bromocriptine therapy starts and hypertension (typically during second week). Monitor blood pressure often if patient takes other antihypertensives.
- If patient has a history of peptic ulcer or GI bleeding, watch for new bleeding.
- Take safety precautions, such as keeping bed in low position with side rails up, because drug can cause dizziness, drowsiness, light-headedness, and syncope.

PATIENT TEACHING

- Tell patient to take each dose with a meal, milk, or a snack to minimize nausea.
- Caution patient about possible dizziness, drowsiness, and light-headedness. Urge patient to avoid hazardous activities until drug effects are known.
- Advise against sudden position changes to minimize orthostatic hypotension.
- Warn patient to avoid alcohol while taking bromocriptine because it may cause disulfiram-like reactions, such as chest pain, confusion, a fast or pounding heartbeat, facial flushing, diaphoresis, nausea, vomiting, a throbbing headache, blurred vision,

and severe weakness.

- Tell patient to take a missed dose as soon as she remembers it, unless it's almost time for the next dose. In that case, tell her to wait until the next scheduled dose. Warn her not to double the dose. Advise her to contact prescriber if she misses more than one dose.
- Urge patient to report adverse reactions, such as unremitting headache, nausea, vomiting, or other signs of CNS toxicity.
- Tell patient who takes large doses of bromocriptine to schedule regular dental checkups because the drug can decrease saliva flow, which may encourage dental caries, periodontal disease, oral candidiasis, and discomfort.
- Tell patient with acromegaly to keep her fingers warm to prevent cold-sensitive digital vasospasm.
- If patient has type 2 diabetes, provide instruction about diet, exercise, effects of hyperglycemia and hypoglycemia, hygiene, foot care, and ways to avoid infection.

budesonide

Entocort EC, Pulmicort Flexhaler, Pulmicort Respules, Pulmicort Turbuhaler, Rhinocort, Rhinocort Aqua, Rhinocort Turbuhaler (CAN)

Class and Category

Chemical class: Glucocorticoid

Therapeutic class: Antiasthmatic, anti-inflammatory

Pregnancy category: B

Indications and Dosages

↗ *To manage symptoms of seasonal or perennial allergic rhinitis*

NASAL AEROSOL

Adults and children over age 6. 64 mcg in each nostril b.i.d. or 128 mcg in each nostril daily. *Maximum:* 256 mcg daily.

Maintenance: Lowest dosage that controls symptoms.

NASAL POWDER

Adults and children over age 6. 200 mcg in each nostril daily. *Maximum:* 800 mcg daily (adults and adolescents); 400 mcg daily (children). *Maintenance:* Lowest dosage that controls symptoms.

NASAL SUSPENSION

Adults and children over age 6. 32 mcg in each nostril daily. *Maximum:* 256 mcg daily (adults and adolescents); 128 mcg daily (children). *Maintenance:* Lowest dosage that controls symptoms.

➤ *To manage symptoms of perennial non-allergic rhinitis*

NASAL AEROSOL

Adults and adolescents. 64 mcg in each nostril b.i.d. or 128 mcg in each nostril daily. *Maximum:* 256 mcg daily. *Maintenance:* Lowest dosage that controls symptoms.

NASAL POWDER

Adults and adolescents. 200 mcg in each nostril daily. *Maximum:* 800 mcg daily. *Maintenance:* Lowest dosage that controls symptoms.

➤ *To provide maintenance therapy in chronic bronchial asthma*

ORAL INHALATION

Adults previously on bronchodilators alone. 1 or 2 inhalations (200 to 400 mcg) b.i.d. *Maximum:* 800 mcg daily.

Adults previously on inhaled corticosteroids. 1 or 2 inhalations (200 to 400 mcg) b.i.d. *Maximum:* 800 mcg b.i.d. as needed and tolerated.

Adults previously on systemic corticosteroids. 2 to 4 inhalations (400 to 800 mcg) b.i.d. *Maximum:* 1,600 mcg daily.

Children age 6 and over. 1 inhalation (200 mcg) b.i.d. *Maximum:* 400 mcg b.i.d. as needed and tolerated.

ORAL INHALATION (PULMICORT FLEXHALER)

Adults and adolescents age 18 and over. *Initial:* 180 or 360 mcg b.i.d., increased as needed. *Maximum:* 720 mcg b.i.d.

Children ages 6 to 17. *Initial:* 180 or 360 mcg b.i.d. *Maximum:* 360 mcg b.i.d.

➤ *To prevent or provide maintenance therapy in chronic bronchial asthma*

NEBULIZED INHALATION (PULMICORT RESPULES)

Children ages 1 to 8 previously on bronchodilators alone. 0.25 mg b.i.d. or 0.5 mg daily by jet nebulizer. *Maximum:* 0.5 mg/day.

Children ages 1 to 8 previously on inhaled steroids. 0.25 mg b.i.d. or 0.5 mg daily inhaled by jet nebulizer. *Maximum:* 1 mg/day.

Children ages 1 to 8 previously on systemic corticosteroids. 0.5 mg b.i.d. or 1 mg daily inhaled by jet nebulizer. *Maximum:* 1 mg/day.

➤ *To treat mild to moderate active Crohn's*

disease involving the ileum, the ascending colon, or both

CAPSULES

Adults. 9 mg daily in the morning for 8 wk. ➤ *To maintain clinical remission of mild to moderate Crohn's disease involving the ileum, the ascending colon, or both*

CAPSULES

Adults. 6 mg daily in the morning for up to 3 months.

DOSAGE ADJUSTMENT Dosage reduced for patients with hepatic insufficiency and those taking ketoconazole or other CYP3A4 inhibitor.

Route	Onset	Peak	Duration
Nasal aerosol	10 hr–3 days	3 days–3 wk	Unknown
Nasal powder or suspension	In 4 wk	Unknown	Unknown
Oral inhalation	In 4 wk	Unknown	Unknown
Nebulized inhalation	2–8 days	4–6 wk	Unknown
P.O. (capsules)	Unknown	30 min–10 hr	Unknown

Mechanism of Action

Inhibits inflammatory cells and mediators, possibly by decreasing influx into nasal passages or bronchial walls. As a result, nasal or airway inflammation decreases. Oral inhalation form also inhibits mucus secretion in airways, decreasing the amount and viscosity of sputum.

Contraindications

Hypersensitivity to budesonide or its components, recent septal ulcers or nasal surgery or trauma (nasal spray); status asthmaticus or other acute asthma episodes (oral inhalation)

Interactions

DRUGS

clarithromycin, erythromycin, itraconazole, ketoconazole, other CYP3A4 inhibitors: Possibly increased blood budesonide level

Adverse Reactions

CNS: Amnesia, asthenia, benign intracranial hypertension, dizziness, fatigue, fever, headache

EENT: Bad taste, cataracts, dry mouth, epistaxis, glaucoma, nasal irritation, oral or pharyngeal candidiasis, pharyngitis, rhinitis, sinusitis

ENDO: Growth suppression in children

GI: Abdominal pain, diarrhea, dyspepsia, flatulence, indigestion, nausea, vomiting

GU: UTI

MS: Arthralgia, back pain

RESP: Bronchospasm, increased cough, respiratory tract infection

SKIN: Contact dermatitis, purpura, rash, urticaria

Other: Anaphylaxis, angioedema

Nursing Considerations

- Use budesonide cautiously if patient has tubercular infection; untreated fungal, bacterial, or systemic viral infection; or ocular herpes simplex.
- Closely monitor a child's growth pattern; budesonide may stunt growth.

WARNING Assess patient who switches from a systemic corticosteroid to inhaled budesonide for adrenal insufficiency (fatigue, hypotension, lassitude, nausea, vomiting, weakness), which may be life-threatening. Hypothalamic-pituitary-adrenal axis function may take several months to recover after stopping systemic corticosteroids. Stopping budesonide abruptly may cause adrenal insufficiency.

- Administer Respules by jet nebulizer connected to an air compressor.
- Patient exposed to chickenpox may receive varicella zoster immune globulin or pooled I.V. immunoglobulin. If chickenpox develops, give antiviral as ordered. A patient exposed to measles may need pooled I.M. immunoglobulin.
- Assess patient for effectiveness of budesonide therapy, especially if being weaned from a systemic corticosteroid. If patient has increased asthma or an immunologic condition previously suppressed by systemic corticosteroid—such as rhinitis, conjunctivitis, an eosinophilic condition, eczema, or arthritis—notify prescriber.
- Pulmicort Flexhaler contains small amounts of lactose, which may trigger coughing, wheezing, or bronchospasm in a patient with a severe milk-protein allergy.
- Monitor patient for evidence of hypersensitivity, such as contact dermatitis, rash, urticaria, angioedema, bronchospasm, or

anaphylaxis. If present, notify prescriber immediately. Expect to stop budesonide and provide emergency supportive care.

PATIENT TEACHING

- Urge patient taking oral capsules to swallow them whole and not to chew or break them.
- Instruct patient who uses nasal spray to shake container before each use. Instruct her to blow her nose, tilt her head slightly forward, and insert tube into a nostril, pointing toward inner corner of eye, away from nasal septum. Tell her to hold the other nostril closed and spray while inhaling gently. Then have her repeat in the other nostril.
- Instruct patient to prime oral inhaler before using it for first time by holding canister upright with mouthpiece on top and twisting base of device fully to right and then fully to left until it clicks. Teach her to load each dose just before use in the same way. After loading a dose, caution patient not to shake device or blow into it. Tell patient to turn her head away from device and exhale. Then have her hold device upright, place her lips around mouthpiece, and inhale deeply. Device will discharge a dose. Tell patient to remove her lips from mouthpiece to exhale.
- Caution patient not to use an oral inhaler with a spacer device.
- Advise patient to rinse her mouth with water after each dose and to spit the water out. Tell her to contact her prescriber if she develops a mouth or throat infection.
- Instruct patient not to use budesonide as a rescue inhaler.
- Tell patient to contact prescriber if symptoms persist or have worsened after 3 weeks. Caution against increasing the dose on her own.
- Inform parents of small children using nebulized Respules that improvement may begin within 2 to 8 days but that full effect may not be evident for 4 to 6 weeks.
- Caution patient to avoid exposure to chickenpox and measles and, if exposed, to contact prescriber immediately.
- Caution against stopping drug abruptly.
- Instruct patient on long-term therapy to have regular eye examinations.
- Urge female patient to notify prescriber if she is or could be pregnant.

bumetanide

Bumex

Class and Category

Chemical class: Sulfonamide derivative

Therapeutic class: Loop diuretic

Pregnancy category: C

Indications and Dosages

➤ *To treat edema caused by heart failure, hepatic disease, and renal disease, including nephrotic syndrome*

TABLETS

Adults. 0.5 to 2 mg daily, increased as needed, with a second or third dose every 4 to 5 hr or 0.5 to 2 mg every other day or daily for 3 or 4 days each week. *Maximum:* 10 mg daily.

I.V. INFUSION, I.V. OR I.V. INJECTION

Adults. 0.5 to 1 mg over 1 to 2 min daily, increased p.r.n. with a second or third dose every 2 to 3 hr. *Maximum:* 10 mg daily.

DOSE ADJUSTMENT In patients with severe chronic renal insufficiency, continuous infusion (12 mg over 12 hr) may be more effective and less toxic than intermittent infusion.

Route	Onset	Peak	Duration
P.O.	30–60 min	1–2 hr	4–6 hr
I.V.	In min	15–30 min	3.5–4 hr

Mechanism of Action

Inhibits reabsorption of sodium, chloride, and water in the ascending limb of the loop of Henle, which promotes their excretion and reduces fluid volume.

Contraindications

Anuria, hepatic coma, hypersensitivity to bumetanide or its components, severe electrolyte depletion

Interactions

DRUGS

aminoglycosides: Increased risk of ototoxicity
antihypertensives: Increased hypotensive effect

indomethacin: Slowed increase in urine and sodium excretion, inhibited plasma renin activity

lithium: Reduced lithium renal clearance, increased risk of lithium toxicity

probenecid: Reduced sodium excretion

Adverse Reactions

CNS: Dizziness, encephalopathy, headache

CV: Hypotension

EENT: Ototoxicity

ENDO: Hyperglycemia

GI: Nausea

GU: Azotemia, elevated serum creatinine level

MS: Muscle spasms

Other: Hyperuricemia, hypocalcemia, hypochloremia, hypokalemia, hyponatremia, hypovolemia

Nursing Considerations

WARNING A patient hypersensitive to sulfonamides may be hypersensitive to bumetanide. Monitor such a patient closely when starting therapy.

- Expect to use parenteral route for patients with impaired GI absorption or in whom the oral route isn't practical. Switch to oral route, as prescribed, as soon as possible.
- Discard unused parenteral solution 24 hours after preparation.
- Assess fluid and electrolyte balance closely because bumetanide is a potent diuretic (40 to 60 times more potent than furosemide). Monitor fluid intake and output once every 8 hours, evaluate serum electrolyte levels when ordered, and assess for imbalances.

WARNING Be aware that high-dose or too-frequent administration can cause profound diuresis and water and electrolyte depletion, especially in elderly patients.

- Monitor serum potassium level regularly to check for hypokalemia, especially if patient takes a digitalis glycoside for heart failure or has hepatic cirrhosis, ascites, aldosteronism, potassium-losing nephropathy, diarrhea, or a history of ventricular arrhythmias.
- Assess for evidence of ototoxicity, such as tinnitus, daily. Rarely, drug may cause ototoxicity, especially with I.V. use, high doses, and increased frequency of dosing in a patient with renal impairment.
- Monitor results of renal function tests during therapy to detect adverse reactions.

PATIENT TEACHING

- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Stress importance of monitoring fluid intake and output and watching for evidence of electrolyte imbalance, such as

- dizziness, headache, and muscle spasms.
- Review adverse reactions, and tell patient to report severe or persistent reactions.
- Review potassium-rich foods, and urge patient to include them in her daily diet.
- Urge patient to return for appropriate follow-up care, especially if she's receiving bumetanide for a chronic condition.
- Tell diabetic patient to monitor blood glucose level regularly and to notify prescriber about persistent hyperglycemia.

buprenorphine hydrochloride

Buprenex, Subutex

Class, Category, and Schedule

Chemical class: Opioid, thebaine derivative

Therapeutic class: Opioid analgesic

Pregnancy category: C

Controlled substance schedule: V

Indications and Dosages

↗ *To control moderate to severe pain*

I.V. OR I.M. INJECTION

Adults and children age 12 and over.

0.3 mg every 6 hr or more, p.r.n. A second 0.3-mg dose given 30 to 60 min after first dose, if needed.

DOSE ADJUSTMENT In patients not at high risk for opioid toxicity, I.M. dose increased to 0.6 mg or frequency increased to every 4 hr, if needed, depending on pain severity and patient response. I.V. or I.M. dose reduced by half in elderly or debilitated patients and those who have respiratory disease or also use another CNS depressant.

Children ages 2 to 12. 0.002 to 0.006 mg/kg every 4 to 6 hr, p.r.n.

↗ *To treat opioid dependence*

SUBLINGUAL TABLETS

Adults. 12 to 16 mg daily.

Mechanism of Action

May bind with CNS receptors to alter the perception of and emotional response to pain. Buprenorphine may act by displacing narcotic agonists from their binding sites and competitively inhibiting their actions.

Incompatibilities

Don't give I.V. buprenorphine through the same I.V. line as diazepam or lorazepam.

Contraindications

Hypersensitivity to buprenorphine or its components

Route	Onset	Peak	Duration
I.V.	Under 15 min	Under 1 hr	6–10 hr*
I.M.	15 min	1 hr	6–10 hr*

Interactions

DRUGS

CNS depressants, MAO inhibitors: Additive hypotensive and respiratory and CNS depressant effects of these drugs

opioid analgesics: Reduced therapeutic effects if buprenorphine is given before another opioid analgesic

Adverse Reactions

CNS: Dizziness, headache, sedation, vertigo

CV: Bradycardia, hypertension, hypotension

EENT: Miosis

GI: Nausea, vomiting

RESP: Bronchospasm, hypoventilation

SKIN: Diaphoresis, pruritus, rash, urticaria

Other: Anaphylaxis; angioedema; injection site pain, redness, and swelling

Nursing Considerations

- Use buprenorphine cautiously in patients with severe hepatic or renal impairment, myxedema, hypothyroidism, adrenal insufficiency, CNS depression, coma, toxic psychosis, prostatic hypertrophy, urethral stricture, acute alcoholism, alcohol withdrawal syndrome, kyphoscoliosis, or biliary tract dysfunction. Also use cautiously in patients who take a drug that decreases hepatic clearance, are known drug abusers, or have been addicted to opioids.
- Use drug cautiously in patients with head injury, intracranial lesions, or other conditions that could increase CSF pressure.
- To avoid causing withdrawal, drug shouldn't be given for opioid dependence until signs of withdrawal occur.
- Give I.V. form over at least 2 minutes.
- Inspect injection site for local reactions; don't use the same site twice.
- Monitor vital signs and response to drug often, especially after giving first dose.

PATIENT TEACHING

- Instruct patient taking sublingual form to

* 4 to 5 hr in children ages 2 to 12.

place tablets under her tongue until they dissolve. If patient takes more than two tablets per dose, tell her to place all tablets under her tongue at the same time. If they won't fit, tell her to place two at a time under her tongue until full dose has dissolved. Caution against swallowing tablets.

bupropion hydrochloride

Wellbutrin, Wellbutrin SR, Wellbutrin XL, Zyban

bupropion hydrobromide

Aplenzin

Class and Category

Chemical class: Aminoketone derivative
Therapeutic class: Antidepressant, smoking cessation adjunct
Pregnancy category: C

Indications and Dosages

↗ *To treat depression*

E.R. TABLETS (WELLBUTRIN SR)

Adults. *Initial:* 150 mg daily in morning for 3 days; then 150 mg b.i.d. and, after several wk, 200 mg b.i.d., as needed and tolerated. *Maximum:* 400 mg daily or 200 mg/dose.

E.R. TABLETS (WELLBUTRIN XL)

Adults. *Initial:* 150 mg daily in morning for at least 3 days; then 300 mg daily and, after 4 wk, 450 mg daily, as needed and tolerated. *Maximum:* 450 mg daily.

E.R. TABLETS (APLENZIN)

Adults. *Initial:* 174 mg daily in the morning for 3 days. Then, if tolerated well, dosage increased to 348 mg daily in the morning. After 4 wk of therapy, dosage increased to 522 mg daily in the morning, if needed.

TABLETS

Adults. *Initial:* 100 mg b.i.d., increased after 3 or more days to 100 mg t.i.d., as needed. *Maximum:* 450 mg daily or 150 mg/dose.

↗ *To aid in smoking cessation*

E.R. TABLETS

Adults. *Initial:* 150 mg daily for 3 days and then 150 mg b.i.d. for 7 to 12 wk. *Maximum:* 300 mg daily or 150 mg/dose.

↗ *To prevent seasonal major depressive*

episodes in patient with seasonal affective disorder

E.R. TABLETS

Adults. *Initial:* 150 mg once daily in morning starting in autumn, increased after 1 wk to 300 mg once daily in morning, if tolerated and needed. Decreased to 150 mg once daily 2 wk before stopping in early spring.

DOSAGE ADJUSTMENT For patients with severe hepatic cirrhosis, no more than 75 mg daily of Wellbutrin, 100 mg daily or 150 mg every other day of Wellbutrin SR, 150 mg every other day of Wellbutrin XL or Zyban, and 174 mg every other day of Aplenzin. In renal impairment, dosage or frequency decreased on an individual basis.

Route	Onset	Peak	Duration
P.O.	1–3 wk	Unknown	Unknown

Mechanism of Action

May inhibit norepinephrine, serotonin, and dopamine uptake by neurons, which significantly relieves evidence of depression.

Contraindications

Anorexia, bulimia, use of another form of bupropion, hypersensitivity to bupropion or its components, seizure disorder, treatment requiring abrupt discontinuation of alcohol or sedatives (including benzodiazepines), use within 14 days of an MAO inhibitor

Interactions

DRUGS

amantadine, levodopa: Increased adverse reactions to bupropion
carbamazepine, cimetidine, phenobarbital, phenytoin: Increased bupropion metabolism
clozapine, fluoxetine, haloperidol, lithium, loxapine, maprotiline, molindone, phenothiazines, thioxanthenes, trazodone, tricyclic antidepressants: Increased risk of major motor seizures

levodopa: Increased adverse bupropion effects

MAO inhibitors: Increased risk of acute bupropion toxicity

nicotine: Possibly increased blood pressure
warfarin: Possibly altered PT and INR; risk of hemorrhagic or thrombotic complications

ACTIVITIES

alcohol use, recreational drug abuse: Lowered seizure threshold

Adverse Reactions

CNS: Agitation, akathisia, anxiety, asthenia, CNS stimulation, coma, confusion, decreased concentration or memory, delusions, depression, dizziness, euphoria, fever, general or migraine headache, hallucinations, hostility, insomnia, irritability, mania, nervousness, paranoia, paresthesia, seizures, sleep disorder, somnolence, stroke, suicidal ideation, syncope, tremor, vertigo

CV: Arrhythmias, chest pain, complete AV block, hypertension, MI, orthostatic hypotension, palpitations, phlebitis, tachycardia, vasodilation

EENT: Altered taste, amblyopia, blurred vision, dry mouth, hearing loss, increased ocular pressure, pharyngitis, sinusitis, taste perversion, tinnitus

ENDO: Hyperglycemia, hypoglycemia, syndrome of inappropriate ADH secretion

GI: Abdominal pain, anorexia, constipation, diarrhea, dysphagia, flatulence, GI hemorrhage, GI ulceration, hepatitis, increased appetite, intestinal perforation, nausea, pancreatitis, vomiting

GU: Urinary frequency and urgency, UTI, vaginal hemorrhage

HEME: Anemia, leukocytosis, leukopenia, lymphadenopathy, pancytopenia, thrombocytopenia

MS: Arthralgia, arthritis, muscle twitching, myalgia, rhabdomyolysis

RESP: Bronchospasm, cough, pulmonary embolism

SKIN: Diaphoresis, exfoliative dermatitis, flushing, pruritus, rash, urticaria

Other: Angioedema, generalized pain, hot flashes, infection, serum sicknesslike reaction, weight loss

Nursing Considerations

- Use cautiously in patients with renal impairment; drug is excreted by kidneys.
- Monitor children, adolescents, and depressed patients closely for worsened depression and increased suicide risk, especially when therapy starts or dosage changes.
- If patient takes bupropion for smoking cessation, watch for neuropsychiatric symptoms, including changes in behavior, hostility, agitation, depressed mood, suicidal ideation, and worsening of psychiatric illness. If present, notify prescriber immediately, begin safety measures, and expect

to discontinue drug.

- To reduce seizure risk, allow at least 4 hours (tablets) or 8 hours (E.R. tablets) between doses.
- Use seizure precautions, especially in patients who take OTC stimulants or anorectics; use excessive alcohol or sedatives; are addicted to opioids, cocaine, or stimulants; take drugs that lower the seizure threshold; have a history of seizures, head trauma, or CNS tumors; have severe hepatic cirrhosis; or take insulin or an oral antidiabetic.
- Using transdermal nicotine with bupropion may cause hypertension. Watch closely.

PATIENT TEACHING

- Advise patient to take bupropion for 7 or more days before stopping smoking.
- Tell patient to swallow E.R. tablets whole and not to cut, crush, or chew them.
- Tell patient to take bupropion with food.
- Urge patient to avoid or minimize consuming alcohol and sedatives during therapy and not to stop drug abruptly because seizures may occur.
- Urge caregivers to monitor depressed patient closely for worsened depression, especially when therapy starts or dosage changes.
- If patient takes bupropion for smoking cessation, explain that it may cause serious adverse effects, including changes in behavior, hostility, agitation, depressed mood, suicidal ideation, and worsening of psychiatric illness. If present, patient should notify prescriber immediately and expect to discontinue drug.

bupirone hydrochloride

**BuSpar, BuSpar DIVIDOSE,
Bustab (CAN)**

Class and Category

Chemical class: Azaspirodecandione

Therapeutic class: Antianxiety

Pregnancy category: B

Indications and Dosages

↗ *To manage anxiety*

TABLETS

Adults. *Initial:* 5 mg t.i.d. or 7.5 mg b.i.d.

increased by 5 mg daily at 2- to 3-day intervals until desired response occurs.

Maintenance: 20 to 30 mg daily (usual therapeutic range). **Maximum:** 60 mg daily.

DOSE ADJUSTMENT When used with nefazodone, dosage as little as 2.5 mg daily.

Route	Onset	Peak	Duration
P.O.	1–4 wk	3–6 wk	Unknown

Mechanism of Action

May act as a partial agonist at serotonin 5-hydroxytryptamine_{1A} receptors in the brain, producing antianxiety effects.

Contraindications

Hypersensitivity to buspirone or its components, severe hepatic or renal impairment

Interactions

DRUGS

diltiazem, erythromycin, itraconazole, nefazodone, nordiazepam, verapamil: Increased blood level and adverse effects of buspirone

haloperidol: Increased haloperidol level
hepatic enzyme CYP3A4 inducers, such as dexamethasone and certain anticonvulsants (phenytoin, phenobarbital, carbamazepine): Possibly increased rate of buspirone metabolism

hepatic enzyme CYP3A4 inhibitors, such as ketoconazole and ritonavir: Possibly inhibited buspirone metabolism and increased blood level

MAO inhibitors: Increased risk of hypertension

rifampin: Decreased blood buspirone level and pharmacodynamic effects

FOODS

food: Possibly decreased buspirone clearance
grapefruit juice: Increased blood buspirone level

Adverse Reactions

CNS: Akathisia, anger, ataxia, cogwheel rigidity, confusion, decreased concentration, depression, dizziness, dream disturbances, drowsiness, dyskinesias, dystonia, excitement, extrapyramidal symptoms, fatigue, headache, hostility, insomnia, lack of coordination, light-headedness, mood swings, nervousness, paresthesia, parkinsonism, restless leg syndrome, restlessness, serotonin syndrome, transient recall

impairment, tremor, weakness

CV: Chest pain, palpitations, tachycardia

EENT: Blurred vision, dry mouth, nasal congestion, pharyngitis, tinnitus, tunnel vision

GI: Abdominal or gastric distress, constipation, diarrhea, nausea, vomiting

GU: Urine retention

MS: Myalgia

SKIN: Diaphoresis, ecchymosis, rash, urticaria

Other: Angioedema

Nursing Considerations

- Use buspirone cautiously in patients with hepatic or renal impairment.
- Institute safety precautions because of possible adverse CNS reactions.
- Follow closely if patient is being withdrawn from long-term therapy with benzodiazepines or other sedative-hypnotic drugs while starting buspirone because buspirone won't prevent withdrawal symptoms.

PATIENT TEACHING

- Advise patient to take buspirone consistently, either always with or always without food.
- Caution patient to avoid drinking large amounts of grapefruit juice.
- Inform patient that 1 to 2 weeks of therapy may be needed before she notices drug's antianxiety effect.
- Stress the importance of not taking more buspirone than prescribed.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.

butabarbital sodium

Busodium, Butalan, Butisol, Sarisol No. 2

Class, Category, and Schedule

Chemical class: Barbiturate

Therapeutic class: Sedative-hypnotic

Pregnancy category: D

Controlled substance schedule: III

Indications and Dosages

↗ *To provide daytime sedation*

ELIXIR, TABLETS

Adults. 15 to 30 mg t.i.d. or q.i.d.

↗ *To treat insomnia*

ELIXIR, TABLETS

Adults. 50 to 100 mg every at bedtime.

↗ *To provide preoperative sedation*

ELIXIR, TABLETS

Adults. 50 to 100 mg 60 to 90 min before surgery.

Children. 2 to 6 mg/kg. *Maximum:* 100 mg/dose.

DOSE ADJUSTMENT Dosage reduced in patients with impaired renal or hepatic function and in elderly or debilitated patients because they may be more sensitive to drug.

Route	Onset	Peak	Duration
P.O.	45–60 min	Unknown	6–8 hr

Mechanism of Action

Inhibits the upward conduction of nerve impulses in the brain's reticular formation, which disrupts impulse transmission to the cortex. As a result, butabarbital depresses the CNS and produces drowsiness, sedation, and hypnosis.

Contraindications

History of addiction to sedative or hypnotic drug, hypersensitivity to butabarbital or its components, porphyria, severe hepatic or respiratory disease

Interactions**DRUGS**

acetaminophen: Increased risk of hepatotoxicity (with large doses of or long-term therapy with butabarbital)

activated charcoal: Reduced butabarbital absorption

carbamazepine: Decreased blood carbamazepine level

chloramphenicol, corticosteroids, digitalis glycosides: Increased metabolism and decreased effects of these drugs

clonazepam: Increased clearance and reduced efficacy of clonazepam

CNS depressants, including OTC sedatives and hypnotics: Additive CNS depression

doxycycline: Shortened half-life and decreased effects of doxycycline

fenopropfen: Reduced bioavailability and effects of fenopropfen

griseofulvin: Reduced griseofulvin absorption

hydantoin, such as phenytoin: Unpredictable effects on barbiturate metabolism

MAO inhibitors: Prolonged barbiturate effects

meperidine: Prolonged CNS depressant effects of meperidine

methadone: Reduced methadone actions

methoxyflurane: Increased risk of nephrotoxicity

metronidazole: Decreased antimicrobial effect of metronidazole

oral anticoagulants: Decreased anticoagulant effect

oral contraceptives with estrogen: Decreased contraceptive effect

phenylbutazone: Reduced elimination half-life of phenylbutazone

rifampin: Decreased butabarbital effectiveness

sodium valproate, valproic acid: Decreased butabarbital metabolism and increased adverse CNS effects

theophylline: Decreased blood level and effects of theophylline

ACTIVITIES

alcohol use: Additive CNS depression

Adverse Reactions

CNS: Agitation, anxiety, ataxia, clumsiness, CNS depression, confusion, depression, dizziness, drowsiness, fever, hallucinations, headache, hyperkinesia, insomnia, irritability, nervousness, nightmares, psychiatric disturbance, sleep driving (see Patient Teaching section), somnolence, syncope

CV: Hypertension

EENT: Laryngospasm

GI: Constipation, hepatic dysfunction, nausea, vomiting

MS: Rickets

RESP: Apnea, bronchospasm, respiratory depression

SKIN: Exfoliative dermatitis, Stevens-Johnson syndrome

Other: Anaphylaxis, angioedema, drug tolerance, physical and psychological dependence

Nursing Considerations

- Use butabarbital cautiously, if at all, in patients with depression, suicidal tendency, history of drug abuse, or hepatic dysfunction. Don't administer drug to patients with premonitory signs of hepatic coma.

WARNING Monitor patient closely following butabarbital ingestion because anaphylaxis

or angioedema, although rare, may occur with first dose or later doses. Notify prescriber immediately, and provide supportive emergency care.

- Expect to give drug for no more than 2 weeks to treat insomnia because, like all barbiturates, it loses effectiveness for sleep induction and sleep maintenance after 2 weeks.
- Monitor butobarbital intake closely during long-term use because tolerance and psychological and physical dependence may develop.
- Avoid abrupt withdrawal of butobarbital to prevent withdrawal symptoms.
- Monitor elderly and debilitated patients closely because drug may cause marked excitement, depression, and confusion in these patients.
- If patient experiencing pain receives butobarbital, monitor closely for paradoxical excitement.
- If pregnant woman took butobarbital during last trimester, monitor infant for withdrawal symptoms.
- Monitor patient for worsening of insomnia or emergence of abnormal thinking or behavior during therapy. If butobarbital unmasks them, patient will need further assessment.

PATIENT TEACHING

- Stress the importance of taking butobarbital exactly as prescribed because it can be addictive. Warn against increasing the dose or decreasing the dosage interval without consulting prescriber.
- Advise patient to notify prescriber if insomnia persists after 7 days of butobarbital therapy.
- Tell patient to avoid alcohol and OTC sedatives and hypnotics during butobarbital therapy because of additive CNS effects.
- Advise patient to avoid hazardous activities until butobarbital's CNS effects are known.
- Advise female patient not to rely on oral contraceptives during butobarbital therapy.
- Explain that butobarbital may cause sleep driving, in which the patient drives while not fully awake and typically cannot recall doing so. Tell family members to report any episodes of sleep driving.

butorphanol tartrate

Stadol, Stadol NS

Class, Category, and Schedule

Chemical class: Opioid

Therapeutic class: Anesthesia adjunct, opioid analgesic

Pregnancy category: C

Controlled substance schedule: II

Indications and Dosages

↗ *To manage pain*

I.V. INJECTION

Adults. 0.5 to 2 mg (usually 1 mg) every 3 to 4 hr, as needed.

I.M. INJECTION

Adults. 1 to 4 mg (usually 2 mg) every 3 to 4 hr, as needed. *Maximum:* 4 mg/single dose.

NASAL INHALATION

Adults. 1 spray (1 mg) in one nostril. Dose repeated after 60 to 90 min; two-dose sequence repeated every 3 to 4 hr, as needed. For severe pain, 2 sprays (1 in each nostril) every 3 to 4 hr, as needed.

DOSAGE ADJUSTMENT Dose reduced to 1 spray in one nostril for elderly patients and those with impaired hepatic or renal function. Dose repeated after 90 to 120 min; two-dose sequence repeated every 6 hr or more, as needed.

↗ *As adjunct to provide preoperative anesthesia*

I.V. OR I.M. INJECTION

Adults. Individualized. *Average:* 2 mg 60 to 90 min before surgery.

↗ *As adjunct to provide anesthesia*

I.V. INJECTION

Adults. Individualized. *Average:* 1 to 4 mg and then supplemental doses of 0.5 to 1 mg, p.r.n. Total usually required during surgery is 60 to 180 mcg/kg.

DOSAGE ADJUSTMENT Paarenteral doses reduced by half for elderly patients and patients with impaired hepatic or renal function.

Mechanism of Action

Binds with specific CNS receptors to alter the perception of and emotional response to pain.

Contraindications

Hypersensitivity to butorphanol or its components (including the preservative benzethonium chloride)

Route	Onset	Peak	Duration
I.V.	2–3 min	30 min	2–4 hr
I.M.	10–30 min	30–60 min	3–4 hr
Inhalation	In 15 min	1–2 hr	4–5 hr

Interactions**DRUGS**

CNS depressants: Additive CNS depression
nasal vasoconstrictors, such as oxymetazoline: Decreased absorption rate and delayed onset of butorphanol

ACTIVITIES

alcohol use: Additive CNS depression

Adverse Reactions

CNS: Anxiety, confusion, difficulty making purposeful movements, difficulty speaking, dizziness, euphoria, floating feeling, headache, insomnia (with nasal form), lethargy, nervousness, paresthesia, sensation of heat, somnolence, syncope, tremor, vertigo

CV: Chest pain, hypotension, palpitations, tachycardia, vasodilation

EENT: Blurred vision, dry mouth, ear pain, epistaxis, nasal congestion or irritation (with nasal form), pharyngitis, rhinitis, sinus congestion, sinusitis, tinnitus, unpleasant taste

GI: Anorexia, constipation, epigastric pain, nausea, vomiting

RESP: Apnea, bronchitis, cough, dyspnea, respiratory depression, shallow breathing, upper respiratory tract infection

SKIN: Clammy skin, pruritus

Nursing Considerations

- Use butorphanol cautiously, if at all, in patients with depression, suicidal tendency, history of drug abuse, or hepatic or renal dysfunction.
- Because drug can raise CSF pressure, use it cautiously, if at all, in patients with head injury. Because it can increase cardiac workload, use with extreme caution in patients with acute MI, ventricular dysfunction, or coronary insufficiency.
- Be aware that butorphanol has a high potential for abuse.
- Monitor patient after first dose of nasal

form; hypotension and syncope may occur.

- Take safety precautions because butorphanol causes CNS depression.
- Assess respiratory status closely because drug causes respiratory depression.
- Monitor blood pressure often after giving drug. If severe hypertension develops (rare), stop drug at once and notify prescriber. If patient isn't narcotic-dependent, expect to administer naloxone to reverse butorphanol's effects.

PATIENT TEACHING

- Stress the importance of taking butorphanol exactly as prescribed because it can be addictive. Warn patient not to increase the dose or decrease the dosage interval without consulting prescriber.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Tell patient to avoid alcohol and other CNS depressants, including OTC drugs, while taking butorphanol because of additive adverse CNS reactions.
- Teach patient how to use nasal form properly by giving these instructions: After blowing nose to clear the nostrils, pull clear cover from the pump unit and remove protective clip from its neck. Prime pump unit by placing the nozzle between first and second fingers with thumb on the bottom of the bottle. Then pump sprayer unit firmly and quickly until a fine spray appears (7 or 8 strokes). Insert spray tip about 1 cm (one-third inch) into one nostril, pointing tip toward the back of the nose. Close other nostril with one finger and tilt head slightly forward. Then pump sprayer unit firmly and quickly by pushing down on the pump unit's finger grips and against the thumb at the bottom of the bottle. Sniff gently with mouth closed. After spraying, remove pump from nose, tilt head back, and sniff gently for a few more seconds. Then replace protective clip and clear cover.

C

C1 esterase inhibitor (human)

Berinerit

Class and Category

Chemical class: Glycoprotein

Therapeutic class: Human plasma C1 esterase inhibitor replacement

Pregnancy category: C

Indications and Dosages

➤ *To treat acute abdominal or facial attacks of hereditary angioedema*

I.V. INJECTION

Adults and adolescents. 20 units/kg given at 4 ml/min.

Mechanism of Action

Suppresses activation of the contact system that may mediate increased vascular permeability and evidence of hereditary angioedema by inactivating plasma kallikrein and factor XIIa, which prevents generation of bradykinin. Patients with hereditary angioedema have low levels of endogenous or functional C1 esterase inhibitor, a normal constituent of plasma. By increasing these levels, the contact system becomes sufficiently inactivated to relieve signs and symptoms.

Incompatibilities

Do not mix C1 esterase inhibitor with other drugs or solutions. Administer by a separate infusion line.

Contraindications

Hypersensitivity (including anaphylaxis) to C1 esterase inhibitor preparation or its components

Interactions

DRUGS

anticoagulants, thrombolytics: Possibly decreased effectiveness

Adverse Reactions

CNS: Chills, fever, headache

CV: Thrombosis

EENT: Laryngeal edema, laryngospasm,

nasopharyngitis, taste abnormality

GI: Abdominal pain, diarrhea, nausea, vomiting

MS: Back pain, muscle spasm

Other: Anaphylaxis, facial or generalized pain, injection site pain and redness, shock, swelling in area of shoulder and chest, worsening of hereditary angioedema

Nursing Considerations

- Reconstitute C1 esterase inhibitor using the Mix2Vial transfer set or a double-ended needle and vented filter spike. After cleaning tops of drug and diluent vials with alcohol and letting them dry, grip the Mix2Vial transfer set together with the clear package (after peeling away the lid) and snap blue end of transfer set onto diluent vial stopper at a 90-degree angle. Carefully remove clear package from transfer set. With drug vial sitting on a flat surface, invert diluent vial with transfer set attached and snap transparent adapter onto drug vial stopper at a 90-degree angle. Gently swirl drug vial to fully dissolve. Do not shake vial. Once drug is dissolved, grasp drug side of transfer set and, with the other hand, grasp blue diluent side of transfer set to unscrew set into two pieces. Draw air into an empty, sterile syringe. With drug vial upright, screw syringe to transfer set and inject air. Invert system upside down while keeping syringe plunger pressed, and draw concentrate into syringe by pulling plunger back slowly. Then unscrew syringe from transfer set keeping plunger of syringe facing down.
- Attach filled syringe to an I.V. administration set and infuse 4 ml/minute within 8 hours after reconstitution. Do not refrigerate or freeze reconstituted solution.
- If patient needs more than one vial, contents of multiple vials may be pooled in a single administration device, using a new unused Mix2Vial transfer set for each drug vial.
- Do not give C1 esterase inhibitor with any other drug. Administer it using a separate infusion line.
- Store C1 esterase inhibitor in its original carton to protect from light. Do not freeze.

WARNING Severe hypersensitivity reactions may occur with signs and symptoms for hereditary angioedema. Monitor patient

closely for evidence of anaphylaxis, generalized urticaria, hives, hypotension, tightness of chest, or wheezing. Discontinue C1 esterase inhibitor immediately and provide supportive care, including epinephrine, as prescribed.

- Thrombotic events may occur, especially when higher-than-recommended doses are given or drug is given for off-label uses.
- Monitor patient for evidence of infection because C1 esterase inhibitor is extracted from human blood. Although safeguards are used, the potential exists for an infectious agent to be transmitted. Reports of acute hepatitis C have been documented after giving C1 esterase inhibitor.

PATIENT TEACHING

- Stress importance of reporting new or persistent signs and symptoms during and after C1 esterase inhibitor therapy.
- Inform patient about the potential for pain, such as back pain or muscle spasms, and reassure patient that comfort measures will be provided.

cabergoline

Dostinex

Class and Category

Chemical class: Ergot alkaloid derivative

Therapeutic class: Antihyperprolactinemic

Pregnancy category: B

Indications and Dosages

➤ *To treat idiopathic or adenoma-induced hyperprolactinemic disorders*

TABLETS

Adults. 0.25 mg twice/wk. Increased by 0.25 mg/wk at 4-wk intervals, if needed, up to 1 mg twice/wk.

Route	Onset	Peak	Duration
P.O.	Unknown	48 hr	Up to 14 days

Mechanism of Action

Binds with dopamine D₂ receptors to block prolactin synthesis and secretion by the anterior pituitary gland, thereby reducing the serum prolactin level.

Contraindications

History of pulmonary, pericardial, cardiac valvular, or retroperitoneal fibrotic disor-

ders; hypersensitivity to cabergoline, ergot derivatives, or their components; uncontrolled hypertension

Interactions

DRUGS

antihypertensives: Increased risk of hypotension

dopamine antagonists (butyrophenones, metoclopramide, phenothiazines, or thioxanthenes): Decreased cabergoline effectiveness

Adverse Reactions

CNS: Aggression, asthenia, depression, fatigue, headache, nervousness, paresthesia, pathological gambling behavior, somnolence, psychotic disorder, vertigo

CV: Orthostatic hypotension, valvulopathy

EENT: Dry mouth

ENDO: Breast pain

GI: Abdominal pain, constipation, diarrhea, flatulence, indigestion, nausea, vomiting

GU: Dysmenorrhea, increased libido

RESP: Pulmonary effusion or fibrosis

SKIN: Alopecia

Nursing Considerations

- Before each dose increase, check serum prolactin level to assess cabergoline's effectiveness.
- If patient has moderate to severe hepatic impairment, monitor closely for adverse reactions because of decreased cabergoline metabolism.
- Expect patient who takes cabergoline long-term to undergo periodic reassessment of cardiac status, including echocardiography, because valvulopathy can occur with prolonged cabergoline use.
- Erythrocyte sedimentation rate may increase in a patient with pleural effusion or pleural fibrosis.

WARNING If you detect evidence of overdose, such as syncope, hallucinations, lightheadedness, tachycardia, and nasal congestion, notify prescriber and treat as ordered.

PATIENT TEACHING

- Urge patient to read and follow printed information that explains how to use cabergoline for best therapeutic results.
- Advise patient to take drug with meals to help decrease GI distress.
- Tell patient to take a missed dose as soon as possible within 1 to 2 days. If missed dose isn't remembered until it's time for the next dose, instruct him to double the

dose if drug is generally well tolerated and doesn't cause nausea. If drug isn't well tolerated, instruct patient to consult prescriber before taking the missed dose.

- Urge patient to change positions slowly to avoid orthostatic hypotension. Tell him to notify prescriber if it occurs.
- Urge patient to keep regular appointments to monitor drug effectiveness.
- Advise patient that drug therapy will end when serum prolactin level is normal for 6 months. Explain that he'll need periodic monitoring to determine whether therapy should resume.
- Tell female patient to notify prescriber if she is, could be, or plans to become pregnant during therapy; drug may need to be discontinued.
- Caution patient to avoid gambling during therapy because drug may increase the risk of pathological gambling behaviors.

calcifediol

Calderol

Class and Category

Chemical class: Sterol derivative, vitamin D analogue

Therapeutic class: Antihypocalcemic

Pregnancy category: C

Indications and Dosages

↗ *To treat metabolic bone disease or hypocalcemia in patients receiving renal dialysis*

CAPSULES

Adults and children age 10 and over. 300 to 350 mcg/wk given in divided doses daily or every other day. Increased at 4-wk intervals, p.r.n. Usual dosage 50 to 100 mcg daily or 100 to 200 mcg every other day.

Children ages 2 to 10. 0.05 mg daily.

Children up to age 2. 0.02 to 0.05 mg daily.

DOSE ADJUSTMENT Dosage decreased to as low as 20 mcg every other day in patients with normal serum calcium level.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	15–20 days

Mechanism of Action

Is converted to calcitriol in kidneys and

then binds to specific receptors in intestinal mucosa to increase calcium absorption from intestine. Calcifediol also may regulate calcium ion transfer from bone to blood and stimulate calcium reabsorption in distal renal tubules, making more calcium available in the body.

Contraindications

Abnormal sensitivity to vitamin D effects, decreased renal function, hypercalcemia, hyperphosphatemia, hypervitaminosis, malabsorption syndrome, vitamin D toxicity

Interactions

DRUGS

aluminum-containing antacids: Increased blood aluminum level, especially in patients with chronic renal failure

barbiturates, corticosteroids, hydantoin anticonvulsants, primidone: Decreased effects of vitamin D

calcitonin, etidronate, gallium nitrate, pamidronate, plicamycin: Decreased effects of these drugs

calcium (high doses), thiazide diuretics:

Increased risk of hypercalcemia
cholestyramine, colestipol, mineral oil:

Decreased vitamin D absorption

digitalis glycosides: Increased risk of

arrhythmias from hypercalcemia

magnesium-containing antacids: Hypermagnesemia, especially in chronic renal failure

phosphorous-containing drugs: Increased risk of hyperphosphatemia

verapamil: Increased risk of atrial fibrillation

vitamin D derivatives, such as calcitriol,

dihydroxycholesterol, ergocalciferol: Increased risk of vitamin D toxicity

Nursing Considerations

- Use calcifediol cautiously in patients with sarcoidosis or other granulomatous disease because of increased sensitivity to effects of vitamin D.
- If hypercalcemia develops, expect to stop drug. Calcium level usually returns to normal in 2 to 4 weeks. To manage acute hypercalcemia, give I.V. normal saline solution and possibly a loop diuretic, as prescribed, to enhance diuresis or prepare for dialysis with a calcium-free dialysate if needed. Chronic hypercalcemia may lead to diffuse vascular calcification, nephrocal-

cinosis, and other soft-tissue calcification.

- If patient receives high-dose or long-term calcifediol therapy, be alert for vitamin D toxicity. Early evidence includes bone pain, constipation, dry mouth, headache, metallic taste, myalgia, nausea, somnolence, vomiting, and weakness. Late evidence includes albuminuria, anorexia, arrhythmias, azotemia, conjunctivitis (calcific), decreased libido, elevated AST and ALT levels, elevated BUN level, generalized vascular calcification, hypercholesterolemia, hypertension, hyperthermia, irritability, mild acidosis, nephrocalcinosis, nocturia, pancreatitis, photophobia, polydipsia, polyuria, pruritus, rhinorrhea, and weight loss.

PATIENT TEACHING

- Instruct patient to swallow capsule whole and not to crush or chew it.
- Advise patient to consult prescriber before taking OTC drugs.
- Instruct patient to store drug tightly capped in a cool, dry place away from direct light.
- Encourage patient to eat a balanced diet that includes foods high in vitamin D and calcium. Calcifediol is most effective with a high-calcium diet.
- If patient takes vitamin supplements, warn him not to exceed recommended amounts.
- Tell patient to avoid calcium-, phosphate-, and magnesium-containing laxatives and antacids; mineral oil; and vitamin D preparations because they may increase the risk of calcifediol's toxic effects.
- Advise patient to immediately report possible toxicity, such as headache, irritability, nausea, photophobia, vomiting, weakness, and weight loss.
- Stress need for follow-up care, including laboratory tests to evaluate progress and identify signs of toxicity early.

calcitonin, human

Cibacalcin

calcitonin, salmon

Calcimar, Miacalcin

Class and Category

Chemical class: Polypeptide hormone

Therapeutic class: Antihypercalcemic, bone resorption inhibitor, osteoporosis therapy adjunct

Pregnancy category: C

Indications and Dosages

↗ *To treat hypercalcemic emergency*

I.M. OR SUBCUTANEOUS INJECTION

Adults. *Initial:* 4 international units/kg every 12 hr. Increased after 1 or 2 days, if needed, to 8 international units/kg every 12 hr. *Maximum:* 8 international units/kg every 6 hr.

↗ *To treat postmenopausal osteoporosis*

I.M. OR SUBCUTANEOUS INJECTION (CALCITONIN, SALMON)

Adults. *Initial:* 100 international units daily, every other day, or 3 times weekly.

Maximum: 100 international units daily.

NASAL SPRAY

Adults. 200 international units (1 spray) daily, alternating nostrils.

↗ *To treat Paget's disease of the bone*

I.M. OR SUBCUTANEOUS INJECTION (CALCITONIN, SALMON)

Adults. *Initial:* 100 international units daily.

Maintenance: 50 to 100 international units daily or every other day. *Maximum:* 100 international units daily.

SUBCUTANEOUS INJECTION (CALCITONIN, HUMAN)

Adults. 0.5 mg daily, 0.5 mg 2 or 3 times/wk, or 0.25 mg daily.

Route	Onset	Peak	Duration
I.M., SubQ	In 15 min*	2 hr†	6–8 hr†

Mechanism of Action

Directly inhibits bone resorption. Besides reducing the serum calcium level, this action slows bone metabolism (a major factor in the development of Paget's disease) and calcium loss from the bone (a major factor in the development of osteoporosis).

Contraindications

Hypersensitivity to calcitonin, human; calcitonin, salmon; or their components

Interactions

DRUGS

lithium: Possibly decreased lithium level

* For hypercalcemia; 6 to 24 mo for Paget's disease.

† For hypercalcemia; unknown for other indications.

Adverse Reactions

CNS: Agitation, anxiety, dizziness, headache, insomnia, neuralgia, paresthesia, stroke, vertigo

CV: Bundle-branch block, hypertension, MI, palpitations, peripheral edema, tachycardia, thrombophlebitis

EENT: Blurred vision; dry mouth; earache; epistaxis; eye pain; hearing loss; nasal irritation, lesions, or redness; pharyngitis; rhinitis; salty taste; sinusitis; taste perversion; tinnitus; vitreous floaters

ENDO: Goiter, hyperthyroidism

GI: Abdominal pain, anorexia, cholelithiasis, diarrhea, epigastric discomfort, flatulence, gastritis, hepatitis, increased appetite, nausea, thirst, vomiting

GU: Hematuria, nocturia, pyelonephritis, renal calculi

HEME: Anemia

MS: Arthritis, arthrosis, back pain, joint stiffness, polymyalgia rheumatica

RESP: Bronchitis, bronchospasm, cough, dyspnea, pneumonia, upper respiratory tract infection

SKIN: Alopecia, diaphoresis, eczema, flushing of face or hands, pruritus of earlobes, rash, ulceration

Other: Anaphylaxis, anaphylactic shock, angioedema, antibody formation, feverish sensation, injection site inflammation, lymphadenopathy, mild tetanic symptoms

Nursing Considerations

- If sensitivity to calcitonin, human; calcitonin, salmon; or their components is suspected, expect to perform a skin test before giving drug. Prepare a mixture of 10 international units/ml by withdrawing 0.05 ml from a 200–international units solution in a tuberculin syringe and filling the syringe to 1 ml with sodium chloride for injection. Mix well, discard 0.9 ml, and inject 0.1 ml intradermally on the inner forearm. Observe the site for 15 minutes after injection. If you detect evidence of sensitivity, such as more than mild erythema or a wheal, notify prescriber.
- If patient receives calcitonin for hypercalcemia, monitor serum calcium level. During first several doses, keep parenteral calcium available in case the calcium level is inadvertently overcorrected.
- If prescribed calcitonin dose exceeds 2 ml, expect to use I.M. route and multiple

injection sites.

- For patient receiving calcitonin for postmenopausal osteoporosis, also expect to give 1.5 g supplemental calcium carbonate and at least 400 units vitamin D daily. Plan to provide a balanced diet that includes foods high in calcium and vitamin D.
- Assess for nausea, especially with the first dose. Nausea tends to decrease or disappear with continued use.
- If patient with Paget's disease relapses after treatment, check for antibody formation, as ordered.

PATIENT TEACHING

- Tell patient to refrigerate injection or unopened nasal spray container.
- Teach patient to self-administer injections.
- If patient has postmenopausal osteoporosis, teach her about dietary needs, including foods rich in calcium and vitamin D.
- For nasal spray, explain how to activate nasal pump by holding the bottle upright and depressing two white side arms toward the bottle six times. When bottle emits a faint spray, pump is activated. Tell patient to store activated nasal pump upright at room temperature and to discard it after 30 days.
- Instruct patient to place nozzle firmly into one nostril while holding head upright. Tell him to then depress the pump toward the bottle.
- Remind patient that he doesn't need to reactivate the pump before each dose.
- Instruct patient to report nasal symptoms, such as redness, lesions, sinusitis, and rhinitis, to prescriber.

calcitriol

(1,25-dihydroxy-cholecalciferol)

Calcijex, Rocaltrol

Class and Category

Chemical class: Sterol derivative, vitamin D analogue

Therapeutic class: Antihypocalcemic, antihypoparathyroid

Pregnancy category: C

Indications and Dosages

➤ To treat hypocalcemia in dialysis patients

CAPSULES, ORAL SOLUTION

Adults. *Initial:* 0.25 mcg daily. Increased by 0.25 mcg daily every 4 to 8 wk, if needed to achieve normal serum calcium level.

Maintenance: 0.5 to 3 mcg daily.

↗ *To treat hypocalcemia in predialysis patients*

CAPSULES, ORAL SOLUTION

Adults and children age 3 and over. *Initial:* 0.25 mcg daily. Increased after 4 to 8 wk, if needed, to 0.5 mcg daily.

ORAL SOLUTION

Children up to age 3. 10 to 15 ng/kg daily.

↗ *To treat hypoparathyroidism*

TABLETS

Adults and children age 6 and over. *Initial:* 0.25 mcg daily in the morning. Increased every 2 to 4 wk, if needed to achieve normal serum calcium level. *Usual:* 0.5 to 2 mcg daily.

Children ages 1 to 5. 0.25 to 0.75 mcg daily in the morning.

I.V. INJECTION

Adults. *Initial:* 1 to 2 mcg 3 times/wk given every other day. Each dose increased 0.5 to 1 mcg at 2- to 4-wk intervals, if needed.

Route	Onset	Peak	Duration
P.O.	2–6 hr	10 hr	3–5 days

Mechanism of Action

Binds to specific receptors on intestinal mucosa to increase calcium absorption from intestine. Drug also may regulate calcium ion transfer from bone to blood and stimulate calcium reabsorption in the distal renal tubules, making more calcium available in the body.

Contraindications

Hypercalcemia, vitamin D toxicity

Interactions**DRUGS**

cholestyramine: Decreased calcitriol absorption

digitalis glycosides: Possibly arrhythmias

ketoconazole: Decreased calcitriol level

magnesium-containing antacids (I.V. form): Hypermagnesemia

mineral oil: Decreased blood calcitriol level (with prolonged use of mineral oil)

phenobarbital, phenytoin: Decreased synthesis and blood level of calcitriol

thiazide diuretics: Hypercalcemia

Adverse Reactions

SKIN: Erythema multiforme, lip swelling, pruritus, rash, urticaria

Other: Anaphylaxis

Nursing Considerations

- Make sure patient receives enough calcium.
- Store drug at room temperature, and protect from heat and direct light.
- In high-dose or long-term calcitriol therapy, be alert for vitamin D toxicity. Early evidence includes abdominal or bone pain, constipation, dry mouth, headache, metallic taste, myalgia, nausea, somnolence, vomiting, and weakness. Late evidence includes albuminuria, anorexia, arrhythmias, azotemia, conjunctivitis (calcific), decreased libido, elevated AST and ALT levels, elevated BUN level, vascular calcification, hypercholesterolemia, hypertension, hyperthermia, irritability, mild acidosis, nephrocalcinosis, nocturia, pancreatitis, photophobia, polydipsia, polyuria, pruritus, rhinorrhea, and weight loss.

PATIENT TEACHING

- Warn patient not to take other forms of vitamin D while taking calcitriol.
- Instruct patient to take a missed dose as soon as possible.
- Advise patient to notify prescriber immediately about possible toxicity, such as headache, irritability, nausea, photophobia, vomiting, weakness, and weight loss.

calcium acetate

PhosLo

calcium carbonate

Apo-Cal (CAN), Calci-Mix, Calsan (CAN), Liqui-Cal, Liquid Cal-600, Titracal

calcium chloride

Calciject (CAN)

calcium citrate

Citracal, Citracal Liquidabs

calcium glubionate

Calcionate, Calcium-Sandoz (CAN), Neo-Calgluon

calcium gluceptate

Calcium Stanley (CAN)

calcium gluconate

calcium lactate

Class and Category

Chemical class: Elemental cation

Therapeutic class: Antacid, antihypermagnesemic, antihyperphosphatemic, antihypocalcemic, calcium replacement, cardiotonic

Pregnancy category: C (Not rated for calcium carbonate, citrate, and lactate)

Indications and Dosages

↗ *To treat hyperphosphatemia*

TABLETS (CALCIUM ACETATE)

Adults. *Initial:* 2 tablets (338 mg elemental calcium, 1,334 mg calcium acetate) t.i.d. with meals. Dosage increased to reduce serum phosphorus level below 6 mg/dl as long as hypercalcemia doesn't develop.

Maintenance: 3 or 4 tablets t.i.d. with each meal.

↗ *To prevent hypocalcemia*

CAPSULES, ORAL SUSPENSION, TABLETS (CALCIUM CARBONATE); EFFERVESCENT TABLETS, TABLETS (CALCIUM CITRATE); SYRUP (CALCIUM GLUBIONATE); TABLETS (CALCIUM GLUCONATE OR LACTATE)

Adults and children over age 10. 800 to 1,200 mg daily.

Pregnant and breast-feeding women. 1,200 mg daily.

Children ages 4 to 10. 800 mg daily.

Children up to age 4. 400 to 800 mg daily.

↗ *To provide antacid effects*

CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS (CALCIUM CARBONATE)

Adults and children age 12 and over.

350 to 1,500 mg 1 hr after meals and at bedtime, p.r.n.

↗ *To replace calcium in hypocalcemia*

I.V. INFUSION (CALCIUM CHLORIDE)

Adults. 0.5 to 1 g every 1 to 3 days, infused at less than 1 ml/min.

Children. 25 mg/kg given over several minutes.

I.V. OR I.M. INJECTION (CALCIUM GLUCEPTATE)

Adults and children. 0.44 to 1.1 g I.M. or 1.1 to 4.4 g I.V. at a rate of no more than

2 ml (36 mg)/min.

I.V. INJECTION (CALCIUM GLUCONATE)

Adults. 970 mg given slowly, repeated if needed, until tetany is controlled.

Children. 200 to 500 mg as a single dose given slowly, repeated if needed, until tetany is controlled.

↗ *As adjunct to treat magnesium intoxication*

I.V. INJECTION (CALCIUM CHLORIDE)

Adults. 500 mg promptly and repeated p.r.n., based on response.

↗ *As adjunct in cardiac resuscitation*

I.V. INJECTION (CALCIUM CHLORIDE)

Adults. 0.5 to 1 g.

Children. 0.2 ml/kg.

↗ *As adjunct in exchange transfusion*

I.V. INJECTION (CALCIUM GLUCONATE)

Adults. 1.35 mEq with each 100 ml of citrated blood exchanged.

Neonates. 0.45 mEq after each 100 ml of citrated blood exchanged.

I.V. INJECTION (CALCIUM GLUCEPTATE)

Neonates. 110 mg after each 100 ml of citrated blood exchanged.

Mechanism of Action

Increases levels of intracellular and extracellular calcium, which is needed to maintain homeostasis, especially in the nervous and musculoskeletal systems. Also plays a role in normal cardiac and renal function, respiration, coagulation, and cell membrane and capillary permeability. Helps regulate the release and storage of neurotransmitters and hormones. Oral forms also neutralize or buffer stomach acid to relieve discomfort caused by hyperacidity.

Contraindications

Hypercalcemia, hypersensitivity to calcium salts or their components, hypophosphatemia, renal calculi

Incompatibilities

To avoid precipitation, don't give I.V. calcium chloride, gluceptate, or gluconate through same I.V. line as bicarbonates, carbonates, phosphates, sulfates, or tartrates.

Interactions

DRUGS

aluminum-containing antacids: Enhanced aluminum absorption with use of calcium citrate

atenolol: Decreased blood atenolol level and

beta blockade

calcitonin: Possibly antagonized effects of calcitonin in hypercalcemia treatment

calcium supplements, magnesium-containing preparations: Increased serum calcium or magnesium level, especially in patients with impaired renal function

cellulose sodium phosphate: Decreased effectiveness of cellulose sodium phosphate in preventing hypercalcemia

digitalis glycosides: Increased risk of arrhythmias

estrogens, oral contraceptives (estrogen-containing): Increased calcium absorption

etidronate: Decreased etidronate absorption

fluoroquinolones: Reduced fluoroquinolone

absorption by calcium carbonate

gallium nitrate: Antagonized effects of gallium nitrate

iron salts: Decreased gastric iron absorption

magnesium sulfate (parenteral): Neutralized effects of magnesium by parenteral calcium

neuromuscular blockers (except succinylcholine): Possibly reversal of neuromuscular blockade by parenteral calcium salts;

enhanced or prolonged neuromuscular blockade induced by tubocurarine

norfloxacin: Decreased norfloxacin bioavailability

phenytoin: Decreased bioavailability of phenytoin and calcium

potassium phosphates, potassium and sodium phosphates: Increased risk of calcium deposition in soft tissue

sodium bicarbonate: Possibly milk-alkali syndrome

sodium fluoride: Reduced fluoride and calcium absorption

sodium polystyrene sulfonate: Possibly metabolic alkalosis if patient has renal impairment

tetracyclines: Decreased tetracycline absorption and blood level, leading to decreased anti-infective response

thiazide diuretics: Possibly hypercalcemia

verapamil: Reversed verapamil effects

vitamin A (more than 25,000 units daily): Possibly stimulation of bone loss, decreased effects of calcium supplementation, and hypercalcemia

vitamin D (high doses): Excessively increased calcium absorption

FOODS

caffeine, high-fiber food: Possibly decreased calcium absorption

ACTIVITIES

alcohol use (excessive), smoking: Possibly decreased calcium absorption

Adverse Reactions

CNS: Paresthesia (parenteral form)

CV: Hypotension, irregular heartbeat (parenteral form)

GI: Nausea or vomiting (parenteral form)

SKIN: Diaphoresis, flushing, or sensation of warmth (parenteral form)

Other: Hypercalcemia; injection site burning, pain, rash, or redness (parenteral form)

Nursing Considerations

- Store at room temperature, and protect from heat, moisture, and direct light. Don't freeze.
- Warm solution to room temperature before parenteral administration.
- Keep patient in a recumbent position for 30 minutes after parenteral administration to prevent dizziness from hypotension.
- Administer I.V. calcium through an infusing I.V. solution using a small-bore needle inserted into a large vein to minimize irritation. Give calcium slowly to prevent excess calcium from reaching the heart and causing adverse cardiovascular reactions. Adverse reactions often result from too-rapid administration. If ECG tracings are abnormal or patient reports injection site discomfort, expect to temporarily discontinue administration.
- Check regularly for infiltration because calcium causes necrosis. If infiltration occurs, stop infusion and tell prescriber immediately.
- Divide I.M. calcium gluceptate dose of 5 ml or more in half and inject in gluteal region.
- Regularly monitor serum calcium level and evaluate therapeutic response by assessing for Chvostek's and Trousseau's signs, which shouldn't appear.
- Be aware that calcium chloride injection contains three times as much calcium per milliliter as calcium gluconate injection.

PATIENT TEACHING

- For chewable tablets, urge patient to chew thoroughly before swallowing and to drink a glass of water afterward.
- If suspension is prescribed, tell patient to shake bottle well before each use.
- If calcium citrate effervescent tablets are

prescribed, tell patient to dissolve them in water and drink immediately.

- Instruct patient to take calcium carbonate tablets 1 to 2 hours after meals, calcium glubionate syrup before meals (diluted in water or fruit juice, if desired, for an infant or a child), and other forms with meals.
- Advise storing calcium at room temperature away from heat, moisture, and light. Warn against freezing suspension or syrup.
- Instruct patient to avoid taking calcium within 2 hours of another oral drug because of risk of interactions.
- Urge patient to ask prescriber before taking OTC drugs because of risk of interactions.
- Tell patient to avoid excessive use of tobacco and excessive consumption of alcoholic beverages, caffeine-containing products, and high-fiber foods because these substances may decrease calcium absorption.

candesartan cilexetil

Atacand

Class and Category

Chemical class: Angiotensin II receptor antagonist

Therapeutic class: Antihypertensive

Pregnancy category: C (first trimester), D (later trimesters)

Indications and Dosages

➤ *To manage, or as adjunct in managing, hypertension*

TABLETS

Adults. *Initial:* 16 mg daily. *Maintenance:* 8 to 32 mg daily or 4 to 16 mg every 12 hr. *Maximum:* 32 mg daily.

DOSAGE ADJUSTMENT Initial dosage decreased to 2 mg for patients with moderate to severe hepatic impairment and to 4 mg for those with renal impairment, need for hemodialysis, or possibly a risk of hypotension.

➤ *To treat heart failure in patients with an ejection fraction of 40% or less and NYHA class II–IV to reduce the risk of death from cardiovascular causes and reduce hospitalizations for heart failure*

TABLETS

Adults. *Initial:* 4 mg daily for 2 wk; then

doubled every 2 wk as tolerated until reaching target dose of 32 mg daily.

Route	Onset	Peak	Duration
P.O.	In 2 wk	4–5 wk	Unknown

Mechanism of Action

Selectively blocks binding of angiotensin (AT) II to AT₁ receptor sites in many tissues, including vascular smooth muscle and adrenal glands. This inhibits vasoconstrictive and aldosterone-secreting effects of AT II, which reduces blood pressure.

Contraindications

Hypersensitivity to candesartan or its components

Interactions

DRUGS

diuretics, other antihypertensives: Possibly increased risk of hypotension
heparin, potassium-sparing diuretics, potassium supplements, potassium-containing salt substitutes: Possibly increased risk of hyperkalemia

lithium: Increased blood lithium level

Adverse Reactions

CNS: Dizziness, headache

CV: Hypotension

EENT: Pharyngitis, rhinitis

GI: Elevated liver function test results, hepatitis

GU: Elevated BUN and serum creatinine levels

HEME: Agranulocytosis, leukopenia, neutropenia

MS: Back pain, rhabdomyolysis

RESP: Upper respiratory tract infection

Other: Hyperkalemia, hyponatremia

Nursing Considerations

- If patient has known or suspected hypovolemia, expect to provide treatment, such as I.V. normal saline solution, as prescribed, to correct it before starting candesartan.
- Monitor patient closely during major surgery and anesthesia because candesartan increases risk of hypotension by blocking renin-angiotensin system.
- Watch for elevated BUN and serum creatinine levels, especially if patient has heart failure or impaired renal function; drug may cause acute renal failure. Report sig-

- nificant or persistent increases immediately.
- If blood pressure isn't controlled with candesartan alone, expect to give a diuretic, such as hydrochlorothiazide, as prescribed.

WARNING If patient receives a diuretic or antihypertensive with candesartan, has heart failure, or is elderly, assess blood pressure often because of added risk of hypotension.

- If patient develops hypotension, expect to stop drug temporarily. Immediately place patient in supine position and prepare to give I.V. normal saline solution, as prescribed. Expect to resume therapy after blood pressure stabilizes.
- If patient receives a diuretic, provide hydration, as ordered, to help prevent hypovolemia. Watch for evidence, such as hypotension with dizziness and fainting. If patient has heart failure and develops hypotension, dosage of diuretic, candesartan, or both may be reduced when blood pressure stabilizes and therapy resumes.
- Check CBC for decreases in hemoglobin and hematocrit. If they're significant or persistent, notify prescriber immediately.

PATIENT TEACHING

- Advise patient that full effects of candesartan may not occur for 4 to 5 weeks.
- Explain importance of lifestyle choices in controlling hypertension.
- Advise female patient to immediately report known or suspected pregnancy. Explain that if she becomes pregnant, prescriber may replace candesartan with another antihypertensive that's safe to use during pregnancy.

capreomycin sulfate

Capastat

Class and Category

Chemical class: Polypeptide antibiotic isolated from *Streptomyces capreolus*

Therapeutic class: Antitubercular

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat pulmonary tuberculosis caused by Mycobacterium tuberculosis in which primary drugs are ineffective or can't be used because of toxicity*

I.V. INFUSION, I.M. INJECTION

Adults. 1 g daily for 60 to 120 days followed by 1 g 2 or 3 times/wk for 12 to 24 mo.
Maximum: 20 mg/kg daily.

DOSAGE ADJUSTMENT For patient with renal impairment, dosage reduced according to patient's creatinine clearance.

Mechanism of Action

May interfere with lipid and nucleic acid biosynthesis in actively growing tubercle bacilli.

Contraindications

Hypersensitivity to capreomycin or its components

Interactions

DRUGS

aminoglycosides (parenteral): Increased risk of ototoxicity, nephrotoxicity, and neuromuscular blockade
nephrotoxic drugs, such as amphotericin B: Increased risk of nephrotoxicity
nondepolarizing neuromuscular blockers: Enhanced neuromuscular blockade
ototoxic drugs, such as quinidine: Increased risk of ototoxicity
polymyxins (parenteral): Increased risk of nephrotoxicity and neuromuscular blockade

Adverse Reactions

CNS: Dizziness, vertigo

EENT: Ototoxicity

GI: Elevated liver function test results

GU: Nephrotoxicity

HEME: Leukocytosis, leukopenia

SKIN: Maculopapular rash, sterile abscess, urticaria

Other: Hypocalcemia, hypokalemia, hypomagnesemia, injection site pain, induration, and bleeding

Nursing Considerations

- Use capreomycin cautiously in patients with renal insufficiency, impaired hearing, or a history of hypersensitivity, especially to other drugs.
- Expect to obtain baseline renal function studies, as ordered, before starting capreomycin and weekly throughout therapy because drug may alter renal function.
- To reconstitute drug for I.V. injection, add 100 ml normal saline solution. Administer over 60 minutes.
- To reconstitute drug for I.M. injection, add 2 ml sodium chloride for injection or

sterile water for injection to each 1-g vial. Allow 2 to 3 minutes for complete dissolution.

- Give I.M. injection deep into a large muscle mass, such as the gluteus maximus.
- Observe injection site for excessive bleeding or sterile abscess.
- Make sure patient receives regular audiometric and vestibular function assessment.
- Closely monitor patient for urticaria and maculopapular rash.
- Check serum electrolyte levels periodically, as ordered, because capreomycin may cause imbalances such as hypocalcemia, hypokalemia, and hypomagnesemia.

PATIENT TEACHING

- Advise patient to alert nurse or prescriber if injection site bleeds excessively.
- Warn patient to contact prescriber immediately about hearing loss or tinnitus.
- Explain the need for frequent laboratory tests to monitor renal function.
- Tell patient that tuberculosis therapy lasts for 12 to 24 months.
- Explain that noncompliance may decrease effectiveness and lengthen treatment.

captopril

Capoten

Class and Category

Chemical class: ACE inhibitor

Therapeutic class: Antihypertensive

Pregnancy category: C (first trimester), D (later trimesters)

Indications and Dosages

➤ *To control hypertension*

TABLETS

Adults and adolescents. *Initial:* 25 mg b.i.d. or t.i.d. Increased to 50 mg b.i.d. or t.i.d. after 1 to 2 wk, if needed. If blood pressure isn't well controlled at this dosage and with the addition of a diuretic, dosage increased to 100 mg b.i.d. or t.i.d. and then, if needed, to 150 mg b.i.d. or t.i.d. while continuing diuretic. *Maximum:* 450 mg daily.

➤ *To control accelerated or malignant hypertension when temporary discontinuation of current antihypertensive therapy isn't practical or when prompt titration of blood pressure is needed*

TABLETS

Adults and adolescents. *Initial:* 25 mg b.i.d. or t.i.d. while continuing diuretic but discontinuing current antihypertensive drug. Increased every 24 hr as needed until satisfactory response is obtained or maximum dosage is reached. *Maximum:* 450 mg daily.

➤ *To treat heart failure that's unresponsive to conventional therapy*

TABLETS

Adults and adolescents. *Initial:* 25 mg b.i.d. or t.i.d. Increased to 50 mg b.i.d. or t.i.d., as needed. After 14 days, increased to 100 mg t.i.d. and then to 150 mg t.i.d., if needed. *Maximum:* 450 mg daily.

➤ *To treat left-sided heart failure after MI*

TABLETS

Adults and adolescents. *Initial:* 6.25 mg as single dose starting 3 days after MI and then 12.5 mg t.i.d. Increased to 25 mg t.i.d. for several days and then again to maintenance dosage. *Maintenance:* 50 mg t.i.d.

➤ *To treat diabetic nephropathy*

TABLETS

Adults and adolescents. 25 mg t.i.d.

DOSAGE ADJUSTMENT Starting dosage reduced to 6.25 mg b.i.d. or t.i.d. if patient with hypertension also has heart failure, is undergoing dialysis, or is being vigorously treated with diuretics that result in hyponatremia or hypovolemia.

Route	Onset	Peak	Duration
P.O.	15–60 min	60–90 min	6–12 hr

Mechanism of Action

By inhibiting angiotensin-converting enzyme, captopril:

- prevents conversion of angiotensin I to angiotensin II, a potent vasoconstrictor that also stimulates the adrenal cortex to secrete aldosterone. Inhibiting aldosterone increases sodium and water excretion, reducing blood pressure.
- may inhibit renal and vascular production of angiotensin II.
- decreases serum angiotensin II level and increases renin activity. This decreases aldosterone secretion, slightly increasing serum potassium level and fluid loss.
- decreases vascular tone and blood pressure.

Contraindications

Hypersensitivity to captopril, other ACE inhibitors, or their components

Interactions

DRUGS

allopurinol: Increased risk of hypersensitivity reactions, including Stevens-Johnson syndrome, skin eruptions, fever, arthralgia

antacids: Possibly impaired captopril absorption

capsaicin: Possibly cause or worsening of cough from ACE inhibitor

cyclosporine, potassium-containing drugs, potassium-sparing diuretics, potassium supplements: Increased risk of hyperkalemia

digoxin: Increased blood digoxin level

diuretics; hypotension-producing drugs, such as hydralazine: Additive hypotensive effects

gold: Increased risk of nitritoid reaction, including facial flushing, nausea, vomiting, and hypotension

lithium: Increased risk of lithium toxicity

NSAIDs: Decreased antihypertensive response to ACE inhibition

probenecid: Increased blood level and decreased total clearance of captopril

ACTIVITIES

alcohol use: Additive hypotensive effects

Adverse Reactions

CNS: Fever

CV: Chest pain, hypotension, orthostatic hypotension, palpitations, tachycardia

EENT: Loss of taste

GU: Dysuria, impotence, nephrotic syndrome, nocturia, oliguria, polyuria, proteinuria, urinary frequency

HEME: Eosinophilia

MS: Arthralgia

RESP: Cough

SKIN: Photosensitivity, pruritus, rash

Other: Angioedema, hyperkalemia, hyponatremia, positive ANA titer

Nursing Considerations

- Closely monitor patient's blood pressure, especially when therapy starts and dosage increases. Keep patient supine if hypotension occurs.
- Monitor renal function tests for signs of nephrotic syndrome, such as proteinuria and increased BUN and serum creatinine levels. Also watch for such renal evidence as oliguria, polyuria, and urinary frequency.
- Monitor WBC regularly, as ordered, especially if patient has collagen vascular disease or renal disease.

PATIENT TEACHING

- Instruct patient to take captopril 1 hour before meals.
- Tell patient to rise slowly from sitting or lying to minimize orthostatic hypotension.
- Tell patient to avoid sunlight or wear sunscreen in direct sunlight because photosensitivity may occur.
- Warn patient not to stop drug abruptly.
- Urge patient not to use salt substitutes that contain potassium and to consult prescriber before increasing potassium intake to avoid increasing risk of hyperkalemia.
- Urge patient to tell prescriber about signs and symptoms of infection, such as sore throat or fever.

carbamazepine

Apo-Carbamazepine (CAN), Atretol, Carbatrol, Epitol, Equetro, Novo-Carbamaz (CAN), Tegretol, Tegretol-XR

Class and Category

Chemical class: Tricyclic iminostilbene derivative

Therapeutic class: Analgesic, anticonvulsant

Pregnancy category: C

Indications and Dosages

↗ *To treat epilepsy*

E.R. CAPSULES (CARBATROL), E.R. TABLETS (TEGRETOL-XR)

Adults and children age 12 and over.

Initial: 200 mg b.i.d. Increased weekly by 200 mg daily, if needed. *Maximum*: 1,600 mg daily in adults, 1,200 mg daily in children age 16 and over, and 1,000 mg daily in children ages 12 to 16.

Children ages 6 to 12. *Initial*: 100 mg b.i.d. Increased weekly by 100 mg daily, if needed. *Maximum*: 1,000 mg daily.

ORAL SUSPENSION

Adults and children age 12 and over.

Initial: 100 mg q.i.d. Increased weekly by 200 mg daily, if needed, given in divided doses t.i.d or q.i.d. *Maximum*: 1,600 mg daily in adults, 1,200 mg daily in children age 16 and over, and 1,000 mg daily in children ages 12 to 16.

Children ages 6 to 12. *Initial*: 50 mg q.i.d. Increased weekly by 100 mg daily, if needed, given in divided doses t.i.d or q.i.d.

Maximum: 1,000 mg daily.

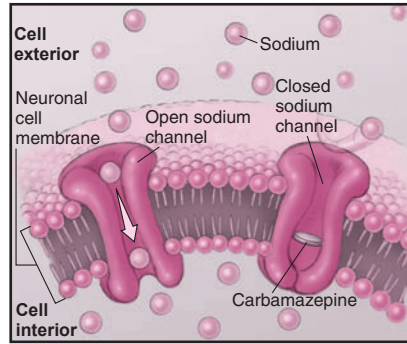

Children up to age 6. *Initial*: 10 to 20 mg/

Mechanism of Action

Normally, sodium moves into a neuronal cell by passing through a gated sodium channel in the cell membrane.

Carbamazepine may prevent or halt seizures by closing or blocking sodium channels, as shown below, thus preventing sodium from entering the cell.

Keeping sodium out of the cell may slow nerve impulse transmission, thus slowing the rate at which neurons fire.

kg/day in divided doses q.i.d. *Maximum:* 35 mg/kg daily.

TABLETS

Adults and children age 12 and over.

Initial: 200 mg b.i.d. Increased weekly by 200 mg/day, if needed, given in divided doses t.i.d. or q.i.d. *Maximum:* 1,600 mg daily in adults, 1,200 mg daily in children age 16 and over, and 1,000 mg daily in children ages 12 to 16.

Children ages 6 to 12. *Initial:* 100 mg b.i.d. Increased weekly by 100 mg daily, if needed, given in divided doses t.i.d. or q.i.d. *Maximum:* 1,000 mg daily.

Children up to age 6. *Initial:* 10 to 20 mg/kg daily in divided doses b.i.d. or t.i.d. Increased weekly, if needed, divided and given t.i.d. or q.i.d. *Maximum:* 35 mg/kg/day.

↗ *To relieve pain in trigeminal neuralgia*

E.R. CAPSULES (CARBATROL), E.R. TABLETS (TEGRETOL-XR), TABLETS

Adults. *Initial:* 100 mg b.i.d. Increased by up to 200 mg daily, if needed, in increments of 100 mg every 12 hr. *Maintenance:* 400 to 800 mg/day. *Maximum:* 1,200 mg daily.

ORAL SUSPENSION (100 MG/5 ML)

Adults. 50 mg q.i.d. Increased by up to 200 mg daily, if needed, in increments of 50 mg q.i.d. *Maintenance:* 400 to 800 mg daily. *Maximum:* 1,200 mg daily.

↗ *To treat acute manic and mixed episodes in bipolar disorder*

E.R. CAPSULES (EQUETRO)

Adults. *Initial:* 200 mg b.i.d., increased as needed in 200-mg increments. *Maximum:* 1,600 mg daily.

Contraindications

History of bone marrow depression; hyper-

sensitivity to carbamazepine, tricyclic compounds, or their components; MAO inhibitor or nefazodone therapy

Route	Onset	Peak	Duration
P.O. (all forms)	In 1 mo*	Unknown	Unknown

Interactions

DRUGS

acetaminophen (long-term use): Increased metabolism, leading to acetaminophen-induced hepatotoxicity or decreased acetaminophen effectiveness
acetazolamide, cimetidine, clarithromycin, danazol, diltiazem, erythromycin, fluconazole, fluoxetine, fluvoxamine, isoniazid, itraconazole, ketoconazole, loratadine, niacinamide, nicotinamide, propoxyphene, protease inhibitors, terfenadine, troleandomycin, valproate, verapamil: Increased blood carbamazepine level

alprazolam, amitriptyline, bupropion, buspirone, citalopram, clobazam, clonazepam, clozapine, cyclosporine, delavirdine, desipramine, diazepam, dicumarol, doxycycline, ethosuximide, felodipine, glucocorticoids, haloperidol, itraconazole, lamotrigine, levothyroxine, lorazepam, methadone, methsuximide, midazolam, mirtazapine, nortriptyline, olanzapine, oral contraceptives, oxcarbazepine, phenytoin, praziquantel, protease inhibitors, quetiapine, risperidone, theophylline, tiagabine, topiramate, tramadol, triazolam, trazodone, valproate, warfarin,

* For anticonvulsant use; 8 to 72 hr for use in trigeminal neuralgia.

ziprasidone, zonisamide: Decreased blood levels of these drugs

cisplatin, doxorubicin, felbamate, methsuximide, phenytoin, rifampin, theophylline:

Decreased blood carbamazepine level

clomipramine, phenytoin, primidone:

Increased blood levels of these drugs

felbamate: Decreased blood level of felbamate or carbamazepine

isoniazid: Increased risk of carbamazepine toxicity and isoniazid hepatotoxicity

lamotrigine, phenobarbital, primidone, tricyclic antidepressants, valproic acid:

Decreased blood levels of these drugs, increased blood level of carbamazepine

lithium: Increased risk of CNS toxicity

nefazodone: Decreased nefazodone effectiveness and increased carbamazepine level

nondepolarizing neuromuscular blockers:

Possibly reduced duration or decreased effectiveness of neuromuscular blocker

oral anticoagulants: Increased metabolism and decreased effectiveness of anticoagulant

FOODS

grapefruit juice: Increased blood carbamazepine level

ACTIVITIES

alcohol use: Increased sedative effect

Adverse Reactions

CNS: Chills, confusion, dizziness, drowsiness, fatigue, fever, headache, suicidal ideation, syncope, talkativeness, unsteadiness, visual hallucinations

CV: Arrhythmias, including AV block; edema; heart failure; hypertension; hypotension; thromboembolism; thrombophlebitis; worsened coronary artery disease

EENT: Blurred vision, conjunctivitis, dry mouth, glossitis, nystagmus, oculomotor disturbances, stomatitis, tinnitus, transient diplopia

ENDO: Syndrome of inappropriate ADH secretion, water intoxication

GI: Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, elevated liver function test results, hepatitis, nausea, pancreatitis, vomiting

GU: Acute urine retention, albuminuria, azotemia, glycosuria, impotence, oliguria, renal failure, urinary frequency

HEME: Acute intermittent porphyria, agranulocytosis, aplastic anemia, bone marrow depression, eosinophilia, leukocytosis, leu-

kopenia, pancytopenia, thrombocytopenia

MS: Arthralgia, leg cramps, myalgia

RESP: Pulmonary hypersensitivity (dyspnea, fever, pneumonia, or pneumonitis)

SKIN: Aggravation of disseminated lupus erythematosus, alopecia, altered skin pigmentation, diaphoresis, erythema multiforme, erythema nodosum, exfoliative dermatitis, jaundice, Lyell's syndrome, photosensitivity reactions, pruritic and erythematous rash, purpura, Stevens-Johnson syndrome, urticaria

Other: Adenopathy, lymphadenopathy

Nursing Considerations

- Avoid using carbamazepine in patients with a history of hepatic porphyria because it may prompt an acute attack.

WARNING If patient has Asian ancestry, make sure he has been evaluated for the genetic allelic variant HLA-B 1502 before starting carbamazepine therapy. Patients positive for HLA-B 1502 shouldn't take carbamazepine because the risk of serious, sometimes fatal, dermatologic reactions is ten times higher than in patients without this variant.

- Use carbamazepine cautiously in patients with impaired hepatic function because it's mainly metabolized in the liver. Monitor liver function tests, as directed.
- Monitor patient closely for adverse reactions because many are serious.
- Periodically monitor blood carbamazepine level to assess for therapeutic and toxic levels; a blood level of 6 to 12 mcg/ml is optimal for anticonvulsant effects.

WARNING Monitor WBC and platelet counts monthly for first 2 months. Decreased counts may indicate bone marrow depression.

- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.
- Withdraw carbamazepine gradually to minimize risk of seizures.

PATIENT TEACHING

- Tell patient to take carbamazepine with food (except the oral suspension form, which shouldn't be taken with other liquid drugs or diluents).
- Warn patient about possible dizziness, blurred vision, and unsteadiness.
- Inform patient that coating of E.R. tablets isn't absorbed and may appear in stool.

- Advise patient not to crush or chew E.R. capsules or tablets. If he can't swallow capsules whole, have him open them and sprinkle contents on food.
- Urge patient to wear sunscreen and protective clothing to reduce photosensitivity.
- Tell patient to report unusual bleeding or bruising, fever, rash, or mouth ulcers.
- Tell woman that drug decreases oral contraceptive effectiveness, and urge her to use different contraception. Because drug may cause fetal harm, tell her to notify prescriber about possible pregnancy.
- If she becomes pregnant during therapy, urge her to enroll in the antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting information about the safety of antiepileptic drugs during pregnancy.
- Instruct caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report such tendencies to prescriber immediately.

carisoprodol

Soma, Vanadom

Class and Category

Chemical class: Dicarbamate

Therapeutic class: Skeletal muscle relaxant

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to relieve acute musculoskeletal pain and stiffness*

TABLETS (SOMA)

Adults and children over age 16. 250 to 350 mg t.i.d. and at bedtime.

TABLETS (VANADOM)

Children ages 5 to 12. 6.25 mg/kg t.i.d. and at bedtime.

Route	Onset	Peak	Duration
P.O.	30 min	Unknown	4–6 hr

Mechanism of Action

Blocks interneuronal activity in descending reticular formation and spinal cord, producing muscle relaxation and sedation.

Contraindications

Hypersensitivity or idiosyncratic reactions

to carisoprodol, to its components, or to meprobamate-related compounds; intermittent porphyria

Interactions

DRUGS

CNS depressants, psychotropic drugs:

Additive CNS depression

fluvoxamine, omeprazole: Increased blood carisoprodol level

rifampin, St. John's wort: Decreased blood carisoprodol level

ACTIVITIES

alcohol use: Additive CNS depression

Adverse Reactions

CNS: Agitation, ataxia, depression, dizziness, drowsiness, fever, headache, insomnia, irritability, seizures, somnolence, syncope, tremor, vertigo

CV: Orthostatic hypotension, tachycardia

EENT: Diplopia, transient vision loss

GI: Epigastric discomfort, hiccups, nausea, vomiting

HEME: Eosinophilia

SKIN: Erythema multiforme, facial flushing, pruritus, rash

Other: Drug dependence or withdrawal

Nursing Considerations

- Use carisoprodol cautiously in patients with history of drug addiction and in patients taking other CNS depressants, including alcohol.
- Carisoprodol therapy should last no longer than 3 weeks.
- Monitor patient closely for hypersensitivity or idiosyncratic reactions. They typically occur before the fourth dose in patients who have no previous carisoprodol exposure.
- Provide rest and other pain-relief measures.
- To avoid mild withdrawal symptoms, expect to taper therapy as prescribed, rather than stopping it abruptly.

PATIENT TEACHING

- Tell patient to take carisoprodol with meals if GI distress occurs.
- Caution patient that drug dependence and withdrawal may occur, especially if therapy lasts a long time or patient changes dosage without consulting prescriber.
- Warn patient about possible dizziness, drowsiness, syncope, and vertigo. Discourage hazardous activities, such as driving, until effects of drug are known.

- Inform patient that abruptly stopping drug can cause headache, insomnia, nausea, and other adverse reactions.
- Instruct patient to avoid alcohol and other CNS depressants while taking drug.
- Explain that saliva, urine, and sweat may appear darker (red, brown, or black). Reassure him that this discoloration is harmless but may stain garments.
- Tell patient to store drug in a tightly capped container at room temperature.
- Tell patient not to store drug in bathroom, near kitchen sink, or in other damp places to protect it from heat and moisture.

carteolol hydrochloride

Cartrol

Class and Category

Chemical class: Beta-adrenergic blocker

Therapeutic class: Antihypertensive

Pregnancy category: C

Indications and Dosages

↗ *To control hypertension*

TABLETS

Adults. *Initial:* 2.5 mg daily. If response is inadequate, dosage increased to 5 mg and then 10 mg daily, p.r.n. *Maintenance:* 2.5 or 5 mg daily.

DOSE ADJUSTMENT Interval increased to every 48 hr for patients with creatinine clearance of 20 to 60 ml/min/1.73 m² or to every 72 hr for clearance of less than 20 ml/min/1.73 m².

Route	Onset	Peak	Duration
P.O.	Unknown	1–3 hr	Unknown

Mechanism of Action

May reduce blood pressure by competing with beta-adrenergic receptor agonists, which helps reduce cardiac output, decrease sympathetic outflow to peripheral blood vessels, and inhibit renin.

Contraindications

Asthma, bradycardia (less than 45 beats/min), cardiogenic shock, hypersensitivity to carteolol or its components, second- or third-degree heart block

Interactions

DRUGS

allergen immunotherapy, allergenic extracts for skin testing: Increased risk of serious systemic reaction or anaphylaxis
catecholamine-depleting drugs, such as reserpine: Additive effects, increased risk of hypotension and bradycardia
clonidine: Increased risk of tachycardia and hypertension after clonidine discontinuation
diltiazem, nifedipine, verapamil: Potentiated effects of carteolol
general anesthetics: Exaggeration of hypotension
NSAIDs: Reduced antihypertensive effect of carteolol
oral antidiabetic drugs: Reduced symptomatic responses to hypoglycemia
sympathomimetics with alpha- and beta-adrenergic effects, such as pseudoephedrine: Possibly hypertension and excessive bradycardia or heart block

Adverse Reactions

CNS: Fatigue, insomnia, lassitude, paresthesia, tiredness, weakness

CV: Chest pain, heart failure, peripheral edema

EENT: Dry mouth, nasal congestion, pharyngitis

GI: Abdominal pain, diarrhea, flatulence, nausea

MS: Arthralgia, back pain, leg pain, muscle spasms

SKIN: Rash

Nursing Considerations

WARNING Be aware that stopping carteolol abruptly in patients with angina may cause worsening of angina or MI; abrupt cessation in patients with hyperthyroidism may cause thyroid storm.

- Carefully monitor blood glucose level in diabetic patient because carteolol can mask hypoglycemic symptoms. It also can interfere with endogenous insulin release in response to hyperglycemia, requiring adjustment of oral antidiabetic dosage.

PATIENT TEACHING

- Advise patient to complete dosing schedule, even if he feels better, and not to discontinue therapy abruptly.
- Instruct patient to report signs of heart failure, such as fatigue, difficulty breath-

ing, cough, and unusually fast heartbeat.

- Tell diabetic patient to check his blood glucose level often.
- Advise patient to consult prescriber before taking OTC preparations, such as nasal decongestants and cold preparations that contain sympathomimetics, because of the risk of serious drug interactions.

carvedilol

Coreg, Coreg CR

Class and Category

Chemical class: Nonselective beta-adrenergic blocker with α_1 -adrenergic blocking activity

Therapeutic class: Antihypertensive, heart failure treatment adjunct

Pregnancy category: C

Indications and Dosages

↗ *To control hypertension*

TABLETS

Adults. 6.25 mg b.i.d. for 7 to 14 days, if tolerated. Then dosage increased to 12.5 mg b.i.d. for 7 to 14 days, and up to 25 mg, if tolerated and needed. *Maximum:* 50 mg daily.

E.R. CAPSULES

Adults. *Initial:* 20 mg once daily with food. After 7 to 14 days, increased to 40 mg once daily. After another 7 to 14 days, increased to 80 mg once daily. *Maximum:* 80 mg once daily.

↗ *As adjunct to treat mild to severe heart failure of ischemic or cardiomyopathic origin*

TABLETS

Adults. 3.125 mg b.i.d. for 2 wk; then increased to 6.25, 12.5, and 25 mg b.i.d. at successive 2-wk intervals, as tolerated. *Maximum (for patients with mild to moderate heart failure):* 50 mg b.i.d. if patient weighs more than 85 kg (187 lb).

E.R. CAPSULES

Adults. *Initial:* 10 mg once daily with food for 2 wk. Then increased to 20 mg once daily, as needed. Subsequent dosage increased by 20 mg every 2 wk, as needed. *Maximum:* 80 mg once daily.

↗ *To reduce CV mortality after acute phase of MI in patients with left ventricular ejection fraction of 40% or less*

TABLETS

Adults. 6.25 mg b.i.d. for 3 to 10 days, if tolerated. Then dosage increased to 12.5 mg b.i.d. for 3 to 10 days and up to 25 mg b.i.d., if needed and tolerated.

E.R. CAPSULES

Adults. *Initial:* 10 to 20 mg once daily. After 3 to 10 days, increased to 20 to 40 mg once daily. Increased again as needed every 3 to 10 days until reaching tolerance or target dose of 80 mg once daily. *Maximum:* 80 mg once daily.

DOSAGE ADJUSTMENT For patient with fluid retention or low blood pressure or heart rate, starting dosage may be decreased to 3.125 mg b.i.d., increase may be slowed, or both for tablet form. For patient with heart rate below 55 beats/min, extended-release dosage decreased as clinical condition indicates.

Route	Onset	Peak	Duration
P.O.	In 30 min	1.5–7 hr	Unknown

Mechanism of Action

Reduces cardiac output and tachycardia, causes vasodilation, and decreases peripheral vascular resistance, which reduces blood pressure and cardiac workload. When given for at least 4 weeks, carvedilol reduces plasma renin activity.

Contraindications

Asthma or related bronchospastic conditions; cardiogenic shock; decompensated heart failure that requires I.V. inotropics; history of serious hypersensitivity reactions, such as anaphylaxis, angioedema, or Stevens-Johnson syndrome; hypersensitivity to carvedilol or its components; second- or third-degree AV block, severe bradycardia or hepatic impairment, or sick sinus syndrome unless pacemaker is in place

Interactions

DRUGS

amiodarone; other CYP2C9 drugs, such as fluconazole: Increased risk of bradycardia or heart block

beta blockers, digoxin: Increased risk of bradycardia

calcium channel blockers (especially diltiazem and verapamil): Abnormal cardiac conduction and, possibly, increased adverse effects of calcium channel blockers

catecholamine-depleting drugs (such as reserpine, MAO inhibitors): Additive effects, increased risk of hypotension and bradycardia

cimetidine: Increased blood carvedilol level

clonidine: Risk of tachycardia and hypertension when clonidine is discontinued

cyclosporine, digoxin: Increased blood levels of these drugs

digoxin: Possibly increased digoxin level

oral antidiabetics: Increased risk of hypoglycemia

rifampin: Decreased blood carvedilol level

Adverse Reactions

CNS: Asthenia, depression, dizziness, fatigue, fever, headache, hypesthesia, hypotonia, insomnia, light-headedness, malaise, paresthesia, somnolence, stroke, syncope, vertigo

CV: Angina, AV block, bradycardia, edema, heart failure, hypertension, hypertriglyceridemia, orthostatic hypotension, palpitations, peripheral vascular disorder

EENT: Blurred vision, dry eyes, periodontitis, pharyngitis, rhinitis

ENDO: Hyperglycemia, hypoglycemia

GI: Abdominal pain, diarrhea, elevated liver function test results, melena, nausea, vomiting

GU: Albuminuria, hematuria, elevated BUN and creatinine levels, impotence, renal insufficiency, UTI

HEME: Aplastic anemia, decreased PT, thrombocytopenia, unusual bleeding or bruising

MS: Arthralgia, arthritis, back pain, muscle cramps

RESP: Dyspnea, increased cough

SKIN: Jaundice, pruritus, purpura, urticaria

Other: Anaphylaxis, angioedema, fluid overload, gout, hyperkalemia, hyperuricemia, hyponatremia, hypovolemia, viral infection, weight gain or loss

Nursing Considerations

- Use carvedilol cautiously in patients with peripheral vascular disease because it may aggravate symptoms of arterial insufficiency. In patients with diabetes mellitus it may mask signs of hypoglycemia, such as tachycardia, and may delay recovery.
- Monitor patient's blood glucose level, as ordered, during carvedilol therapy because drug may alter blood glucose level.

WARNING Avoid stopping drug abruptly in patients with hyperthyroidism because thyroid storm may occur and in patients with angina because it may worsen or MI may occur.

- If patient has heart failure, expect to also give digoxin, a diuretic, and an ACE inhibitor.

PATIENT TACHING

- Instruct patient prescribed extended-release capsules to swallow them whole. If swallowing capsules is difficult, tell patient he may open capsule and sprinkle beads on a spoonful of cold applesauce and then eat the applesauce immediately without chewing.
- Warn patient that drug may cause orthostatic hypotension, light-headedness, and dizziness; advise him to take precautions.
- Tell patient with heart failure to notify prescriber if he gains 5 lb or more in 2 days or if shortness of breath increases, which may signal worsening heart failure.
- Alert patient with diabetes to monitor his glycemic control closely because drug may increase blood glucose level or mask symptoms of hypoglycemia.
- Stress the need to seek emergency care if patient develops hives or swelling of the face, lips, tongue, or throat that causes trouble swallowing or breathing.

caspofungin acetate

Candidas

Class and Category

Chemical class: Echinocandins

Therapeutic class: Antifungal

Pregnancy category: C

Indications and Dosages

➤ *To treat invasive aspergillosis in patients refractory to or intolerant of other therapies; to treat candidemia and candidal infections in intra-abdominal abscesses, peritonitis, and pleural space infections*

I.V. INFUSION

Adults. *Initial:* 70 mg on day 1, followed by 50 mg daily. *Maximum:* 70 mg daily.

Children ages 3 months to 17 years. *Initial:* 70 mg/m² on day 1, followed by 50 mg/m² daily. *Maximum:* 70 mg daily regardless of

Mechanism of Action

Casposfungin acetate interferes with fungal cell membrane synthesis by inhibiting the synthesis of β (1,3)-D-glucan. A polypeptide, β (1,3)-D-glucan is the essential component of the fungal cell membrane that makes it rigid and protective. Without it, fungal cells rupture and die. This mechanism of action is most effective against susceptible filamentous fungi, such as *Aspergillus*.

dose calculated based on patient’s body surface area.

➤ *To treat presumed fungal infections in febrile, neutropenic patients*

I.V. INFUSION

Adults. *Initial:* 70 mg on day 1, followed by 50 mg daily for at least 14 days, including at least 7 days after neutropenia and symptoms have resolved. Increased to 70 mg daily as needed. *Maximum:* 70 mg daily.

Children ages 3 months to 17 years. *Initial:* 70 mg/m² on day 1, followed by 50 mg/m² daily for at least 14 days, including at least 7 days after neutropenia and symptoms have resolved. *Maximum:* 70 mg daily regardless of dose calculated based on patient’s body surface area.

DOSAGE ADJUSTMENT Dosage reduced to 35 mg daily after initial 70-mg loading dose in moderate hepatic insufficiency.

➤ *To treat esophageal candidiasis*

I.V. INFUSION

Adults. 50 mg daily.

Children ages 3 months to 17 years. *Initial:* 70 mg/m² on day 1, followed by 50 mg/m² daily. *Maximum:* 70 mg daily regardless of dose calculated based on patient’s body surface area.

DOSAGE ADJUSTMENT Dosage reduced to 35 mg daily in moderate hepatic insufficiency.

Incompatibilities

Don’t mix or infuse with other drugs. Don’t admix with diluents that contain dextrose.

Contraindications

Hypersensitivity to casposfungin acetate or

its components

Interactions

DRUGS

carbamazepine, dexamethasone, efavirenz, nelfinavir, nevirapine, phenytoin, rifampin: Possibly decreased blood casposfungin level
cyclosporine: Transient increases in ALT and AST levels
tacrolimus: Possibly decreased blood tacrolimus level

Adverse Reactions

CNS: Chills, dizziness, fever, headache, insomnia, paresthesia, tremor
CV: Edema, hypertension, hypotension, phlebitis, tachycardia, thrombophlebitis
EENT: Mucosal inflammation
GI: Abdominal pain, diarrhea, elevated liver function test results, hepatic dysfunction, jaundice, nausea, vomiting
GU: Elevated BUN or serum creatinine level, proteinuria, renal insufficiency
HEME: Decreased hemoglobin and hematocrit
MS: Back pain, myalgia
RESP: Bronchospasm, cough, crackles, dyspnea, pleural effusion, pneumonia, respiratory failure, stridor, tachypnea
SKIN: Diaphoresis, erythema, flushing, pruritus, rash, sensation of warmth
Other: Anaphylaxis, decreased serum bicarbonate level, facial edema, hypercalcemia, hyperkalemia, hyperphosphatemia, hypokalemia, hypomagnesemia, infusion site reaction, sepsis, septic shock

Nursing Considerations

• To prepare 70-mg loading dose, let vial

reach room temperature. Reconstitute by adding 10.5 ml normal saline solution to vial. Dilute for administration by transferring 10 ml of reconstituted drug to 250 ml normal saline solution.

- To prepare 70-mg loading dose from two 50-mg vials, add 10.5 ml normal saline solution to each vial; then transfer 14 ml of prepared solution to 250 ml normal saline solution.
- To prepare daily 50-mg infusion, let vial reach room temperature. Reconstitute by adding 10.5 ml normal saline solution to vial. Dilute for administration by transferring only 10 ml of reconstituted drug to 250 ml normal saline solution.
- To prepare daily 50-mg infusion at reduced volume, add 10 ml of reconstituted drug to 100 ml normal saline solution.
- To prepare 35-mg daily dose for patient with moderate hepatic insufficiency, reconstitute 50-mg vial with 10.5 ml normal saline solution. To dilute, transfer only 7 ml of reconstituted drug to 250 ml normal saline solution or, if needed, to 100 ml normal saline solution.
- When preparing powder for reconstitution, mix gently to obtain clear solution. Don't use if solution is cloudy or contains precipitate. Discard unused solution after 24 hours.
- Infuse drug slowly over about 1 hour.
- Expect to increase daily dose to 70 mg for adults and 70 mg/m² for children (not to exceed the adult dose of 70 mg regardless of calculated dose), as prescribed, for patients also receiving carbamazepine, dexamethasone, efavirenz, nelfinavir, nevirapine, phenytoin, or rifampin.
- Watch for flushed skin, and assess patient often for unexplained temperature elevation.
- Assess for airway patency if patient develops excessive facial edema or respiratory stridor. Provide emergency airway management if complete obstruction occurs.
- Monitor patient's liver function test results, as ordered, and report abnormalities.

PATIENT TEACHING

- Urge patient to notify prescriber immediately if he has difficulty talking, swallowing, or breathing during drug administration.

cefaclor

Apo-Cefaclor (CAN), Ceclor, Ceclor CD, Raniclor

Class and Category

Chemical class: Second-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ *To treat otitis media caused by Haemophilus influenzae, staphylococci, Streptococcus pneumoniae, and Streptococcus pyogenes; lower respiratory tract infections, including pneumonia caused by H. influenzae, S. pneumoniae, and S. pyogenes; pharyngitis and tonsillitis caused by S. pyogenes; UTI, including cystitis and pyelonephritis, caused by Escherichia coli, Klebsiella species, Proteus mirabilis, and coagulase-negative staphylococci; and skin and soft-tissue infections caused by S. pyogenes and Staphylococcus aureus*

CAPSULES

Adults and adolescents. 250 mg every 8 hr. For severe infections, such as pneumonia, or those caused by less susceptible organisms, 500 mg every 8 hr. *Maximum:* 4 g daily.

CHEWABLE TABLETS, ORAL SUSPENSION

Adults and adolescents. 250 mg every 8 hr. For severe infections, such as pneumonia, or those caused by less susceptible organisms, 500 mg every 8 hr. *Maximum:* 4 g daily.

Children. 20 mg/kg daily in divided doses every 8 hr. For serious infections, such as otitis media, and infections caused by less susceptible organisms, 40 mg/kg daily in divided doses every 8 hr. For otitis media and pharyngitis, total daily dosage divided and given every 12 hr, if needed. *Maximum:* 1 g daily.

↗ *To treat acute bacterial infection in chronic bronchitis or secondary bacterial infection in acute bronchitis (not caused by H. influenzae)*

E.R. TABLETS

Adults and adolescents age 16 and over.

500 mg every 12 hr for 7 days.

➤ *To treat pharyngitis and tonsillitis (not caused by H. influenzae)*

E.R. TABLETS

Adults and adolescents age 16 and over.

375 mg every 12 hr for 10 days.

➤ *To treat uncomplicated skin and soft-tissue infections caused by S. aureus*

E.R. TABLETS

Adults and adolescents age 16 and over.

375 mg every 12 hr for 7 to 10 days.

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting cross-linking of peptidoglycan strands, which stiffen cell membranes. As a result, bacterial cells rupture.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity

antacids: Decreased blood cefaclor level (E.R. tablets)

oral anticoagulants: Increased anticoagulation

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Eczymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis, superinfection

Nursing Considerations

- Use cefaclor cautiously in patients with impaired renal function or a history of GI disease, particularly colitis, and in patients who are hypersensitive to penicillin; about

10% of them have cross-sensitivity.

- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
- Monitor BUN and serum creatinine levels for early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Be aware that an allergic reaction may occur a few days after therapy starts.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Assess patient for superinfection: perineal itching, fever, malaise, redness, pain, swelling, rash, drainage, diarrhea, cough, sputum changes.

PATIENT TEACHING

- Instruct patient to complete the prescribed course of therapy, even if he feels better.
- Tell patient to swallow E.R. tablets whole and not to crush, break, or chew them.
- Advise patient to take E.R. tablets with food to enhance absorption.
- Instruct patient to take capsules or E.R. tablets with a full glass of water.
- Tell patient to shake oral suspension well before measuring and to use a calibrated measuring device to ensure accurate dose.
- Tell patient to refrigerate oral suspension and to discard unused portion after 14 days.
- Instruct patient to immediately report severe diarrhea to prescriber.
- Explain that yogurt and buttermilk protect intestinal flora and decrease diarrhea.
- Urge patient to report evidence of superinfection.

cefadroxil

Duricef

Class and Category

Chemical class: First-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat UTI caused by Escherichia coli, Klebsiella species, or Proteus mirabilis*

CAPSULES, TABLETS

Adults. For uncomplicated lower UTI, 1 to

2 g daily or in divided doses every 12 hr.
For all other UTIs, 2 g every 12 hr.

ORAL SUSPENSION

Adults. For uncomplicated lower UTI, 1 to 2 g daily or in divided doses every 12 hr.
For all other UTIs, 2 g every 12 hr.

Children. 30 mg/kg daily in divided doses every 12 hr. *Maximum:* Adult dosage.

➤ *To treat skin and soft-tissue infections caused by staphylococci or streptococci*

CAPSULES, TABLETS

Adults. 1 g daily or 500 mg every 12 hr.

ORAL SUSPENSION

Adults. 1 g daily or 500 mg every 12 hr.

Children. 30 mg/kg daily in divided doses every 12 hr. *Maximum:* Adult dosage.

➤ *To treat pharyngitis and tonsillitis caused by group A beta-hemolytic streptococci*

CAPSULES, TABLETS

Adults. 1 g daily or 500 mg b.i.d for 10 days.

ORAL SUSPENSION

Adults. 1 g daily or 500 mg b.i.d. for 10 days.

Children. 30 mg/kg daily in divided doses every 12 hr for 10 days. *Maximum:* 1 g daily or 500 mg b.i.d. for 10 days.

DOSAGE ADJUSTMENT Initial dose of 1 g; then maintenance of 0.5 g every 12 hr if creatinine clearance is 25 to 50 ml/min/1.73 m²; 0.5 g every 24 hr if creatinine clearance is 10 to 25 ml/min/1.73 m²; and 0.5 g every 36 hr if creatinine clearance is 0 to 10 ml/min/1.73 m².

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased toxicity of these drugs

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated

liver function test results, hepatic failure, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprotrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis, superinfection

Nursing Considerations

- Use cefadroxil cautiously in patients with impaired renal function or a history of GI disease, particularly colitis. Also use drug cautiously in patients who are hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
 - If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
 - Be aware that an allergic reaction may occur a few days after therapy starts.
 - Monitor BUN and serum creatinine levels for early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
 - Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
 - Assess for signs of superinfection, such as perineal itching, fever, malaise, redness, pain, swelling, drainage, rash, diarrhea, and cough or sputum changes.
- #### PATIENT TEACHING
- Instruct patient to complete the prescribed course of therapy.
 - Tell patient to shake oral suspension before measuring and to use a liquid-measuring device to ensure accurate doses.
 - Tell patient to refrigerate oral suspension and to discard the unused portion after 14 days.
 - Urge patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.
 - Inform patient that yogurt and buttermilk can help maintain intestinal flora and decrease diarrhea.
 - Teach patient to recognize and report evidence of superinfection, such as furry

tongue, perineal itching, and loose, foul-smelling stools.

cefazolin sodium

Ancef

Class and Category

Chemical class: First-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat respiratory tract infections caused by group A beta-hemolytic streptococci, Haemophilus influenzae, Klebsiella species, Staphylococcus aureus, and Streptococcus pneumoniae; skin and soft-tissue infections caused by S. aureus, group A beta-hemolytic and other strains of streptococci; biliary tract infections caused by Escherichia coli, Klebsiella species, Proteus mirabilis, S. aureus, and various strains of streptococci; bone and joint infections caused by S. aureus; genital infections, such as epididymitis and prostatitis, caused by E. coli, Klebsiella species, P. mirabilis, and some strains of enterococci; septicemia caused by E. coli, Klebsiella species, P. mirabilis, S. aureus, and S. pneumoniae; and endocarditis caused by group A beta-hemolytic streptococci and S. aureus*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. For mild infections, 250 to 500 mg every 8 hr; for moderate to severe infections, 500 to 1,000 mg every 6 to 8 hr; and for severe life-threatening infections, 1,000 to 1,500 mg every 6 hr. *Maximum:* 6 g daily.

Children: For mild to moderate infections, 25 to 50 mg/kg daily divided equally and given t.i.d. or q.i.d.; for severe infections, 100 mg/kg daily divided equally and given t.i.d. or q.i.d.

➤ *To treat pneumococcal pneumonia*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 500 mg every 12 hr.

➤ *To treat acute uncomplicated UTI caused by E. coli, Klebsiella species, P. mirabilis, and some strains of Enterobacter and Enterococcus*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 1 g every 12 hr.

➤ *To provide surgical prophylaxis*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 1 g 30 to 60 min before surgery; 0.5 to 1 g during surgery if it lasts 2 hr or longer; 0.5 to 1 g every 6 to 8 hr for 24 hr after surgery.

DOSAGE ADJUSTMENT After initial loading dose appropriate to infection's severity, dosage interval restricted to at least 8 hr for adults with creatinine clearance of 35 to 54 ml/min/1.73 m²; dosage reduced by 50% and given every 12 hr for adults with creatinine clearance of 11 to 34 ml/min/1.73 m²; and dosage reduced by 50% and given every 18 to 24 hr for adults with creatinine clearance of 10 ml/min/1.73 m² or less. Dosage reduced to 60% and given every 12 hr for children with creatinine clearance of 40 to 70 ml/min/1.73 m²; dosage reduced to 25% and given every 12 hr for children with creatinine clearance of 20 to 40 ml/min/1.73 m²; and dosage reduced to 10% and given every 24 hr for children with creatinine clearance of 5 to 20 ml/min/1.73 m².

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

Incompatibilities

To prevent mutual inactivation, don't mix cefazolin with aminoglycosides. Also avoid mixing cefazolin with other drugs, including pentamidine isethionate.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Additive nephrotoxicity

probenecid: Increased and prolonged blood cefazolin level

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure,

hepatitis, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN and serum creatinine levels, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis; injection site pain, redness, and swelling; superinfection

Nursing Considerations

- Use cefazolin cautiously in patients with impaired renal function or a history of GI disease, particularly colitis. Also use cautiously in patients hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.

WARNING To prevent unintentional overdose, cefazolin for injection USP and dextrose injection USP shouldn't be used in children who require less than the full adult dose.

- Reconstitute 500-mg drug vial with 2 ml of sterile water for injection (or 1-g vial with 2.5 ml). Shake well until dissolved.
- For direct I.V. injection, further dilute reconstituted solution with at least 5 ml sterile water for injection. Inject slowly over 3 to 5 minutes through tubing of a flowing compatible I.V. solution.
- For intermittent I.V. infusion, reconstitute 500 to 1,000 mg in 50 to 100 ml normal saline solution, D₅W, D₁₀W, dextrose 5% in lactated Ringer's solution, dextrose 5% in quarter-normal (0.2) saline solution, dextrose 5% in half-normal (0.45) saline solution, dextrose 5% in normal saline solution, lactated Ringer's injection, 5% or 10% invert sugar in sterile water for injection, 5% sodium bicarbonate (Ancef), or Ringer's injection.
- Administer I.M. injection deep into large muscle mass, such as the gluteus maximus.
- Store reconstituted drug up to 24 hours at room temperature or 10 days refrigerated.
- Monitor I.V. site for irritation, phlebitis,

and extravasation.

- Monitor BUN and serum creatinine for early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Be aware that an allergic reaction may occur a few days after therapy starts.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Watch for evidence of superinfection: cough, diarrhea, drainage, fever, malaise, pain, perineal itching, rash, redness, swelling.
- Assess for pharyngitis, ecchymosis, bleeding, and arthralgia; they may indicate a blood dyscrasia.

PATIENT TEACHING

- Instruct patient to complete the prescribed course of therapy.
- Reassure patient that I.M. injection doesn't typically cause pain.
- Tell patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

cefdinir

Omnicef

Class and Category

Chemical class: Cephalosporin

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ To treat community-acquired pneumonia caused by *Haemophilus influenzae* (including beta-lactamase-producing strains), *Haemophilus parainfluenzae* (including beta-lactamase-producing strains), *Streptococcus pneumoniae* (penicillin-susceptible strains only), and *Moraxella catarrhalis* (including beta-lactamase-producing strains)

CAPSULES

Adults and adolescents. 300 mg every 12 hr for 10 days. *Maximum:* 600 mg daily.

↗ To treat pharyngitis or tonsillitis caused by *Streptococcus pyogenes* and acute exacerbations of chronic bronchitis caused by *H. influenzae* (including beta-lactamase-producing strains), *H. parainfluenzae* (including beta-lactamase-producing strains), *S. pneu-*

moniae (penicillin-susceptible strains only), and *M. catarrhalis* (including beta-lactamase-producing strains)

CAPSULES

Adults and adolescents. 300 mg every 12 hr for 5 to 10 days or 600 mg every 24 hr for 10 days. *Maximum:* 600 mg daily.

ORAL SUSPENSION

Children ages 6 months to 12 years. 7 mg/kg every 12 hr for 5 to 10 days or 14 mg/kg every 24 hr for 10 days (for pharyngitis or tonsillitis).

➤ *To treat acute maxillary sinusitis caused by H. influenzae (including beta-lactamase-producing strains), S. pneumoniae (penicillin-susceptible strains only), and M. catarrhalis (including beta-lactamase-producing strains)*

CAPSULES

Adults and adolescents. 300 mg every 12 hr or 600 mg every 24 hr for 10 days. *Maximum:* 600 mg daily.

ORAL SUSPENSION

Children ages 6 months to 12 years. 7 mg/kg every 12 hr or 14 mg/kg every 24 hr for 10 days.

➤ *To treat uncomplicated skin and soft-tissue infections caused by Staphylococcus aureus (including beta-lactamase-producing strains) and Streptococcus pyogenes*

CAPSULES

Adults and adolescents. 300 mg every 12 hr for 10 days. *Maximum:* 600 mg daily.

ORAL SUSPENSION

Children ages 6 months to 12 years. 7 mg/kg every 12 hr for 10 days.

➤ *To treat acute bacterial otitis media caused by H. influenzae (including beta-lactamase-producing strains), S. pneumoniae (penicillin-susceptible strains only), and M. catarrhalis (including beta-lactamase-producing strains)*

ORAL SUSPENSION

Children ages 6 months to 12 years. 7 mg/kg every 12 hr for 5 to 10 days or 14 mg/kg every 24 hr for 10 days.

DOSAGE ADJUSTMENT For adults with creatinine clearance less than 30 ml/min/1.73 m², expect to reduce cefdinir dosage to 300 mg daily; for children with creatinine clearance less than 30 ml/min/1.73 m², dosage is 7 mg/kg (up to 300 mg) daily. For patients

undergoing intermittent hemodialysis, dosage is 300 mg or 7 mg/kg every other day, beginning at the end of each hemodialysis session, as prescribed.

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die. Because cefdinir is not degraded by some bacterial beta-lactamase enzymes, it's effective against many organisms that are resistant to both penicillins and some cephalosporins.

Contraindications

Hypersensitivity to cefdinir, other cephalosporins, or their components

Interactions

DRUGS

antacids that contain aluminum or magnesium: Decreased cefdinir absorption if given within 2 hours of antacid
iron salts: Reduced cefdinir absorption if given within 2 hours of iron
probenecid: Increased blood level and prolonged half-life of cefdinir

Adverse Reactions

CNS: Asthenia, dizziness, drowsiness, headache, insomnia, somnolence
EENT: Dry mouth, pharyngitis, rhinitis
GI: Abdominal pain, anorexia, constipation, diarrhea, flatulence, indigestion, nausea, pseudomembranous colitis, stool discoloration, vomiting
GU: Leukorrhea, vaginal candidiasis, vaginitis
HEME: Leukopenia
SKIN: Pruritus, rash
Other: Anaphylaxis, serum sicknesslike reaction

Nursing Considerations

- To constitute cefdinir powder for oral suspension, tap bottle to loosen powder, and then dilute with water to 125 mg/5 ml. Shake well before each use. Discard any unused portion after 10 days. Keep suspension bottle tightly closed, and store it at room temperature.
- Give antacids that contain aluminum or magnesium and iron salts at least 2 hours before or after cefdinir because they may

interfere with cefdinir absorption.

- Monitor patient allergic to penicillin for evidence of hypersensitivity reaction, from a mild rash to fatal anaphylaxis, because cross-sensitivity can occur.
- Monitor patient with a chronic GI condition, such as colitis, for signs and symptoms of a drug-related exacerbation.
- Because all cephalosporins have the potential to cause bleeding, monitor elderly patients and patients with a preexisting coagulopathy, including vitamin K deficiency, for elevated PT or APTT.
- Monitor patient closely for diarrhea, which may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold cefdinir and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- Assess for other evidence of superinfection, including perineal itching; loose, foul-smelling stools; and vaginal drainage.

PATIENT TEACHING

- Advise patient taking cefdinir oral suspension to shake bottle well before use and to use a liquid-measuring device to ensure accurate dose.
- Inform patient that tablet coating may cause stools to become a reddish color.
- Instruct patient to complete entire course of therapy, even if he feels better.
- Advise patient to take iron salts and aluminum- or magnesium-containing antacids at least 2 hours before or after taking cefdinir.
- Inform patient with history of colitis that cefdinir may worsen it; urge him to notify prescriber promptly if symptoms develop.
- Inform patient with diabetes mellitus that oral suspension contains 2.86 g of sucrose per teaspoon; advise him to monitor his blood glucose levels as appropriate.
- Teach patient to recognize and report evidence of superinfection, such as perineal itching; loose, foul-smelling stools; and vaginal drainage.
- Inform patient that yogurt and buttermilk can help prevent superinfection and may decrease diarrhea.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months

after antibiotic therapy and can be serious, requiring prompt treatment.

cefditoren pivoxil

Spectracef

Class and Category

Chemical class: Cephalosporin

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat mild to moderate acute bacterial exacerbation of chronic bronchitis or community-acquired pneumonia caused by Haemophilus influenzae (including beta-lactamase-producing strains), Haemophilus parainfluenzae (including beta-lactamase-producing strains), Streptococcus pneumoniae (penicillin-susceptible strains), or Moraxella catarrhalis (including beta-lactamase-producing strains)*

TABLETS

Adults and children age 12 and over.

400 mg b.i.d. for 10 days or for 14 days for community-acquired pneumonia.

➤ *To treat mild to moderate pharyngitis and tonsillitis caused by Streptococcus pyogenes*

TABLETS

Adults and children age 12 and over.

200 mg b.i.d. for 10 days.

➤ *To treat mild to moderate uncomplicated skin and soft-tissue infections caused by Staphylococcus aureus (including beta-lactamase-producing strains) or S. pyogenes*

TABLETS

Adults and children age 12 and over.

200 mg b.i.d. for 10 days.

DOSAGE ADJUSTMENT In moderate renal impairment (creatinine clearance 30 to 49 ml/min/1.73 m²), maximum dosage reduced to 200 mg b.i.d. In severe renal impairment (creatinine clearance less than 30 ml/min/1.73 m²), maximum dosage reduced to 200 mg daily.

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptido-

glycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die. This mechanism of action is most effective against bacteria that divide rapidly, including many gram-positive and gram-negative bacteria. Cefditoren isn't inactivated by beta lactamase produced by some bacteria.

Contraindications

Carnitine deficiency or inborn metabolic disorder that causes it; hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aluminum- and magnesium-containing antacids, H₂-receptor antagonists: Reduced cefditoren absorption

probenecid: Increased and prolonged blood cefditoren level

FOODS

food: Increased cefditoren absorption

Adverse Reactions

CNS: Headache, hyperactivity, hypertonia, seizures

GI: Abdominal pain, diarrhea, dyspepsia, hepatic dysfunction, nausea, pseudomembranous colitis, vomiting

GU: Acute renal failure, renal dysfunction, toxic nephropathy

HEME: Aplastic anemia, hemolytic anemia, hemorrhage, thrombocytopenia

MS: Arthralgia

RESP: Pneumonia

SKIN: Erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Allergic reaction, anaphylaxis, carnitine deficiency, drug fever, serum sicknesslike reaction, superinfection

Nursing Considerations

WARNING Before starting cefditoren therapy, determine if patient is hypersensitive to milk protein because cefditoren contains sodium caseinate, a milk protein. Drug should not be given to patient with this hypersensitivity. Also determine if patient has had a hypersensitivity reaction to cefditoren or other cephalosporins (because drug is contraindicated in these patients) or to penicillin (because cross-sensitivity has occurred in about 10% of such patients).

- Cefditoren shouldn't be used for prolonged treatment because of the risk of carnitine deficiency.
- If possible, obtain culture and sensitivity test results before giving cefditoren.
- Assess patient for evidence of *Clostridium difficile* infection and pseudomembranous colitis, such as profuse, watery diarrhea. For mild cases, expect to discontinue cefditoren. For moderate to severe cases, expect to also give fluids and electrolytes, protein supplementation, and an antibacterial drug effective against *C. difficile*.
- If an allergic reaction occurs, expect to discontinue drug, as prescribed. For serious acute hypersensitivity reactions, expect to also give epinephrine, oxygen, and I.V. fluids, antihistamines, corticosteroids, and vasopressors, as prescribed.
- Monitor BUN and serum creatinine levels to detect early signs of renal dysfunction. Also monitor fluid intake and output.
- Watch for a decreased PT, as ordered, in at-risk patients, such as those with renal or hepatic impairment, those with a poor nutritional state, and those receiving anticoagulant or prolonged antibiotic therapy. Notify prescriber if a decrease occurs, and give vitamin K as ordered.

PATIENT TEACHING

- Urge patient to complete prescribed course of therapy.
- Instruct patient to take cefditoren with meals to enhance drug absorption.
- Advise patient not to take cefditoren with aluminum- or magnesium-containing antacids or other drugs used to reduce stomach acids because these drugs may interfere with cefditoren absorption.
- Explain that yogurt and buttermilk help maintain normal intestinal flora and can decrease diarrhea during therapy.
- Instruct patient to immediately report severe diarrhea to prescriber.

cefepime hydrochloride

Maxipime

Class and Category

Chemical class: Fourth-generation cephalo-

sporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ *To treat mild to moderate UTI caused by Escherichia coli, Klebsiella pneumoniae, or Proteus mirabilis*

I.V. INFUSION, I.M. INJECTION (ONLY FOR UTI CAUSED BY E. COLI)

Adults and children age 12 and over. 500 to 1,000 mg every 12 hr for 7 to 10 days.

↗ *To treat severe UTI caused by E. coli or K. pneumoniae, moderate to severe skin and soft-tissue infections caused by Staphylococcus aureus or Streptococcus pyogenes*

I.V. INFUSION

Adults and children age 12 and over. 2 g every 12 hr for 10 days.

↗ *To treat moderate to severe pneumonia caused by Enterobacter species, K. pneumoniae, Pseudomonas aeruginosa, or Streptococcus pneumoniae*

I.V. INFUSION

Adults and children age 12 and over. 1 to 2 g every 12 hr for 10 days.

↗ *To treat febrile neutropenia*

I.V. INFUSION

Adults and children age 12 and over. 2 g every 8 hr for 7 days or until neutropenia resolves.

↗ *To treat complicated intra-abdominal infections (together with metronidazole) caused by alpha-hemolytic streptococci, Bacteroides fragilis, E. coli, Enterobacter species, K. pneumoniae, or P. aeruginosa*

I.V. INFUSION

Adults and children age 12 and over. 2 g every 12 hr for 7 to 10 days.

DOSE ADJUSTMENT Dosing interval increased from 12 to 24 hr and from 8 to 12 hr if creatinine clearance is 30 to 60 ml/min/1.73 m². Interval increased from 8 or 12 hr to 24 hr and dose decreased from 2 g every 12 hr to 1 g every 24 hr (all other doses unchanged) if creatinine clearance is 11 to 29 ml/min/1.73 m². Dosage decreased from 500 mg every 12 hr to 250 mg every 24 hr, from 1,000 mg every 12 hr to 250 mg every 24 hr, from 2,000 mg every 12 hr to 500 mg every 24 hr, and from 2 g every 8 hr to 1 g every 24 hr if creatinine clearance is less than 11 ml/min/1.73 m².

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

Incompatibilities

Don't add cefepime to solutions that contain ampicillin in a concentration of more than 40 mg/ml. Don't add drug to solutions that contain aminophylline, gentamycin, metronidazole, netilmicin sulfate, tobramycin, or vancomycin.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of renal failure in renal disease

Adverse Reactions

CNS: Chills, coma, confusion, fever, hallucinations, headache, myoclonus, seizures, stupor

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis; injection site pain, redness, and swelling; superinfection

Nursing Considerations

- Use cefepime cautiously in patients with impaired renal function or a history of GI disease, particularly colitis. Also use cautiously in patients hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.

- For I.V. infusion, reconstitute using manufacturer's guidelines. Give over 30 minutes.
- For I.M. injection, reconstitute 500-mg vial of drug with 1.3 ml of diluent, such as sterile water for injection (or 1-g vial with 2.4 ml of diluent). See drug guidelines for complete list of appropriate diluents.
- Be aware that an allergic reaction may occur a few days after therapy starts.
- Monitor BUN and serum creatinine levels for early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity. Be aware that unadjusted dosages of cefixime in renally impaired patients may cause myoclonus and seizures.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Assess for signs of superinfection, such as perineal itching, fever, malaise, redness, pain, swelling, drainage, rash, diarrhea, and cough or sputum changes.
- Assess for pharyngitis, ecchymosis, bleeding, and arthralgia; they may indicate a blood dyscrasia.
- Monitor patient for evidence of encephalopathy, such as changes in level of consciousness, myoclonus, and seizures. Patient will need immediate treatment, and the cefixime dosage will need to be adjusted or the drug discontinued.

PATIENT TEACHING

- Tell patient to immediately report severe diarrhea to prescriber.
- Instruct patient and caregiver to immediately seek emergency care for any change in mental status, such as coma, hallucinations, decreased responsiveness, abnormal movements, or seizures. Cefixime should be stopped until patient is evaluated.

cefixime

Suprax

Class and Category

Chemical class: Third-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ *To treat uncomplicated UTI caused by Escherichia coli and Proteus mirabilis;*

otitis media caused by Haemophilus influenzae, Moraxella catarrhalis, or Streptococcus pyogenes; pharyngitis and tonsillitis caused by S. pyogenes; acute bronchitis and acute exacerbations of chronic bronchitis caused by H. influenzae and Streptococcus pneumoniae

ORAL SUSPENSION

Children. 8 mg/kg daily or 4 mg/kg every 12 hr.

TABLETS

Adults and children over 50 kg (110 lb) or age 12. 400 mg daily or 200 mg every 12 hr.

↗ *To treat uncomplicated gonorrhea caused by Neisseria gonorrhoeae*

TABLETS

Adults and children over 50 kg or age 12. 400 mg daily.

DOSAGE ADJUSTMENT Dosage reduced to 75% for patients who have creatinine clearance of 21 to 60 ml/min/1.73 m² or receive hemodialysis. Dosage reduced to 50% for patients who have creatinine clearance of 20 ml/min/1.73 m² or less.

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity

carbamazepine: Increased blood carbamazepine level

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatitis, hepatomegaly, jaundice, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, angioedema, facial edema, superinfection

Nursing Considerations

- Use cefixime cautiously in patients with impaired renal function or a history of GI disease, especially colitis. Also use cautiously in patients hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
- Tablets shouldn't be substituted for oral suspension to treat otitis media because cefixime suspension produces a higher peak blood level than do tablets when administered at the same dose.
- Monitor BUN and serum creatinine for early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Be aware that an allergic reaction may occur a few days after therapy starts.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Assess for signs of superinfection, such as perineal itching, fever, malaise, redness, pain, swelling, drainage, rash, diarrhea, and cough or sputum changes.
- Assess for pharyngitis, ecchymosis, bleeding, and arthralgia; they may indicate a blood dyscrasia.

PATIENT TEACHING

- Instruct patient to complete the prescribed course of therapy.
- Advise patient to shake oral suspension well before pouring dose and to use a calibrated device to obtain an accurate dose.
- Instruct patient to store oral suspension at room temperature and to discard unused portion after 14 days.
- Tell patient to immediately report severe diarrhea to prescriber.
- Inform patient that yogurt and buttermilk can help maintain intestinal flora and decrease diarrhea.

- Teach patient to recognize and report signs of superinfection, such as furry tongue, perineal itching, and loose, foul-smelling stools.

cefmetazole sodium

Zefazone

Class and Category

Chemical class: Second-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ *To treat UTI caused by Escherichia coli; lower respiratory tract infections, such as bronchitis and pneumonia, caused by E. coli, Haemophilus influenzae, Staphylococcus aureus, and Streptococcus pneumoniae; skin and soft-tissue infections caused by Bacteroides fragilis, Bacteroides melaninogenicus, E. coli, Klebsiella oxytoca, Klebsiella pneumoniae, Morganella morganii, Proteus mirabilis, Proteus vulgaris, S. aureus, Staphylococcus epidermidis, Streptococcus agalactiae, and Streptococcus pyogenes; intra-abdominal infections caused by B. fragilis, Clostridium perfringens, E. coli, K. oxytoca, and K. pneumoniae*

I.V. INFUSION

Adults. 2 g every 6 to 12 hr for 5 to 14 days.

DOSAGE ADJUSTMENT Dosage reduced to 1 to 2 g every 12 hr if creatinine clearance is 50 to 90 ml/min/1.73 m²; 1 to 2 g every 16 hr if creatinine clearance is 30 to 49 ml/min/1.73 m²; 1 to 2 g every 24 hr if creatinine clearance is 10 to 29 ml/min/1.73 m²; and 1 to 2 g every 48 hr if creatinine clearance is less than 10 ml/min/1.73 m².

↗ *To provide surgical prophylaxis for vaginal hysterectomy*

I.V. INFUSION

Adults. 2 g as a single dose 30 to 90 min before surgery or 1 g 30 to 90 min before surgery and repeated 8 and 16 hr later.

↗ *To provide surgical prophylaxis for abdominal hysterectomy and for high-risk cholecystectomy*

I.V. INFUSION

Adults. 1 g 30 to 90 min before surgery and repeated 8 and 16 hr later.

↗ *To provide surgical prophylaxis for cesarean section*

I.V. INFUSION

Adults. 2 g as a single dose after cord is clamped or 1 g after cord is clamped and then repeated 8 and 16 hr later.

↗ *To provide surgical prophylaxis for colorectal surgery*

I.V. INFUSION

Adults. 2 g as a single dose 30 to 90 min before surgery or 2 g 30 to 90 min before surgery and repeated 8 and 16 hr later.

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity

anticoagulants: Possibly increased anticoagulant effect

probenecid: Increased and prolonged blood cefmetazole level

ACTIVITIES

alcohol use: Possibly disulfiram-like reaction

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis; injection site pain, redness, and swelling; superinfection

Nursing Considerations

- Use cefmetazole cautiously in patients hypersensitive to penicillin; cross-sensitivity has occurred in about 10% of such patients.
- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
- Reconstitute drug with sterile or bacteriostatic water for injection or sodium chloride for injection.
- Dilute primary solution as needed to 1 to 20 mg/ml in D₅W, normal saline solution, lactated Ringer's solution, or 1% lidocaine solution without epinephrine.
- Store reconstituted solution for up to 24 hours at room temperature or 7 days refrigerated.
- Monitor BUN and serum creatinine levels and fluid intake and output to detect early signs of nephrotoxicity.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Assess for signs of superinfection, such as perineal itching, fever, malaise, redness, rash, diarrhea, and cough or sputum changes.
- Assess for pharyngitis, bleeding, and arthralgia, which may indicate blood dyscrasia. Monitor PT and bleeding time, as ordered.

PATIENT TEACHING

- Advise patient to immediately report severe diarrhea to prescriber.
- Instruct patient to avoid alcohol during therapy and for at least 3 days after last dose.

cefonicid sodium

Monocid

Class and Category

Chemical class: Second-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

- ↗ *To treat lower respiratory tract infections caused by Escherichia coli, Haemophilus influenzae, Klebsiella*

pneumoniae, and *Streptococcus pneumoniae*; *UTI caused by E. coli*, *K. pneumoniae*, *Morganella morganii*, *Proteus mirabilis*, *Proteus vulgaris*, and *Providencia rettgeri*; *skin and soft-tissue infections caused by Staphylococcus aureus*, *Staphylococcus epidermidis*, *Streptococcus agalactiae*, and *Streptococcus pyogenes*; *septicemia caused by E. coli and S. pneumoniae*; and *bone and joint infections caused by S. aureus*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. For mild to moderate infections, 1 g every 24 hr. For severe or life-threatening infections, 2 g every 24 hr.

↗ *To treat uncomplicated UTI*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 500 mg every 24 hr.

DOSE ADJUSTMENT Initial dose reduced to 75 mg/kg I.V. or I.M. in patients with impaired renal function. Then reduced to 10 to 25 mg/kg every 24 hr if creatinine clearance is 60 to 79 ml/min/1.73 m²; 8 to 20 mg/kg every 24 hr if creatinine clearance is 40 to 59 ml/min/1.73 m²; 4 to 15 mg/kg every 24 hr if creatinine clearance is 20 to 39 ml/min/1.73 m²; 4 to 15 mg/kg every 48 hr if creatinine clearance is 10 to 19 ml/min/1.73 m²; 4 to 15 mg/kg every 3 to 5 days if creatinine clearance is 5 to 9 ml/min/1.73 m²; and 3 to 4 mg/kg every 3 to 5 days if creatinine clearance is less than 5 ml/min/1.73 m².

↗ *To provide surgical prophylaxis*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 1 g 60 min before surgery. Dose repeated once daily, if needed, for 2 days after prosthetic arthroplasty or open-heart surgery.

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

Incompatibilities

To prevent mutual inactivation, don't mix cefonicid with aminoglycosides.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, *loop diuretics*: Increased risk of nephrotoxicity

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis; injection site pain, redness, and swelling; superinfection

Nursing Considerations

- Use cefonicid cautiously in patients with impaired renal function. Also use cautiously in patients hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
- Reconstitute each 500-mg vial of drug with 2 ml sterile water for injection (or each 1-g vial with 2.5 ml).
- For I.V. infusion, dilute further in 50 to 100 ml compatible solution, such as D₅W, D₁₀W, dextrose 5% in quarter-normal (0.2) saline solution, dextrose 5% in half-normal (0.45) saline solution, or dextrose 5% in normal saline solution.
- Give I.V. injection slowly over 3 to 5 minutes through tubing of a flowing compatible I.V. solution.
- For I.M. dose larger than 1 g, divide dose in half and give into large muscle mass, such as the gluteus maximus, at two different sites.
- Reconstituted solution may be stored 24 hours at room temperature, 72 hours refrigerated.
- Monitor patient's BUN and serum creatinine levels to detect early signs of nephro-

toxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.

- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Watch for evidence of superinfection, such as perineal itching, fever, malaise, redness, pain, swelling, drainage, rash, diarrhea, and cough or sputum changes.
- Assess patient for pharyngitis, ecchymosis, bleeding, and arthralgia; they may indicate a blood dyscrasia.

PATIENT TEACHING

- Warn patient that I.M. injection may be painful.
- Tell patient to immediately report severe diarrhea to prescriber.

cefoperazone sodium

Cefobid

Class and Category

Chemical class: Third-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat respiratory tract infections caused by Enterobacter species, Escherichia coli, Haemophilus influenzae, Klebsiella pneumoniae, Proteus mirabilis, Pseudomonas aeruginosa, Staphylococcus aureus, Streptococcus pneumoniae, Streptococcus pyogenes, and other streptococci (excluding enterococci); UTI caused by E. coli and P. aeruginosa; uncomplicated gonorrhea caused by Neisseria gonorrhoeae; gynecologic infections caused by anaerobic gram-positive cocci, Bacteroides species, Clostridium species, E. coli, Staphylococcus epidermidis, and Streptococcus agalactiae; bacterial septicemia caused by E. coli, Klebsiella species, S. aureus, Serratia marcescens, and streptococci; skin and soft-tissue infections caused by P. aeruginosa, S. aureus, and S. pyogenes; and intra-abdominal infections caused by anaero-*

bic gram-negative bacilli, E. coli, and P. aeruginosa

I.V. INFUSION, I.M. INJECTION

Adults. 1 to 2 g every 12 hr. For severe infections or those caused by less sensitive organisms, 6 to 12 g daily divided into equal doses and given b.i.d., t.i.d., or q.i.d. *Maximum:* 12 g daily.

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

Incompatibilities

To prevent mutual inactivation, don't mix cefoperazone with aminoglycosides. Also avoid mixing cefoperazone with other drugs, including pentamidine isethionate.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity
oral anticoagulants, other drugs that affect blood clotting: Increased anticoagulant effect

ACTIVITIES

alcohol use: Disulfiram-like reaction

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis; injection site pain, redness, and swelling; superinfection

Nursing Considerations

- Use cefoperazone cautiously in patients with a history of bleeding problems, GI disease (especially colitis), or severely impaired hepatic or renal function. Also use cautiously in patients hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
- For I.V. use, reconstitute with required amount of diluent. Then further dilute in compatible solution, such as D₅W, D₁₀W, dextrose 5% in lactated Ringer's solution, dextrose 5% in quarter-normal (0.2) saline solution, dextrose 5% in normal saline solution, lactated Ringer's injection, normal saline solution, Normosol M and D₅W, or Normosol R. (See manufacturer's guidelines for details.)
- Give I.V. drug as intermittent infusion over 15 to 30 minutes or as continuous infusion. Direct bolus injection isn't recommended.
- For I.M. injection, reconstitute drug with bacteriostatic water for injection (that contains benzyl alcohol or parabens) or sterile water for injection.
- After reconstitution, let foam dissipate, and inspect the solution to ensure complete dissolution.
- Store reconstituted solution at room temperature for 24 hours.
- Monitor BUN and serum creatinine levels to detect early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Assess for pharyngitis, ecchymosis, bleeding, and arthralgia; they may indicate a blood dyscrasia.
- Assess for evidence of superinfection, such as perineal itching, fever, malaise, redness, pain, swelling, drainage, rash, diarrhea, and cough or sputum changes.

PATIENT TEACHING

- Advise patient to avoid alcohol during therapy and for at least 3 days after last dose.
- Explain that I.M. injection may hurt.
- Tell patient to immediately report severe diarrhea to prescriber.

cefotaxime sodium

Claforan

Class and Category

Chemical class: Third-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ *To provide perioperative prophylaxis*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults and children weighing more than 50 kg (110 lb). 1 g 30 to 90 min before surgery.

↗ *To provide perioperative prophylaxis related to cesarean section*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 1 g as soon as cord is clamped, then 1 g every 6 hr for up to two doses.

↗ *To treat gonococcal urethritis and cervicitis in men and women*

I.M. INJECTION

Adults weighing more than 50 kg. 500 mg as a single dose.

↗ *To treat rectal gonorrhea in women*

I.M. INJECTION

Adults weighing more than 50 kg. 500 mg as a single dose.

↗ *To treat rectal gonorrhea in men*

I.M. INJECTION

Adults weighing more than 50 kg. 1 g as a single dose.

↗ *To treat disseminated gonorrhea*

I.V. INFUSION OR INJECTION

Adults and children weighing more than 50 kg. 1 g every 8 hr.

↗ *To treat uncomplicated infections caused by susceptible organisms*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults and children weighing more than 50 kg. 1 g every 12 hr.

Children ages 1 month to 12 years weighing less than 50 kg. 50 to 180 mg/kg daily in four to six divided doses.

Children ages 1 to 4 weeks. 50 mg/kg I.V. every 8 hr.

Children age 1 week and under. 50 mg/kg I.V. every 12 hr.

↗ *To treat moderate to severe infections caused by susceptible organisms*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults and children weighing more than

50 kg. 1 to 2 g every 8 hr.

Children ages 1 month to 12 years weighing less than 50 kg. 50 to 180 mg/kg daily in four to six divided doses. For more serious infections, including meningitis, higher dosages are used.

Children ages 1 to 4 weeks. 50 mg/kg I.V. every 8 hr.

Children age 1 week and younger. 50 mg/kg I.V. every 12 hr.

↗ *To treat septicemia and other infections that commonly require antibiotics in higher doses than those used to treat moderate to severe infections*

I.V. INFUSION OR INJECTION

Adults and children weighing more than 50 kg. 2 g every 6 to 8 hr.

↗ *To treat life-threatening infections caused by susceptible organisms*

I.V. INFUSION OR INJECTION

Adults and children weighing more than 50 kg. 2 g every 4 hr. *Maximum:* 12 g daily.

Children ages 1 month to 12 years weighing less than 50 kg. 50 to 180 mg/kg daily in four to six divided doses.

Children ages 1 to 4 weeks. 50 mg/kg every 8 hr.

Children age 1 week and younger. 50 mg/kg every 12 hr.

DOSE ADJUSTMENT Dosage reduced by 50% for patients with estimated creatinine clearance below 20 ml/min/1.73 m².

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

Incompatibilities

To prevent mutual inactivation, don't mix cefotaxime with aminoglycosides. Also avoid mixing cefotaxime with other drugs, including pentamidine isethionate.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity

probenecid: Increased and prolonged blood cefotaxime level

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, cholestasis, diarrhea, elevated liver function test results, hepatic failure, hepatitis, hepatomegaly, jaundice, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprotrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis; injection site pain, redness, and swelling; superinfection

Nursing Considerations

- Use cefotaxime cautiously in patients with impaired renal function, a history of GI disease (especially colitis), or hypersensitivity to penicillin because cross-sensitivity has occurred in about 10% of such patients.
 - If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
 - For I.V. use, reconstitute each 0.5-, 1-, or 2-g vial with 10 ml of sterile water for injection. Shake to dissolve.
 - For intermittent I.V. infusion, further dilute in 50 to 100 ml of D₅W or normal saline solution.
 - For I.M. use, reconstitute each 500-mg vial with 2 ml sterile water for injection or bacteriostatic water for injection; each 1-g vial with 3 ml diluent; and each 2-g vial with 5 ml diluent. Shake to dissolve.
- WARNING** When preparing drug for a neonate, don't use diluent that contains benzyl alcohol; it could cause a fatal toxic syndrome.
- Give cefotaxime by I.V. injection over 3 to 5 minutes through tubing of a free-flowing compatible I.V. solution. Temporarily stop other solutions being given through same I.V. site.
 - Discard unused drug after 24 hours if stored at room temperature, 5 days if refrigerated.

- Protect cefotaxime powder and solution from light and heat.
- Monitor I.V. sites for signs of phlebitis or extravasation. Rotate I.V. sites every 72 hours.
- Monitor BUN and serum creatinine levels and fluid intake and output for signs of nephrotoxicity.
- Be aware that allergic reaction may occur a few days after cefotaxime therapy starts.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold cefotaxime and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- Assess patient for pharyngitis, ecchymosis, bleeding, and arthralgia, which may indicate a blood dyscrasia. Monitor CBC, PT, and bleeding time, as ordered.
- Monitor patient closely for superinfection. If evidence appears, notify prescriber and expect to stop drug and provide care.

PATIENT TEACHING

- Explain that I.M. injection may be painful.
- Instruct patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

cefotetan disodium

Cefotan

Class and Category

Chemical class: Second-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ *To provide surgical prophylaxis*

I.V. INJECTION

Adults. 1 to 2 g 30 to 60 min before surgery or, in cesarean section, as soon as cord is clamped.

↗ *To treat lower respiratory tract infections caused by Escherichia coli, Haemophilus influenzae, Klebsiella species, Proteus mirabilis, Serratia marcescens, Staphylococcus aureus, and Streptococcus pneumoniae; gynecologic infections caused by Bacteroides species (excluding B. distasonis, B. ova-*

tus, and B. thetaiotaomicron), E. coli, Fusobacterium species, gram-positive anaerobic cocci, Neisseria gonorrhoeae, P. mirabilis, S. aureus, Staphylococcus epidermidis, and Streptococcus species (excluding enterococci); intra-abdominal infections caused by Bacteroides species (excluding B. distasonis, B. ova-

tus, and B. thetaiotaomicron), Clostridium species, E. coli, Klebsiella species, and Streptococcus species (excluding enterococci); and bone and joint infections caused by S. aureus

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. For mild to moderate infections, 1 to 2 g every 12 hr.

I.V. INFUSION OR INJECTION

Adults. For severe infections, 2 g every 12 hr; for life-threatening infections, 3 g every 12 hr.

↗ *To treat UTI caused by E. coli, Klebsiella species, or Proteus species*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 0.5 to 2 g every 12 hr or 1 to 2 g every 24 hr.

↗ *To treat skin and soft-tissue infections caused by E. coli, Klebsiella pneumoniae, Peptostreptococcus species, S. aureus, S. epidermidis, Streptococcus pyogenes, and Streptococcus species (excluding enterococci)*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. For mild to moderate infections due to *K. pneumoniae*, 1 or 2 g every 12 hr. For mild to moderate infections caused by other organisms, 1 g I.M. or I.V. every 12 hr or 2 g I.V. every 24 hr; for severe infections, 2 g I.V. every 12 hr.

DOSAGE ADJUSTMENT Dosing interval reduced to 24 hr if creatinine clearance is 10 to 30 ml/min/1.73 m² and to 48 hr if creatinine clearance is less than 10 ml/min/1.73 m².

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

Incompatibilities

To prevent mutual inactivation, don't mix cefotetan with aminoglycosides.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity
oral anticoagulants, other drugs that affect blood clotting: Enhanced anticoagulant effect

probenecid: Increased and prolonged blood cefotetan level

ACTIVITIES

alcohol use: Disulfiram-like reaction

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis; injection site pain, redness, and swelling; superinfection

Nursing Considerations

- Use cefotetan cautiously in patients with impaired renal function or a history of GI disease, especially colitis. Also use cautiously in patients hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
- For I.V. use, reconstitute each 1-g vial of drug with 10 ml sterile water for injection. For each 2-g vial, use 10 to 20 ml diluent. For I.V. infusion, further dilute solution in 50 to 100 ml D₅W or normal saline solution.
- For direct I.V. injection, give drug slowly over 3 to 5 minutes through tubing of a flowing compatible I.V. solution.

- For I.M. use, reconstitute each 1-g vial of drug with 2 ml of sterile or bacteriostatic water for injection, or sodium chloride for injection. For a 2-g vial, use 3 ml diluent.
- Monitor I.V. site for signs and symptoms of phlebitis and extravasation; rotate sites every 72 hours.
- Protect reconstituted solution from light, and store for up to 24 hours at room temperature or 96 hours under refrigeration.
- Be aware that an allergic reaction may occur a few days after therapy starts.
- Monitor BUN and serum creatinine levels and fluid intake and output for signs of nephrotoxicity.
- Monitor patient receiving even short-term cefotetan therapy for signs and symptoms of hemolytic anemia, such as marked pallor and fatigue.
- If patient receives long-term therapy, monitor CBC and serum AST, ALT, bilirubin, LD, and alkaline phosphatase levels.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Watch for pharyngitis, ecchymosis, bleeding, and arthralgia, which may indicate a blood dyscrasia. Monitor PT and bleeding time, as ordered. Be prepared to give vitamin K, if ordered, to treat hypoprothrombinemia.

PATIENT TEACHING

- Explain that I.M. injection may be painful.
- Tell patient to immediately report severe diarrhea to prescriber.
- Urge patient to avoid alcohol during and for at least 3 days after cefotetan therapy.

cefoxitin sodium

Mefoxin

Class and Category

Chemical class: Second-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To provide surgical prophylaxis*

I.V. INFUSION OR INJECTION

Adults. 2 g 30 to 60 min before surgery and then 2 g every 6 hr after first dose for up to 24 hr.

Children age 3 months or over. 30 to 40 mg/kg 30 to 60 min before surgery and every 6 hr after first dose for up to 24 hr.

➤ *To provide surgical prophylaxis for cesarean section*

I.V. INFUSION OR INJECTION

Adults. 2 g as a single dose as soon as cord is clamped or 2 g as soon as cord is clamped followed by 2 g 4 and 8 hr after initial dose.

➤ *To provide surgical prophylaxis for transurethral prostatectomy*

I.V. INFUSION OR INJECTION

Adults. 1 g 30 to 60 min before surgery and then 1 g every 8 hr for up to 5 days.

➤ *To treat infections, including septicemia, gynecologic infections, intra-abdominal infections, UTI, and infections of the lower respiratory tract, skin, soft tissue, bones, and joints caused by anaerobes (including Bacteroides species, Clostridium species, Fusobacterium species, Peptococcus niger, and Peptostreptococcus species), gram-negative organisms (including Escherichia coli, Haemophilus influenzae [also ampicillin-resistant strains], Klebsiella, and Proteus species), and gram-positive organisms (including Staphylococcus aureus [penicillinase- and non-penicillinase-producing strains], Staphylococcus epidermidis, Streptococcus agalactiae, Streptococcus pneumoniae, and Streptococcus pyogenes)*

I.V. INFUSION OR INJECTION

Adults. For uncomplicated infections, 1 g every 6 to 8 hr; for moderate to severe infections, 1 g every 4 hr or 2 g every 6 to 8 hr. For infections that commonly require high-dose antibiotics (such as gas gangrene), 2 g every 4 hr or 3 g every 6 hr.

Children age 3 months or over. 80 to 160 mg/kg daily in equal doses given every 4 to 6 hr (higher dosages used for more severe infections). *Maximum:* 12 g daily.

➤ *To treat uncomplicated gonorrhea*

I.M. INJECTION

Adults. 2 g as a single dose along with 1 g oral probenecid concurrently or within 30 min of cefoxitin.

DOSAGE ADJUSTMENT Dosage reduced to 1 to 2 g every 8 to 12 hr if creatinine clearance is 30 to 50 ml/min/1.73 m²; 1 to 2 g

every 12 to 24 hr if clearance is 10 to 29 ml/min/1.73 m²; 0.5 to 1 g every 12 to 24 hr if clearance is 5 to 9 ml/min/1.73 m²; and 0.5 to 1 g every 24 to 48 hr if clearance is less than 5 ml/min/1.73 m².

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

Incompatibilities

To prevent mutual inactivation, don't mix cefoxitin with aminoglycosides. Also avoid mixing cefoxitin with other drugs, including pentamidine isethionate.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, flushing, pruritus, rash, Stevens-Johnson syndrome, urticaria

Other: Anaphylaxis; injection site pain, redness, and swelling; superinfection

Nursing Considerations

- Use cefoxitin cautiously in patients hypersensitive to penicillin; cross-sensitivity has occurred in about 10% of such patients.
- Also use cautiously in patients with a history of GI disease, particularly colitis, because of an increased risk of

pseudomembranous colitis.

- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
- For I.V. use, reconstitute 1 g with 10 ml sterile water for injection or 2 g with 10 to 20 ml diluent.
- For I.V. injection, give slowly over 3 to 5 minutes through tubing of a flowing compatible I.V. solution.
- For intermittent infusion, further dilute with 50 to 100 ml D₅W or normal saline solution.
- For continuous high-dose infusion, add cefoxitin to I.V. solutions of D₅W, normal saline solution, or dextrose 5% in normal saline solution.
- For I.M. use, reconstitute each 1 g with 2 ml sterile water for injection.
- Discard unused drug after 24 hours if stored at room temperature or after 1 week if refrigerated.
- Be aware that powder or solution may darken during storage, which doesn't reflect altered potency.
- Be aware that an allergic reaction may occur a few days after therapy starts.
- Monitor BUN and serum creatinine for early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Assess for pharyngitis, ecchymosis, bleeding, and arthralgia; they may indicate a blood dyscrasia.

PATIENT TEACHING

- Tell patient to immediately report severe diarrhea to prescriber.
- Instruct patient to complete the course of therapy as prescribed.

cefepodoxime proxetil

Vantin

Class and Category

Chemical class: Third-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat acute community-acquired pneumonia caused by Haemophilus influenzae or Streptococcus pneumoniae*

ORAL SUSPENSION, TABLETS

Adults and adolescents over age 13.

200 mg every 12 hr for 14 days.

➤ *To treat acute bacterial exacerbation of chronic bronchitis caused by H. influenzae, Moraxella catarrhalis, or S. pneumoniae*

TABLETS

Adults and adolescents over age 13.

200 mg every 12 hr for 10 days.

➤ *To treat uncomplicated gonorrhea in men and women and rectal gonococcal infections in women caused by Neisseria gonorrhoeae*

ORAL SUSPENSION, TABLETS

Adults. 200 mg as a single dose.

➤ *To treat uncomplicated UTI caused by Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis, or Staphylococcus saprophyticus*

ORAL SUSPENSION, TABLETS

Adults. 100 mg every 12 hr for 7 days.

➤ *To treat skin and soft-tissue infections caused by Staphylococcus aureus or Staphylococcus pyogenes*

ORAL SUSPENSION, TABLETS

Adults and adolescents over age 13.

400 mg every 12 hr for 7 to 14 days.

➤ *To treat acute otitis media caused by H. influenzae, M. catarrhalis, or S. pneumoniae*

ORAL SUSPENSION, TABLETS

Children ages 5 months through 12 years.

5 mg/kg every 12 hr (*maximum:* 200 mg/dose) or 10 mg/kg every 24 hr (*maximum:* 400 mg/dose) for 10 days.

➤ *To treat pharyngitis and tonsillitis caused by S. pyogenes*

ORAL SUSPENSION, TABLETS

Adults and adolescents over age 13.

100 mg every 12 hr for 5 to 10 days.

Children ages 2 months through 12 years.

5 mg/kg every 12 hr for 5 to 10 days.

Maximum: 100 mg/dose.

DOSAGE ADJUSTMENT Dosing interval increased to 24 hr in patients with creatinine clearance less than 30 ml/min/1.73 m².

Mechanism of Action

Interferes with bacterial cell wall synthesis

by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity

antacids, H₂-receptor antagonists: Reduced bioavailability and blood level of cefpodoxime

oral anticholinergics: Delayed peak blood level of cefpodoxime

probenecid: Possibly increased and prolonged blood cefpodoxime level

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Eczymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis, superinfection

Nursing Considerations

- Use cefpodoxime cautiously in patients who have impaired renal function or are receiving potent diuretics. Also use drug cautiously in patients hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- If possible, obtain culture and sensitivity test results, as ordered, before giving cefpodoxime.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Be aware that an allergic reaction may

occur a few days after therapy starts.

PATIENT TEACHING

- Urge patient to complete the prescribed course of therapy.
- Tell patient to take tablets with food to enhance absorption.
- Advise patient to refrigerate oral suspension and discard after 14 days.
- Instruct patient to shake oral suspension bottle well before pouring dose and to use a calibrated liquid-measuring device to ensure accurate doses.
- Inform patient that yogurt and buttermilk can help maintain intestinal flora and decrease diarrhea.
- Warn patient not to take an antacid within 2 hours before or after taking cefpodoxime.
- Tell patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

cefprozil

Cefzil

Class and Category

Chemical class: Second-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ *To treat secondary bacterial infections in patients with acute bronchitis and acute bacterial exacerbations of acute bronchitis caused by Haemophilus influenzae, Moraxella catarrhalis, and Streptococcus pneumoniae*

ORAL SUSPENSION, TABLETS

Adults and adolescents. 500 mg every 12 hr for 10 days.

↗ *To treat uncomplicated skin and soft-tissue infections caused by Staphylococcus aureus and Streptococcus pyogenes*

ORAL SUSPENSION, TABLETS

Adults and adolescents. 250 mg every 12 hr or 500 mg every 12 to 24 hr for 10 days.

Children ages 2 to 12. 20 mg/kg every 24 hr for 10 days.

↗ *To treat pharyngitis and tonsillitis caused by S. pyogenes*

ORAL SUSPENSION, TABLETS

Adults and adolescents. 500 mg every 24 hr for 10 days.

Children ages 2 to 12. 7.5 mg/kg every 12 hr for 10 days.

↗ *To treat otitis media caused by H. influenzae, M. catarrhalis, and S. pneumoniae*

ORAL SUSPENSION, TABLETS

Children ages 6 months to 12 years.

15 mg/kg every 12 hr for 10 days.

↗ *To treat acute sinusitis caused by H. influenzae, M. catarrhalis, and S. pneumoniae*

ORAL SUSPENSION, TABLETS

Adults and adolescents. 250 to 500 mg every 12 hr for 10 days.

Children ages 6 months to 12 years. 7.5 or 15 mg/kg every 12 hr for 10 days.

DOSE ADJUSTMENT Dosage reduced by half and given at usual intervals in patients with creatinine clearance less than 30 ml/min/1.73 m².

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions**DRUGS**

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity

probenecid: Increased blood ceftazidime level

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis, superinfection

Nursing Considerations

- Use cefprozil cautiously in patients who have impaired renal function or a history of GI disease, especially colitis. Also use drug cautiously in patients who are hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
- **WARNING** Don't administer oral suspension to patients with phenylketonuria because it contains phenylalanine 28 mg/5 ml.
- Monitor BUN and serum creatinine levels to detect early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Be aware that an allergic reaction may occur a few days after therapy starts.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.

PATIENT TEACHING

- Urge patient to complete the prescribed course of therapy.
- Tell patient to refrigerate oral suspension and discard after 14 days.
- Instruct patient to shake oral suspension well before pouring and to use a calibrated measuring device to ensure accurate doses.
- Inform patient that yogurt and buttermilk can help maintain intestinal flora and decrease diarrhea.
- Tell patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

ceftazidime

Ceptaz, Fortaz, Tazicef, Tazidime

Class and Category

Chemical class: Third-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat infections caused by gram-negative organisms (including Acinetobacter, Citrobacter, Enterobacter, Escherichia coli, Haemophilus influenzae, Klebsiella, Neisseria, Proteus mirabilis, Proteus vulgaris, Pseudomonas aeruginosa, Salmonella, Serratia, and Shigella), gram-positive organisms (including Streptococcus agalactiae, Streptococcus pneumoniae, and Streptococcus pyogenes [group B streptococci]), as well as Staphylococcus aureus (penicillinase- and non-penicillinase-producing strains)*

I.V. INFUSION, I.M. INJECTION

Adults and children age 12 and over. 1 g every 8 to 12 hr.

I.V. INFUSION

Children age 1 month to 12 years. 30 to 50 mg/kg every 8 hr.

Neonates up to age 1 month. 30 mg/kg every 12 hr. *Maximum:* 6 g daily.

➤ *To treat uncomplicated UTI*

I.V. INFUSION, I.M. INJECTION

Adults and children age 12 and over. 250 mg every 12 hr.

➤ *To treat complicated UTI*

I.V. INFUSION, I.M. INJECTION

Adults and children age 12 and over. 500 mg every 8 to 12 hr.

➤ *To treat uncomplicated pneumonia and mild skin and soft-tissue infections*

I.V. INFUSION, I.M. INJECTION

Adults and children age 12 and over. 0.5 to 1 g every 8 hr.

➤ *To treat bone and joint infections*

I.V. INFUSION

Adults and children age 12 and over. 2 g every 12 hr.

➤ *To treat serious gynecologic and intra-abdominal infections, meningitis, and life-threatening infections, especially in immunocompromised patients*

I.V. INFUSION

Adults and children age 12 and over. 2 g every 8 hr.

➤ *To treat pseudomonal lung infection in patients with cystic fibrosis and normal renal function*

I.V. INFUSION

Adults and children age 1 month and over. 30 to 50 mg/kg every 8 hr. *Maximum:* 6 g daily.

Neonates up to age 1 month. 30 mg/kg every 12 hr.

DOSAGE ADJUSTMENT Dosage reduced to 1 g every 12 hr if creatinine clearance is 31 to 50 ml/min/1.73 m²; to 1 g every 24 hr if 16 to 30 ml/min/1.73 m²; to 0.5 g every 24 hr if 6 to 15 ml/min/1.73 m²; and to 0.5 g every 48 hr if less than 6 ml/min/1.73 m².

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die.

Incompatibilities

Don't mix ceftazidime with aminoglycosides to prevent mutual inactivation.

Vancomycin is physically incompatible with ceftazidime (precipitate may form); flush I.V. line between these drugs if given through same tubing. Avoid mixing ceftazidime with other drugs, including pentamidine isethionate.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity
oral combined estrogen-progesterone contraceptives: Decreased effectiveness of oral contraceptive

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis; injection site pain, redness, and swelling; superinfection

Nursing Considerations

- Use ceftazidime cautiously in patients hypersensitive to penicillin because cross-sensitivity occurs in about 10% of such patients. Watch for allergic reactions a few days after therapy starts.
- Use cautiously in patients with a history of GI disease, particularly colitis, because risk of pseudomembranous colitis is increased.
- Ceftazidime l-arginine (Ceptaz) is not recommended for children under age 12.
- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
- Protect ceftazidime powder and reconstituted drug from heat and light; both tend to darken during storage.
- If pharmacy delivers frozen solution, thaw it at room temperature, not in water bath or microwave. Store thawed solution for up to 12 hours at room temperature or 7 days in refrigerator; don't refreeze.

WARNING When preparing drug for neonates or immature infants, don't use diluents containing benzyl alcohol because they are linked to a fatal toxic syndrome.

- For I.V. bolus, reconstitute 1 to 2 g with 10 ml sterile water for injection, D₅W, or sodium chloride for injection. Shake to dissolve. Administer I.V. injection slowly over 3 to 5 minutes through tubing of a flowing compatible I.V. fluid.
- For intermittent infusion, further dilute in 50 to 100 ml D₅W or normal saline solution. Avoid using sodium bicarbonate injection as a diluent because drug is least stable in it. During ceftazidime administration, temporarily stop other solutions being given at the same I.V. site.
- For I.M. use, reconstitute each gram with 3 ml sterile water for injection or bacteriostatic water for injection.
- Give I.M. injection deep into large muscle mass, such as gluteus maximus.
- Rotate I.V. sites every 72 hours. Assess for phlebitis and extravasation.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Monitor CBC, hematocrit, and serum AST, ALT, bilirubin, LD, and alkaline phosphatase levels during long-term therapy.
- Monitor PT, as ordered, in at-risk patients,

such as those with renal or hepatic impairment or poor nutritional state and those receiving anticoagulant or prolonged antibiotic therapy. Notify prescriber if PT decreases, and expect to give vitamin K.

- Assess patient for perineal itching, fever, malaise, redness, swelling, rash, and change in cough or sputum; they may indicate a superinfection.
- Watch for pharyngitis, ecchymosis, bleeding, and arthralgia (possible blood dyscrasia). Monitor PT and bleeding time.

PATIENT TEACHING

- Tell patient to take ceftazidime exactly as prescribed.
- Tell patient to immediately report evidence of blood dyscrasia or superinfection to prescriber.
- Urge patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

ceftibuten

Cedax

Class and Category

Chemical class: Third-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat acute bacterial exacerbations of chronic bronchitis caused by Haemophilus influenzae, Moraxella catarrhalis, or Streptococcus pneumoniae; pharyngitis and tonsillitis caused by Streptococcus pyogenes; and acute bacterial otitis media caused by H. influenzae, M. catarrhalis, or S. pneumoniae*

CAPSULES, ORAL SUSPENSION

Adults and children age 12 and over.

400 mg daily for 10 days.

➤ *To treat pharyngitis and tonsillitis caused by S. pyogenes and acute bacterial otitis media caused by H. influenzae, M. catarrhalis, or S. pneumoniae*

ORAL SUSPENSION

Children under age 12. 9 mg/kg daily for 10 days. *Maximum:* 400 mg daily.

DOSAGE ADJUSTMENT Dosage reduced to 4.5 mg/kg or 200 mg every 24 hr if creatinine clearance is 30 to 49 ml/min/1.73 m²;

to 2.25 mg/kg or 100 mg every 24 hr if it's 5 to 29 ml/min/1.73 m².

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity

Adverse Reactions

CNS: Aphasia, chills, fever, headache, psychosis, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, jaundice, melena, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, serum sickness, superinfection

Nursing Considerations

- Use ceftibuten cautiously in patients hypersensitive to penicillins because cross-sensitivity occurs in up to 10% of such patients.
- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
- Refrigerate oral suspension; shake well before using. Discard after 14 days.
- Monitor BUN and serum creatinine levels to detect early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Be aware that an allergic reaction may

occur a few days after therapy starts.

- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Assess patient for perineal itching, fever, malaise, redness, swelling, rash, and change in cough or sputum; they may indicate a superinfection.
- Assess for pharyngitis, ecchymosis, bleeding, and arthralgia; they may indicate a blood dyscrasia.

PATIENT TEACHING

- Urge patient to complete the drug therapy as prescribed.
- Instruct patient to take drug on an empty stomach at least 2 hours before or 1 hour after meals.
- Inform patient that unflavored oral suspension has a bitter taste. Suggest having a flavor added when prescription is filled.
- Advise patient that yogurt and buttermilk can help maintain intestinal flora and decrease diarrhea during therapy.
- Tell patient to immediately report hypersensitivity reactions, severe diarrhea, and evidence of blood dyscrasia or superinfection.

ceftizoxime sodium

Cefizox

Class and Category

Chemical class: Third-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat mild to moderate infections of the lower respiratory tract, skin, soft tissue, bones, and joints; septicemia; meningitis; and intra-abdominal infections caused by anaerobes (such as Bacteroides species, Peptococcus, and Peptostreptococcus), gram-negative organisms (including Escherichia coli, Haemophilus influenzae, Klebsiella, and Proteus mirabilis), and gram-positive organisms (including Enterobacter species, Serratia species, Staphylococcus aureus, Staphylococcus epidermidis, Streptococcus agalactiae, Streptococcus pneumoniae, and Streptococcus pyogenes)*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults and children age 12 and over. 1 to 2 g every 8 to 12 hr.

↗ *To treat severe or refractory infections of the type listed above*

I.V. INFUSION OR INJECTION

Adults and children age 12 and over. 1 g every 8 hr or 2 g every 8 to 12 hr.

↗ *To treat life-threatening infections of the type listed above*

I.V. INFUSION OR INJECTION

Adults and children age 12 and over. 3 to 4 g every 8 hr or, if required, up to 2 g every 4 hr.

↗ *To treat bacterial infections in children*

I.V. INFUSION, I.V. OR I.M. INJECTION

Children age 6 months and over. 50 mg/kg every 6 to 8 hr.

↗ *To treat uncomplicated UTI*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 500 mg every 12 hr.

↗ *To treat pelvic inflammatory disease*

I.V. INFUSION OR INJECTION

Adults. 2 g every 8 hr.

↗ *To treat uncomplicated gonococcal infections*

I.M. INJECTION

Adults. 1 g as a single dose.

DOSE ADJUSTMENT Dosage reduced to 0.5 g every 8 hr for less severe infections and 0.75 to 1.5 g every 8 hr for life-threatening infections if creatinine clearance is 50 to 79 ml/min/1.73 m²; to 0.25 to 0.5 g every 12 hr for less severe infections and 0.5 to 1 g every 12 hr for life-threatening infections if creatinine clearance is 5 to 49 ml/min/1.73 m²; and to 0.5 g every 48 hr or 0.25 g every 24 hr for less severe infections and 0.5 to 1 g every 48 hr or 0.5 g every 24 hr for life-threatening infections if creatinine clearance is 4 ml/min/1.73 m² or less.

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions**DRUGS**

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis; injection site pain, redness, and swelling; superinfection

Nursing Considerations

- Use ceftizoxime cautiously in patients hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
- For I.V. administration, reconstitute with sterile water for injection as follows: for 500-mg vial, add 5 ml; for 1-g vial, add 10 ml; and for 2-g vial, add 20 ml. Shake well. Dilute reconstituted solution further with 50 to 100 ml of a compatible solution, such as normal saline solution or D₅W, before administration. Give I.V. injection slowly over 3 to 5 minutes through tubing of a flowing compatible I.V. fluid.
- For I.M. administration, reconstitute with sterile water for injection as follows: for 500-mg vial, add 1.5 ml; for 1-g vial, add 3 ml; and for 2-g vial, add 6 ml. Shake well. Divide 2-g doses and administer in different sites. Inject deep in large muscle mass, such as the gluteus maximus.
- Reconstituted drug may be stored 24 hours at room temperature or 96 hours if refrigerated.
- Assess I.V. site for extravasation and

- phlebitis.
- Monitor BUN and serum creatinine levels to detect early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Monitor patient for allergic reactions a few days after therapy starts.
- Assess CBC, hematocrit, and serum AST, ALT, bilirubin, LD, and alkaline phosphatase levels during long-term therapy.
- Assess patient for pharyngitis, ecchymosis, bleeding, and arthralgia; they may indicate a blood dyscrasia.

PATIENT TEACHING

- Advise patient to immediately report severe or persistent diarrhea or evidence of blood dyscrasia to prescriber.

ceftriaxone sodium

Rocephin

Class and Category

Chemical class: Third-generation cephalosporin, 7-aminocephalosporanic acid
Therapeutic class: Antibiotic
Pregnancy category: B

Indications and Dosages

- ↗ *To treat infections of the lower respiratory tract, skin, soft tissue, urinary tract, bones, and joints; sinusitis; intra-abdominal infections; and septicemia caused by anaerobes (including Bacteroides bivius, Bacteroides fragilis, Bacteroides melaninogenicus, and Peptostreptococcus species), gram-negative organisms (including Citrobacter species, Enterobacter aerogenes, Escherichia coli, Haemophilus influenzae, Klebsiella species, Neisseria species, Proteus mirabilis, Proteus vulgaris, Providencia species, Salmonella species, Serratia marcescens, Shigella, and some strains of Pseudomonas aeruginosa), and gram-positive organisms (including Staphylococcus aureus, Streptococcus pneumoniae, and Streptococcus pyogenes)*

I.V. INFUSION, I.M. INJECTION

Adults. 1 to 2 g daily or in equally divided doses b.i.d. *Maximum:* 4 g daily.

Children. 50 to 75 mg/kg daily in divided doses every 12 hr. *Maximum:* 2 g daily.

↗ *To treat meningitis*

I.V. INFUSION

Children. *Initial:* 100 mg/kg on first day, then 100 mg/kg daily or in divided doses every 12 hr for 7 to 14 days. *Maximum:* 4 g daily.

↗ *To treat acute bacterial otitis media*

I.M. INJECTION

Children. 50 mg/kg as a single dose.

Maximum: 1 g.

↗ *To treat chancroid (Haemophilus ducreyi infection) and uncomplicated gonorrhea*

I.M. INJECTION

Adults. 250 mg as a single dose.

↗ *To treat gonococcal conjunctivitis*

I.M. INJECTION

Adults. 1 g as a single dose.

↗ *To treat disseminated gonococcal infection and pelvic inflammatory disease*

I.V. INFUSION, I.M. INJECTION

Adults. 1 g every 24 hr.

↗ *To treat gonococcal meningitis and endocarditis*

I.V. INFUSION

Adults. 1 to 2 g every 12 hr for 10 to 14 days (meningitis) or for 4 wk or longer (endocarditis).

↗ *To provide surgical prophylaxis*

I.V. INFUSION

Adults. 1 g 30 min to 2 hr before surgery.

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die.

Incompatibilities

Don't admix ceftriaxone with pentamidine isethionate, labetalol, or other antibiotics, such as aminoglycosides, because of potential for incompatibility, such as substantial mutual inactivation. Also don't mix with calcium-containing solutions or products because a ceftriaxone-calcium salt may precipitate in the lungs and kidneys and may be fatal, especially in newborns.

Contraindications

Calcium-containing I.V. solutions; hyper-

bilirubinemic neonates 28 days old or less if they're expected to need calcium-containing solutions, including parenteral nutrition; hypersensitivity to ceftriaxone, other cephalosporins, or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity

Adverse Reactions

CNS: Chills, fever, headache, hypertonia, reversible hyperactivity, seizures

CV: Edema

EENT: Glossitis, hearing loss, stomatitis

GI: Abdominal cramps, cholestasis, diarrhea, elevated liver function test results, gallbladder dysfunction, hepatic failure, hepatomegaly, nausea, oral candidiasis, pancreatitis, pseudolithiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, oliguria, renal failure, vaginal candidiasis

HEME: Aplastic anemia, eosinophilia, hemolytic anemia, hemorrhage, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Allergic pneumonitis, dyspnea

SKIN: Allergic dermatitis, ecchymosis, erythema, erythema multiforme, exanthema, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis; drug fever; injection site pain, redness, and swelling; serum sickness; superinfection

Nursing Considerations

WARNING Calcium-containing products must not be given I.V. within 48 hours of ceftriaxone, including solutions given through a different I.V. line and at a different site, because a ceftriaxone-calcium salt may precipitate in the lungs and kidneys and could be fatal.

- Use ceftriaxone cautiously in patients who are hypersensitive to penicillins because cross-sensitivity has occurred in about 10% of such patients.
- If possible, obtain culture and sensitivity results, as ordered, before giving drug.
- Protect powder from light.
- For I.V. use, reconstitute with an appropriate diluent, such as sterile water for injection or sodium chloride for injection, as

follows: for 250-mg vial, add 2.4 ml; for 500-mg vial, add 4.8 ml; for 1-g vial, add 9.6 ml; and for 2-g vial, add 19.2 ml to yield 100 mg/ml. For piggyback bottles, reconstitute with 10 ml of diluent indicated above for 1-g bottle and 20 ml for 2-g bottle. After reconstitution, further dilute to 50 to 100 ml with diluent indicated above and infuse over 30 minutes.

WARNING Never give ceftriaxone by I.V. infusion and calcium-containing IV solutions at the same time, including such continuous calcium-containing infusions as parenteral nutrition via Y-site. For patients other than neonates, ceftriaxone and calcium-containing solutions may be given sequentially if infusion lines are thoroughly flushed with a compatible fluid between infusions.

- For I.M. administration, reconstitute with an appropriate diluent, such as sterile water for injection or sodium chloride for injection, as follows: for 250-mg vial, add 0.9 ml; for 500-mg vial, add 1.8 ml; for 1-g vial, add 3.6 ml; and for 2-g vial, add 7.2 ml to make a 250-mg/ml concentration. Shake well. Inject deep into large muscle mass, such as the gluteus maximus.
- Monitor BUN and serum creatinine levels to detect early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Monitor patient for allergic reactions a few days after therapy starts.
- Assess CBC, hematocrit, and serum AST, ALT, bilirubin, LD, and alkaline phosphatase levels during long-term therapy. If abnormalities occur, notify prescriber. Drug may need to be discontinued.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold cefotaxime and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- Monitor patient for evidence of gallbladder disease (abdominal pain, nausea, vomiting) because drug may cause ceftriaxone-calcium salt to deposit in the gallbladder, which may mimic gallstones. Expect drug to be discontinued if gallbladder disorders arise.

- Assess for perineal itching, fever, malaise, redness, swelling, rash, and change in cough or sputum; they may indicate a superinfection.
- Assess for pharyngitis, ecchymosis, bleeding, and arthralgia; they may indicate a blood dyscrasia.

PATIENT TEACHING

- Tell patient to immediately report evidence of blood dyscrasia or superinfection to prescriber.
- Urge patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

cefuroxime axetil

Ceftin

cefuroxime sodium

Zinacef

Class and Category

Chemical class: Second-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ *To treat pharyngitis and tonsillitis*

ORAL SUSPENSION

Children ages 3 months to 12 years. 10 mg/kg daily in equally divided doses b.i.d. for 10 days. *Maximum:* 500 mg daily.

TABLETS

Adults and children age 13 and over.

250 mg b.i.d. for 10 days.

Children under age 13 who can swallow tablets. 125 mg b.i.d. for 10 days.

↗ *To treat acute otitis media*

ORAL SUSPENSION

Children ages 3 months to 12 years.

30 mg/kg daily in equally divided doses b.i.d. for 10 days. *Maximum:* 1,000 mg daily.

TABLETS

Children under age 13 who can swallow tablets. 250 mg b.i.d. for 10 days.

↗ *To treat impetigo*

ORAL SUSPENSION

Children ages 3 months to 12 years. 30 mg/kg daily in equally divided doses b.i.d. for 10 days. *Maximum:* 1,000 mg daily.

↗ *To treat acute bacterial maxillary sinusitis*

ORAL SUSPENSION

Children ages 3 months to 12 years. 30 mg/kg daily in equally divided doses b.i.d. for 10 days. *Maximum:* 1,000 mg daily.

TABLETS

Adults and children age 13 and over and children under age 13 who can swallow tablets. 250 mg b.i.d. for 10 days.

↗ *To treat acute bacterial exacerbations of chronic bronchitis and uncomplicated skin and soft-tissue infections*

TABLETS

Adults and children age 13 and over.

250 to 500 mg b.i.d. for 10 days.

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 750 mg every 8 hr.

↗ *To treat secondary bacterial infection in patients with acute bronchitis*

Adults and children age 13 and over.

250 to 500 mg b.i.d. for 5 to 10 days.

↗ *To treat early Lyme disease*

TABLETS

Adults and children age 13 and over.

500 mg b.i.d. for 20 days.

↗ *To treat uncomplicated UTI*

TABLETS

Adults. 125 to 250 mg b.i.d. for 7 to 10 days.

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 750 mg every 8 hr.

↗ *To treat uncomplicated gonorrhea*

TABLETS

Adults. 1 g as a single dose.

I.V. INJECTION

Adults. 1.5 g as a single dose divided equally and injected into two different sites; given with oral probenecid 1 g.

↗ *To treat disseminated gonococcal infection and uncomplicated pneumonia*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 750 mg every 8 hr.

↗ *To treat bone and joint infections*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 1.5 g every 8 hr.

Children over age 3 months. 50 to 150 mg/kg daily in divided doses every 8 hr.

Maximum: Adult dose.

↗ *To treat bacterial meningitis*

I.V. INFUSION

Adults. 1.5 to 3 g every 8 hr.

Children over age 1 month. 50 to 80 mg/kg every 6 to 8 hr.

Neonates up to age 1 month. 33.3 to 50 mg/kg every 8 to 12 hr.

↗ *To treat moderate infections other than those listed above*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 750 mg every 8 hr for 5 to 10 days.

I.V. INFUSION OR INJECTION

Children over age 3 months. 50 mg/kg daily in equally divided doses every 6 to 8 hr.

↗ *To treat severe or complicated infections other than those listed above*

I.V. INFUSION OR INJECTION

Adults. 1.5 g every 8 hr.

Children over age 3 months. 100 mg/kg daily in equally divided doses every 6 to 8 hr.

↗ *To treat life-threatening infections other than those listed above*

I.V. INFUSION OR INJECTION

Adults. 1.5 g every 6 hr.

↗ *To provide perioperative prophylaxis*

I.V. INFUSION OR INJECTION

Adults. 1.5 g 30 to 60 min before surgery (at induction of anesthesia for open-heart surgery), and then 0.75 g every 8 hr thereafter (1.5 g every 12 hr for total of 6 g with open-heart surgery).

DOSE ADJUSTMENT Parenteral dosage reduced to 0.75 g every 12 hr if creatinine clearance is 10 to 20 ml/min/1.73 m² or to 0.75 g every 24 hr if creatinine clearance less than 10 ml/min/1.73 m².

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die.

Incompatibilities

Don't admix parenteral cefuroxime with other antibiotics, such as aminoglycosides, because of potential for incompatibility, such as substantial mutual inactivation. If they're administered concurrently, don't mix them in the same I.V. bag or bottle.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity

antacids, H₂-receptor antagonists, omeprazole: Decreased cefuroxime axetil absorption
probenecid: Increased and prolonged blood cefuroxime level

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss, oral candidiasis

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis; injection site edema, pain, and redness; superinfection

Nursing Considerations

- Use cefuroxime cautiously in patients hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- If possible, obtain culture and sensitivity results, as ordered, before giving drug.
- Give oral form with food to decrease GI distress, as needed.
- Remember that oral forms—tablets and suspension—aren't bioequivalent.
- For I.V. use, reconstitute using manufacturer's instructions according to type of preparation available. Solution ranges in color from light yellow to amber.
- For I.M. use, add 3 or 3.6 ml sterile water for injection to each 750-mg vial to yield 220 mg/ml.
- If using a container of frozen parenteral solution, thaw at room temperature or under refrigeration before administration; make sure all ice crystals have melted. Don't force thawing by microwaving.
- Store reconstituted parenteral drug for up to 24 hours at room temperature or 96 hours in refrigerator. (Thawed solutions may be stable 24 hours at room temperature or 28 days if refrigerated.) Store reconstituted oral suspension in refrigera-

- tor or at room temperature up to 10 days.
- Give I.V. injection over 3 to 5 minutes through tubing of a flowing compatible I.V. fluid.
 - Monitor I.V. site for extravasation and phlebitis.
 - Monitor BUN and serum creatinine levels and fluid intake and output to detect signs of nephrotoxicity. Monitor patients with renal impairment closely because they may have greater toxic reactions to cefuroxime.
 - Monitor patient for allergic reactions continuing up to a few days after therapy starts. Patients with a history of some form of allergy, especially to drugs, are at increased risk for an allergic reaction.
 - Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis. If it's suspected, stop drug, as ordered, and provide treatment as prescribed.
 - Assess patient for pharyngitis, ecchymosis, bleeding, and arthralgia, which may indicate a blood dyscrasia.
 - Monitor PT and bleeding time, as ordered. Be prepared to administer vitamin K, if ordered, to treat hypotherbinemia.

PATIENT TEACHING

- Instruct patient to shake oral suspension well before measuring each dose and to use a calibrated liquid-measuring device.
- Advise patient using single-dose packets of oral suspension to empty contents of one packet into a glass and add at least 10 ml (2 tsp) of cold water; apple, grape, or orange juice; or lemonade. Tell him to stir well and consume entire mixture at once.
- Inform patient that yogurt and buttermilk help maintain intestinal flora and can decrease diarrhea during therapy.
- Instruct patient to report evidence of blood dyscrasia to prescriber immediately.
- Urge patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

celecoxib

Celebrex

Class and Category

Chemical class: Diaryl-substituted pyrazole derivative

Therapeutic class: Anti-inflammatory, anti-rheumatic

Pregnancy category: C

Indications and Dosages

➤ *To relieve signs and symptoms of osteoarthritis*

CAPSULES

Adults. 200 mg daily or 100 mg b.i.d.

➤ *To relieve signs and symptoms of rheumatoid arthritis*

CAPSULES

Adults. 100 to 200 mg b.i.d.

➤ *To relieve signs and symptoms of juvenile rheumatoid arthritis*

CAPSULES

Children age 2 and older weighing 10 to 25 kg (22 to 55 lb). 50 mg b.i.d.

Children age 2 and older weighing more than 25 kg. 100 mg b.i.d.

➤ *To relieve pain from ankylosing spondylitis*

CAPSULES

Adults. 200 mg daily or 100 mg b.i.d.

Dosage increased to 400 mg daily or 200 mg b.i.d. after 6 weeks if needed.

➤ *As adjunct to reduce adenomatous col-orectal polyps in patients with familial adenomatous polyposis*

CAPSULES

Adults. 400 mg b.i.d.

➤ *To manage acute pain, to treat primary dysmenorrhea*

CAPSULES

Adults. 400 mg, followed by 200 mg if needed, on 1st day. On subsequent days, 200 mg b.i.d. as needed.

DOSAGE ADJUSTMENT Daily dosage reduced for patients with hepatic impairment. For those weighing less than 50 kg (110 lb), expect to start with lowest recommended dose. For patients who are poor CYP2C9 metabolizers, starting dosage should be half the lowest recommended dose.

Mechanism of Action

Selectively inhibits the enzymatic activity of cyclooxygenase-2 (COX-2), the enzyme needed to convert arachidonic acid to prostaglandin. Prostaglandins are responsible for mediating the inflammatory response and causing local vasodilation, swelling, and pain. Prostaglandins also play a role in peripheral pain transmission to the spinal cord. By inhibiting COX-2 activity

and prostaglandin production, this NSAID reduces inflammatory symptoms and relieves pain. Celecoxib's mechanism of action in reducing the number of colorectal polyps is unknown.

Contraindications

Allergic reaction (such as anaphylaxis or angioedema) to aspirin, other NSAIDs, or sulfonamide derivatives or history of aspirin-induced nasal polyps with bronchospasm; hypersensitivity to celecoxib or its components; treatment of perioperative pain after coronary artery bypass graft surgery

Interactions

DRUGS

ACE inhibitors, angiotensin II receptor antagonists: Decreased antihypertensive effect of ACE inhibitors and angiotensin II receptor antagonists, increased risk of renal failure

aspirin: Increased risk of GI ulceration and other GI complications

fluconazole: Increased blood celecoxib level
furosemide, thiazide diuretics: Reduced diuretic effects of these drugs, increased risk of renal failure

lithium: Possibly elevated blood lithium level

warfarin: Possibly increased PT and risk of bleeding

Adverse Reactions

CNS: Aseptic meningitis, cerebral hemorrhage, depression, dizziness, fever, headache, insomnia, ischemic stroke, stroke, suicidal ideation, syncope, transient ischemic attacks, vertigo

CV: Aortic valve incompetence, chest pain, congestive heart failure, deep vein thrombosis, fluid retention, hypertension, MI, palpitations, peripheral edema or gangrene, sinus bradycardia, tachycardia, thrombosis, unstable angina, vasculitis, ventricular fibrillation, ventricular hypertrophy

EENT: Conjunctival hemorrhage, deafness, labyrinthitis, nasopharyngitis, pharyngitis, rhinitis, sinusitis, vitreous floaters

ENDO: Hyperglycemia, hypoglycemia

GI: Abdominal pain, diarrhea, elevated liver function test results, esophageal perforation, flatulence, GI bleeding or ulceration, hepatic failure, ileus, indigestion, jaundice, nausea, pancreatitis, perforation of stomach

or intestine, vomiting

GU: Acute renal failure, interstitial nephritis, ovarian cyst, proteinuria, UTI, urinary incontinence

HEME: Agranulocytosis, aplastic anemia, decreased hematocrit and hemoglobin, leukopenia, pancytopenia, prolonged APTT, thrombocytopenia

MS: Arthralgia, back pain, elevated serum CK level, epicondylitis, tendon rupture

RESP: Bronchospasm, cough, dyspnea, pneumonia, pulmonary embolism, upper respiratory tract infection

SKIN: Erythema multiforme, exfoliative dermatitis, phototoxicity, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, hyperkalemia, hyponatremia, hyponatremia, sepsis

Nursing Considerations

- Use celecoxib with extreme caution in patients who have a history of ulcer disease or GI bleeding because NSAIDs, such as celecoxib, increase the risk of GI bleeding and ulceration. In these patients, drug should be used for shortest time possible.
- Be aware that serious GI tract ulceration and bleeding, as well as perforation of stomach or intestine, can occur without warning or symptoms. Elderly patients are at greatest risk. To minimize risk, give celecoxib with food. If patient develops GI distress, withhold celecoxib and notify prescriber immediately.
- Use celecoxib cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy because drug can start or worsen hypertension.
- Use celecoxib cautiously in children with systemic onset juvenile rheumatoid arthritis because serious adverse reactions can occur, including disseminated intravascular coagulation.
- Use celecoxib cautiously in patients known to be poor CYP2C9 metabolizers based on history or experience with other CYP2C9 substrates, such as warfarin or phenytoin. Dosage should start at half the lowest recommended amount. For patients with juvenile rheumatoid arthritis who are also poor CYP2C9 metabolizers, alternative management should be considered.

WARNING Monitor patient closely for

thrombotic events, including MI and stroke, because use (especially long-term use) of NSAIDs such as celecoxib increases the risk.

WARNING In patient who has bone marrow suppression or is receiving antineoplastic therapy, monitor laboratory results (including WBC) and assess for infection because celecoxib' anti-inflammatory and antipyretic actions may mask signs and symptoms, such as fever and pain.

- Monitor patient—especially if elderly or receiving long-term celecoxib therapy—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver function test results because, in rare cases, elevation may progress to severe hepatic reaction, including fatal hepatitis, hepatic necrosis, and hepatic failure.
- Monitor BUN and serum creatinine levels in elderly patients; patients taking diuretics, ACE inhibitors, or angiotensin II receptor antagonists; and patients with heart failure, impaired renal function, or hepatic dysfunction because drug may cause renal failure.
- Monitor CBC for decreased hemoglobin level and hematocrit because drug may worsen anemia.
- Assess patient's skin regularly for signs of rash or other hypersensitivity reaction because celecoxib is a sulfur drug and may cause serious skin reactions without warning, even in patients with no history of sensitivity to sulfur. At first sign of reaction, stop drug and notify prescriber.
- Avoid using celecoxib with a non-aspirin NSAID, regardless of the dose, because celecoxib reduces inflammation and fever, which may mask signs of infection.

PATIENT TEACHING

- Instruct patient to swallow celecoxib capsules whole with a full glass of water and with food or milk to prevent stomach upset.
- Tell patient to take celecoxib exactly as prescribed and not to increase dosage or take drug longer than prescribed because serious adverse reactions can occur.

- Advise patient to notify prescriber if pain continues or is poorly controlled.
- Explain that celecoxib may increase the risk of serious adverse CV events; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, slurred speech, and weakness.
- Tell patient that celecoxib may increase the risk of serious adverse GI reactions. Stress the need to seek immediate medical attention if signs or symptoms develop, such as epigastric or abdominal pain, indigestion, black or tarry stools, and vomiting blood or material that resembles coffee grounds.
- Alert patient that celecoxib may cause serious skin reactions. Advise immediate medical attention if signs or symptoms develop, such as rash, blisters, fever, itching, or other evidence of hypersensitivity.
- Urge patient to avoid smoking and alcohol consumption during celecoxib therapy because they may increase the risk of adverse GI reactions.

cephalexin hydrochloride

Keftab

cephalexin monohydrate

Apo-Cephalex (CAN), Keflex, Novo-Lexin (CAN), Nu-Cephalex (CAN), PMS-Cephalexin (CAN)

Class and Category

Chemical class: First-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ To treat streptococcal tonsillitis, pharyngitis, and skin and soft-tissue infections

CAPSULES, ORAL SUSPENSION, TABLETS

Adults and adolescents age 15 and over. 500 mg every 12 hr. *Maximum:* 4 g daily.

Children and adolescents ages 2 to 15. 25 to 50 mg/kg daily divided into two equal doses and given every 12 hr. If infection is severe, dose may be doubled.

Mechanism of Action

Like all cephalosporins, cephalexin interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die. This mechanism of action is most effective against bacteria that divide rapidly, including many gram-positive and gram-negative bacteria.

➤ *To treat mild to moderate respiratory tract, skin, soft-tissue, bone, and GU infections caused by susceptible organisms other than streptococci*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults. 250 mg every 6 hr.

ORAL SUSPENSION

Children. 25 to 50 mg/kg daily in equally divided doses b.i.d. or q.i.d.

➤ *To treat severe respiratory tract, skin, soft-tissue, bone, and GU infections*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults. 0.5 to 1 g every 6 hr. *Maximum:* 4 g daily.

Children. 50 to 100 mg/kg daily in equally divided doses q.i.d.

➤ *To treat otitis media*

ORAL SUSPENSION

Children. 75 to 100 mg/kg daily in equally divided doses q.i.d.

➤ *To treat uncomplicated cystitis*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults and adolescents age 15 and over. 500 mg every 12 hr.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity
probenecid: Increased and prolonged blood cephalexin level

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Echymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis, superinfection

Nursing Considerations

- Use cephalexin cautiously in patients hypersensitive to penicillin because cross-sensitivity occurs in about 10% of them.
- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
- Monitor patient's BUN and serum creatinine levels to detect early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Monitor for allergic reactions a few days after therapy starts.
- Assess CBC, hematocrit, and serum AST, ALT, bilirubin, LD, and alkaline phosphatase levels during long-term therapy.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold cefotaxime and treat

with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

- Assess patient for pharyngitis, ecchymosis, bleeding, and arthralgia; they may indicate a blood dyscrasia.

PATIENT TEACHING

- Advise patient to complete prescribed course of therapy.
- Instruct patient to shake oral suspension well before measuring each dose and to use a calibrated liquid-measuring device to ensure an accurate dose.
- Tell patient that yogurt and buttermilk can help maintain intestinal flora and decrease diarrhea during therapy.
- Urge patient to immediately report watery, bloody stools to prescriber, even if they occur up to 2 months after cephalixin therapy has ended.

cephalirin sodium

Cefadyl

Class and Category

Chemical class: First-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat respiratory tract infection, skin and soft-tissue infections, UTI, septicemia, endocarditis, and osteomyelitis caused by gram-negative organisms (including Escherichia coli, Haemophilus influenzae, Klebsiella species, and Proteus mirabilis) and gram-positive organisms (including group A beta-hemolytic streptococci, Streptococcus pneumoniae, and staphylococci, including coagulase-positive, coagulase-negative, and penicillinase-producing strains but not methicillin-resistant Staphylococcus aureus)*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 0.5 to 1 g every 4 to 6 hr.

Maximum: 12 g daily. For serious infections, higher doses are given by I.V. route.

Children over age 3 months. 40 to 80 mg/kg daily divided into four equal doses and given every 6 hr. *Maximum:* 12 g daily.

➤ *To provide surgical prophylaxis*

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 1 to 2 g 30 to 60 min before surgery, 1 to 2 g during long procedure, and 1 to 2 g every 6 hr after surgery for 24 hr.

DOSAGE ADJUSTMENT For open-heart surgery or prosthetic arthroplasty, prophylaxis continued 3 to 5 days after procedure, if needed.

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity

probenecid: Increased and prolonged blood cephalirin level

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, oral candidiasis, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis; injection site pain, redness, and swelling; superinfection

Other: Anaphylaxis; injection site pain, redness, and swelling; superinfection

Other: Anaphylaxis; injection site pain, redness, and swelling; superinfection

Nursing Considerations

- Use cephalirin cautiously in patients hypersensitive to penicillins because cross-sensitivity has occurred in about 10% of such patients.
- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
- For I.V. injection, reconstitute 1 g with 10 ml or more of appropriate diluent, such

as sterile water for injection. Administer I.V. injection slowly over 3 to 5 minutes through tubing of a flowing compatible I.V. fluid.

- For I.V. infusion, dilute further in 50 ml of D₅W or normal saline solution and infuse over 15 to 30 minutes. Stop primary I.V. solution during cephalirin delivery.
- For I.M. injection, reconstitute 1-g vial with 2 ml sterile water for injection or bacteriostatic water for injection. Inject deep into large muscle mass, such as the gluteus maximus.
- Store reconstituted drug up to 24 hours at room temperature or 10 days refrigerated.
- Don't give cloudy solution.
- Assess I.V. site for extravasation and phlebitis.
- Monitor BUN and serum creatinine levels to detect early signs of nephrotoxicity. Also, monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Monitor patient for allergic reactions a few days after therapy starts.
- Assess CBC, hematocrit, and serum AST, ALT, bilirubin, LD, and alkaline phosphatase levels during long-term therapy.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Assess patient for pharyngitis, ecchymosis, bleeding, and arthralgia; they may indicate a blood dyscrasia.
- Assess patient for furry tongue, perineal itching, and loose, foul-smelling stool; they may indicate superinfection.

PATIENT TEACHING

- Instruct patient to immediately report severe diarrhea or evidence of blood dyscrasia or superinfection to prescriber.

cephradine

Velosef

Class and Category

Chemical class: First-generation cephalosporin, 7-aminocephalosporanic acid

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat respiratory tract infections*

(other than lobar pneumonia) and skin and soft-tissue infections

CAPSULES, ORAL SUSPENSION

Adults. 250 mg every 6 hr or 500 mg every 12 hr. *Maximum:* 4 g daily.

ORAL SUSPENSION

Children age 9 months and over. 25 to 50 mg/kg daily in equally divided doses every 6 or 12 hr. *Maximum:* 4 g daily.

➤ *To treat lobar pneumonia*

CAPSULES, ORAL SUSPENSION

Adults. 0.5 g every 6 hr or 1 g every 12 hr. *Maximum:* 4 g daily.

ORAL SUSPENSION

Children age 9 months and over. 25 to 50 mg/kg daily in equally divided doses every 6 or 12 hr. *Maximum:* 4 g daily.

➤ *To treat uncomplicated UTI*

CAPSULES, ORAL SUSPENSION

Adults. 500 mg every 12 hr. For more serious infections, 500 mg every 6 hr or 1,000 mg every 12 hr. *Maximum:* 4 g daily.

➤ *To treat otitis media caused by Haemophilus influenzae*

ORAL SUSPENSION

Children. 75 to 100 mg/kg daily in equally divided doses every 6 to 12 hr. *Maximum:* 4 g daily.

DOSAGE ADJUSTMENT Dosage reduced to 500 mg every 6 hr if creatinine clearance exceeds 20 ml/min/1.73 m²; 250 mg every 6 hr if clearance is 5 to 20 ml/min/1.73 m²; and 250 mg every 12 hr if clearance is less than 5 ml/min/1.73 m².

Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die.

Contraindications

Hypersensitivity to cephalosporins or their components

Interactions

DRUGS

aminoglycosides, loop diuretics: Increased risk of nephrotoxicity

probenecid: Increased and prolonged blood cephradine level

Adverse Reactions

CNS: Chills, fever, headache, seizures

CV: Edema

EENT: Hearing loss, oral candidiasis

GI: Abdominal cramps, diarrhea, elevated liver function test results, hepatic failure, hepatomegaly, nausea, pseudomembranous colitis, vomiting

GU: Elevated BUN level, nephrotoxicity, renal failure, vaginal candidiasis

HEME: Eosinophilia, hemolytic anemia, hypoprothrombinemia, neutropenia, thrombocytopenia, unusual bleeding

MS: Arthralgia

RESP: Dyspnea

SKIN: Ecchymosis, erythema, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome

Other: Anaphylaxis, superinfection

Nursing Considerations

- If possible, obtain culture and sensitivity test results, as ordered, before giving drug.
- Monitor patients hypersensitive to penicillin for evidence of hypersensitivity reaction because cross-sensitivity has occurred in about 10% of such patients.
- Store oral suspension for 7 days at room temperature or for 14 days if refrigerated.
- Monitor BUN and serum creatinine levels to detect early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Monitor patient for allergic reactions a few days after therapy starts. If hypersensitivity develops, be prepared to stop drug and administer antihistamines, corticosteroids, and vasopressors, as ordered. Also prepare to administer oxygen, maintain an open airway, and assist with endotracheal intubation, as appropriate.
- Assess CBC, hematocrit, and serum AST, ALT, bilirubin, LD, and alkaline phosphatase levels during long-term therapy.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis. Obtain a stool specimen to test for *Clostridium difficile*. Keep in mind that this serious adverse reaction can occur during therapy or up to several weeks after therapy ends. Also avoid giving antiperistaltic anti-diarrheals, such as atropine and diphenoxylate or loperamide, because they may delay elimination of toxins from the bowel and damage the colon from toxin retention. Mild cases may respond after

cephradine is discontinued. For moderate or severe cases, be prepared to administer fluids, electrolytes, and protein replacement as ordered.

- If patient has a history of GI disease, especially ulcerative colitis, regional enteritis, or antibiotic-associated colitis, assess him often for diarrhea because he is at risk for pseudomembranous colitis.
- Assess patient for pharyngitis, ecchymosis, bleeding, and arthralgia; these may indicate a blood dyscrasia.
- If patient has a seizure, notify prescriber immediately and expect to discontinue drug. Institute seizure precautions according to facility policy.

PATIENT TEACHING

- If patient develops GI distress, advise him to take cephradine with food.
- Advise patient to complete prescribed course of therapy.
- Urge patient to avoid missing doses and to take the drug at evenly spaced intervals. If patient misses a dose, instruct him to take it as soon as possible unless it's almost time for the next dose. Emphasize that he shouldn't double the dose.
- Tell patient that yogurt and buttermilk help maintain intestinal flora and can decrease diarrhea during therapy.
- Instruct patient to immediately report to prescriber severe diarrhea or evidence of blood dyscrasia or superinfection. Warn patient not to take any OTC anti-diarrheals before consulting prescriber.
- Tell patient to notify prescriber if symptoms don't improve within a few days.

certolizumab pegol

Cimzia

Class and Category

Chemical class: Recombinant, humanized antibody Fab fragment

Therapeutic class: Disease modifying anti-inflammatory

Pregnancy category: B

Indications and Dosages

↗ *To reduce signs and symptoms of Crohn's disease and maintain clinical response in patients with moderately to severely active disease who have had an*

inadequate response to conventional therapy

SUBCUTANEOUS INJECTION

Adults. *Initial:* 400 mg (given as two 200-mg injections) and repeated at wk 2 and 4. *Maintenance:* 400 mg (given as two 200-mg injections) every 4 wk if clinical response occurs.

➤ *To treat moderate to severe active rheumatoid arthritis*

SUBCUTANEOUS INJECTION

Adults. *Initial:* 400 mg (given as two 200-mg injections) and repeated at wk 2 and 4. *Maintenance:* 200 mg every other wk or 400 mg (given as two 200-mg injections) every 4 wk if clinical response occurs.

Route	Onset	Peak	Duration
SubQ	Unknown	54–171 hr	Unknown

Mechanism of Action

Binds to human tumor necrosis factor (TNF) alpha, inhibiting it. TNF alpha stimulates production of inflammatory mediators, including interleukin-1, prostaglandins, platelet activating factor, and nitric oxide. TNF alpha level is increased in patients with Crohn's disease. Inhibition of TNF alpha causes C-reactive protein level to decline in patients with Crohn's disease, and the disease improves.

Contraindications

Active infection, hypersensitivity to certolizumab or its components, I.V. administration

Interactions

DRUGS

anakinra: Possibly increased risk of serious infection and neutropenia
immunosuppressants: Possibly increased risk of infection
live-virus vaccines: Increased risk of adverse vaccine effects

Adverse Reactions

CNS: Anxiety, bipolar disorder, dizziness, fever, malaise, suicidal ideation, syncope
CV: Angina, arrhythmias, heart failure, hypertension, hypotension, MI, pericardial effusion, pericarditis, peripheral edema, vasculitis
EENT: Optic neuritis, retinal hemorrhage, uveitis

ENDO: Hot flashes

GI: Abdominal pain, diarrhea, elevated liver enzymes, hepatitis, intestinal obstruction

GU: Menstrual dysfunction, nephrotic syndrome, pyelonephritis, renal failure, UTI

HEME: Anemia, leukopenia, lymphadenopathy, pancytopenia, thrombophilia

MS: Arthralgia, extremity pain

RESP: Dyspnea, pneumonia, upper respiratory infection

SKIN: Allergic dermatitis, alopecia, erythema multiforme, erythema nodosum, new or worsening psoriasis, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Angioedema; bacterial and viral infections; injection site reactions (redness, pain); leukemia, lymphomas, and other malignancies; lupus-like syndrome; serum sickness; tuberculosis

Nursing Considerations

- Use certolizumab cautiously in patients with recurrent or increased risk of infection, patients who live in regions where tuberculosis and histoplasmosis are endemic, and patients with a history of CNS demyelinating disorders because any of these disorders can occur, rarely, during certolizumab therapy.
- Use cautiously in patients who are chronic carriers of hepatitis B virus because drug may reactivate the virus. Assess patient for evidence of hepatitis B viral infection before starting and periodically throughout certolizumab therapy. If HBV reactivation occurs, notify prescriber, stop drug, and start appropriate therapy, as ordered.

WARNING If patient has evidence of an active infection when drug is prescribed, therapy shouldn't begin until infection has been treated. Monitor all patients for infection during therapy, especially those receiving immunosuppressants. If serious infection develops, expect prescriber to stop drug.

- Make sure patient has a tuberculin skin test before therapy starts. If skin test is positive, treatment of latent tuberculosis must start before certolizumab is given, as prescribed.
- Reconstitute two 200-mg certolizumab vials for each dose after drug has reached room temperature. Inject 1 ml sterile water for injection using a 20G needle into each vial. Gently swirl each vial without

shaking. Then leave vials undisturbed for up to 30 minutes to allow time for powder to completely dissolve. Do not leave at room temperature, once reconstituted, for more than 2 hours before administration. If administration will be delayed, reconstituted drug can be refrigerated up to 24 hours. Do not let drug freeze.

- Administer drug only when solution has reached room temperature. Using a 20G needle, withdraw drug from vial using a separate syringe and needle for each vial. Switch to a 23G needle and administer subcutaneously into two separate areas on patient's abdomen or thigh.

WARNING Stop drug immediately and notify prescriber if patient has an allergic reaction. Expect to provide supportive care.

- Monitor patient closely for evidence of congestive heart failure (sudden, unexplained weight gain; dyspnea; crackles; anxiety), and notify prescriber if they occur.
- Monitor patient's CBC, as ordered, because certolizumab may have adverse hematologic effects. Notify prescriber about persistent fever, bruising, bleeding, or pallor.
- Certolizumab is a TNF inhibitor. Although rare, malignancies (especially lymphomas and leukemias) have been reported in patients receiving these drugs, including children. Patients with rheumatoid arthritis, especially those with very active disease, are at greatest risk. Monitor them closely.

PATIENT TEACHING

- Review signs and symptoms of allergic reaction (rash, swollen face, trouble breathing), and tell patient to seek emergency care immediately if these occur.
- Inform patient that injection site reactions such as redness or pain may occur and usually are mild and transient. Instruct him to apply a towel soaked in cold water to the site if it hurts. Tell patient to call prescriber if reaction persists or worsens.
- Inform patient that tuberculosis may occur during therapy. Instruct him to report persistent cough, wasting or weight loss, and low-grade fever to prescriber.
- Tell patient to report evidence of infections and bleeding disorders to prescriber; drug may need to be stopped. Advise

patient to avoid people with infections and to comply with all prescribed tests.

- Inform patient that certain kinds of cancer, especially lymphomas and leukemias, are more likely in patients taking certolizumab but still rare. Stress need to keep follow-up visits and report unusual or sudden signs or symptoms.
- Caution against receiving live-virus vaccines while taking certolizumab; doing so may adversely effect the immune system.
- Instruct patient to report lupus-like signs and symptoms that, although rare, may occur during therapy, such as chest pain that doesn't go away, shortness of breath, joint pain, or rash on cheeks or arms that's sensitive to the sun. Explain that drug may need to be discontinued if these occur.
- Advise patient to inform all health care providers about certolizumab use and to inform prescriber about any OTC medications, herbal remedies, and vitamin and mineral supplements being taken.

cevimeline hydrochloride

Evoxac

Class and Category

Chemical class: Quinuclidine derivative of acetylcholine

Therapeutic class: Cholinergic enhancer, dry mouth reliever

Pregnancy category: C

Indications and Dosages

↗ *To treat dry mouth associated with Sjögren's syndrome*

CAPSULES

Adults. 30 mg t.i.d. *Maximum:* 90 mg daily.

Mechanism of Action

As a cholinergic agonist, binds to and activates muscarinic receptors of the parasympathetic nervous system and increases secretions of the exocrine glands, such as salivary glands.

Contraindications

Acute iritis, angle-closure glaucoma, hypersensitivity to cevimeline or its components, uncontrolled asthma

Interactions

DRUGS

amiodarone, cimetidine, clarithromycin, diltiazem, erythromycin, fluconazole, haloperidol, itraconazole, ketoconazole, metoclopramide, mibefradil, nefazodone, propafenone, quinidine, ritonavir, selective serotonin reuptake inhibitors, thioridazine, tricyclic antidepressants, troleandomycin, verapamil: Possibly inhibited metabolism and increased blood level of cevimeline

anticholinergics: Decreased effectiveness of anticholinergics

antimuscarinics: Altered effects of antimuscarinics and decreased therapeutic action of cevimeline

beta blockers: Possibly cardiac conduction disturbances

parasympathomimetics: Additive effects of either drug

Adverse Reactions

CNS: Depression, fatigue, fever, hypoesthesia, insomnia, migraine headache, tremor

CV: Edema, palpitations

EENT: Abnormal vision, conjunctivitis, dry mouth, earache, epistaxis, excessive salivation, eye pain, rhinitis, salivary gland pain

GI: Abdominal pain, anorexia, cholecystitis, constipation, eructation, heartburn, hiccups, nausea, vomiting

HEME: Anemia

MS: Arthralgia, leg cramps, myalgia

RESP: Cough, dyspnea

SKIN: Diaphoresis, pruritus

Other: Flulike symptoms, hot flashes

Nursing Considerations

- Give cevimeline on an empty stomach because food may decrease rate and extent of absorption, delaying peak concentration.
- Assess patient with a pulmonary disorder for wheezing and increased respiratory secretions because drug may cause increased bronchiolar smooth-muscle contractions, airway resistance, and respiratory secretions.
- Monitor patient with known or suspected gallbladder disease for abdominal pain and other warnings of biliary obstruction, cholecystitis, or cholangitis; each of these conditions may be precipitated by cevimeline.

PATIENT TEACHING

- Instruct patient to take cevimeline on an

empty stomach.

- Inform patient that cevimeline may cause vision changes; advise him to avoid driving at night or performing hazardous activities until drug's adverse effects are known.
- Urge patient to drink plenty of fluids during hot weather and while exercising because drug may cause excessive sweating and dehydration.

chloral hydrate

Aquachloral Supporettes, Novo-Chlorhydrate (CAN), PMS-Chloral Hydrate (CAN)

Class, Category, and Schedule

Chemical class: Chloral derivative

Therapeutic class: Sedative-hypnotic

Pregnancy category: C

Controlled substance schedule: IV

Indications and Dosages

➤ *To prevent or suppress alcohol withdrawal symptoms, act as an adjunct to opioids and analgesics to control postoperative pain*

CAPSULES, SYRUP, SUPPOSITORIES

Adults. 250 mg t.i.d. after meals. *Maximum:* 2,000 mg.

➤ *To produce nocturnal sedation*

CAPSULES, SYRUP, SUPPOSITORIES

Adults. 0.5 to 1 g 30 min before bedtime.

Maximum: 2 g.

➤ *To produce preoperative sedation*

CAPSULES, SYRUP, SUPPOSITORIES

Adults. 0.5 to 1 g 30 min before surgery.

➤ *To provide sedation before dental or medical procedure*

SYRUP, SUPPOSITORIES

Children. 25 mg/kg up to 500 mg/single dose; up to 75 mg/kg for dental procedure supplemented by nitrous oxide.

Route	Onset	Peak	Duration
P.O.	30–60 min	Unknown	4–8 hr
P.R.	Unknown	Unknown	4–8 hr

Mechanism of Action

Produces CNS depression by an unknown mechanism involving trichloroethanol, the drug's active metabolite.

Contraindications

Gastritis; hypersensitivity or idiosyncrasy to chloral hydrate or its components; severe cardiac, hepatic, or renal disease

Interactions**DRUGS**

CNS depressants: Increased CNS effects of chloral hydrate

furosemide (I.V.): Increased adverse effects when given after chloral hydrate

phenytoin: Increased excretion and decreased effectiveness of phenytoin

warfarin: Transient increase in anticoagulant effect

ACTIVITIES

alcohol use: Increased CNS effects of chloral hydrate

Adverse Reactions

CNS: Ataxia, disorientation, hangover, incoherence, paranoia, somnolence

GI: Gastric irritation, nausea, vomiting

SKIN: Rash, urticaria

Other: Drug dependence

Nursing Considerations

- Administer with full glass of water or juice to minimize GI distress from chloral hydrate capsules. Dilute syrup in a half-glass of water, ginger ale, or fruit juice.

WARNING Monitor carefully for hypersensitivity reaction in patients with a history of tartrazine sensitivity.

- Suspect physical or psychological dependence if withdrawal of chloral hydrate produces confusion, hallucinations, nausea, nervousness, restlessness, stomach pain, tremor, unusual excitement, or vomiting.

PATIENT TEACHING

- Instruct patient to take capsules with a full glass of water or juice or to mix syrup in a half-glass of water, ginger ale, or fruit juice.
- Advise patient to avoid hazardous activities until CNS effects of chloral hydrate are known.
- Caution patient that drug may be habit-forming. Advise taking it exactly as prescribed and not to stop taking it abruptly because withdrawal symptoms could occur.
- Instruct patient to notify prescriber right away about stomach pains or tarry stools.

chloramphenicol

Chloromycetin, Novochlorocap (CAN)

chloramphenicol palmitate

Chloromycetin

chloramphenicol sodium succinate

Chloromycetin

Class and Category

Chemical class: Dichloroacetic acid derivative

Therapeutic class: Antibiotic

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat serious infections for which less potentially dangerous drugs are ineffective or contraindicated*

I.V. INFUSION

Adults. 12.5 mg/kg every 6 hr. *Maximum*: 4 g daily.

Children. 50 to 75 mg/kg daily in divided doses every 6 hr.

Full-term infants age 2 weeks and over.

12.5 mg/kg every 6 hr or 25 mg/kg every 12 hr.

Preterm and full-term infants up to age 2 weeks. 6.25 mg/kg every 6 hr.

↗ *To treat bacteremia or meningitis*

I.V. INFUSION

Children. 50 to 100 mg/kg daily in divided doses every 6 hr.

DOSAGE ADJUSTMENT Dosage limited to 25 mg/kg daily for infants and children with immature metabolic processes.

Mechanism of Action

Produces a bacteriostatic effect on susceptible organisms by inhibiting protein synthesis, thus preventing amino acids from being transferred to growing polypeptide chains.

Contraindications

Hypersensitivity to chloramphenicol or its components

Interactions**DRUGS**

alfentanil: Prolonged alfentanil effect

barbiturates: Increased blood barbiturate level; decreased chloramphenicol level
blood-dyscrasia-causing drugs (such as captopril and cephalosporins), bone marrow depressants (including colchicine and methotrexate): Increased bone marrow depression
chlorpropamide, tolbutamide: Increased hypoglycemic effects
clindamycin, erythromycin, lincomycin: Decreased antibacterial effects of these drugs
cyclophosphamide: Decreased or delayed activation of cyclophosphamide, increased bone marrow depression
hepatic enzyme inducers (including rifampin): Decreased chloramphenicol level
hydantoins: Increased blood hydantoin level, possibly resulting in toxicity; increased or decreased blood chloramphenicol level
iron salts: Increased serum iron level
oral anticoagulants: Enhanced anticoagulant action
oral contraceptives containing estrogen: Decreased contraceptive effect with prolonged chloramphenicol use
penicillins: Decreased penicillin activity; synergistic effects with treatment of certain microorganisms
vitamin B₁₂: Antagonized hematopoietic response to vitamin B₁₂

Adverse Reactions

CNS: Confusion, delirium, depression, fever, headache, peripheral neuropathy

CV: Gray syndrome in neonates

EENT: Optic neuritis

GI: Diarrhea, nausea, vomiting

HEME: Aplastic anemia, bone marrow depression, granulocytopenia, hypoplastic anemia, leukopenia, reticulocytopenia, thrombocytopenia

SKIN: Rash

Other: Anaphylaxis, angioedema

Nursing Considerations

- As appropriate and ordered, obtain specimen for culture and sensitivity testing before starting chloramphenicol therapy.
- Keep in mind that chloramphenicol should never be used to treat minor infections or as prophylaxis because of its many serious toxicities.
- Repeated courses of therapy should be avoided because of the risk of serious

adverse reactions.

- For I.V. use, prepare a 10% solution by adding 10 ml sterile water for injection or D₅W to each 1-g vial. Administer over at least 1 minute.
 - Know that diluted I.V. solution is stable for 24 to 48 hours when stored at room temperature or refrigerated. Don't use if cloudy.
 - Assess patient for fever, sore throat, tiredness, unusual bleeding, or ecchymosis; these may indicate a blood dyscrasia.
 - Perform neurologic assessments regularly, looking for signs of peripheral neuropathy.
- WARNING** If early signs of gray syndrome appear (failure to eat, pallor, cyanosis, abdominal distention, irregular respirations, and vasomotor collapse), notify prescriber and be prepared to stop drug immediately.
- Monitor blood chloramphenicol level as appropriate. Keep in mind that therapeutic peak levels are 10 to 20 mcg/ml and trough levels are 5 to 10 mcg/ml.
 - Monitor CBC and platelet and reticulocyte counts as ordered to detect signs of blood dyscrasia. Notify prescriber immediately about abnormal results.

PATIENT TEACHING

- Instruct patient to immediately report to prescriber signs of blood dyscrasia.

WARNING Tell patient to stay alert for signs of potentially fatal, irreversible bone marrow depression that leads to aplastic anemia and is characterized by fever, pallor, pharyngitis, severe fatigue and weakness, and unusual bleeding or bruising. Bone marrow depression may occur weeks to months after therapy stops. Stress the need for follow-up care.

chlordiazepoxide hydrochloride

Apo-Chlordiazepoxide (CAN), Librium, Novo-Poxide (CAN)

Class, Category, and Schedule

Chemical class: Benzodiazepine

Therapeutic class: Antianxiety

Pregnancy category: Not rated

Controlled substance schedule: IV

Indications and Dosages

↗ *To provide short-term management of mild anxiety*

CAPSULES, TABLETS

Adults. 5 to 10 mg t.i.d. or q.i.d.

Children over age 6. 5 mg b.i.d. to q.i.d. increased as needed to 10 mg b.i.d. or t.i.d., or 0.5 mg/kg daily in equally divided doses every 6 to 8 hr.

↗ *To provide short-term management of severe anxiety*

CAPSULES, TABLETS

Adults. 20 to 25 mg t.i.d. or q.i.d.

I.V. OR I.M. INJECTION

Adults. *Initial:* 50 to 100 mg. Then, 25 to 50 mg t.i.d. or q.i.d., p.r.n. *Maximum:* 300 mg daily.

I.M. INJECTION

Children age 12 and over. 0.5 mg/kg daily in equally divided doses every 6 to 8 hr.

↗ *To provide short-term treatment of acute alcohol withdrawal*

CAPSULES, TABLETS, I.V. OR I.M. INJECTION

Adults. *Initial:* 50 to 100 mg, usually given I.V. or I.M. Repeated in 2 to 4 hr followed by individualized oral dosage if needed to control symptoms. *Maximum:* 300 mg daily.

↗ *To provide perioperative relaxation and reduce apprehension and anxiety*

CAPSULES, TABLETS, I.M. INJECTION

Adults. 5 to 10 mg P.O. t.i.d. or q.i.d. several days before surgery; 50 to 100 mg I.M. 1 hr before surgery.

DOSAGE ADJUSTMENT Dosage reduced to 5 mg P.O. b.i.d. to q.i.d., p.r.n., for elderly or debilitated patients.

Mechanism of Action

May potentiate the effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptors in limbic and cortical areas of the CNS. By binding to these receptors, chlordiazepoxide increases GABA's inhibitory effects and blocks cortical and limbic arousal, which helps control emotional behavior. It also helps relieve symptoms of alcohol withdrawal by causing CNS depression.

Contraindications

Hypersensitivity to chlordiazepoxide or its components

Interactions

DRUGS

antacids: Altered rate of chlordiazepoxide absorption
cimetidine, disulfiram, fluoxetine, isoniazid, ketoconazole, metoprolol, oral contraceptives, propoxyphene, propranolol, valproic acid: Increased blood chlordiazepoxide level
CNS depressants: Increased CNS effects
digoxin: Increased blood digoxin level and risk of digitalis toxicity
levodopa: Decreased efficacy of levodopa's antiparkinsonian effects
neuromuscular blockers: Potentiated, counteracted, or diminished effects of neuromuscular blockers
phenytoin: Possibly increased phenytoin toxicity
probenecid: Shortened onset of action or prolonged effect of chlordiazepoxide
rifampin: Decreased chlordiazepoxide effect
theophyllines: Antagonized sedative effects of chlordiazepoxide

ACTIVITIES

alcohol use: Increased CNS effects

Adverse Reactions

CNS: Ataxia, confusion, depression, drowsiness, suicidal ideation
CV: ECG changes, hypotension, tachycardia
GI: Hepatic dysfunction
HEME: Agranulocytosis
SKIN: Jaundice
Other: Injection site pain, redness, and swelling

Nursing Considerations

- Use chlordiazepoxide cautiously in patients with renal or hepatic impairment or porphyria.

WARNING Be aware that prolonged use of chlordiazepoxide at therapeutic doses can lead to dependence.

- For I.V. use, reconstitute ampule contents with 5 ml sterile water for injection or sodium chloride for injection. Agitate gently until completely dissolved. Give slowly over 1 minute.
- For I.M. use, reconstitute only with diluent provided by manufacturer.

WARNING Don't use supplied diluent to prepare drug for I.V. use because air bubbles form on the surface.

- Don't give opalescent or hazy solution.
- Monitor patient for evidence of phlebitis

or thrombophlebitis after I.V. chlor-diazepoxide administration.

- Monitor liver function test results during therapy.
- If patient is a hyperactive, aggressive child or has a history of psychiatric disorders, watch for paradoxical reactions, such as excitement, stimulation, and acute rage, during first 2 weeks of therapy.
- Watch patients closely (especially children, adolescents, and young adults) for suicidal tendencies, particularly when chlorthiazepoxide therapy starts and dosage changes.

PATIENT TEACHING

- Warn that drug may cause drowsiness.
- Advise patient to avoid other CNS depressants during therapy.
- Warn patient not to take antacids with chlorthiazepoxide.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.

chlorothiazide

Diuril

chlorothiazide sodium

Diuril

Class and Category

Chemical class: Sulfonamide derivative

Therapeutic class: Antihypertensive, diuretic

Pregnancy category: B

Indications and Dosages

↗ *To treat hypertension*

ORAL SUSPENSION, TABLETS

Adults. 250 to 1,000 mg daily in a single dose or divided doses b.i.d. *Maximum:* 2,000 mg daily in divided doses.

Children age 6 months and over. 10 to 20 mg/kg daily in a single dose or divided doses b.i.d. *Maximum:* 1,000 mg daily for ages 2 to 12; 375 mg daily for ages 6 months to 2 years.

Children under age 6 months. Up to 30 mg/kg daily in divided doses given b.i.d.

↗ *To produce diuresis*

ORAL SUSPENSION, TABLETS

Adults. 250 mg every 6 to 12 hr.

Administered on an intermittent schedule, if needed, such as alternate days or 3 to 5 days/wk.

Children age 6 months and over. 10 to 20 mg/kg daily in a single dose or divided doses b.i.d. *Maximum:* 1,000 mg daily for children ages 2 to 12; 375 mg daily for children ages 6 months to 2 years.

Children under age 6 months. Up to 33 mg/kg daily in divided doses b.i.d.

I.V. INFUSION OR INJECTION

Adults. 250 mg every 6 to 12 hr.

Route	Onset	Peak	Duration
P.O.	2 hr	4 hr	6–12 hr
I.V.	15 min	4 hr	6–12 hr

Mechanism of Action

May promote sodium, chloride, and water excretion by inhibiting sodium reabsorption in the kidneys' distal tubules. Initially, chlorothiazide may reduce blood pressure by decreasing extracellular fluid volume, plasma volume, and cardiac output. It also may dilate arteries directly, reducing peripheral vascular resistance. After several weeks, extracellular fluid and plasma volume and cardiac output return to normal, but peripheral vascular resistance remains decreased.

Contraindications

Anuria; hepatic coma; hypersensitivity to chlorothiazide or its components, sulfonamides, or related thiazide diuretics; renal failure

Interactions

DRUGS

allopurinol: Increased risk of allopurinol hypersensitivity

amiodarone: Increased risk of arrhythmias from hypokalemia

amphotericin B, glucocorticoids: Intensified electrolyte depletion

anesthetics: Potentiated effects of anesthetics

anticholinergics: Increased chlorothiazide absorption

anticoagulants, methenamines, sulfonyleureas: Decreased effects of these drugs

antihypertensives: Increased antihypertensive effect

antineoplastics: Prolonged antineoplastic-induced leukopenia

calcium: Possibly increased blood calcium level

cholestyramine, colestipol: Decreased chlorothiazide absorption

diazoxide: Hyperglycemia, hypotension

digitalis glycosides: Increased risk of digitalis-induced arrhythmias

dopamine: Increased diuretic effect

lithium: Increased risk of lithium toxicity

loop diuretics: Synergistic effects, resulting in profound diuresis and serious electrolyte imbalances

methyl dopa: Potential development of hemolytic anemia

neuromuscular blockers: Increased neuromuscular blockade

NSAIDs: Possibly reduced diuretic effect of chlorothiazide; increased risk of renal failure if patient has compromised renal function

sympathomimetics: Possibly inhibited anti-hypertensive effect of chlorothiazide

vitamin D: Enhanced vitamin D action

Adverse Reactions

CNS: Dizziness, headache, paresthesia, restlessness, vertigo, weakness

CV: Orthostatic hypotension

ENDO: Hyperglycemia

GI: Abdominal cramps, anorexia, constipation, diarrhea, gastric irritation, nausea, pancreatitis, vomiting

GU: Glycosuria, hematuria (I.V. form), impotence, interstitial nephritis, renal dysfunction or failure

HEME: Agranulocytosis, aplastic anemia, hemolytic anemia, leukopenia, thrombocytopenia

MS: Muscle spasms

SKIN: Jaundice, photosensitivity, purpura, rash, urticaria

Other: Anaphylactic reactions, hypercalcemia, hyperuricemia, hypochloremic alkalosis, hypokalemia, hypomagnesemia, hyponatremia, hypovolemia

Nursing Considerations

- Don't give parenteral form of chlorothiazide by I.M. or subcutaneous route.
- For I.V. use, reconstitute with at least 18 ml of sterile water for injection. Discard unused solution after 24 hours. Reconstituted solution is compatible with dextrose solution or normal saline solution for infusion.

- Watch I.V. site closely. If extravasation occurs, stop infusion and tell prescriber at once.
- Weigh patient daily to assess fluid loss and drug effectiveness. If used to treat hypertension, check blood pressure often; anti-hypertensive effect may not appear for days.
- Assess patient for electrolyte imbalances.
- Monitor renal function closely, especially in elderly patients, because risk of toxicity increases with renal impairment.

PATIENT TEACHING

- Tell patient to take chlorothiazide early in the day to avoid nocturia and to take it with food or milk if GI distress occurs.
- Urge patient to eat a high-potassium diet.
- Instruct patient to rise slowly to minimize effects of orthostatic hypotension.
- Urge patient to weigh himself at least weekly and to notify prescriber if weight rises or falls by 5 lb (2.25 kg) or more in 2 days.
- Tell patient to immediately notify prescriber if he develops weakness, cramps, nausea, vomiting, restlessness, excessive thirst, drowsiness, tiredness, increased heart rate, diarrhea, sudden joint pain, or dizziness.
- If patient has diabetes mellitus, tell him to check blood glucose level often. Oral antidiabetic dosage may need to be increased.
- Tell patient to avoid prolonged exposure to sun, use sunscreen, and wear protective clothing.
- Advise patient to consult prescriber or pharmacist before using alcohol and such OTC drugs as those used for appetite control, colds, cough, hay fever, and sinus problems.

chlorphenesin carbamate

Maolate

Class and Category

Chemical class: Chemically related to mephenesin

Therapeutic class: Skeletal muscle relaxant

Pregnancy category: Not rated

Indications and Dosages

↗ *As adjunct to relieve pain in acute musculoskeletal conditions*

TABLETS

Adults. 800 mg t.i.d. until desired effect occurs. *Maintenance:* 400 mg q.i.d or less, p.r.n.

Mechanism of Action

May act on the CNS, rather than directly on skeletal muscle, producing a sedative effect that aids in muscle relaxation.

Contraindications

Hypersensitivity to chlorphenesin or its components

Interactions

DRUGS

CNS depressants: Increased adverse CNS effects

ACTIVITIES

alcohol use: Increased adverse CNS effects

Adverse Reactions

CNS: Confusion, dizziness, drowsiness, headache, insomnia, nervousness, paradoxical stimulation

EENT: Diplopia, transient vision loss

GI: Epigastric discomfort, nausea

Other: Anaphylaxis, drug-induced fever

Nursing Considerations

WARNING Use chlorphenesin cautiously in patients hypersensitive to aspirin; it contains tartrazine, which may cause hypersensitivity.

- Expect drug therapy to last for no more than 8 weeks because safety beyond this point is unknown.
- Provide rest and other pain-relief measures.

PATIENT TEACHING

- Because of possible reduced alertness, advise patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Instruct patient to notify prescriber if these symptoms occur: confusion, dizziness, drowsiness, insomnia, nervousness, or paradoxical stimulation.
- Tell patient to immediately notify prescriber if he develops a fever or any signs or symptoms of an allergic reaction, such as rash, hives, itching, facial swelling, or difficulty breathing.

chlorpromazine

Largactil (CAN), Thorazine

chlorpromazine hydrochloride

Chlorpromanyl (CAN), Novo-Chlorpromazine (CAN), Thorazine, Thorazine Spansule

Class and Category

Chemical class: Propylamine derivative of phenothiazine

Therapeutic class: Antiemetic, antipsychotic, tranquilizer

Pregnancy category: Not rated

Indications and Dosages

↗ *To manage symptoms of psychotic disorders or control manic manifestations of manic-depression in outpatients*

E.R. CAPSULES

Adults. 30 to 300 mg 1 to 3 times daily, with dosage adjusted as needed. *Maximum:* 1 g daily.

ORAL CONCENTRATE, SYRUP, TABLETS

Adults. 10 mg t.i.d. or q.i.d., or 25 mg b.i.d. or t.i.d. After 1 or 2 days, dose increased by 20 to 50 mg semiweekly until patient is calm. After 2 wk of calmness, dosage gradually reduced to maintenance level of 200 to 800 mg daily in equally divided doses.

↗ *To control acutely disturbed or manic hospitalized patients*

I.M. INJECTION

Adults. 25 mg. Repeated 25 to 50 mg in 1 hr, if needed. Increased gradually over several days up to 400 mg every 4 to 6 hr for severe cases until behavior is controlled. Then, regimen switched to oral form and outpatient dosage.

↗ *To treat severe behavioral problems in children*

ORAL CONCENTRATE, SYRUP, TABLETS

Children ages 6 months to 12 years.

0.55 mg/kg every 4 to 6 hr, p.r.n.

SUPPOSITORIES

Children ages 6 months to 12 years. 1 mg/kg every 6 to 8 hr, p.r.n.

I.M. INJECTION

Children ages 6 months to 12 years.

0.55 mg/kg every 6 to 8 hr. *Maximum:*

75 mg daily for children ages 5 to 12 years

or weighing 50 to 100 lb (23 to 45 kg), except in unmanageable cases; 40 mg daily for children up to age 5 or weighing up to 50 lb.

↗ *To treat nausea and vomiting*

ORAL CONCENTRATE, SYRUP, TABLETS

Adults and adolescents. 10 to 25 mg every 4 to 6 hr, p.r.n.

Children ages 6 months to 12 years.

0.55 mg/kg every 4 to 6 hr, p.r.n.

I.M. INJECTION

Adults. 25 mg. If no hypotension occurs, 25 to 50 mg every 3 to 4 hr, p.r.n., until vomiting stops; then drug switched to oral form.

Children age 6 months and over. 0.55 mg/kg every 6 to 8 hr, p.r.n. *Maximum:* 75 mg daily for children ages 5 to 12 or weighing 50 to 100 lb; 40 mg daily for children up to age 5 or weighing up to 50 lb.

SUPPOSITORIES

Adults and adolescents. 50 to 100 mg every 6 to 8 hr, p.r.n.

Children ages 6 months to 12 years. 1 mg/kg every 6 to 8 hr, p.r.n.

↗ *To provide intraoperative control of nausea and vomiting*

I.V. INJECTION

Adults. 25 mg diluted to 1 mg/ml with sodium chloride for injection and given at no more than 2 mg every 2 min. *Maximum:* 25 mg.

Children age 6 months and over. 0.275 mg/kg diluted to at least 1 mg/ml with sodium chloride for injection and given at no more than 1 mg every 2 min. *Maximum:* 75 mg/day for children ages 5 to 12 or weighing 50 to 100 lb; 40 mg daily for children up to age 5 years or weighing up to 50 lb.

I.M. INJECTION

Adults. 12.5 mg. Repeated in 30 min if needed and no hypotension occurs.

Children age 6 months and over. 0.275 mg/kg. Repeated in 30 min if needed and tolerated.

↗ *To treat intractable hiccups*

TABLETS

Adults. 25 to 50 mg t.i.d. or q.i.d. If hiccups last longer than 2 days, route switched to I.M., as prescribed.

I.V. INFUSION

Adults. 25 to 50 mg diluted in 500 to 1,000 ml of normal saline solution and given at 1 mg/min with patient supine.

I.M. INJECTION

Adults. 25 to 50 mg given only if oral route is ineffective. If symptoms persist, route switched to I.V., as prescribed.

↗ *To provide preoperative relaxation*

ORAL CONCENTRATE, SYRUP, TABLETS

Adults and adolescents. 25 to 50 mg 2 to 3 hr before surgery.

Children ages 6 months to 12 years.

0.55 mg/kg 2 to 3 hr before surgery.

I.M. INJECTION

Adults. 12.5 to 25 mg 1 to 2 hr before surgery.

Children age 6 months and over. 0.55 mg/kg 1 to 2 hr before surgery.

↗ *To treat acute intermittent porphyria*

ORAL CONCENTRATE, SYRUP, TABLETS

Adults and adolescents. 25 to 50 mg t.i.d. or q.i.d.

I.M. INJECTION

Adults. 25 mg t.i.d. or q.i.d. until oral route is possible.

↗ *To treat tetanus (usually as adjunct with barbiturates)*

I.V. INFUSION

Adults. 25 to 50 mg diluted to at least 1 mg/ml and given at no more than 1 mg/min.

Children age 6 months and over. 0.55 mg/kg every 6 to 8 hr, diluted to at least 1 mg/ml and given at no more than 1 mg/2 min. *Maximum:* 75 mg daily for children ages 5 to 12 years or weighing 50 to 100 lb; 40 mg daily for children up to age 5 years or weighing up to 50 lb.

I.M. INJECTION

Adults. 25 to 50 mg t.i.d. or q.i.d.

Children age 6 months and over. 0.55 mg/kg every 6 to 8 hr. *Maximum:* 75 mg daily for children ages 5 to 12 or weighing 50 to 100 lb; 40 mg daily for children up to age 5 years or weighing up to 50 lb.

DOSAGE ADJUSTMENT Dosage possibly reduced for patients with hepatic dysfunction. Dosage reduced to one-third to one-half the normal adult dosage for elderly or debilitated patients.

Mechanism of Action

Depresses brain areas that control activity and aggression, including the cerebral cortex, hypothalamus, and limbic system, by an unknown mechanism. Prevents nausea and vomiting by inhibiting or blocking dopamine receptors in the medullary

chemoreceptor trigger zone and peripherally by blocking the vagus nerve in the GI tract. May relieve anxiety by indirect reduction in arousal and increased filtering of internal stimuli to the reticular activating system in the brain stem.

Incompatibilities

Don't mix chlorpromazine with thiopental, atropine, or solutions that don't have a pH of 4 to 5 because a precipitate will form. Don't mix chlorpromazine injection with other drugs in a syringe.

Contraindications

Comatose states; hypersensitivity to chlorpromazine, phenothiazines, or their components; use of large amounts of CNS depressants

Interactions

DRUGS

amphetamines: Decreased amphetamine effectiveness, decreased antipsychotic effectiveness of chlorpromazine

antacids (aluminum hydroxide or magnesium trisilicate gel): Decreased chlorpromazine absorption and effectiveness

barbiturates: Decreased plasma level and, possibly, effectiveness of chlorpromazine

CNS depressants: Prolonged and intensified CNS depression

metrizamide: Possibly lowered seizure threshold

oral anticoagulants: Decreased anticoagulation

phenytoin: Interference with phenytoin metabolism, increased risk of phenytoin toxicity

propranolol: Increased plasma levels of both drugs

thiazide diuretics: Possibly increased orthostatic hypotension

ACTIVITIES

alcohol use: Prolonged and intensified CNS depression

Adverse Reactions

CNS: Drowsiness, extrapyramidal reactions (such as dystonia, fever, motor restlessness, pseudoparkinsonism, and tardive dyskinesia), neuroleptic malignant syndrome, seizures

CV: ECG changes, such as nonspecific, usually reversible Q- and T-wave changes; orthostatic hypotension; tachycardia

EENT: Blurred vision, dry mouth, nasal congestion, ocular changes (fine particle deposits in lens and cornea) with long-term therapy

ENDO: Gynecomastia, hyperglycemia, hypoglycemia, lactation, moderate breast engorgement

GI: Constipation, ileus, nausea

GU: Amenorrhea, ejaculation disorders, impotence, priapism, urine retention

HEME: Agranulocytosis, aplastic anemia, eosinophilia, hemolytic anemia, leukopenia, pancytopenia, thrombocytopenic purpura

SKIN: Exfoliative dermatitis, jaundice, photosensitivity, tissue necrosis, urticaria

Nursing Considerations

- Don't open or crush E.R. capsules.
- Chlorpromazine shouldn't be used to treat dementia-related psychosis in the elderly because of an increased risk of death.
- Use chlorpromazine cautiously in patients (especially children) with chronic respiratory disorders (such as severe asthma or emphysema) or acute respiratory tract infections because drug has CNS depressant effect. Also use cautiously in patients with cardiovascular, hepatic, or renal disease because of increased risk of developing hypotension, heart failure, and arrhythmias.
- Because of chlorpromazine's anticholinergic effects, use it cautiously in patients with glaucoma. Also use it cautiously in those who are exposed to extreme heat or organophosphate insecticides and those receiving atropine or related drugs.
- Protect concentrate from light. Refrigeration isn't required.
- Dilute concentrate in at least 60 ml of diluent just before administering it. Use tomato or fruit juice, milk, simple syrup, orange syrup, a carbonated beverage, coffee, tea, water, or semisolid food, such as pudding and soup.
- Protect parenteral solution from light. Solution should be clear and colorless to pale yellow. Discard markedly discolored solution.
- Don't inject drug by subcutaneous route because it can cause severe tissue necrosis.
- Wear gloves when working with liquid or injectable form because parenteral solution may cause contact dermatitis.

- For I.V. injection, dilute chlorpromazine with sodium chloride to a concentration of 1 mg/ml.
- Give I.M. injection slowly and deep into upper outer quadrant of buttocks, such as in the gluteus maximus. To minimize hypotensive effects, keep patient lying flat and monitor blood pressure for 30 minutes after injection.

WARNING Stay alert for possible suppressed cough reflex, which increases the risk of the patient's aspirating vomitus.

- Monitor patient for increased sensitivity to drug's CNS effects if patient has a history of hepatic encephalopathy from cirrhosis.

WARNING If neuroleptic malignant syndrome (hyperpyrexia, muscle rigidity, altered mental status, autonomic instability) develops, notify prescriber immediately and expect to stop drug and start intensive treatment. Watch for recurrence if patient resumes antipsychotic therapy.

PATIENT TEACHING

- Instruct patient to swallow E.R. capsules whole and not to crush, break, or chew them.
- Tell patient not to take drug within 2 hours of an antacid. Allow him to take drug with food or a full glass of milk or water.
- If patient uses suppository form, tell him to chill the suppository, moisten it with cold water, and insert it well into rectum.
- Tell patient to store oral concentrate at room temperature, away from light, to measure it with the dropper provided, and to dilute it in 4 oz of fluid just before use.
- Because of possible drowsiness, dizziness, and blurred vision (especially during the first few days of therapy), advise patient to avoid hazardous activities until drug's CNS effects are known.
- Tell patient to avoid alcohol because of possible additive effects and hypotension.
- Advise patient, especially if elderly, to rise slowly from a supine or seated position to avoid dizziness, light-headedness, and fainting.
- Tell patient to inform doctors and dentists that he's taking chlorpromazine before he has surgery, medical tests, or dental work.
- Explain that drug may reduce the body's response to heat and cold; tell patient to avoid temperature extremes, as in a sauna,

hot tub, or very cold or hot shower.

Remind patient to dress warmly in cold weather.

- Warn patient not to take OTC drugs for a cold or an allergy because they can increase the risk of heatstroke and other unwanted effects.
- Inform patient that drug increases sensitivity to sunlight; tell him to stay out of the sun as much as possible and to protect his skin.
- If patient has dry mouth, suggest sugarless chewing gum, hard candy, and fluids.
- Urge patient to report sudden sore throat or other signs of infection.

chlorpropamide

Apo-Chlorpropamide (CAN), Diabinese, Novo-Propamide (CAN)

Class and Category

Chemical class: Sulfonylurea

Therapeutic class: Antidiabetic

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to manage non-insulin-dependent diabetes when diet alone fails to lower blood glucose level*

TABLETS

Adults. *Initial:* 250 mg daily for 5 to 7 days. After therapy begins, dosage may be adjusted up or down in increments of 50 to 125 mg at intervals of 3 to 5 days to obtain optimal control. *Maintenance:* 100 to 500 mg daily. *Maximum:* 750 mg daily.

DOSAGE ADJUSTMENT If patient takes more than 40 units of insulin daily, dosage reduced to half usual insulin dose for first few days of chlorpropamide therapy. Insulin dose can be reduced, depending on response. If patient takes oral antidiabetic drug or less than 40 units of insulin daily, it may be stopped abruptly when chlorpropamide starts.

Dosage reduced to half usual dose if patient has mild renal failure because metabolites and unchanged drug are excreted in urine. To avoid hypoglycemic reactions, initial dosage reduced to 100 to 125 mg daily for elderly, debilitated, or malnourished patients and patients with impaired hepatic function.

Mechanism of Action

Lowers blood glucose level by stimulating release of insulin from the pancreas in patients who have functioning beta cells. It also may increase insulin sensitivity in target tissues, which may result in a decrease in liver breakdown of glycogen to glucose or the liver's production of new glucose.

Route	Onset	Peak	Duration
P.O.	1 hr	3–6 hr	24–72 hr

Contraindications

Diabetic ketoacidosis (with or without coma), hypersensitivity to chlorpropamide or its components, type I diabetes mellitus

Interactions

DRUGS

androgens, anticoagulants, azole antifungals, chloramphenicol, clofibrate, fenfluramine, fluconazole, gemfibrozil, H₂-receptor antagonists, magnesium salts, MAO inhibitors, methyl dopa, probenecid, salicylates, sulfonpyrazone, sulfonamides, tricyclic antidepressants, urinary acidifiers: Increased hypoglycemic effect

barbiturates: Prolonged barbiturate action
beta blockers, calcium channel blockers, cholestyramine, corticosteroids, diazoxide, estrogens, hydantoins, isoniazid, nicotinic acid, oral contraceptives, phenothiazines, rifampin, sympathomimetics, thiazide diuretics, thyroid drugs, urinary alkalizers:

Decreased hypoglycemic effect
digitalis glycosides: Increased blood digitalis level

oral miconazole: Risk of severe hypoglycemia

ACTIVITIES

alcohol use: Disulfiram-like reaction

Adverse Reactions

ENDO: Hypoglycemia

GI: Anorexia, diarrhea, hunger, nausea, vomiting

HEME: Hemolytic anemia

SKIN: Maculopapular eruptions, photosensitivity, pruritus, urticaria

Other: Disulfiram-like reaction

Nursing Considerations

- Use chlorpropamide cautiously in patients with renal or hepatic dysfunction; in elderly, debilitated, or malnourished patients; and in those with adrenal or pituitary

insufficiency because of increased susceptibility to drug's hypoglycemic action.

- Use chlorpropamide cautiously in patients with glucose 6-phosphate dehydrogenase deficiency because sulfonureas, such as chlorpropamide, can cause hemolytic anemia.
- Monitor patient's blood glucose level often at start of therapy and during dosage adjustments or changes in patient's life, such as during stress and illness. Hypoglycemia may be difficult to recognize in elderly patients and those who take beta-adrenergic blockers.
- Assess patient for hypoglycemia—the most common adverse reaction to chlorpropamide—especially in patients whose caloric intake is deficient, who have just engaged in strenuous or prolonged exercise, who have ingested alcohol, or who take more than one glucose-lowering drug.
- Treat hypoglycemia promptly by giving 15 g of simple carbohydrate, such as 4 oz of orange juice or soda or 8 oz of milk. Repeat in 15 minutes, if needed. Because of drug's long half-life, careful monitoring and frequent feedings are required for 3 to 5 days after a hypoglycemic episode. Hospitalization and I.V. glucose may be needed.
- Monitor patients receiving long-term chlorpropamide therapy for secondary failure, which causes loss of blood glucose control despite adherence to prescribed drug therapy and diet and exercise guidelines. If secondary failure occurs, therapy should be discontinued and a different antidiabetic drug substituted.

PATIENT TEACHING

- Instruct patient to store chlorpropamide in a sealed container, protected from heat and light.
- Tell patient to take chlorpropamide with breakfast.
- Stress that drug works with diet and exercise to help control blood glucose level and isn't a substitute for them.
- Tell patient to monitor blood glucose level as instructed.
- Instruct patient not to skip meals or exercise excessively.
- Teach patient how to recognize and treat hypoglycemia. Tell him to report frequent

- or severe hypoglycemia to prescriber.
- Caution patient with confirmed or suspected hypoglycemia not to drive or operate machinery until blood glucose levels return to normal.
- Tell patient to take a missed dose as soon as he remembers it unless it's almost time for the next scheduled dose.
- Urge patient to wear or carry medical identification showing that he has diabetes and listing his drugs.
- Advise the patient to protect his skin from the sun.
- Instruct patient to report about fever, sore throat, dark yellow or brown urine, yellow skin and eyes, bleeding, and bruising.

chlorthalidone

Apo-Chlorthalidone (CAN), Hygroton, Novo-Thalidone (CAN), Thalitone, Uridon (CAN)

Class and Category

Chemical class: Phthalimidine derivative of benzenesulfonamide (thiazide-like diuretic)
Therapeutic class: Antihypertensive, diuretic
Pregnancy category: B

Indications and Dosages

↗ *To reduce edema caused by heart failure, hepatic cirrhosis, corticosteroid or estrogen therapy, or renal dysfunction*

TABLETS

Adults. *Initial:* 50 to 100 mg (Thalitone, 30 to 60 mg) daily, 100 mg (Thalitone, 60 mg) every other day, or 150 to 200 mg (Thalitone, 90 to 120 mg) daily or every other day. *Maintenance:* Individualized; may be lower than initial dosage.

↗ *To treat hypertension*

TABLETS

Adults. *Initial:* 25 mg daily (Thalitone, 15 mg daily). If response is insufficient, dosage increased to 50 mg daily (Thalitone, 30 to 50 mg daily). If additional control is required, dosage increased to 100 mg daily (except Thalitone) or a second antihypertensive added. *Maintenance:* Individualized; may be lower than initial dosage.

Mechanism of Action

May promote sodium, chloride, and water excretion by inhibiting sodium reabsorp-

tion in the distal tubules of the kidneys. Initially, chlorthalidone may decrease extracellular fluid volume, plasma volume, and cardiac output, which helps explain how it reduces blood pressure. It also may dilate arteries directly, which helps reduce peripheral vascular resistance and blood pressure. After several weeks, extracellular fluid and plasma volume and cardiac output return to normal, but peripheral vascular resistance remains decreased.

Route	Onset	Peak	Duration
P.O.	2–3 hr	2–6 hr	24–72 hr

Contraindications

Anuria; hypersensitivity to chlorthalidone, other sulfonamides, or their components; renal decompensation

Interactions

DRUGS

allopurinol: Increased risk of allopurinol hypersensitivity
amphotericin B, glucocorticoids: Intensified electrolyte depletion
anesthetics: Potentiated effects of anesthetics
anticholinergics: Increased chlorthalidone absorption
antidiabetics, methenamines, oral anticoagulants, sulfonyleureas: Decreased effects of these drugs
antihypertensives: Potentiated action of antihypertensives and chlorthalidone
antineoplastics: Prolonged antineoplastic-induced leukopenia
cholestyramine, colestipol: Decreased chlorthalidone absorption
diazoxide: Increased risk of hyperglycemia and hypotension
digitalis glycosides: Increased risk of digitalis-induced arrhythmias
lithium: Decreased renal lithium clearance and increased risk of lithium toxicity
loop diuretics: Increased synergistic effects, resulting in profound diuresis and serious electrolyte imbalances
methyl dopa: Potential development of hemolytic anemia
neuromuscular blockers: Increased neuromuscular blockade
NSAIDs: Possibly reduced diuretic effect of chlorthalidone
vitamin D: Enhanced vitamin D action

Adverse Reactions

CNS: Dizziness, headache, insomnia, light-headedness, paresthesia, restlessness, vertigo, weakness

CV: Orthostatic hypotension, vasculitis

EENT: Yellow vision

ENDO: Hyperglycemia

GI: Abdominal cramps or pain, anorexia, bloating, constipation, diarrhea, gastric irritation, nausea, pancreatitis, vomiting

GU: Decreased libido, impotence

HEME: Agranulocytosis, aplastic anemia, hypoplastic anemia, leukopenia, thrombocytopenia

MS: Gout attacks, muscle spasms

SKIN: Cutaneous vasculitis, exfoliative dermatitis, jaundice, necrotizing vasculitis, photosensitivity, purpura, rash, urticaria

Other: Hyperuricemia

Nursing Considerations

- Use chlorthalidone cautiously in patients with impaired hepatic function or progressive hepatic disease because minor changes in fluid and electrolyte balance may cause hepatic coma.
- Assess BUN, serum electrolyte, uric acid, and blood glucose levels before therapy and periodically throughout therapy. Monitor patient for signs of fluid and electrolyte imbalance.

WARNING Monitor renal function periodically to detect cumulative drug effects, which may cause azotemia in patients with impaired renal function.

PATIENT TEACHING

- Stress the importance of taking chlorthalidone even when feeling well.
- Tell patient to store drug at room temperature in tightly closed container.
- Tell patient to take drug in the morning with food or milk.
- To minimize effects of orthostatic hypotension, instruct patient to rise slowly from a seated or lying position.
- Advise patient to check blood pressure regularly.
- Instruct patient to report signs of low potassium level, such as muscle weakness and fatigue.
- Advise patient to protect his skin from the sun.
- Urge patient to immediately report sudden joint pain to prescriber because drug can cause sudden gout attacks.

- Instruct patient to take a missed dose as soon as he remembers it. If he misses one day in an every-other-day schedule, tell him to take the dose on the off day and then resume usual dosing schedule. Warn against taking double or extra doses.

chlorzoxazone

EZE-DS, Paraflex, Parafon Forte DSC, Relaxazone, Remular, Remular-S, Strifon Forte DSC

Class and Category

Chemical class: Benzoxazole derivative

Therapeutic class: Skeletal muscle relaxant

Pregnancy category: C (Parafon Forte DSC, not rated)

Indications and Dosages

➤ *As adjunct to relieve acute musculoskeletal pain and stiffness*

TABLETS

Adults. 250 to 750 mg t.i.d. or q.i.d., usually 500 mg t.i.d. or q.i.d., increased or decreased according to patient response.

Route	Onset	Peak	Duration
P.O.	In 1 hr	Unknown	3–4 hr

Mechanism of Action

Reduces muscle spasm by inhibiting multi-synaptic reflex arcs at the level of the spinal cord and subcortical areas of the brain that are active in producing and maintaining skeletal muscle spasm.

Contraindications

Hypersensitivity or known intolerance to chlorzoxazone or any of its components

Interactions

DRUGS

CNS depressants: Additive CNS depression

ACTIVITIES

alcohol use: Additive CNS depression

Adverse Reactions

CNS: Dizziness, drowsiness, headache, light-headedness, malaise, paradoxical stimulation

GI: Abdominal cramps or pain, constipation, diarrhea, GI bleeding, heartburn, hepatotoxicity, nausea, vomiting

GU: Urine discoloration

HEME: Agranulocytosis, anemia

SKIN: Allergic dermatitis, ecchymosis, petechiae

Other: Anaphylaxis, angioedema

Nursing Considerations

- If needed, crush chlorzoxazone tablets and mix with food or liquid for easier swallowing.
- Assess patients, especially those who have a history of allergies, for evidence of hypersensitivity, such as rash, hives, and itching.

WARNING Monitor patient for signs of hepatotoxicity, including fever, rash, jaundice, and darkened urine. Notify prescriber immediately and expect to discontinue drug if any of these signs or symptoms occur. Monitor patient for abnormal liver function test results, such as elevated AST, ALT, alkaline phosphatase, and bilirubin levels, and expect to discontinue drug, as ordered, if any of these occurs.

- Ensure adequate rest, and provide other pain-relief measures as needed.
- Institute safety measures to prevent falls or injury (such as raising bed rails and assisting with ambulation) until drug's full CNS effects are known.

PATIENT TEACHING

- Advise patient to take a missed dose of chlorzoxazone as soon as possible unless it's almost time for the next dose.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to avoid alcohol and other CNS depressants during therapy.
- Inform patient that, in rare instances, urine may turn orange or reddish purple during therapy.
- Advise patient to store drug in a tightly capped container at room temperature.

cholestyramine

Questran, Questran Light

Class and Category

Chemical class: Quaternary ammonium anion exchange resin

Therapeutic class: Antihyperlipidemic, antipruritic (cholestasis)

Pregnancy category: Not rated

Indications and Dosages

↗ *As adjunct to reduce serum cholesterol level in patients with primary hypercholesterolemia, to relieve pruritus associated with partial biliary obstruction*

ORAL SUSPENSION

Adults. *Initial:* 4 g once or twice daily before meals. *Maintenance:* 8 to 24 g equally divided and given 2 to 6 times a day.

Maximum: 24 g daily when used as antihyperlipidemic and 16 g daily when used as antipruritic.

Route	Onset	Peak	Duration
P.O.	In 1–2 wk*	Unknown	2–4 wk†

Mechanism of Action

Increases bile acid excretion in feces. The resulting decreased bile acid level increases the activity of the enzyme that regulates cholesterol synthesis in the liver. As a result, the liver increases its cholesterol synthesis to produce more bile acids. However, the liver's synthesis of cholesterol typically can't match the amount needed to synthesize bile acids, which reduces the cholesterol level. Also, a decreased cholesterol level causes liver cells to increase their uptake of LDLs, which further reduces the cholesterol level.

Cholestyramine may relieve pruritus by decreasing the body's bile acid level. This reduces the amount of excess bile acids that are deposited in the dermis and that typically cause pruritus in patients with cholestasis.

Contraindications

Complete biliary obstruction (when bile isn't excreted into intestine), hypersensitivity to cholestyramine or its components

Interactions

DRUGS

chenodioid, digitalis glycosides, fat-soluble vitamins, folic acid, gemfibrozil, penicillin G (oral), phenylbutazone, propranolol (oral), tetracyclines (oral), thiazide diuretics (oral), thyroid hormones, ursodioid, vancomycin (oral): Decreased absorption and effects of

* For hypercholesterolemia; in 1 to 3 wk for pruritus.

† For hypercholesterolemia; 1 to 2 wk for pruritus.

these drugs

oral anticoagulants: Decreased or increased anticoagulant effect

Adverse Reactions

CNS: Headache, dizziness

GI: Bloating, constipation, diarrhea, epigastric pain, eructation, fecal impaction, flatulence, indigestion, nausea, vomiting

Nursing Considerations

- Store cholestyramine at room temperature.
- Don't give dry powder because it may cause esophageal distress; mix it in a beverage.

WARNING Be aware that long-term use may increase bleeding tendency from hyperprothrombinemia caused by vitamin K deficiency. If this occurs, patient will require treatment with vitamin K₁.

- Monitor for deficiencies of fat-soluble vitamins, such as A and D. If long-term therapy prevents absorption of these vitamins, expect to provide supplementation.

PATIENT TEACHING

- Urge patient to follow a low-cholesterol, low-fat diet and regular exercise program.
- Tell patient to take drug before meals.
- Instruct patient to mix dry powder as follows: Place amount of powder needed for dose in any beverage and stir vigorously. Then, vigorously stir in another 2 to 4 oz of beverage. After drinking mixture, rinse glass with more liquid, and swallow it to make sure full dose is taken. Patient also may mix drug in thin soups or moist, pulpy fruits, such as applesauce or crushed pineapple.
- Tell patient to drink plenty of fluids and increase bulk in his diet to minimize constipation; remind him to notify prescriber if constipation, nausea, or other adverse GI reactions develop.
- Explain that serum cholesterol level will need to be measured often for first few months of therapy and periodically thereafter.
- Advise patient to take other drugs at least 1 hour before or 4 to 6 hours after cholestyramine to avoid interference with their absorption.
- Tell patient to take a missed dose as soon as he remembers but not to take double or extra doses.

choline salicylate

Arthropan

Class and Category

Chemical class: Salicylate

Therapeutic class: Analgesic, anti-inflammatory, antipyretic

Pregnancy category: C (first trimester), Not rated (later trimesters)

Indications and Dosages

➤ To treat mild to moderate pain, reduce fever

LIQUID

Adults and adolescents. 435 to 870 mg every 4 hr, p.r.n. *Maximum*: 5,325 mg daily.

Children ages 11 to 12. 435 to 652.5 mg every 4 hr, p.r.n. *Maximum*: Five doses daily.

Children ages 9 to 11. 435 to 543.8 mg every 4 hr, p.r.n. *Maximum*: Five doses daily.

Children ages 6 to 9. 435 mg every 4 hr, p.r.n. *Maximum*: Five doses daily.

Children ages 4 to 6. 326.5 mg every 4 hr, p.r.n. *Maximum*: Five doses daily.

Children ages 2 to 4. 217.5 mg every 4 hr, p.r.n. *Maximum*: Five doses daily.

Children up to age 2. Individualized dosage. *Maximum*: Five doses daily.

➤ To treat rheumatoid arthritis

LIQUID

Adults and adolescents. 870 to 1,740 mg up to four times daily.

Children age 12 and younger. 107 to 133 mg/kg daily in divided doses.

Route	Onset	Peak	Duration
P.O.	Unknown	Several wk*	Unknown

Mechanism of Action

Blocks cyclooxygenase, an enzyme needed for prostaglandin synthesis. As mediators in the inflammatory process, prostaglandins cause local vasodilation, swelling, and pain. They also influence pain transmission from the periphery to the spinal cord. By blocking cyclooxygenase and inhibiting prostaglandins, this NSAID decreases inflammatory symptoms and relieves pain. It also

* For rheumatoid arthritis.

acts on the heat-regulating center in the hypothalamus and causes peripheral vasodilation, sweating, and heat loss.

Contraindications

Hypersensitivity to nonacetylated salicylates

Interactions

DRUGS

antacids: Increased clearance and decreased blood level of salicylate

carbonic anhydrase inhibitors, phenytoin, valproic acid: Decreased blood levels and therapeutic effects of these drugs

corticosteroids: Decreased blood salicylate level, increased salicylate dosage requirements

insulin, sulfonylureas: Increased hypoglycemic response

methotrexate: Increased therapeutic and toxic effects of methotrexate, especially when given in chemotherapeutic doses

oral anticoagulants: Increased blood level of unbound anticoagulant and risk of bleeding

salicylate-containing products: Increased plasma salicylate level, possibly to toxic level

uricosuric drugs: Decreased uricosuric drug efficacy

Adverse Reactions

CNS: Confusion, dizziness, drowsiness, hallucinations, headache, light-headedness

CV: Tachycardia

EENT: Hearing loss, tinnitus

GI: Constipation, diarrhea, epigastric pain, heartburn, indigestion, nausea, vomiting

HEME: Easy bruising, unusual bleeding

Nursing Considerations

- Use choline salicylate cautiously in patients with renal impairment.
- Don't give salicylates to children and adolescents with chickenpox or influenza symptoms because of the risk of Reye's syndrome.

WARNING During high-dose or long-term therapy, watch for salicylate intoxication, (headache, dizziness, tinnitus, hearing loss, confusion, drowsiness, diaphoresis, vomiting, diarrhea, hyperventilation, and possibly CNS disturbance, electrolyte imbalance, respiratory acidosis, hyperthermia, and dehydration). Prepare for induced vomiting, gastric lavage, activated charcoal, and peritoneal dialysis or hemodialy-

sis, as ordered.

PATIENT TEACHING

- Tell patient to store drug at room temperature, away from heat, light, and moisture.
- Instruct patient to take drug with full glass of water or with food.
- Tell patient to take a missed dose as soon as he remembers but to avoid doubling the dose.
- If patient has arthritis, explain that optimal drug effects may not occur for 2 to 3 weeks.
- Teach patient to recognize and immediately report signs of salicylate toxicity.
- Because drug is closely related to aspirin, advise against taking aspirin-containing OTC products during therapy.

ciclesonide

Alvesco

Class and Category

Chemical class: Non-halogenated glucocorticoid

Therapeutic class: Antiasthmatic, anti-inflammatory

Pregnancy category: C

Indications and Dosages

↗ *To prevent asthma attacks as part of maintenance therapy*

INHALATION AEROSOL

Adults and children age 12 and over using bronchodilator therapy. *Initial*: 80 mcg

b.i.d. *Maximum*: 160 mcg b.i.d.

Adults and children age 12 and over switching from another inhaled corticosteroid. *Initial*: 80 mcg b.i.d., adjusted to lowest effective dose when stabilized.

Maximum: 320 mg b.i.d.

Adults and children age 12 and older using oral corticosteroid therapy. *Initial and maximum*: 320 mcg b.i.d., adjusted to lowest effective dose when stabilized.

↗ *To treat nasal congestion in seasonal or allergic rhinitis*

INHALATION AEROSOL

Adults and children age 6 and over.

200 mcg daily as 2 sprays in each nostril.

Mechanism of Action

Inhibits cells involved in the asthma inflammatory response, such as mast cells,

eosinophils, basophils, lymphocytes, macrophages, and neutrophils. Ciclesonide also inhibits production or secretion of chemical mediators, such as histamine, eicosanoids, leukotrienes, and cytokines.

Route	Onset	Peak	Duration
Inhalation	Unknown	4 wk or longer	Several days

Contraindications

Hypersensitivity to ciclesonide or its components, primary treatment of status asthmaticus or other acute asthma episodes that require intensive measures

Interactions

DRUGS

ketoconazole: Increased exposure time of ciclesonide

Adverse Reactions

CNS: Dizziness, fatigue, headache

EENT: Cataracts, conjunctivitis, dry mouth or throat, dysphonia, glaucoma, hoarseness, nasal congestion, nasopharyngitis, oral candidiasis, pharyngolaryngeal pain, sinusitis

ENDO: Adrenal insufficiency, cushingoid symptoms, decreased bone mineral density, hyperglycemia, slower growth in children

GI: Nausea

MS: Arthralgia, back or limb pain, musculoskeletal chest pain

RESP: Bronchospasm, cough, pneumonia, upper respiratory tract infection

SKIN: Facial edema, urticaria

Other: Angioedema, influenza

Nursing Considerations

- Use cautiously in patients with tuberculosis; fungal, bacterial, viral, or parasitic infection; ocular herpes simplex; or measles or chickenpox because these conditions may worsen with ciclesonide therapy.
- Also use cautiously in patients with a history of increased intraocular pressure, glaucoma, or cataracts because ciclesonide may increase intraocular pressure or cause cataract formation and in patients with major risk factors for decreased bone mineral content, such as prolonged immobilization, family history of osteoporosis, or long-term use of drugs that can reduce bone mass, such as anticonvulsants and

oral corticosteroids.

- Inspect patient's oral cavity regularly for abnormalities. Have patient rinse mouth following inhalation of ciclesonide to reduce risk of oral candidiasis. If oral candidiasis occurs, expect to continue ciclesonide therapy, unless severe.
- If patient takes a systemic corticosteroid, expect to taper dosage by no more than 2.5 mg/day at weekly intervals, starting 1 week after ciclesonide therapy begins.

WARNING If patient is switched from systemic corticosteroid to ciclesonide, assess for adrenal insufficiency (fatigue, hypotension, lassitude, nausea, vomiting, weakness) early in therapy and whenever patient has infection, stress, trauma, surgery, or other steroid-depleting conditions or procedures. Notify prescriber immediately if signs or symptoms develop.

- As prescribed, administer a fast-acting inhaled bronchodilator if an acute asthma attack occurs. Ciclesonide is not a bronchodilator and its action takes longer than needed to abort acute asthma symptoms. If bronchospasm occurs immediately after ciclesonide use, expect to stop drug and start another drug regimen.
- Monitor growth in children because ciclesonide may suppress growth

PATIENT TEACHING

- Urge patient to use ciclesonide regularly, as prescribed, but not for acute bronchospasm. Also tell her never to increase or decrease the dosage without consulting prescriber.
- Tell patient to use ciclesonide only with the actuator supplied with the product. Explain that when the dose indicator shows a red zone in the window, about 20 inhalations are left, indicating a need for a refill. When the indicator shows zero, she should discard the inhaler. Advise against relying solely on the dose indicator, especially if inhaler has been dropped, but to keep track of number of inhalations used.
- Instruct patient to use inhaler according to package instructions. Stress need to make sure canister is firmly seated in the plastic mouthpiece adapter before each use and to press inhaler slowly but firmly until it can go no further in the adapter for each spray. Inform patient that she doesn't need to shake inhaler before use.

- On first use, advise her to spray three times into the air (away from her eyes) looking for a fine mist. If inhaler hasn't been used for more than 10 days, it should be primed again.
- Instruct patient to gargle and rinse her mouth after each dose to help prevent dry mouth and throat, relieve throat irritation, and prevent oral yeast infection.
- Tell patient to always replace cap after use, to keep mouthpiece clean, and to clean mouthpiece once a week with a clean, dry tissue or cloth.
- Explain that the full effect of drug may not occur for 4 weeks or more.
- Stress importance of notifying prescriber if symptoms continue or worsen.
- Instruct patient to notify prescriber immediately if asthma attacks don't respond to bronchodilators during ciclesonide use.
- If patient is switching from an oral corticosteroid to ciclesonide, urge her to carry medical identification indicating the need for supplemental systemic corticosteroids during stress or severe asthma attack.
- Caution patient to avoid contact with people who have infections because drug suppresses the immune system, increasing the risk of infection. Instruct patient to notify prescriber about exposure to chickenpox, measles, or other infections because additional treatment may be needed.

cilostazol

Pletal

Class and Category

Chemical class: Quinolinone derivative

Therapeutic class: Phosphodiesterase III inhibitor, platelet aggregation inhibitor

Pregnancy category: C

Indications and Dosages

↗ *To reduce symptoms of intermittent claudication*

TABLETS

Adults. 100 mg b.i.d. taken at least 30 min before or 2 hr after breakfast and dinner.

Mechanism of Action

May inhibit phosphodiesterase, decreasing phosphodiesterase activity and suppressing cyclic adenosine monophosphate (cAMP)

degradation. This action increases cAMP in platelets and blood vessels, which inhibits platelet aggregation and causes vasodilation. This in turn relieves symptoms of claudication.

Contraindications

Heart failure, hypersensitivity to cilostazol or its components

Interactions

DRUGS

diltiazem, erythromycin, itraconazole, ketoconazole, omeprazole: Increased plasma cilostazol level

FOODS

grapefruit: Increased risk of adverse reactions

high-fat foods: Faster cilostazol absorption and increased risk of adverse reactions

ACTIVITIES

smoking: Decreased cilostazol effects by about 20%

Adverse Reactions

CNS: Cerebral hemorrhage, dizziness, headache, paresthesia

CV: Angina, chest pain, hypertension, hypotension, palpitations, peripheral edema, prolonged QT interval, subacute thrombosis, tachycardia, torsades de pointes

EENT: Pharyngitis, rhinitis

ENDO: Diabetes mellitus, hot flashes, hyperglycemia

GI: Abdominal pain, abnormal stool, diarrhea, elevated liver function test results,

flatulence, GI hemorrhage, hepatic dysfunction, indigestion, jaundice, vomiting

GU: Elevated BUN level, hematuria

HEME: Agranulocytosis, aplastic anemia, bleeding tendency, decreased platelet count, granulocytopenia, leukopenia, thrombocytopenia

MS: Back pain, myalgia

RESP: Cough, interstitial pneumonia, pulmonary hemorrhage

SKIN: Eruptions, pruritus, rash, Stevens-Johnson syndrome

Other: Infection, increased blood uric acid level

Nursing Considerations

- Monitor patient's vital signs and cardiovascular status closely because cilostazol may cause cardiovascular lesions, which could lead to problems, such as endocar-

dial hemorrhage.

- Monitor blood glucose level to detect hyperglycemia. Also assess for signs of type 2 diabetes mellitus, such as polyuria, polydipsia, polyphagia, and fatigue.

PATIENT TEACHING

- Instruct patient to take cimetazole on an empty stomach because high-fat foods can increase the risk of adverse reactions.
- Warn patient to avoid grapefruit juice during therapy because it can increase the risk of adverse reactions.
- Urge patient not to smoke because it decreases drug's effects.
- Explain that assessment of drug effectiveness is based on ability to walk increased distances. Stress that drug effects won't appear until 2 to 4 weeks after therapy starts and that full effects may take up to 12 weeks.

cimetidine

Apo-Cimetidine (CAN), Gen-Cimetidine (CAN), Novo-Cimetidine (CAN), Nu-Cimet (CAN), PMS-Cimetidine (CAN), Tagamet, Tagamet HB

cimetidine hydrochloride

Novo-Cimetidine (CAN), Tagamet

Class and Category

Chemical class: Imidazole derivative

Therapeutic class: Antiulcer agent, gastric acid secretion inhibitor, H₂-receptor antagonist

Pregnancy category: B

Indications and Dosages

↗ *To treat and prevent recurrence of duodenal ulcer*

ORAL SOLUTION, TABLETS

Adults and adolescents. *Initial:* 800 mg at bedtime, 300 mg q.i.d. with meals and at bedtime, or 400 to 600 mg in morning and at bedtime for 4 to 6 wk. *Maintenance:* 400 mg at bedtime.

Children. 20 to 40 mg/kg daily in divided doses q.i.d. with meals and at bedtime.

I.V. OR I.M. INJECTION

Adults. *Initial:* 300 mg every 6 to 8 hr. Dosage increased, if needed, by increasing

frequency. *Maximum:* 2,400 mg daily.

↗ *To treat active, benign gastric ulcer*

ORAL SOLUTION, TABLETS

Adults and adolescents. 800 mg at bedtime, 300 mg q.i.d. with meals and at bedtime, or 600 mg b.i.d. in morning and at bedtime, or 800 mg at bedtime for up to 8 wk.

Children. 20 to 40 mg/kg daily in divided doses q.i.d. with meals and at bedtime.

I.V. ORI.M. INJECTION

Adults and adolescents. *Initial:* 300 mg every 6 to 8 hr. Dosage increased, if needed, by increasing frequency. *Maximum:* 2,400 mg daily.

↗ *To manage gastroesophageal reflux disease*

ORAL SOLUTION, TABLETS

Adults and adolescents. 1,600 mg daily in divided doses (800 mg b.i.d. or 400 mg q.i.d.) for up to 12 wk.

Children. 40 to 80 mg/kg daily in divided doses q.i.d.

↗ *To treat pathological hypersecretory conditions, such as Zollinger-Ellison syndrome*

ORAL SOLUTION, TABLETS

Adults and adolescents. 300 mg q.i.d. with meals and at bedtime. Given more often, if needed. *Maximum:* 2,400 mg daily.

I.V. OR I.M. INJECTION

Adults and adolescents. *Initial:* 300 mg every 6 to 8 hr. Dosage increased, if needed, by increasing frequency. *Maximum:* 2,400 mg daily.

↗ *To treat heartburn and acid indigestion*

ORAL SOLUTION, TABLETS

Adults and adolescents. *Initial:* 200 mg with water at onset of symptoms.

Maximum: 400 mg every 24 hr for no more than 2 wk unless prescribed.

DOSAGE ADJUSTMENT Oral dosage for all indications reduced to 300 mg every 12 hr (and increased to every 8 hr with caution, if needed) for patients with renal impairment.

↗ *To prevent stress-related upper GI bleeding during hospitalization*

I.V. INFUSION

Adults. 50 mg/hr by continuous infusion for 7 days.

Mechanism of Action

Blocks histamine's action at H₂-receptor sites on stomach's parietal cells. This action reduces gastric fluid volume and acidity.

Cimetidine also decreases the amount of gastric acid secreted in response to food, caffeine, insulin, betazole, or pentagastrin.

Route	Onset	Peak	Duration
P.O.	Unknown	1–2 hr	4–5 hr
I.V., I.M.	Unknown	Unknown	4–5 hr

Incompatibilities

Don't mix cimetidine with aminophylline or barbiturates in I.V. solution. Don't mix drug with pentobarbital sodium in the same syringe.

Contraindications

Hypersensitivity to cimetidine or its components

Interactions

DRUGS

antacids, anticholinergics, metoclopramide: Decreased cimetidine absorption
benzodiazepines, calcium channel blockers, carbamazepine, chloroquine, labetalol, lidocaine, metoprolol, metronidazole, moricizine, pentoxifylline, phenytoin, propafenone, propranolol, quinidine, quinine, sulfonyleureas, tacrine, theophyllines, triamterene, tricyclic antidepressants, valproic acid, warfarin: Reduced metabolism and increased blood levels and effects of these drugs, possibly toxicity from these drugs
carmustine: Increased carmustine myelotoxicity

digoxin, fluconazole: Possibly decreased blood levels of these drugs

ferrous salts, indomethacin, ketoconazole, tetracyclines: Decreased effects of these drugs

flecainide: Increased flecainide effects

flourouracil: Increased blood fluorouracil level after long-term cimetidine use

ketoconazole: Decreased blood ketoconazole level

opioid analgesics: Increased toxic effects of opioid analgesics

oral anticoagulants: Increased anticoagulant effect

procainamide: Increased blood procainamide level

succinylcholine: Increased neuromuscular blockade

tocainide: Decreased tocainide effects

FOODS

caffeine: Reduced metabolism and increased

blood level and effects of caffeine

ACTIVITIES

alcohol use: Possibly increased blood alcohol level

Adverse Reactions

CNS: Confusion, dizziness, hallucinations, headache, peripheral neuropathy, somnolence

ENDO: Mild gynecomastia if used longer than 1 month

GI: Mild and transient diarrhea

GU: Impotence, transiently elevated serum creatinine level

SKIN: Rash

Other: Pain at I.M. injection site

Nursing Considerations

WARNING Be aware that rapid administration of cimetidine can increase risk of arrhythmias and hypotension.

- For I.V. injection, dilute cimetidine in normal saline solution to a total volume of 20 ml. Inject over 5 minutes or more.
- For intermittent I.V. infusion, dilute cimetidine in at least 50 ml of D₅W or other compatible I.V. solution. Infuse over 15 to 20 minutes.
- For I.M. injection, don't dilute cimetidine before administering it.
- Be alert for confusion in elderly or debilitated patients who receive cimetidine.

PATIENT TEACHING

- Tell patient to use a liquid-measuring device to ensure accurate dose of solution.
- Advise patient to avoid alcohol while taking cimetidine to prevent interactions.
- Instruct patient to avoid taking antacids within 1 hour of taking cimetidine.
- Warn patient that cigarette smoking increases gastric acid secretion and can worsen gastric disease.
- Caution patient not to take drug for more than 14 days, unless prescribed.

cinalcet hydrochloride

Sensipar

Class and Category

Chemical class: Calcimimetic

Therapeutic class: Calcium reducer

Pregnancy category: C

Indications and Dosages

↗ *To treat secondary hyperparathyroidism in patients with chronic renal disease who are on dialysis*

TABLETS

Adults. *Initial:* 30 mg daily P.O., increased every 2 to 4 wk in sequential doses of 60, 90, 120, and 180 mg daily, as needed.

↗ *To treat hypercalcemia in patients with parathyroid carcinoma*

TABLETS

Adults. *Initial:* 30 mg daily P.O., increased every 2 to 4 wk in sequential doses of 30 mg b.i.d., 60 mg b.i.d., 90 mg b.i.d., and then 90 mg t.i.d. or q.i.d., as needed to normalize serum calcium level.

Route	Onset	Peak	Duration
P.O.	Unknown	2–6 hr	Unknown

Mechanism of Action

Increases sensitivity of calcium-sensing receptors on the surface of parathyroid cells to extracellular calcium. This sensitivity directly reduces parathyroid hormone (PTH) level, which in turn decreases serum calcium level.

Contraindications

Hypersensitivity to cinacalcet or its components

Interactions

DRUGS

amitriptyline, carvedilol, desipramine, flecainide, metoprolol, thioridazine, tricyclic antidepressants (most), vinblastine: Possibly increased blood level of these drugs
erythromycin, itraconazole, ketoconazole: Possibly increased blood cinacalcet level

Adverse Reactions

CNS: Asthenia, dizziness

CV: Arrhythmia, hypertension, hypotension, worsening heart failure

ENDO: Hypocalcemia

GI: Anorexia, diarrhea, nausea, vomiting

MS: Myalgia

SKIN: Rash, urticaria

Other: Allergic reaction, angioedema, non-cardiac chest pain

Nursing Considerations

- Use cinacalcet cautiously in patients with a

history of seizures because reduced blood calcium level may lower seizure threshold. Also use cautiously in patients with hepatic insufficiency because cinacalcet metabolism may be reduced.

- Monitor patient for hypocalcemia exhibited by cramping, myalgia, paresthesia, seizures, and tetany. Also monitor patient's blood calcium and phosphorus levels within 1 week after starting therapy or adjusting dosage, and every month or two once maintenance dose is established, as ordered. If hypocalcemia develops, notify prescriber immediately because treatment to raise calcium level will be needed.

Treatment may include giving supplemental calcium, starting or increasing dosage of calcium-based phosphate binder or vitamin D sterols, or temporarily withholding cinacalcet.

- Be aware that if patient starts or stops therapy with a strong CYP3A4 inhibitor, such as erythromycin, itraconazole, or ketoconazole, cinacalcet dosage may need to be adjusted.
- Monitor dialysis patient's intact PTH levels 1 to 4 weeks after therapy starts or dose is adjusted and then every 1 to 3 months thereafter, as ordered. Expect to reduce dosage or discontinue cinacalcet, as ordered, in a patient whose intact PTH level falls below the target range of 150 to 300 pg/ml.

PATIENT TEACHING

- Instruct patient to take cinacalcet with food or shortly after a meal.
- Caution patient to take tablet whole and not divide it or crush it.
- Review signs and symptoms of hypocalcemia with patient and urge him to notify prescriber of changes.

cinoxacin

Cinobac

Class and Category

Chemical class: Quinolone derivative

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ *To treat UTI caused by Enterobacter species, Escherichia coli, Klebsiella*

species, *Proteus mirabilis*, or *Proteus vulgaris*

CAPSULES

Adults. 1 g daily in divided doses b.i.d. to q.i.d. for 7 to 14 days.

DOSAGE ADJUSTMENT After initial 500-mg dose, dosage reduced to 250 mg t.i.d. if creatinine clearance is 50 to 80 ml/min/1.73 m², 250 mg b.i.d. if clearance is 20 to 50 ml/min/1.73 m², and 250 mg daily if clearance is less than 20 ml/min/1.73 m².

↗ *To prevent UTI in women with a history of chronic UTI*

CAPSULES

Adults. 250 mg at bedtime for up to 5 mo.

Mechanism of Action

Inhibits the enzyme DNA gyrase, which is responsible for the unwinding and supercoiling of bacterial DNA before it replicates. By inhibiting this enzyme, cinoxacin causes bacterial cells to die.

Contraindications

Hypersensitivity to cinoxacin, other quinolones, or their components

Interactions

DRUGS

antacids that contain aluminum or magnesium, didanosine (chewable tablets, buffered tablets, pediatric powder for oral solution), metal cations (such as iron), multivitamins that contain zinc, sucralfate: Possibly interference with cinoxacin absorption
probenecid: Increased blood cinoxacin level
theophylline: Possibly increased blood theophylline level

FOODS

caffeine: Decreased metabolism of caffeine, resulting in increased blood caffeine level

Adverse Reactions

CNS: Dizziness, headache

CV: Edema

EENT: Altered taste

GI: Abdominal cramps, anorexia, diarrhea, elevated liver function test results, nausea, vomiting

GU: Perineal burning

HEME: Eosinophilia

SKIN: Angioedema, photosensitivity, pruritus, rash, urticaria

Nursing Considerations

• Obtain results of urine culture and sensi-

tivity test before administering first dose of cinoxacin.

- Review results of liver function tests, as indicated, during treatment.
- Administer drug with food, if needed; food decreases peak blood level but doesn't change total absorption.

PATIENT TEACHING

- Tell patient to take cinoxacin with food, if needed, to avoid GI distress.
- Instruct patient to drink 2 to 3 L of fluid daily unless contraindicated.
- Tell patient not to take antacids that contain aluminum or magnesium; didanosine chewable tablets, buffered tablets, or pediatric powder for oral solution; sucralfate; metal cations such as iron; or multivitamins that contain zinc for at least 2 hours before or after taking cinoxacin because they can interfere drug's absorption.
- Advise patient to limit caffeine intake while taking cinoxacin because drug may cause caffeine to accumulate in the body.
- Advise patient to immediately report edema, rash, or severe adverse GI reactions.
- Tell patient to immediately report tendon inflammation, pain, or rupture to prescriber because other drugs in the same class as cinoxacin have caused tendon rupture, requiring drug to be discontinued.
- Warn patient about the potential for seizures, which have occurred with other drugs in the same class as cinoxacin.

ciprofloxacin

Cipro, Cipro I.V., Cipro XR, Proquin XR

Class and Category

Chemical class: Fluoroquinolone derivative

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

↗ *To prevent inhalation anthrax after exposure or to treat inhalation anthrax*

ORAL SUSPENSION, TABLETS

Adults and adolescents. 500 mg every 12 hr for 60 days.

Children. 15 mg/kg every 12 hr for 60 days.
Maximum: 500 mg/dose.

I.V. INFUSION

Adults and adolescents. 400 mg every 12 hr for 60 days.

Children. 10 mg/kg every 12 hr for 60 days. *Maximum:* 400 mg/dose or 800 mg daily.

↗ *To treat acute sinusitis caused by gram-negative organisms (including Campylobacter jejuni, Citrobacter diversus, Citrobacter freundii, Enterobacter cloacae, Escherichia coli, Haemophilus influenzae, Haemophilus parainfluenzae, Klebsiella pneumoniae, Morganella morganii, Neisseria gonorrhoeae, Proteus mirabilis, Proteus vulgaris, Providencia rettgeri, Providencia stuartii, Pseudomonas aeruginosa, Serratia marcescens, Shigella flexneri, and Shigella sonnei) and gram-positive organisms (including Enterococcus faecalis, Staphylococcus aureus, Staphylococcus epidermidis, and Streptococcus pneumoniae)*

ORAL SUSPENSION, TABLETS

Adults. 500 mg every 12 hr for 10 days.

I.V. INFUSION

Adults. For mild to moderate infections, 400 mg every 12 hr.

↗ *To treat bone and joint infections caused by susceptible organisms listed above*

ORAL SUSPENSION, TABLETS

Adults. For mild to moderate infections, 500 mg every 12 hr for 4 to 6 wk. For severe or complicated infections, 750 mg every 12 hr for 4 to 6 wk.

I.V. INFUSION

Adults. For mild to moderate infections, 400 mg every 12 hr for 4 to 6 wk. For severe or complicated infections, 400 mg every 8 hr.

↗ *To treat skin and soft-tissue infections caused by susceptible organisms listed above*

ORAL SUSPENSION, TABLETS

Adults. For mild to moderate infections, 500 mg every 12 hr for 7 to 14 days. For severe or complicated infections, 750 mg every 12 hr for 7 to 14 days.

I.V. INFUSION

Adults. For mild to moderate infections, 400 mg every 12 hr. For severe or complicated infections, 400 mg every 8 hr.

↗ *To treat chronic bacterial prostatitis caused by susceptible organisms listed above*

ORAL SUSPENSION, TABLETS

Adults. 500 mg every 12 hr for 28 days.

I.V. INFUSION

Adults. 400 mg every 12 hr.

↗ *To treat infectious diarrhea caused by susceptible organisms listed above*

ORAL SUSPENSION, TABLETS

Adults. 500 mg every 12 hr for 5 to 7 days.

↗ *To treat UTI caused by susceptible organisms listed above*

ORAL SUSPENSION, TABLETS

Adults. For acute uncomplicated infections, 100 mg every 12 hr for 3 days. For mild to moderate infections, 250 mg every 12 hr for 7 to 14 days. For severe or complicated infections, 500 mg every 12 hr for 7 to 14 days.

I.V. INFUSION

Adults. For mild to moderate infections, 200 mg every 12 hr. For severe or complicated infections, 400 mg every 12 hr.

↗ *To treat complicated UTI caused by E. coli, K. pneumoniae, Enterococcus faecalis, P. mirabilis, or P. aeruginosa or acute uncomplicated pyelonephritis caused by E. coli*

E.R. TABLETS

Adults. 1,000 mg daily for 7 to 14 days.

↗ *To treat acute cystitis caused by E. coli, P. mirabilis, E. faecalis, or Staphylococcus saprophyticus*

E.R. TABLETS

Adults. 500 mg daily for 3 days.

↗ *To treat lower respiratory tract infections caused by susceptible organisms listed above*

ORAL SUSPENSION, TABLETS

Adults. For mild to moderate infections, 500 mg every 12 hr for 7 to 14 days. For severe or complicated infections, 750 mg every 12 hr for 7 to 14 days.

I.V. INFUSION

Adults. For mild to moderate infections, 400 mg every 12 hr. For severe or complicated infections, 400 mg every 8 hr.

↗ *To treat intra-abdominal infections caused by susceptible organisms listed above*

I.V. INFUSION

Adults. 400 mg every 8 hr along with parenteral metronidazole.

↗ *To treat mild to severe nosocomial pneumonia caused by susceptible organisms listed above*

I.V. INFUSION

Adults. 400 mg every 8 hr.

➤ *To treat typhoid fever caused by Salmonella typhi or infectious diarrhea caused by C. jejuni, E. coli, S. flexneri, or S. sonnei*

ORAL SUSPENSION, TABLETS

Adults. 500 mg every 12 hr for 10 days.

➤ *To treat uncomplicated urethral or cervical gonococcal infections caused by N. gonorrhoeae*

ORAL SUSPENSION, TABLETS

Adults. 250 mg as a single dose.

DOSE ADJUSTMENT Dosage reduced to 250 to 500 mg every 12 hr if creatinine clearance is 30 to 50 ml/min/1.73 m²; and to 250 to 500 mg P.O. or 200 to 400 mg I.V. every 18 hr if creatinine clearance is 5 to 29 ml/min/1.73 m².

➤ *To treat acute cystitis caused by E. coli or K. pneumoniae*

E.R. TABLETS (PROQUIN XR)

Adults. 500 mg daily for 3 days with evening meal.

Mechanism of Action

Inhibits the enzyme DNA gyrase, which is responsible for the unwinding and supercoiling of bacterial DNA before it replicates. By inhibiting this enzyme, ciprofloxacin causes bacterial cells to die.

Incompatibilities

Don't administer parenteral ciprofloxacin with aminophylline, amoxicillin, cefepime, clindamycin, dexamethasone, floxacillin, furosemide, heparin, or phenytoin.

Contraindications

Hypersensitivity to ciprofloxacin, quinolones, or their components

Interactions**DRUGS**

antacids, didanosine, iron supplements, sucralfate, multivitamins that contain iron or zinc: Decreased ciprofloxacin absorption
cyclosporine: Elevated serum creatinine and blood cyclosporine levels
glyburide: Severe hypoglycemia
methotrexate: Increased blood methotrexate level and increased risk of toxicity
NSAIDs (except acetylsalicylic acid): Increased risk of seizures with high doses of ciprofloxacin
oral anticoagulants: Enhanced anticoagulant

effects

phenytoin: Increased or decreased blood phenytoin level

probenecid: Increased blood ciprofloxacin level and, possibly, toxicity

theophylline: Increased blood level, half-life, and risk of adverse effects of theophylline

tizanidine: Increased tizanidine effects

FOODS

caffeine: Increased caffeine effects

dairy products: Delayed drug absorption

Adverse Reactions

CNS: Agitation, anxiety, cerebral thrombosis, confusion, dizziness, headache, insomnia, light-headedness, migraine, nightmares, paranoia, peripheral neuropathy, restlessness, seizures, syncope, toxic psychosis

CV: Angina, atrial flutter, cardiopulmonary arrest, cardiovascular collapse, hypertension, MI, orthostatic hypotension, palpitations, phlebitis, tachycardia, torsades de pointes, vasculitis, ventricular ectopy

EENT: Oral candidiasis

GI: Abdominal pain, constipation, diarrhea, elevated liver function test results, flatulence, GI bleeding, hepatic failure or necrosis, hepatitis, indigestion, intestinal perforation, jaundice, nausea, pancreatitis, pseudomembranous colitis, vomiting

GU: Crystalluria, hematuria, increased serum creatinine level, interstitial nephritis, nephrotoxicity, renal calculi, renal failure, urine retention, vaginal candidiasis

HEME: Agranulocytosis, bone marrow depression, hemolytic anemia, lymphadenopathy, pancytopenia

MS: Tendinitis, tendon rupture

SKIN: Erythema multiforme, exfoliative dermatitis, photosensitivity, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

RESP: Bronchospasm, pulmonary embolism, respiratory arrest

Other: Acidosis, anaphylaxis, angioedema, serum sicknesslike reaction

Nursing Considerations

- Obtain culture and sensitivity test results, as ordered, before giving ciprofloxacin.
- Use drug cautiously in patients with CNS disorders and patients who may be more susceptible to drug's effect on QT interval, such as those taking Class IA or III antiar-

rhythmics or those with uncorrected hypokalemia or a history of QT-interval prolongation.

- Dilute I.V. ciprofloxacin concentrate to 1 to 2 mg/ml using D₅W or sodium chloride for injection. Don't dilute solutions that come from manufacturer in D₅W before I.V. infusion. Infuse slowly over 1 hour.
- Store reconstituted solution up to 14 days at room temperature or refrigerated.
- Don't give oral suspension by feeding tube.
- Be aware that E.R. and immediate-release tablets aren't interchangeable and that Proquin XR and Cipro XR aren't interchangeable.
- Patient should be well hydrated during therapy to help prevent alkaline urine, which may lead to crystalluria and nephrotoxicity.
- Assess patient's hepatic, renal, and hematologic functions periodically, as ordered, if he's receiving prolonged therapy.
- Monitor patient closely for diarrhea, which may reflect pseudomembranous colitis. If it occurs, notify prescriber and expect to withhold drug and treat diarrhea.
- Assess patient for evidence of peripheral neuropathy. Notify prescriber and expect to stop drug if patient complains of burning, numbness, pain, tingling, or weakness in extremities or if physical examination reveals deficits in light touch, pain, temperature, position sense, vibratory sensation, or motor strength.
- Monitor patients (especially children, elderly patients, patients receiving corticosteroids, and patients who have renal failure or who have had a kidney, heart, or lung transplant) for evidence of tendon rupture, such as inflammation, pain, and swelling at the site. Be aware that tendon rupture may occur during or after ciprofloxacin therapy. Notify prescriber about suspected tendon rupture, and have patient rest and refrain from exercise until tendon rupture has been ruled out. If present, expect to provide supportive care as ordered.
- Assess patient routinely for signs of rash or other hypersensitivity reactions, even after patient has received multiple doses. Stop drug at first sign of rash, jaundice, or

other sign of hypersensitivity, and notify prescriber immediately. Be prepared to provide supportive emergency care.

PATIENT TEACHING

- Urge patient to complete the prescribed course of therapy, even if he feels better before it's finished.
- Tell patient not to take drug with dairy products or calcium-fortified juices alone.
- Advise patient to take ciprofloxacin 2 hours before or 6 hours after antacids, iron supplements, or multivitamins that contain iron or zinc. Tell him to shake oral suspension for 15 seconds, not to chew microcapsules, and not to split, crush, or chew E.R. tablets.
- Encourage patient to drink plenty of fluids during therapy to help prevent crystalluria.
- Urge patient to avoid caffeinated products because caffeine may accumulate in the body during ciprofloxacin therapy and cause excessive stimulation.
- Caution patient to avoid excessive exposure to sunlight or artificial ultraviolet light because severe sunburn may result. Tell patient to notify prescriber if sunburn develops; drug will need to be stopped.
- Urge patient to avoid hazardous activities until CNS effects of drug are known.
- Advise patient to notify prescriber about changes in limb sensation or movement and about inflammation, pain, or swelling over a joint. Urge patient to rest the affected limb at the first sign of discomfort.
- Tell patient to stop taking drug and to notify prescriber at first sign of rash or other hypersensitivity reaction.
- Urge patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

citalopram hydrobromide

Celexa

Class and Category

Chemical class: Racemic, bicyclic phthalate derivative

Therapeutic class: Antidepressant

Pregnancy category: C

Indications and Dosages

↗ To treat depression

ORAL SOLUTION, TABLETS

Adults. *Initial:* 20 mg daily. Increased by 20 mg at weekly intervals, as prescribed. *Usual:* 40 mg daily. *Maximum:* 60 mg daily.

DOSE ADJUSTMENT For elderly patients, maximum dosage is 40 mg daily.

Route	Onset	Peak	Duration
P.O.	1-wk	Unknown	Unknown

Mechanism of Action

Blocks serotonin reuptake by adrenergic nerves, which normally release this neurotransmitter from their storage sites when activated by a nerve impulse. This blocked reuptake increases serotonin levels at nerve synapses, which may elevate mood and reduce depression.

Contraindications

Hypersensitivity to citalopram or its components, use within 14 days of MAO inhibitor therapy

Interactions

DRUGS

amitriptyline, bromocriptine, buspirone, clomipramine, dextromethorphan, fluoxetine, fluvoxamine, furazolidone, imipramine, levodopa, lithium, mepredine, naratriptan, nefazodone, paroxetine, pentazocine, phenelzine, procarbazine, selegiline, sertraline, sibutramine, sumatriptan, tramadol, tranylcypromine, trazodone, venlafaxine, zolmitriptan: Possibly enhanced serotonergic effects of citalopram, resulting in agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperreflexia, hypomania, incoordination, myoclonus, or tremor
aspirin, NSAIDs, warfarin: Increased risk of bleeding ranging from ecchymoses to life-threatening hemorrhage
carbamazepine: Possibly increased clearance of citalopram
cimetidine: Possibly increased blood citalopram level
desipramine, metoprolol: Increased blood levels of these drugs
furazolidone, procarbazine, selegiline: Possibly hyperthermia, rigidity, myoclonus, and extreme agitation progressing to delirium and coma
itraconazole, ketoconazole, macrolide antibi-

otics, omeprazole: Possibly decreased clearance of citalopram

MAO inhibitors: Increased risk of life-threatening serotonin syndrome or neuroleptic malignant syndrome

warfarin: Possibly increased PT

Adverse Reactions

CNS: Agitation, akathisia, anxiety, asthenia, delirium, dizziness, drowsiness, dyskinesia, fatigue, fever, insomnia, myoclonus, neuroleptic malignant syndrome, seizures, serotonin syndrome, suicidal ideation, tremor

CV: Chest pain, prolonged QT interval, thrombosis, ventricular arrhythmias

EENT: Blurred vision, dry mouth, rhinitis, sinusitis

GI: Abdominal pain, anorexia, diarrhea, GI bleeding, hepatic necrosis, indigestion, nausea, pancreatitis, vomiting

GU: Acute renal failure, anorgasmia, decreased libido, dysmenorrhea, ejaculation disorders, impotence, priapism

HEME: Abnormal bleeding, decreased PT, hemolytic anemia, thrombocytopenia

MS: Arthralgia, myalgia, rhabdomyolysis

RESP: Upper respiratory tract infection

SKIN: Diaphoresis, ecchymosis, erythema multiforme

Other: Anaphylaxis, angioedema, hyponatremia, weight gain or loss

Nursing Considerations

WARNING When citalopram dosage increases, monitor patient for possible serotonin syndrome, which may include agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. In its most severe form, serotonin syndrome can resemble neuroleptic malignant syndrome, which includes a high fever, muscle rigidity, autonomic instability with possible changes in vital signs, and mental status changes.

- Be aware that effective antidepressant therapy may convert depression into mania in predisposed people. If patient develops symptoms of mania, notify prescriber immediately and expect to discontinue citalopram.
- Monitor patient with hepatic disease for increased adverse reactions because drug is extensively metabolized in the liver.

- Assess elderly patients and those taking diuretics for signs suggesting syndrome of inappropriate secretion of antidiuretic hormone, including hyponatremia and increased serum and urine osmolarity.
- If patient (especially a child or adolescent) takes citalopram for depression, monitor him closely for suicidal tendencies, especially when therapy starts or dosage changes, because depression may worsen at these times.
- To stop therapy, expect to reduce dosage gradually to avoid serious adverse reactions.

PATIENT TEACHING

- Inform patient that citalopram's full effects may take up to 4 weeks.
- Advise patient not to self-medicate for coughs, colds, or allergies without consulting prescriber because these preparations can increase the risk of adverse reactions.
- Caution patient not to stop citalopram abruptly because doing so may lead to serious adverse reactions.
- If patient (especially a child or adolescent) takes citalopram for depression, urge caregivers to monitor him closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Caution against taking OTC NSAIDs, aspirin, or other remedies (including herbal products, such as St. John's wort) while taking citalopram because they may increase the risk of bleeding.
- Urge patient to report sudden, severe, or unusual adverse reactions promptly to prescriber. Although uncommon, life-threatening adverse effects may occur.

clarithromycin

Biaxin, Biaxin XL, Biaxin XL-PAK

Class and Category

Chemical class: Macrolide derivative

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

↗ *To treat pharyngitis and tonsillitis caused by Streptococcus pyogenes*

ORAL SUSPENSION, TABLETS

Adults and adolescents. 250 mg every 12 hr for 10 days.

Children. 15 mg/kg daily in divided doses every 12 hr for 10 days.

↗ *To treat acute maxillary sinusitis caused by Haemophilus influenzae, Moraxella catarrhalis, or Streptococcus pneumoniae*

ORAL SUSPENSION, TABLETS

Adults and adolescents. 500 mg every 12 hr for 14 days.

Children. 15 mg/kg daily in divided doses every 12 hr for 10 days.

E.R. TABLETS

Adults and adolescents. 1,000 mg every 24 hr for 14 days.

↗ *To treat acute exacerbations of chronic bronchitis caused by H. influenzae, M. catarrhalis, or S. pneumoniae*

ORAL SUSPENSION, TABLETS

Adults and adolescents. 250 to 500 mg every 12 hr for 7 to 14 days.

Children. 15 mg/kg daily in divided doses every 12 hr for 10 days.

E.R. TABLETS

Adults and adolescents. 1,000 mg every 24 hr for 7 days.

↗ *To treat uncomplicated skin and soft-tissue infections caused by Staphylococcus aureus or S. pyogenes*

ORAL SUSPENSION, TABLETS

Adults and adolescents. 250 mg every 12 hr for 7 to 14 days.

Children. 15 mg/kg daily in divided doses every 12 hr for 10 days.

↗ *To treat pneumonia caused by Chlamydia pneumoniae, Mycoplasma pneumoniae, or S. pneumoniae*

ORAL SUSPENSION, TABLETS

Adults and adolescents. 250 mg every 12 hr for 7 to 14 days.

Children. 15 mg/kg daily in divided doses every 12 hr for 10 days.

↗ *To treat pneumonia caused by H. influenzae*

ORAL SUSPENSION, TABLETS

Adults and adolescents. 250 mg every 12 hr for 7 days.

Children. 15 mg/kg daily in divided doses every 12 hr for 10 days.

↗ *To treat acute otitis media caused by H. influenzae, M. catarrhalis, or S. pneumoniae*

ORAL SUSPENSION, TABLETS

Children. 15 mg/kg daily in divided doses every 12 hr for 10 days.

➤ *To treat active duodenal ulcer caused by Helicobacter pylori*

ORAL SUSPENSION, TABLETS

Adults and adolescents. 500 mg every 8 hr for 14 days with omeprazole 40 mg daily in the morning. Then, omeprazole continued at 20 mg daily in the morning days 15 through 28. Or, 500 mg every 12 hr for 14 days with lansoprazole 30 mg and amoxicillin 1 g every 12 hr for 14 days.

➤ *To prevent or treat Mycobacterium avium complex in patients with HIV infection*

ORAL SUSPENSION, TABLETS

Adults and adolescents. 500 mg every 12 hr for 7 to 14 days.

Children. 7.5 mg/kg every 12 hr. *Maximum:* 500 mg b.i.d.

Mechanism of Action

Inhibits RNA-dependent protein synthesis in many types of aerobic, anaerobic, gram-positive, and gram-negative bacteria. By binding with the 50S ribosomal subunit of the bacterial 70S ribosome, clarithromycin causes bacterial cells to die.

Contraindications

Concurrent therapy with astemizole, cispripide, pimozide, or terfenadine; hypersensitivity to clarithromycin, erythromycin, or any macrolide antibiotic

Interactions

DRUGS

astemizole, disopyramide, quinidine: Possibly prolonged QT interval or torsades de pointes

carbamazepine, other drugs metabolized by cytochrome P450 enzyme system: Increased blood levels of these drugs

cisapride, disopyramide, pimozide, quinidine, terfenadine: Increased risk of arrhythmias
colchicine: Increased risk of colchicine toxicity

digoxin: Increased serum digoxin level
dihydroergotamine, ergotamine: Risk of acute ergot toxicity

lovastatin, simvastatin: Risk of rhabdomyolysis

oral anticoagulants: Potentiated anticoagulant effects

rifabutin, rifampin: Decreased blood clarithromycin level by more than 50%

sildenafil: Possibly prolonged blood silde-

nafil level

theophylline: Increased blood theophylline level

triazolam: Possibly increased CNS effects

zidovudine: Decreased blood zidovudine level

Adverse Reactions

CNS: Anxiety, confusion, dizziness, fatigue, hallucinations, headache, insomnia, mania, nightmares, seizures, somnolence, tremor, vertigo

CV: Prolonged QT interval, ventricular arrhythmias

EENT: Altered smell, altered taste, glossitis, hearing loss, oral moniliasis, stomatitis, tinnitus, tongue or tooth discoloration

ENDO: Hypoglycemia

GI: Abdominal pain, diarrhea, indigestion, nausea, pancreatitis, pseudomembranous colitis

GU: Anorexia, elevated BUN level, hepatic dysfunction, vomiting

HEME: Leukopenia, neutropenia, increased prothrombin time, thrombocytopenia

SKIN: Pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, new or worsening myasthenia gravis symptoms, superinfection

Nursing Considerations

- Expect to obtain a specimen for culture and sensitivity tests before giving first dose.
- Use clarithromycin cautiously in patients with renal impairment. Be aware that patients with severe renal impairment may need decreased dosage or prolonged dosage interval and that clarithromycin is not recommended in combination with ranitidine bismuth citrate therapy if patient has a creatinine clearance less than 2.5 ml/min/1.73 m² or a history of acute porphyria.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold clarithromycin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

PATIENT TEACHING

- Stress the importance of taking the full course of clarithromycin exactly as pre-

- scribed, even after feeling better.
- Caution patient not to crush or chew E.R. tablets.
 - Advise patient to take drug with food if he takes E.R. tablets or has GI distress.
 - If patient takes suspension form, instruct him not to refrigerate it.
 - Tell patient to report severe nausea, rash, or itching.
 - Instruct patient not to take OTC or prescription drugs without consulting prescriber of clarithromycin.
 - Urge patient to immediately report watery, bloody stools to prescriber, even if they occur up to 2 months after therapy has ended.

clidinium bromide

Quarzan

Class and Category

Chemical class: Synthetic quaternary ammonium derivative

Therapeutic class: Anticholinergic

Pregnancy category: Not rated

Indications and Dosages

↗ *As adjunct to treat peptic ulcer*

CAPSULES

Adults. 2.5 to 5 mg t.i.d. or q.i.d. 30 to 60 min before meals and at bedtime.

DOSAGE ADJUSTMENT Dosage limited to 2.5 mg t.i.d. before meals for elderly or debilitated patients.

Route	Onset	Peak	Duration
P.O.	1 hr	Unknown	Up to 3 hr

Mechanism of Action

Inhibits acetylcholine's muscarinic actions at postganglionic parasympathetic receptor sites, including smooth muscles, secretory glands, and the CNS. These actions relax smooth muscles and diminish GI, GU, and biliary tract secretions.

Contraindications

Angle-closure glaucoma, benign bladder neck obstruction, hypersensitivity to clidinium bromide or its components, ileus, intestinal atony (elderly or debilitated patients), intestinal obstruction, myasthenia gravis, myocardial ischemia, ocular adhe-

sions between lens and iris, prostatic hypertrophy, renal disease, severe ulcerative colitis, tachycardia, toxic megacolon, unstable cardiovascular status in acute hemorrhage

Interactions

DRUGS

amantadine: Increased risk of clidinium adverse effects

atenolol: Increased atenolol effects

CNS depressants: Increased clidinium effects
phenothiazines: Decreased antipsychotic effectiveness

tricyclic antidepressants: Increased clidinium adverse effects

ACTIVITIES

alcohol use: Increased clidinium effects

Adverse Reactions

CNS: Confusion, dizziness, drowsiness, excitement, fever, headache, insomnia, memory loss, nervousness, weakness

CV: Palpitations, tachycardia

EENT: Blurred vision, cycloplegia, dry mouth, increased intraocular pressure, loss of taste, mydriasis, nasal congestion, pharyngitis, photophobia

GI: Bloating, constipation, dysphagia, heartburn, ileus, nausea, vomiting

GU: Impotence, urinary hesitancy, urine retention

SKIN: Decreased sweating, flushing, rash, urticaria

Nursing Considerations

- Avoid high doses in patients with ulcerative colitis because clidinium may inhibit intestinal motility and cause or worsen toxic megacolon. Also avoid high doses in patients with hiatal hernia or reflux esophagitis because drug may aggravate esophagitis.
- Use drug cautiously in patients with heart failure, arrhythmias, hypertension, autonomic neuropathy, hyperthyroidism, allergies, asthma, or debilitating chronic lung disease.

WARNING Monitor elderly patients for excitement, agitation, drowsiness, and confusion, even with small doses, because these patients are more sensitive to clidinium's effects. If these reactions occur, notify prescriber and expect to decrease dosage.

- Take safety precautions to protect patient from injury from falling.

PATIENT TEACHING

- Instruct patient to take clindinium exactly as prescribed and not to stop taking it suddenly because it can cause withdrawal symptoms, such as vomiting, diaphoresis, and dizziness.
- Advise patient to take drug 30 to 60 minutes before meals.
- Tell patient not to store capsules in damp places, such as the bathroom.
- Teach patient how to prevent or relieve constipation and dry mouth.
- Instruct patient to avoid alcohol and other CNS depressants because they increase the drug's effects.
- Instruct patient to report constipation, vision changes, sore throat, difficulty urinating, and palpitations.

clindamycin hydrochloride

Cleocin, Dalacin C

clindamycin palmitate hydrochloride

Cleocin Pediatric, Dalacin C Flavored Granules (CAN)

clindamycin phosphate

Cleocin, Clindesse, Dalacin C Phosphate (CAN), Evoclin

Class and Category

Chemical class: Lincosamide

Therapeutic class: Antibacterial and anti-protozoal antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat serious respiratory tract infections caused by anaerobes such as occur with anaerobic pneumonitis, empyema, and lung abscess and those caused by pneumococci, staphylococci, and streptococci; serious skin and soft-tissue infections caused by anaerobes, staphylococci, and streptococci; septicemia caused by*

anaerobes; intra-abdominal infections caused by anaerobes such as occur with intra-abdominal abscess and peritonitis; infections of the female pelvis and genital tract caused by anaerobes such as occur with endometritis, nongonococcal tubo-ovarian abscess, pelvic cellulitis, and postsurgical vaginal cuff infection; bone and joint infections caused by Staphylococcus aureus; as adjunct therapy in chronic bone and joint infections

CAPSULES, ORAL SOLUTION

Adults and adolescents. For serious infections, 150 to 300 mg every 6 hr; for severe infections, 300 to 450 mg every 6 hr.

Children. For serious infections, 8 to 16 mg/kg daily in equally divided doses t.i.d. or q.i.d.; for severe infections, 16 to 20 mg/kg/day in equally divided doses t.i.d. or q.i.d.

I.V. INFUSION, I.M. INJECTION

Adults and adolescents age 16 and over.

For serious infections, 600 to 1,200 mg daily in equally divided doses b.i.d. to q.i.d.; for severe infections, 1,200 to 2,700 mg daily in equally divided doses b.i.d. to q.i.d.; for life-threatening infections, 4,800 mg daily in equally divided doses b.i.d. to q.i.d.

Children ages 1 month to 16 years. 20 to 40 mg/kg daily in equally divided doses t.i.d. or q.i.d., depending on severity of infection.

Neonates less than age 1 month. 15 to 20 mg/kg daily in equally divided doses t.i.d. or q.i.d., depending on severity of infection.

➤ *To treat vaginal infections caused by Gardnerella or Haemophilus*

VAGINAL CREAM

Nonpregnant adults. 100 mg (1 applicatorful) into vagina daily, preferably at bedtime, for 3 to 7 consecutive days.

Pregnant adults in second or third trimester. 100 mg (1 applicatorful) into vagina daily, preferably at bedtime, for 7 consecutive days.

➤ *To treat acne vulgaris*

FOAM

Adults and adolescents. Apply to affected area daily.

Mechanism of Action

Inhibits protein synthesis in susceptible bacteria by binding to the 50S subunits of

bacterial ribosomes and preventing peptide bond formation, which causes bacterial cells to die.

Incompatibilities

To prevent physical incompatibility, don't administer with aminophylline, ampicillin, barbiturates, calcium gluconate, magnesium sulfate, or phenytoin.

Contraindications

Hypersensitivity to clindamycin or lincomycin

Interactions

DRUGS

erythromycin: Possibly blocked access of clindamycin to its site of action

kaolin-pectin antidiarrheals: Decreased absorption of oral clindamycin

neuromuscular blockers: Increased neuromuscular blockade

Adverse Reactions

CNS: Fatigue, headache

CV: Hypotension, thrombophlebitis (after I.V. injection)

EENT: Glossitis, metallic or unpleasant taste (with high I.V. doses), stomatitis

GI: Abdominal pain, diarrhea, esophagitis, nausea, pseudomembranous colitis, vomiting

GU: Cervicitis, vaginitis, and vulvar irritation (with vaginal form)

HEME: Agranulocytosis, eosinophilia, leukopenia, neutropenia, thrombocytopenic purpura

SKIN: Pruritus, rash, urticaria

Other: Anaphylaxis; induration, pain, or sterile abscess after injection; superinfection

Nursing Considerations

- Expect to obtain a specimen for culture and sensitivity testing before giving first dose.
- Use clindamycin cautiously in patients who have a history of asthma, significant allergies, or GI disease; in those with renal or hepatic dysfunction; and in elderly or atopic patients.

WARNING Don't give 75- and 150-mg capsules to tartrazine-sensitive patients.

- Store oral solution for up to 2 weeks at room temperature or reconstituted parenteral solution for up to 24 hours at room temperature.

- Give I.V. dose by infusion only; don't give bolus dose. Dilute 300 mg of clindamycin in 50 ml of diluent and give over 10 minutes. Dilute 600 mg of clindamycin in 100 ml of diluent and give over 20 minutes. Dilute 900 mg of clindamycin in 100 ml of diluent and give over 30 minutes.

WARNING Don't use diluents that contain benzyl alcohol when clindamycin is to be administered to neonates because a fatal toxic syndrome may occur.

- Give I.M. injection deep into large muscle mass, such as the gluteus maximus. Rotate injection sites, and avoid giving more than 600 mg by I.M. injection.
- Check I.V. site often for phlebitis and irritation.
- For topical foam, wash the affected area with mild soap, let it dry fully, and then apply foam to entire affected area.
- Monitor results of liver function tests, CBC, and platelet counts during prolonged therapy.
- Observe patient for signs and symptoms of superinfection, such as vaginal itching and sore mouth, which may occur 2 to 9 days after therapy begins.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold clindamycin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

PATIENT TEACHING

- Tell patient to complete the prescribed course of therapy, even if he feels better before it's finished.
- Instruct patient to take oral clindamycin with at least 8 oz of water to prevent esophageal irritation.
- Advise patient to take oral drug with food, if needed, to reduce GI distress.
- Tell patient not to refrigerate reconstituted oral solution because it may become thick and difficult to pour and to discard unused drug after 14 days.
- If patient will use topical foam, tell him to wash affected area with mild soap, let it dry fully, and then apply foam to entire area. Caution against dispensing foam directly onto hands or face because foam will melt when it contacts warm skin. Instead, patient should dispense amount

to be used into the cap or onto a cool surface. Tell patient to pick up a small amount with fingertips and gently massage into affected area until foam disappears. If foam feels warm or looks runny, tell patient to run the can under cold water before dispensing.

- Warn patient not to rely on latex or rubber condoms and diaphragms for 72 hours after vaginal treatment because mineral oil in vaginal cream may weaken these items.
- Explain that having sexual intercourse after using vaginal cream can increase irritation.
- Inform patient that I.M. injection may be painful.
- Tell patient to immediately report an inflamed mouth or vagina, and rash or lesions.
- Urge patient to immediately report watery, bloody stools to prescriber, even up to 2 months after drug therapy has ended.

clofibrate

Abibrate, Atromid-S, Claripex (CAN), Novofibrate (CAN)

Class and Category

Chemical class: Aryloxyisobutyric acid derivative

Therapeutic class: Antihyperlipidemic

Pregnancy category: C

Indications and Dosages

➤ *To treat primary hyperlipidemia (type III) that doesn't respond to diet, and type IV and type V hyperlipidemia that don't respond to diet in patients at risk for abdominal pain and pancreatitis*

CAPSULES

Adults. 1.5 to 2 g daily in divided doses b.i.d. to q.i.d.

Route	Onset	Peak	Duration
P.O.	2–5 days	3 wk	3 wk

Mechanism of Action

Increases the amount of cholesterol that's secreted into bile and of bile that's excreted in the feces. Clofibrate also may increase the activity of lipoprotein lipase, which degrades VLDLs.

Contraindications

Hepatic dysfunction, hypersensitivity to clofibrate, lactation, peptic ulcer, pregnancy, primary biliary cirrhosis, renal dysfunction

Interactions

DRUGS

chenodiol, ursodiol: Counteracted effectiveness of these drugs

dantrolene: Decreased plasma protein binding of dantrolene

furosemide: Increased furosemide and clofibrate effects

insulin, sulfonylureas: Increased antidiabetic effect

oral anticoagulants: Increased bleeding tendency

oral contraceptives: Decreased effectiveness of clofibrate

phenytoin: Displacement of phenytoin from binding site

probenecid: Increased clofibrate effects

rifampin: Decreased clofibrate effects

Adverse Reactions

CNS: Dizziness, drowsiness, fatigue, headache, weakness

CV: Angina, edema, phlebitis

EENT: Stomatitis

GI: Abdominal pain, bloating, diarrhea, flatulence, nausea, vomiting

GU: Decreased libido, decreased urine output, impotence, proteinuria

HEME: Eosinophilia

MS: Arthralgia, myalgia

SKIN: Alopecia, dry skin and hair, pruritus, rash, urticaria

Other: Weight gain

Nursing Considerations

- Obtain baseline CBC, liver and renal function studies, and cholesterol profile, as ordered.

- Use clofibrate cautiously in patients with a history of hepatic disease or jaundice and in those with peptic ulcer disease.

PATIENT TEACHING

- Tell patient to take clofibrate with milk or food to reduce GI distress.
- Tell patient that repeated laboratory tests will be needed to evaluate serum cholesterol and triglyceride levels.
- Stress the importance of diet, exercise, and weight loss to control cholesterol.
- Tell patient to report ankle or leg swelling, chest pain, decreased urine output, severe

GI reactions, and unusual weight gain.

- If patient takes an anticoagulant, tell him to watch carefully for signs and symptoms of abnormal bleeding.
- If patient takes antidiabetic drugs, instruct him to stay alert for signs of hypoglycemia from interactions with these drugs.
- Advise women of childbearing age to use contraception during and for several months after clofibrate therapy because of teratogenic effects.

clomipramine hydrochloride

Anafranil

Class and Category

Chemical class: Dibenzazepine derivative

Therapeutic class: Antiobsessional tricyclic antidepressant

Pregnancy category: C

Indications and Dosages

↗ *To treat obsessive-compulsive disorder*

CAPSULES, TABLETS

Adults. *Initial:* 25 mg daily. Gradually increased to 100 mg daily in divided doses over 2 wk, then to maximum of 250 mg daily in divided doses over next few weeks. At maximum dose, total daily amount may be given at bedtime.

Children age 10 and over. *Initial:* 25 mg daily. Gradually increased to the lesser of 3 mg/kg daily or 100 mg daily in divided doses over 2 wk, then to maximum of 3 mg/kg daily or 200 mg daily, whichever is less. At maximum dose, total daily amount may be given at bedtime.

Route	Onset	Peak	Duration
P.O.	Unknown	2–4 wk	Unknown

Mechanism of Action

May inhibit neuronal reuptake of norepinephrine and serotonin, which may be a factor in normalizing neurotransmission in obsessive-compulsive behavior.

Contraindications

Acute recovery period after MI, hypersensitivity to clomipramine or its components, use of an MAO inhibitor within 14 days

Interactions

DRUGS

anticholinergics: Increased anticholinergic effects

barbiturates: Decreased level and effects of clomipramine; additive CNS depression

bupropion, cimetidine, haloperidol, H₂-receptor antagonists, selective serotonin reuptake inhibitors, valproic acid: Increased blood level and therapeutic and adverse effects of clomipramine

carbamazepine: Decreased blood clomipramine level; increased carbamazepine level

clonidine: Severely increased blood pressure and risk of hypertensive crisis

CNS depressants: Increased CNS depression

dicumarol: Increased anticoagulant effect

grepafloxacin, quinolones, sparfloxacin:

Increased risk of life-threatening arrhythmias

guanethidine: Antagonized antihypertensive effect of guanethidine

levodopa: Delayed absorption and decreased bioavailability of levodopa

MAO inhibitors: Increased risk of seizures, coma, or death

rifamycins: Decreased clomipramine level

sympathomimetics: Possibly potentiated cardiovascular effects

thyroid drugs: Increased effects of thyroid drugs and clomipramine

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Anxiety, confusion, depersonalization, depression, dizziness, drowsiness, emotional lability, fatigue, headache, insomnia, panic reaction, paresthesia, somnolence, suicidal ideation (children and teens), syncope, tremor, unusual dreams, yawning

CV: Orthostatic hypotension, palpitations, tachycardia

EENT: Blurred vision, dry mouth, epistaxis, pharyngitis, rhinitis, sinusitis, unpleasant taste

GI: Abdominal pain, anorexia, constipation, diarrhea, flatulence, increased appetite, indigestion, nausea, vomiting

GU: Dysmenorrhea, ejaculation failure, impotence, urinary hesitancy, urine retention

RESP: Bronchospasm

SKIN: Abnormal skin odor, acne, dermatitis, dry skin, photosensitivity, rash, urticaria

Other: Weight gain

Nursing Considerations

• Be aware that stopping clomipramine abruptly may cause withdrawal symptoms and worsen disorder.

WARNING Don't give drug within 14 days of an MAO inhibitor to avoid possible seizures, coma, or death.

WARNING Monitor children and teens closely for evidence of suicidal ideation; clomipramine increases the risk in these groups.

PATIENT TEACHING

- Tell patient not to use alcohol, barbiturates, or other CNS depressants; clomipramine increases their effects.
- WARNING** Urge parents to watch their child or teen closely for abnormal thinking or behavior or increased aggression or hostility. Stress the need to notify prescriber if they occur.
- Inform male patients about risk of sexual dysfunction while taking drug.
- Caution patient that drug may cause drowsiness, especially during initial dosage adjustment.
- Warn patient not to stop taking drug abruptly.
- Instruct patient to take a missed dose as soon as he remembers unless it's almost time for the next scheduled dose, in which case he should skip the missed dose. Warn against doubling the next dose.
- Teach patient how to prevent photosensitivity reactions.
- Tell patient to report difficulty urinating, dizziness, dry mouth, sedation, and mental changes.
- Caution patient to avoid hazardous activities until CNS effects of drug are known.

clonazepam

Apo-Clonazepam (CAN), Clonapam (CAN), Gen-Clonazepam (CAN), Klonopin, Rivotril (CAN)

Class, Category, and Schedule

Chemical class: Benzodiazepine
Therapeutic class: Anticonvulsant
Pregnancy category: D
Controlled substance schedule: IV

Indications and Dosages

↗ To treat Lennox-Gastaut syndrome

(type of absence seizure disorder) and akinetic and myoclonic seizures

TABLETS

Adults and children over age 10. 1.5 mg daily in divided doses t.i.d. Increased by 0.5 to 1 mg every 3 days, if needed, until seizures are controlled. *Maximum:* 20 mg daily.

Children age 10 and under or weighing less than 30 kg (66 lb). 0.01 to 0.03 mg/kg daily in divided doses b.i.d. or t.i.d.

Increased by 0.25 to 0.5 mg every third day up to maintenance dosage. *Maintenance:* 0.1 to 0.2 mg/kg daily, preferably in three equal doses, or if unequal, with largest dose given at bedtime. *Maximum:* 0.05 mg/kg daily.

↗ To treat panic disorder

TABLETS

Adults. *Initial:* 0.25 mg b.i.d. Increased, if needed, to 1 mg daily after 3 days. If more than 1 mg daily is required, dosage increased in increments of 0.125 to 0.25 mg b.i.d. every 3 days until panic disorder is controlled or adverse reactions make further increases undesirable. This maintenance dosage may be given as a single dose at bedtime. *Maximum:* 4 mg daily.

Mechanism of Action

Prevents seizures by potentiating the effects of gamma-aminobutyric acid (GABA), which is an inhibitory neurotransmitter. Suppresses the spread of seizure activity caused by seizure-producing foci in the cortex, thalamus, and limbic structures.

Contraindications

Acute angle-closure glaucoma, hepatic disease, hypersensitivity to benzodiazepines or their components

Interactions

DRUGS

antianxiety drugs, barbiturates, MAO inhibitors, opioids, phenothiazines, tricyclic antidepressants: Increased CNS depression

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Ataxia, confusion, depression, dizziness, drowsiness, emotional lability, fatigue, headache, memory loss, nervousness, reduced intellectual ability, suicidal ideation
CV: Palpitations

EENT: Blurred vision, eyelid spasm, increased salivation, loss of taste, pharyngitis, rhinitis, sinusitis

GI: Abdominal pain, anorexia, constipation

GU: Difficult ejaculation, dysmenorrhea, dysuria, enuresis, impotence, nocturia, urine retention, UTI

HEME: Anemia, eosinophilia, leukopenia, thrombocytopenia

MS: Dysarthria, myalgia

RESP: Bronchitis, cough

Other: Allergic reaction

Nursing Considerations

- Use clonazepam cautiously in patients with renal failure, mixed seizure disorder (because drug can increase the risk of generalized tonic-clonic seizures), or respiratory disease and troublesome secretions (because clonazepam increases salivation) and in elderly patients (because they're more sensitive to drug's CNS effects).
- Monitor blood drug level, CBC, and liver function test results during long-term or high-dose therapy, as ordered.

WARNING Don't stop drug abruptly; expect to taper dosage gradually to avoid withdrawal symptoms and seizures.

- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

PATIENT TEACHING

- Tell patient to take drug exactly as prescribed. Explain that stopping abruptly can cause seizures and withdrawal symptoms.
- Advise patient to avoid alcohol and sleep-inducing drugs during therapy. Instruct him to consult prescriber before taking any OTC drugs.
- Urge patient to carry medical identification of his seizure disorder and drug therapy.
- Warn patient about possible drowsiness.
- Instruct patient to report severe dizziness, persistent drowsiness, palpitations, difficulty urinating, seizure activity, and other disruptive adverse reactions.
- Suggest that parents monitor child's performance in school because clonazepam can cause drowsiness or inattentiveness.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report concerns to prescriber

immediately.

- Urge female patient who becomes pregnant while taking clonazepam to enroll in the Antiepileptic Drug Pregnancy Registry by calling 1-888-233-2334. Explain that the registry is studying the safety of antiepileptic drugs during pregnancy.

clonidine

Catapres-TTS

clonidine hydrochloride

Catapres, Dixarit (CAN), Duraclon

Class and Category

Chemical class: Imidazoline derivative

Therapeutic class: Analgesic, antihypertensive

Pregnancy category: C

Indications and Dosages

➤ *To manage hypertension*

TABLETS

Adults. *Initial:* 0.1 mg b.i.d., increased by 0.1 mg/wk to produce desired response.

Maintenance: 0.2 to 0.6 mg daily in divided doses b.i.d. or t.i.d. *Maximum:* 2.4 mg daily.

TRANSDERMAL PATCH

Adults. *Initial:* 0.1-mg patch applied to hairless area of intact skin on upper arm or torso every 7 days. After 1 to 2 wk, if blood pressure isn't controlled, two 0.1-mg patches or one 0.2-mg patch applied to skin.

Dosage adjusted, as needed, every 7 days.

Maximum: Two 0.3-mg patches worn at same time.

➤ *To treat severe hypertension*

TABLETS

Adults. 0.2 mg, then 0.1 mg every 1 hr until diastolic blood pressure reaches acceptable range or 0.8 mg has been administered.

DOSAGE ADJUSTMENT Dosage individualized for patients with renal failure.

➤ *As adjunct to relieve severe pain (in cancer patients) that isn't adequately relieved by opioid analgesics alone*

CONTINUOUS EPIDURAL INFUSION

Adults. *Initial:* 30 mcg/hr. Titrated up or down, if needed, depending on comfort.

Maximum: 40 mcg/hr.

Children old enough to tolerate placement

and management of epidural catheter.

Initial: 0.5 mcg/kg/hr. Then, titrated to achieve comfort.

Route	Onset	Peak	Duration
P.O.	30–60 min	2–4 hr	8 hr
Trans-dermal	2–3 days	Unknown	7 days

Mechanism of Action

Stimulates peripheral alpha-adrenergic receptors in the CNS to produce transient vasoconstriction and then stimulates central alpha-adrenergic receptors in the brain stem to reduce peripheral vascular resistance, heart rate, and systolic and diastolic blood pressure. May produce analgesia by preventing transmission of pain signals to the brain at presynaptic and postjunctional alpha₂-adrenoreceptors in the spinal cord. With epidural administration, clonidine produces analgesia in body areas innervated by the spinal cord segments in which the drug concentrates.

Contraindications

Anticoagulant therapy (epidural infusion); bleeding diathesis; hypersensitivity to clonidine or its components, including adhesive used in transdermal patch; injection site infection (epidural infusion)

Interactions**DRUGS**

barbiturates, other CNS depressants:

Increased depressant effects of these drugs
beta blockers, calcium channel blockers, digoxin: Additive effects, such as bradycardia and AV block; increased risk of worsened hypertensive response when clonidine is withdrawn (beta blockers only)

diuretics, other antihypertensive drugs:

Increased hypotensive effect
epidural local anesthetics: Prolonged effects of epidural local anesthetics when used with epidural clonidine

levodopa: Decreased levodopa effectiveness
prazosin, tricyclic antidepressants: Decreased antihypertensive effect of clonidine

ACTIVITIES

alcohol use: Enhanced CNS depressant effects of alcohol

Adverse Reactions

CNS: Agitation, delusional perception,

depression, dizziness, drowsiness, fatigue, headache, malaise, nervousness, paresthesia, sedation, syncope, weakness

CV: Arrhythmias, chest pain, congestive heart failure, high-degree AV block, orthostatic hypotension, Raynaud's phenomenon

EENT: Accommodation disorder, blurred vision, burning eyes, decreased lacrimation, dry eyes and mouth, salivary gland pain

GI: Constipation, hepatitis, mildly elevated liver function test results, nausea, vomiting

GU: Decreased libido, erectile dysfunction, nocturia

HEME: Thrombocytopenia

SKIN: Angioneurotic edema, pruritus, rash, urticaria

Other: Weight gain, withdrawal symptoms

Nursing Considerations

- Use clonidine cautiously in elderly patients, who may be more sensitive to its hypotensive effect.
- Monitor blood pressure and heart rate often during clonidine therapy.
- Expect transdermal clonidine to take 2 to 3 days to lower blood pressure.
- Remove patch before patient has an MRI to avoid possible burns at the patch site.
- Be aware that stopping drug abruptly can elevate serum catecholamine levels and cause such withdrawal symptoms as nervousness, agitation, headache, confusion, tremor, and rebound hypertension.
- Expect hypertension to return within 48 hours after drug is discontinued.

PATIENT TEACHING

- Advise patient to take drug exactly as prescribed and not to stop abruptly because withdrawal symptoms and severe hypertension may occur.
- Instruct patient to consult prescriber if dry mouth or drowsiness becomes a problem during oral clonidine therapy. To minimize these effects, prescriber may suggest taking most of dosage at bedtime.
- If a transdermal patch loosens during 7-day application period, tell patient to place adhesive overlay directly over patch to ensure adhesion.
- Tell patient to rotate transdermal sites.
- Instruct patient to remove patch and place a fresh one on another site if skin irritation, redness, or rash develops at patch site.

- Advise patient to fold used transdermal patch in half with adhesive sides together and discard it out of the reach of children.
- Because of possible sedation, advise patient to avoid hazardous activities until drug's CNS effects are known.
- Advise men that libido may decrease.
- Instruct patient to report chest pain, dizziness with position changes, excessive drowsiness, rash, urine retention, and vision changes. As needed, tell patient to rise slowly to avoid hypotensive effects.
- Inform patient who wears contact lenses that clonidine may cause dry eyes.

clopidogrel bisulfate

Plavix

Class and Category

Chemical class: Thienopyridine derivative

Therapeutic class: Platelet aggregation inhibitor

Pregnancy category: B

Indications and Dosages

↗ *To reduce atherosclerotic events, such as stroke and MI, in patients with atherosclerosis documented by recent stroke, MI, or peripheral artery disease*

TABLETS

Adults. 75 mg daily.

↗ *To reduce atherosclerotic events, such as stroke and MI, in patients with acute coronary syndrome (unstable angina or non-Q-wave MI)*

TABLETS

Adults. *Loading dose:* 300 mg. *Maintenance:* 75 mg daily.

↗ *To reduce rate of death, reinfarction, or stroke in patients with ST-segment elevation acute MI*

TABLETS

Adults. 75 mg once daily. Or, loading dose of 300 mg followed by 75 mg once daily.

Mechanism of Action

Binds to adenosine diphosphate (ADP) receptors on the surface of activated platelets. This action blocks ADP, which deactivates nearby glycoprotein IIb/IIIa receptors and prevents fibrinogen from

attaching to receptors. Without fibrinogen, platelets can't aggregate and form thrombi.

Route	Onset	Peak	Duration
P.O.	2 hr	3–7 days*	5 days

Contraindications

Active pathological bleeding, including peptic ulcer and intracranial hemorrhage; hypersensitivity to clopidogrel or its components

Interactions

DRUGS

aspirin: Increased risk of bleeding
CYP2C19 inhibitors, such as cimetidine, esomeprazole, etravirine, felbamate, fluconazole, fluoxetine, fluvoxamine, ketoconazole, omeprazole, ticlopidine, voriconazole: Decreased plasma clopidogrel level, decreased platelet inhibition
fluvastatin, phenytoin, tamoxifen, tolbutamide, torsemide: Interference with metabolism of these drugs
NSAIDs: Increased risk of GI bleeding, interference with NSAID metabolism
warfarin: Prolonged bleeding time, interference with warfarin metabolism

Adverse Reactions

CNS: Confusion, depression, dizziness, fatigue, hallucinations, headache
CV: Chest pain, edema, hypercholesterolemia, hypertension, hypotension, vasculitis
EENT: Altered taste; conjunctival, ocular, or retinal bleeding; epistaxis; rhinitis; taste disorders
GI: Abdominal pain; acute liver failure; colitis; diarrhea; duodenal, gastric, or peptic ulcer; elevated liver function test results; gastritis; indigestion; nausea; noninfectious hepatitis; pancreatitis
GU: Elevated serum creatinine level, glomerulopathy, UTI
HEME: Agranulocytosis, aplastic anemia, neutropenia, pancytopenia, prolonged bleeding time, thrombocytopenic purpura, thrombotic thrombocytopenic purpura, unusual bleeding or bruising
MS: Arthralgia, back pain, myalgia
RESP: Bronchitis, bronchospasm, cough, dyspnea, interstitial pneumonitis, upper respiratory tract infection

* With repeated doses.

SKIN: Erythema multiforme, lichen planus, pruritus, purpura, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, angioedema, flulike symptoms, serum sickness

Nursing Considerations

- Avoid clopidogrel in patients who have a genetic variation in CYP2C19 or are receiving CYP2C19 inhibitors. Platelet inhibition may decline, increasing the risk of adverse cardiovascular effects after MI.
- Use clopidogrel cautiously in patients with severe hepatic or renal disease, risk of bleeding from trauma or surgery, or conditions that predispose to bleeding (such as peptic ulcer disease or thrombotic thrombocytopenic purpura).
- In patient with acute coronary syndrome, expect to give aspirin with clopidogrel.

WARNING Clopidogrel prolongs bleeding time; expect to stop it 5 days before elective surgery.

- Obtain blood cell count, as ordered, whenever signs and symptoms suggest a hematologic problem.
- Monitor patient who takes aspirin closely because risk of bleeding is increased.

PATIENT TEACHING

- Discourage use of NSAIDs, including OTC preparations, during clopidogrel therapy because of potential for bleeding.
- Caution patient that bleeding may continue longer than usual. Instruct him to report unusual bleeding or bruising.
- Because he has an increased risk of bleeding, urge patient to inform all other health care providers, including dentists, that he takes clopidogrel before having surgery or other procedures or taking a new drug.
- Instruct patient to inform his health care providers about his clopidogrel therapy.

clorazepate dipotassium

Apo-Clorazepate (CAN), Novo-Clopat (CAN), Tranxene (CAN), Tranxene-SD, Tranxene-SD Half Strength

Class, Category, and Schedule

Chemical class: Benzodiazepine

Therapeutic class: Alcohol withdrawal

adjunct, antianxiety drug, anticonvulsant

Pregnancy category: Not rated

Controlled substance schedule: IV

Indications and Dosages

↗ *To relieve anxiety*

CAPSULES, TABLETS

Adults and adolescents. *Initial:* 15 mg at bedtime or 7.5 to 15 mg b.i.d. Dosage adjusted, as needed, to 15 to 60 mg daily in divided doses b.i.d. to q.i.d. *Maximum:* 90 mg daily.

E.R. TABLETS

Adults and adolescents. 11.25 mg daily as substitute for capsules or tablets in patients who were stabilized on 3.75 mg t.i.d. of those forms; 22.5 mg daily as substitute for capsules or tablets in patients who were stabilized on 7.5 mg t.i.d. of those forms.

↗ *To relieve symptoms of acute alcohol withdrawal*

CAPSULES, TABLETS

Adults. *Initial:* 30 mg followed by 15 mg b.i.d. to q.i.d. on day 1 of therapy; 15 mg three to six times on day 2; 7.5 to 15 mg t.i.d. on day 3; 7.5 mg b.i.d. to q.i.d. on day 4; and thereafter, 3.75 mg b.i.d. to q.i.d. *Maximum:* 90 mg daily.

↗ *As adjunct to treat partial seizure disorder*

CAPSULES, TABLETS

Adults and adolescents. *Initial:* Up to 7.5 mg t.i.d. Increased, if needed, by up to 7.5 mg/wk. *Maximum:* 90 mg daily.

Children ages 9 to 12. *Initial:* 7.5 mg b.i.d. Increased, if needed, by up to 7.5 mg/wk. *Maximum:* 60 mg daily.

E.R. TABLETS

Adults and adolescents. 11.25 mg daily as substitute for capsules or tablets in patients who were stabilized on 3.75 mg t.i.d. of those forms; 22.5 mg daily as substitute for capsules or tablets in patients who were stabilized on 7.5 mg t.i.d. of those forms.

DOSAGE ADJUSTMENT Initial dosage reduced to 3.75 to 15 mg daily to treat anxiety in elderly patients.

Mechanism of Action

Potentiates action of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptor sites in limbic and cortical areas of CNS, which helps control emotional behavior and suppresses spread of seizure

activity. Drug also helps relieve symptoms of alcohol withdrawal by depressing CNS.

Contraindications

Angle-closure glaucoma, hypersensitivity to clorazepate or its components

Interactions

DRUGS

barbiturates, MAO inhibitors, opioids, other antidepressants, phenothiazines: Potentiated effects of clorazepate

cimetidine, disulfiram, fluoxetine, isoniazid, ketoconazole, metoprolol, oral contraceptives, propoxyphene, propranolol, valproic acid:

Increased blood clorazepate level

clozapine: Possibly increased risk of shock

ACTIVITIES

alcohol use: Potentiated clorazepate effects

Adverse Reactions

CNS: Anxiety, ataxia, confusion, depression, dizziness, drowsiness, fatigue, headache, insomnia, irritability, nervousness, psychosis, slurred speech, suicidal ideation, tremor

CV: Hypotension

EENT: Blurred vision, diplopia, dry mouth

GI: Anorexia, constipation, diarrhea, elevated liver function test results, nausea, vomiting

GU: Elevated BUN and serum creatinine levels, incontinence, libido changes, menstrual irregularities, urine retention

HEME: Decreased hematocrit

SKIN: Rash

Other: Drug dependence

Nursing Considerations

WARNING Be aware that prolonged use of therapeutic doses can lead to dependence.

- Monitor liver function test results during therapy.
- Watch closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

PATIENT TEACHING

- Tell patient to take clorazepate with food if GI distress occurs.
- Advise patient to avoid alcohol and other CNS depressants while taking drug.
- Urge patient to avoid hazardous activities until CNS effects of drug are known.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report concerns to prescriber

immediately.

- Urge female patient who becomes pregnant while taking clorazepate to enroll in the antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is studying the safety of antiepileptic drugs during pregnancy.

cloxacillin sodium

Apo-Cloxi (CAN), **Cloxapen**, **Novo-Cloxin** (CAN), **Nu-Cloxi** (CAN), **Orbenin** (CAN), **Tegopen**

Class and Category

Chemical class: Penicillinase-resistant isoxazolyl penicillin derivative

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat mild to moderate upper respiratory tract infections or localized skin and soft-tissue infections caused by penicillinase-producing staphylococci*

CAPSULES, ORAL SOLUTION, I.V. INFUSION, I.V. OR I.M. INJECTION

Adults and children weighing 20 kg (44 lb) or more. 250 mg every 6 hr. *Maximum:* 6 g daily.

Children and infants weighing less than 20 kg. 50 mg/kg daily in equally divided doses every 6 hr.

➤ *To treat severe lower respiratory tract infections or disseminated infections caused by penicillinase-producing staphylococci*

CAPSULES, ORAL SOLUTION, I.V. INFUSION, I.V. OR I.M. INJECTION

Adults and children weighing 20 kg or more. 500 mg every 6 hr. *Maximum:* 6 g daily.

Infants and children weighing less than 20 kg. 100 mg/kg daily in divided doses every 6 hr.

Mechanism of Action

Inhibits cell wall synthesis and causes cell lysis and death in bacteria that make rigid, cross-linked cell walls in several steps. Cloxacillin affects the final stage of cross-linking by binding with and inactivating penicillin-binding protein, the enzyme that causes linkage in cell wall strands.

Incompatibilities

Don't mix cloxacillin with aminoglycosides because of risk of mutual inactivation.

Contraindications

Hypersensitivity to cloxacillin, penicillin, or their components

Interactions**DRUGS**

chloramphenicol, erythromycins, sulfonamides, tetracyclines: Decreased cloxacillin effects

hepatotoxic drugs, such as fluconazole:

Increased risk of hepatotoxicity

methotrexate: Increased blood methotrexate level and risk of toxicity

probenecid: Increased and prolonged blood cloxacillin level

Adverse Reactions

CNS: Headache

EENT: Glossitis, oral candidiasis

GI: Abdominal pain, diarrhea, elevated liver function test results, nausea, pseudomembranous colitis, vomiting

GU: Hematuria, vaginal candidiasis

MS: Muscle twitching

SKIN: Pruritus, rash, urticaria

Other: Anaphylaxis

Nursing Considerations

- Use cloxacillin cautiously in patients hypersensitive to cephalosporins (allergic reaction may be delayed) and those with hypertension (drug is relatively high in sodium).
- For I.V. injection, reconstitute 250-mg vial with 4.9 ml of sterile water for injection, 500-mg vial with 4.8 ml, and 2,000-mg vial with 6.8 ml. Shake to dissolve.
- For direct I.V. injection, give over 2 to 4 minutes through tubing of a compatible infusing I.V. solution. If giving by intermittent I.V. infusion, further dilute with a suitable diluent (see package insert) and administer over 30 to 40 minutes.
- For I.M. injection, reconstitute 250-mg vial with 1.9 ml of sterile water for injection and 500-mg vial with 1.7 ml of sterile water. Shake to dissolve.
- Be aware that parenteral solutions are stable 24 hours at room temperature and 72 hours if refrigerated.

PATIENT TEACHING

- Tell patient to finish full course of therapy,

even if he feels better before drug is gone.

- Instruct patient to take oral cloxacillin 1 to 2 hours before meals.
- Tell patient to take oral form of cloxacillin with a full glass of water (not fruit juice or soda).
- Instruct patient taking oral solution to refrigerate container and to discard unused portion after 14 days. Also instruct him to use a calibrated measuring device to ensure accurate doses.
- Advise patient to report signs or symptoms of allergic reaction.

clozapine

Clozaril, Fazaclo

Class and Category

Chemical class: Dibenzodiazepine derivative

Therapeutic class: Antipsychotic

Pregnancy category: B

Indications and Dosages

↗ *To treat severe schizophrenia unresponsive to standard drugs; to reduce risk of recurrent suicidal behavior in schizophrenia or schizoaffective disorders*

ORALLY DISINTEGRATING TABLETS, TABLETS

Adults. *Initial:* 12.5 mg once or twice daily. Increased by 25 to 50 mg daily to 300 to 450 mg daily by the end of 2 wk. Dosage adjustments shouldn't exceed 100 mg once or twice per wk. *Maximum:* 900 mg daily.

Route	Onset	Peak	Duration
P.O.	1–6 hr	Unknown	4–12 hr

Mechanism of Action

May produce antipsychotic effects by interfering with dopamine binding to dopamine—especially D₄—receptors in the limbic region of the brain and by antagonizing adrenergic, cholinergic, histaminic, and serotonergic receptors.

Contraindications

Angle-closure glaucoma, coma, history of clozapine-induced agranulocytosis or severe granulocytopenia, hypersensitivity to clozapine or its components, myeloproliferative disorders, severe CNS depression, uncontrolled epilepsy, WBC count below 3,500/mm³

Interactions

DRUGS

anticholinergics: Potentiated anticholinergic effects

benzodiazepines, psychotropics: Additive hypotensive effects; increased risk of cardiopulmonary collapse

bone marrow depressants: Potentiated myelosuppressive effects

carbamazepine, phenytoin: Decreased blood clozapine level

cimetidine, citalopram, erythromycin: Increased blood clozapine level

CNS depressants: Increased CNS depression
digoxin, warfarin: Increased blood level of digoxin and warfarin; displacement of clozapine from its binding site

lithium: Increased risk of confusion, dyskinesia, neuroleptic malignant syndrome, and seizures

selective serotonin reuptake inhibitors: Markedly increased blood clozapine level; increased risk of adverse effects and leukocytosis

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Agitation, akinesia, anxiety, ataxia, confusion, depression, dizziness, drowsiness, dystonia, fatigue, fever, headache, hyperkinesia, hypokinesia, insomnia, lethargy, myoclonic jerks, neuroleptic malignant syndrome, nightmares, restlessness, rigidity, sedation, seizures, sleep disturbance, slurred speech, syncope, tardive dyskinesia, tremor, vertigo, weakness

CV: Cardiac arrest, cardiomyopathy, chest pain, deep vein thrombosis, ECG changes, hypercholesterolemia, hypertension, hypertriglyceridemia, hypotension, myocarditis, orthostatic hypotension, tachycardia

EENT: Blurred vision, dry mouth, increased nasal congestion, increased salivation, pharyngitis, tongue numbness or soreness

ENDO: Ketoacidosis, severe hyperglycemia

GI: Abdominal discomfort, anorexia, constipation, diarrhea, elevated liver function test results, heartburn, nausea, vomiting

GU: Abnormal ejaculation; urinary frequency, urgency, and incontinence; urine retention

HEME: Agranulocytosis, eosinophilia, leukopenia, neutropenia

MS: Back or leg pain, muscle spasm or

weakness, myalgia

RESP: Dyspnea, respiratory arrest

SKIN: Rash

Other: Weight gain

Nursing Considerations

- Use clozapine cautiously in patients with hepatic, renal, or cardiovascular disease and in elderly patients with dementia-related psychosis because they have increased risk of serious or fatal adverse reactions.

WARNING Rarely, clozapine causes severe or life-threatening adverse reactions, such as agranulocytosis, cardiac or respiratory arrest, deep vein thrombosis, myocarditis (especially in first month), neuroleptic malignant syndrome, and severe hyperglycemia with ketoacidosis in nondiabetic patients. It also may cause seizures and tardive dyskinesia. Monitor patient closely.

WARNING Check patient's baseline WBC count and absolute neutrophil count (ANC) before therapy and weekly for first 6 months. If WBC count is at least $3,500/\text{mm}^3$ and ANC at least $2,000/\text{mm}^3$, check every 2 weeks for next 6 months. If counts remain stable, expect to continue checking every 4 weeks thereafter.

- If patient develops mild leukopenia (WBCs $3,000$ to $3,500/\text{mm}^3$) or granulocytopenia (ANC $1,500$ to $2,000/\text{mm}^3$), expect to check counts twice weekly until normal. In moderate leukopenia (WBCs $2,000$ to $3,000/\text{mm}^3$) or granulocytopenia (ANC $1,000$ to $1,500/\text{mm}^3$), expect to stop drug temporarily and check counts daily until improved. Follow manufacturer's direction for resuming drug and monitoring. In severe leukopenia (WBCs less than $2,000/\text{mm}^3$) or granulocytopenia (ANC less than $1,000/\text{mm}^3$), expect to stop drug permanently and monitor counts daily, then as specified by manufacturer.
- Monitor temperature. A transient increase above 100.4°F (38°C) may occur, most often within the first 3 weeks of therapy.
- When therapy ends, expect to check WBC count and ANC weekly for at least 4 weeks or until WBC count is $3,500/\text{mm}^3$ or more and ANC is $2,000/\text{mm}^3$ or more.
- Monitor patients, especially male patients and younger patients, for dystonia, particularly during the first few days of treatment. Be alert for complaints of neck

spasms, which sometimes may progress to throat tightness, trouble swallowing or breathing, and tongue protrusion.

PATIENT TEACHING

- Tell patient that he'll receive only a 1-week supply at a time.
- Instruct patient taking orally disintegrating tablets (Fazacló) to leave tablet in blister pack until ready to take it. Tell him to peel foil back to remove tablet (rather than pushing tablet through foil) and then to immediately place tablet in mouth and let it dissolve before swallowing. Explain that no water is needed.
- Inform patient that he'll need weekly blood tests. Review evidence of dyscrasias (fatigue, fever, sore throat, weakness); urge patient to report them to prescriber if they occur.
- Instruct patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to rise slowly from lying or sitting position to minimize orthostatic hypotension.
- If patient stops drug for more than 2 days, stress need to contact prescriber for instructions; dosage will need to be changed.
- Tell patient to consult prescriber before using alcohol or taking OTC drugs.
- Advise female patients to notify prescriber if pregnancy occurs or is suspected.

coagulation factor VIIa (recombinant)

NovoSeven, NovoSeven RT

Class and Category

Chemical class: Vitamin K–dependent glycoprotein

Therapeutic class: Antihemophilic, hemostatic

Pregnancy category: C

Indications and Dosages

↗ *To treat bleeding episodes in patients with hemophilia A or B or with inhibitors to Factor VIII or Factor IX*

I.V. INJECTION

Adults. 90 mcg/kg as bolus injected over 2 to 5 min every 2 hr until hemostasis achieved; then every 3 to 6 hr, as needed.

↗ *To prevent bleeding in surgical intervention or invasive procedure in hemophilia A or B patients with inhibitors to factor VIII or factor IX*

I.V. INJECTION

Adults. 90 mcg/kg as bolus injected over 2 to 5 min immediately before surgery or procedure; then every 2 hr throughout surgery or procedure. *After minor surgery:* 90 mcg/kg injected over 2 to 5 min every 2 hr for 48 hr; then 90 mcg/kg injected over 2 to 5 min every 2 to 6 hr until healing has occurred. *After major surgery:* 90 mcg/kg over 2 to 5 min every 2 hr for 5 days; then 90 mcg/kg over 2 to 5 min every 4 hr until healing has occurred.

↗ *To treat or prevent bleeding episodes in patients with congenital factor VII deficiency*

I.V. INFUSION

Adults. 15 to 30 mcg/kg over 2 to 5 min every 4 to 6 hr until hemostasis occurs.

↗ *To treat patients with acquired hemophilia*

I.V. INFUSION

Adults. 70 to 90 mcg/kg over 2 to 5 min every 2 to 3 hr until hemostasis occurs.

Mechanism of Action

Activates the extrinsic pathway of coagulation by forming complexes with tissue factor to activate factors IX and X. Activated factor X complexes with other factors to convert prothrombin to thrombin. Thrombin then converts fibrinogen to fibrin, which leads to formation of a hemostatic plug to produce local hemostasis. This process may also occur on the surface of activated platelets.

Contraindications

Hypersensitivity to recombinant coagulation factor VIIa, to its components, or to mouse, hamster, or bovine proteins

Interactions

DRUGS

activated and nonactivated prothrombin complex concentrates: Increased risk of thrombosis

warfarin: Possibly reversed warfarin effects

Adverse Reactions

CNS: Fever, headache

CV: Acute MI, bradyarrhythmia, chest tightness or pain, edema, hypertension,

hypotension, supraventricular tachycardia, thrombosis

EENT: Epistaxis

GI: Nausea, vomiting

HEME: Disseminated intravascular coagulation, hemorrhage

MS: Arthralgia

RESP: Wheezing

SKIN: Pruritus, purpura, rash, urticaria

Other: Anaphylaxis, injection site reaction

Nursing Considerations

- Patients with disseminated intravascular coagulation, advanced atherosclerotic disease, crush injury, septicemia, or concomitant treatment with activated or nonactivated prothrombin complex concentrate are at increased risk for a thrombotic event such as myocardial ischemia or infarction and cerebral ischemia or infarction.
- Monitor factor VII–deficient patient’s PT and factor VII coagulant activity before and after giving drug. If factor VIIa activity fails to reach the expected level, the PT isn’t corrected, or bleeding isn’t controlled, notify prescriber. Patient may have developed antibodies to the drug. Be prepared to obtain specimen for antibody analysis.
- Reconstitute drug with correct amount of sterile water (2.2 ml for 1.2-mg vial, 4.3 ml for 2.4-mg vial, and 8.5 ml for 4.8-mg vial). Clean the rubber stopper with alcohol, and insert syringe needle into center of the stopper, aiming needle against the side of the vial so a stream of sterile water runs down vial wall. Do not inject diluent directly onto powder. Gently swirl vial until powder is dissolved. Don’t shake reconstituted solution. If solution is foamy, let it settle before giving drug. Once reconstituted, use within 3 hours.
- Monitor patient’s clotting status closely. If intravascular coagulation is confirmed by test results or if signs and symptoms occur, notify prescriber and expect to reduce dosage or stop drug.

PATIENT TEACHING

- Tell patient to immediately report evidence of allergic reaction, such as hives, rash, chest tightness, or difficulty breathing.
- Tell patient that he’ll need regular laboratory tests to check effectiveness of drug.

codeine phosphate codeine sulfate

Class, Category, and Schedule

Chemical class: Phenanthrene derivative

Therapeutic class: Antitussive, opioid analgesic

Pregnancy category: C

Controlled substance schedule: II

Indications and Dosages

↗ *To treat mild to moderate pain*

ORAL SOLUTION, TABLETS, I.M. OR SUBCUTANEOUS INJECTION

Adults. 15 to 60 mg (usual, 30 mg) every 4 hr, p.r.n.

Children age 1 year or over. 0.5 mg/kg every 4 to 6 hr, p.r.n.

I.V. INJECTION

Adults. 15 to 60 mg (usual, 30 mg) every 4 hr.

↗ *To treat cough from chemical or mechanical irritation of respiratory system*

ORAL SOLUTION, TABLETS

Adults and adolescents. 10 to 20 mg every 4 to 6 hr. *Maximum:* 120 mg daily.

Children ages 6 to 12. 5 to 10 mg every 4 to 6 hr. *Maximum:* 60 mg daily.

Children ages 2 to 6. 2.5 to 5 mg every 4 to 6 hr. *Maximum:* 30 mg daily.

Route	Onset	Peak	Duration
P.O.	30–45 min	1–2 hr	4 hr*
I.M.	10–30 min	30–60 min	4 hr*
SubQ	10–30 min	Unknown	4 hr*

Mechanism of Action

May produce analgesia through partial metabolism to morphine. Drug binds with mu, delta, and kappa receptors in the spinal cord and with mu₁ and kappa₃ receptors higher in the CNS, decreasing intracellular cAMP, which inhibits adenylate cyclase activity and prevents release of pain neurotransmitters, such as substance P and dopamine, and altering perception of and emotional response to pain. Drug also sup-

* For pain; 4 to 6 hr for cough.

presses cough by acting on opiate receptors in the cough center.

Contraindications

Hypersensitivity to codeine, other opioids, or their components; significant respiratory depression

Interactions

DRUGS

anticholinergics, paregoric: Increased risk of severe constipation

antihypertensives, diuretics: Potentiated hypotensive effects

buprenorphine: Decreased codeine effectiveness

CNS depressants: Additive CNS effects

hydroxyzine: Increased analgesia; increased CNS depressant and hypotensive effects

MAO inhibitors: Increased risk of unpredictable, severe, and sometimes fatal reactions

metoclopramide: Antagonized effect of metoclopramide on GI motility

naloxone: Antagonized codeine effect

naltrexone: Precipitated withdrawal symptoms in codeine-dependent patients

neuromuscular blockers: Additive respiratory depressant effects

other opioids: Additive CNS, respiratory depressant, and hypotensive effects

ACTIVITIES

alcohol use: Additive CNS effects

Adverse Reactions

CNS: Coma, delirium, depression, disorientation, dizziness, drowsiness, euphoria, hallucinations, headache, lack of coordination, lethargy, light-headedness, mental and physical impairment, mood changes, restlessness, sedation, seizures, tremor

CV: Bradycardia, heart block, hypertension, orthostatic hypotension, palpitations, tachycardia

EENT: Altered taste, blurred vision, diplopia, dry mouth, laryngeal edema, laryngospasm, miosis

GI: Abdominal cramps and pain, anorexia, constipation, flatulence, gastroesophageal reflux, ileus, indigestion, nausea, vomiting

GU: Decreased libido, difficult ejaculation, dysuria, impotence, oliguria, ureteral spasm, urinary incontinence, urine retention

MS: Muscle rigidity

RESP: Apnea, bronchoconstriction,

bronchospasm, depressed cough reflex, respiratory depression

SKIN: Diaphoresis, flushing, pallor, pruritus, rash, urticaria

Other: Anaphylaxis, facial edema, physical and psychological dependence

Nursing Considerations

- Evaluate patient for therapeutic response, including decreased pain, cough, and facial grimacing.
- Take safety precautions, if needed.
- Monitor respiratory depth, effort, and rate. Notify prescriber immediately if respiratory rate drops below 10 breaths/min.
- Assess urine output to detect retention.

WARNING Assess patient for evidence of physical and psychological dependence.

- Rotate sites for subcutaneous delivery. Repeated injection in same site may cause tissue irritation, pain, and induration.

PATIENT TEACHING

- Advise patient to avoid alcohol or other CNS depressants while taking codeine.
- To minimize nausea, suggest that patient take drug with food.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Caution patient to get up slowly from a sitting or lying position.
- To prevent constipation, urge patient to consume plenty of fluids and high-fiber foods, if not contraindicated.
- Instruct patient to take codeine exactly as prescribed and not to adjust dose or frequency without consulting prescriber.
- Advise patient to report shortness of breath or difficulty breathing.
- Urge breast-feeding women to notify prescriber before taking codeine because drug appears in breast milk and could lead to overdose in infant.

colchicine

Colcrlys

Class and Category

Chemical class: Colchicum alkaloid derivative

Therapeutic class: Antigout, anti-inflammatory

Pregnancy category: C (oral form), D (parenteral forms)

Indications and Dosages

↗ *To prevent gouty arthritis attacks*

TABLETS (COLCRYS)

Adults and adolescents age 16 and over.

0.5 to 0.6 mg once or twice daily.

Maximum: 1.2 mg daily.

I.V. INFUSION OR INJECTION

Adults. 0.5 to 1 mg once or twice daily.

Maximum: 4 mg daily.

↗ *To treat acute gouty arthritis*

TABLETS (COLCRYS)

Adults. *Initial:* 1.2 mg at first sign of flare; then 0.6 mg 1 hr later. *Maximum:* 1.8 mg over a 1-hr period.

I.V. INFUSION OR INJECTION

Adults. 2 mg over 2 to 5 min; then 0.5 mg every 6 hr or 1 mg every 6 to 12 hr until pain decreases. *Maximum:* 4 mg daily.

DOSE ADJUSTMENT For elderly patients, maximum I.V. dosage reduced to 2 mg/24 hr; maximum oral dosage to 2 mg/24 hr. After initial I.V. course, elderly patient should receive no form of colchicine for 21 days. If treatment of a gout flare occurs during prophylactic treatment, dosage shouldn't exceed 1.2 mg at the first sign of flare, followed by 0.6 mg 1 hour later, and then prophylactic dose resumed 12 hr later.

For patient taking strong CYP3A4 inhibitor (atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin), moderate CYP3A4 inhibitor (amprenavir, aprepitant, diltiazem, erythromycin, fluconazole, fosamprenavir, grapefruit juice, verapamil), or P-gp inhibitor (cyclosporine, ranolazine), dosage usually halved and not repeated for 3 days.

For patient with moderate to severe renal impairment, dosage adjusted on individual basis. For patient with severe hepatic impairment receiving colchicine prophylactically, dosage decreased on individual basis. For patient with severe hepatic impairment receiving colchicine treatment for acute gout flare but not prophylaxis, dosage not adjusted but treatment course shouldn't be repeated more than once every 2 weeks.

↗ *To treat familial Mediterranean fever (FMF)*

TABLETS (COLCRYS)

Adults and adolescents ages 12 and over.

1.2 mg to 2.4 mg daily, with daily total divided into two doses, if desired.

Mechanism of Action

In gouty arthritis, leukocytes phagocytose urate crystals in affected joints, a process that releases chemotactic factors, degradation enzymes, and other inflammatory substances. Colchicine helps stop this process, probably by disrupting microtubules in leukocytes. Normally, microtubules contribute to cell structure and movement. When colchicine binds to tubulin (protein from which microtubules are made), the microtubule falls apart, as shown. This process disrupts cell function and prevents leukocytes from invading joints and causing inflammation.

Children ages 6 to 12. 0.9 mg to 1.8 mg daily, with daily total divided into two doses, if desired.

Children ages 4 to 6. 0.3 mg to 1.8 mg daily, with daily total divided into two doses, if desired.

DOSE ADJUSTMENT For adults needing control of FMF, dosage increased in increments of 0.3 mg daily to a maximum of 2.4 mg daily.

For adults with intolerable adverse effects, dosage decreased in increments of 0.3 mg daily to tolerable level.

For patients taking strong CYP3A4 inhibitor (atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin), moderate CYP3A4 inhibitor (amprenavir, aprepitant, diltiazem, erythromycin, fluconazole, fosamprenavir, grapefruit juice, verapamil), or P-gp inhibitor (cyclosporine, ranolazine), dosage usually

halved and not repeated for 3 days.

For patient with moderate to severe renal impairment or severe hepatic impairment, dosage adjusted on individual basis.

Route	Onset	Peak	Duration
P.O.	In 12 hr	In 24–48 hr	Unknown
I.V.	In 6–12 hr	Unknown	Unknown

Contraindications

Blood dyscrasias; hypersensitivity to colchicine or its components; serious cardiac, GI, hepatic, or renal disorders

Incompatibilities

Don't combine colchicine with bacteriostatic agents, any solution or injection that contains D₅W, and any other solution that may change colchicine's pH because precipitation may occur.

Interactions

DRUGS

anticoagulants, such as heparin; platelet aggregation inhibitors, such as aspirin; thrombolytics, such as alteplase: Increased risk of GI ulcers or hemorrhage
antineoplastics: Possibly increased serum uric acid level and decreased therapeutic effectiveness of colchicine
cyclosporine: Increased cyclosporine level
moderate CYP3A4 inhibitors, such as amprenavir, aprepitant, diltiazem, erythromycin, fluconazole, fosamprenavir, grapefruit juice, verapamil: Increased risk of colchicine toxicity
NSAIDs, such as phenylbutazone: Possibly increased risk of bone marrow depression, GI bleeding, leukopenia, thrombocytopenia
strong CYP3A4 inhibitors, such as atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin: Increased risk of colchicine toxicity
P-gp inhibitors, such as cyclosporine, ranolazine: Increased risk of colchicine toxicity
vitamin B₁₂: Possibly impaired absorption of and increased dosage requirements for vitamin B₁₂

ACTIVITIES

alcohol use: Increased risk of adverse GI effects

Adverse Reactions

CNS: Peripheral neuropathy

CV: Arrhythmias (I.V. form)

GI: Abdominal pain, anorexia, diarrhea, nausea, vomiting

HEME: Agranulocytosis, aplastic anemia, thrombocytopenia

MS: Myopathy

SKIN: Alopecia, rash

Other: Injection site pain and tenderness, median nerve neuritis in affected arm, and skin and soft-tissue necrosis if extravasation occurs (I.V. form)

Nursing Considerations

- Patients receiving prophylactic treatment for gout and who have hepatic impairment or are being treated with CYP3A4 inhibitors shouldn't receive colchicine for acute gout flares.

WARNING Avoid subcutaneous or I.M. administration of colchicine because these routes may cause tissue necrosis and sloughing. To prevent extravasation, make sure I.V. catheter is patent and correctly positioned before giving drug. Throughout therapy, check I.V. injection site often for pain, tenderness, and skin peeling. Consult prescriber about switching to oral form.

WARNING To reduce risk of toxicity, avoid giving colchicine by any route within 7 days after full I.V. course (4 mg). If patient takes any drug that increases risk of colchicine toxicity, expect to wait 3 days after oral therapy before starting second oral course. Elderly or debilitated patients and those with a history of cardiac disease or impaired renal or hepatic function are at increased risk for cumulative toxicity.

- Dilute I.V. form with 10 to 20 ml of normal saline solution. Or, give colchicine into a large vein through an I.V. line with normal saline solution infusion.
- Administer I.V. form over 2 to 5 minutes.
- Expect to monitor CBC and platelet and reticulocyte counts at baseline and every 3 months after therapy starts.
- Notify prescriber immediately and expect to stop colchicine if patient develops evidence of toxicity, such as abdominal pain, diarrhea, nausea, or vomiting.

PATIENT TEACHING

- Instruct patient to have blood tests every 3 months, as ordered, during therapy.
- Explain that gouty arthritis pain and

swelling typically subside in 24 to 48 hours after therapy begins.

- Advise patient to notify prescriber immediately if abdominal pain, diarrhea, nausea, or vomiting occurs.

colesevelam hydrochloride

Welchol

Class and Category

Chemical class: Nonabsorbed hydrogel polymer

Therapeutic class: Bile acid sequestrant

Pregnancy category: B

Indications and Dosages

- ↗ *As adjunct to diet and exercise to reduce elevated LDL cholesterol levels in patients with primary hypercholesterolemia; as adjunct to diet and exercise to improve glycemic control in type 2 diabetes mellitus*

TABLETS

Adults. 3.75 g once daily or 1.875 g b.i.d. with a meal and a beverage.

Mechanism of Action

Binds with bile acids in intestine, preventing their absorption and forming an insoluble complex that's excreted in feces. This action decreases amount of bile acids returning through enterohepatic circulation to the liver. As a result, the liver must convert more cholesterol to bile acids, which increases liver's demand for cholesterol. This, in turn, causes increase in production and activity of the hepatic enzyme hydroxymethyl-glutaryl-coenzyme A (HMG-CoA) reductase, which is needed for cholesterol production. However, synthesis of cholesterol in the liver typically can't match the amount needed to synthesize bile acids. Because cholesterol levels can't be sustained, LDLs, lipoproteins composed mostly of cholesterol, are increasingly removed from the blood, thereby decreasing the LDL level in the blood.

Contraindications

History of bowel obstruction or pancreatitis induced by hypertriglyceridemia, hypersensitivity to colesevelam or its components,

serum triglyceride level greater than 500 mg/dl

Interactions

DRUGS

drugs with narrow therapeutic index, glyburide, levothyroxine, oral contraceptives, phenytoin: Possibly altered effectiveness of these drugs

warfarin: Reduced INR

Adverse Reactions

CNS: Asthenia

CV: Hypertension, hypertriglyceridemia

EENT: Oral blistering, pharyngitis, rhinitis

ENDO: Hypoglycemia, hypertriglyceridemia

GI: Abdominal distention or pain, bowel or esophageal obstruction, constipation, dyspepsia, elevated liver enzymes, fecal impaction, indigestion, nausea, pancreatitis, worsening of hemorrhoids

MS: Myalgia

SKIN: Rash

Other: Flu syndrome

Nursing Considerations

- Colesevelam shouldn't be given to patients with gastroparesis or other GI motility disorders or to patients who had major GI tract surgery and are at risk for bowel obstruction from constipating effects.
- Use cautiously in patients with dysphagia or esophageal obstruction because size of tablet can cause dysphagia or esophageal obstruction.
- Use colesevelam cautiously in patients whose total triglycerides exceed 300 mg/dl; bile acid sequestrants can increase it.
- Evaluate patient's lipid levels before starting therapy for primary hyperlipidemia, again in 4 to 6 weeks, and then periodically, as ordered, during therapy. Expect drug to be discontinued if patient develops hypertriglyceridemia-induced pancreatitis or triglyceride level exceeds 500 mg/dl.
- Monitor diabetic patient's blood glucose level regularly, as ordered, to assess effectiveness of colesevelam therapy.
- When giving colesevelam with a drug that has a narrow therapeutic index, expect to give that drug at least 4 hours before colesevelam to prevent reduced effectiveness.
- Because colesevelam may decrease or delay absorption of other drugs, administer it separately if possible.

- Make sure that patient drinks enough fluid when taking drug.

WARNING Monitor patients with preexisting constipation, who are at increased risk for developing fecal impaction.

- Monitor frequency of bowel movements and consistency of stools in patients with coronary artery disease or hemorrhoids because constipation may aggravate these conditions.

PATIENT TEACHING

- Instruct patient to take drug with meals and drink plenty of liquids when taking it.
- Tell patient to protect tablets from moisture.
- Caution patient against changing prescribed dosage or stopping colestipol abruptly because serum lipid level may increase significantly.
- Remind patient that drug therapy doesn't reduce the need for dietary changes.
- Urge patient to keep regularly scheduled appointments for follow-up blood tests.
- Instruct patient to take vitamin supplements at least 4 hours before colestipol.

colestipol hydrochloride

Colestid

Class and Category

Chemical class: Diethylenetriamine and 1-chloro-2,3-epoxypropane copolymer, high-molecular-weight anion exchange resin

Therapeutic class: Antihyperlipidemic

Pregnancy category: Not rated

Indications and Dosages

➤ *To treat primary hypercholesterolemia*

GRANULES

Adults. 15 to 30 g daily in divided doses b.i.d. to q.i.d., before meals and at bedtime.

TABLETS

Adults. *Initial:* 2 g once daily or in divided doses b.i.d., increased every 1 to 2 mo in 2-g increments once or twice daily.

Maximum: 16 g daily.

Mechanism of Action

Combines with bile acids in the intestine, preventing their absorption and forming an insoluble complex that's excreted in feces. Loss of bile acids increases hepatic produc-

tion of cholesterol to form new bile acids and increases oxidation of cholesterol to bile acids. Depletion of cholesterol increases hepatic LDL receptor activity, which removes LDLs from the blood.

Contraindications

Complete biliary obstruction, hypersensitivity to colestipol or its components

Interactions

DRUGS

chenodiol, ursodiol: Possibly reduced therapeutic effects of colestipol

digitalis glycosides: Possibly increased risk of digitalis toxicity when colestipol is stopped

furosemide, sulfonyleureas, thyroid hormones: Decreased absorption and therapeutic effects of these drugs

oral anticoagulants: Possibly increased or decreased anticoagulant effect

penicillin G, propranolol, tetracyclines (oral), thiazide diuretics: Decreased absorption of these drugs

vancomycin (oral): Possibly marked decrease in vancomycin antibacterial action

vitamins (fat-soluble): Possibly interference with vitamin absorption

Adverse Reactions

CNS: Headache

GI: Abdominal distention and pain, constipation, diarrhea, eructation, esophageal reaction, fecal impaction, heartburn, nausea, vomiting

Nursing Considerations

- Mix colestipol granules with at least 90 ml of fluid before giving it to prevent accidental inhalation or esophageal distress.
- Because colestipol may interact with various drugs, give it on a separate schedule from other drugs when possible.
- Make sure patient has adequate fluid intake, and obtain an order for a stool softener or laxative to prevent constipation. To prevent impaction, expect to decrease dosage or discontinue drug if constipation occurs or worsens.
- Expect to discontinue drug if no response occurs after 3 months.
- Monitor patient's serum cholesterol level as appropriate, usually at baseline, 4 to 6 weeks after starting therapy, and then every 3 months. Expect to reduce monitoring frequency to every 4 months if

response is adequate.

- Be aware that HDL and serum triglyceride levels may increase or remain unchanged during colestipol therapy.
- Keep in mind that adverse GI reactions are more common in patients over age 60.

PATIENT TEACHING

- To help minimize adverse GI reactions, advise patient to mix granules thoroughly in fluid so they're completely wet before drinking.
- Remind patient that colestipol doesn't reduce the importance of dietary changes.
- Caution patient not to increase or decrease prescribed dosage or to suddenly stop taking drug. Explain that stopping drug abruptly may significantly increase serum lipid levels.
- Instruct patient to keep appointments for follow-up blood tests.
- Teach patient how to prevent constipation, and advise him to contact prescriber if constipation occurs or worsens.

colistimethate sodium

Coly-Mycin M

Class and Category

Chemical class: Polypeptide

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

➤ *To treat acute or chronic gram-negative infections caused by Enterobacter aerogenes, Escherichia coli, Klebsiella pneumoniae, and Pseudomonas aeruginosa*

I.M. INJECTION, I.V. INJECTION, I.V. INFUSION

Adults. 2.5 to 5 mg/kg daily in 2 to 4 divided doses. *Maximum:* 5 mg/kg/day.

DOSAGE ADJUSTMENT For obese patients, dosage should be based on ideal body weight. For patients with severe renal impairment, dosage reduced to 1.5 mg/kg daily and interval reduced to every 36 hr. For patients with moderate renal impairment, interval shouldn't exceed twice daily and may need to be once daily or every 36 hr. For patients with mild renal impairment, interval shouldn't exceed twice daily.

Mechanism of Action

Penetrates into and disrupts bacterial cell membrane, resulting in cell death. Colistimethate is an inactive pro-drug of the bioactive form colistin. Colistin binds to gram-negative bacterial cell membrane phospholipids, increasing cell membrane permeability and causing loss of metabolites essential to bacterial existence.

Contraindications

Hypersensitivity to colistimethate or its components, renal disease

Interactions

DRUGS

aminoglycosides, vancomycin: Increased risk of developing nephrotoxicity
curaniform muscle relaxants, such as tubocurarine, decamethonium, ether, gallamine, succinylcholine: Potentiated neuromuscular blocking effect of these drugs
sodium cephalothin: Possibly enhanced nephrotoxicity

Adverse Reactions

CNS: Dizziness, fever, paresthesia, slurred speech, tingling of extremities, vertigo

GI: Nausea, pseudomembranous colitis, vomiting

GU: Decreased creatinine clearance and urine output, increased BUN and serum creatinine, nephrotoxicity

MS: Muscle weakness

RESP: Apnea, respiratory distress

SKIN: Pruritus, rash, urticaria

Nursing Considerations

- Use colistimethate cautiously in patients with impaired renal function.
- Reconstitute each 150-mg vial with 2 ml sterile water for injection to yield 75 mg/ml. During reconstitution, swirl vial gently to avoid frothing.
- When giving by I.V. injection, slowly inject half of total daily dose over 3 to 5 minutes and repeat dose 12 hours later, as ordered.
- When giving by I.V. infusion, slowly inject half of total daily dose over 3 to 5 minutes. Then add remaining half of total daily dose to an appropriate solution, such as normal saline solution or D₅W, with type and amount of solution dictated by patient's fluid and electrolyte needs. Starting 1 to 2 hours after first dose, slowly infuse remaining drug over 22 to 23 hours.

If patient has renal impairment, use a reduced infusion rate. Once the infusion is prepared, use within 24 hours.

- Notify prescriber if patient develops neurologic changes (paresthesia, tingling of limbs, pruritus, vertigo, dizziness, slurred speech). Dosage may need to be reduced.

WARNING Monitor patient's BUN and serum creatinine levels, as ordered. If elevated, notify prescriber because drug may cause nephrotoxicity (usually reversible if drug is stopped) with possible renal shutdown. Toxic levels interfere with nerve transmission at neuromuscular junctions, resulting in apnea and muscle weakness.

- Monitor patient receiving drug I.M. because apnea and neuromuscular blockade may occur with this route, especially in patients with impaired renal function. Before giving drug I.M., make sure dose is appropriate for degree of renal function.
- Monitor patient's bowel elimination. If diarrhea develops, obtain stool culture to check for pseudomembranous colitis. If confirmed, expect to stop drug and give fluid, electrolytes, and antibiotics effective against *Clostridium difficile*.

PATIENT TEACHING

- Caution patient to avoid performing hazardous activities, including driving, during colistimethate therapy.
- Tell patient to immediately report tingling in her extremities, vertigo, dizziness, generalized pruritus, or slurred speech because dosage may need to be decreased.
- Explain need for frequent blood tests during therapy to check kidney function.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.

conivaptan hydrochloride

Vaprisol

Class and Category

Chemical class: Arginine vasopressin antagonist (antidiuretic hormone)

Therapeutic class: Aquaretic (sodium/water stabilizer)

Pregnancy category: C

Indications and Dosages

➤ *To treat euvolemic and hypervoemic hyponatremia in hospitalized patients such as may occur in the syndrome of inappropriate antidiuretic hormone, hypothyroidism, adrenal insufficiency, or pulmonary disorders*

I.V. INFUSION

Adults. *Loading dose:* 20 mg over 30 minutes followed by 20 mg as a continuous infusion over 24 hours. Additional 20 mg daily may be given by continuous infusion for 1 to 3 days, as needed. *Maximum:* 40 mg daily with total duration of therapy, including loading dose, not to exceed 4 days.

Route	Onset	Peak	Duration
I.V.	Unknown	24 hr	Unknown

Mechanism of Action

Binds with arginine vasopressin V2 receptor sites in collecting ducts of kidneys. By doing so, drug blocks action of arginine vasopressin on V2 receptor, decreases water resorption in collecting ducts, increases excretion of free water (urine output), and increases serum sodium concentration, thus correcting water and sodium imbalance.

Incompatibilities

Don't mix with lactated Ringer's solution, normal saline solution, or other drugs.

Contraindications

Hypersensitivity to conivaptan or its components; patients with hypovolemic hyponatremia; use with potent CYP3A4 inhibitors such as clarithromycin, indinavir, itraconazole, ketoconazole, and ritonavir

Interactions

DRUGS

amphotericin B, cisplatin, corticosteroids: Possibly additive hypokalemic effects
clarithromycin, indinavir, itraconazole, ketoconazole, ritonavir, and other strong CYP3A4 inhibitors: Increased blood conivaptan level
digoxin: Possibly increased digoxin level and risk of digoxin toxicity
drugs metabolized by CYP3A4, such as HMG-CoA reductase inhibitors: Possibly increased risk of rhabdomyolysis

Adverse Reactions

CNS: Confusion, fever, headache, insomnia

CV: Atrial fibrillation, hypertension, hypotension, orthostatic hypotension, peripheral edema

EENT: Dry mouth, oral candidiasis, pharyngeal pain

ENDO: Hyperglycemia, hypoglycemia

GI: Constipation, diarrhea, nausea, thirst, vomiting

GU: Hematuria, pollakiuria, polyuria, UTI

HEME: Anemia

RESP: Pneumonia

SKIN: Erythema, pruritus

Other: Dehydration, hypokalemia, hypomagnesemia, hyponatremia, infusion site reactions (erythema, pain, phlebitis, swelling)

Nursing Considerations

- Conivaptan shouldn't be used to treat patients with heart failure.
- Use cautiously in patients with hepatic or renal dysfunction because levels remain elevated longer in these patients.
- Give drug only through large veins, and change infusion site every 24 hours. Drug may cause serious infusion site reactions even when diluted and infused correctly. Inspect site regularly; change immediately if reactions occur.
- Dilute 20-mg (4-ml) loading dose with 100 ml of 5% dextrose injection before administration. Gently invert bag several times to mix thoroughly. Use mixture within 24 hours, infusing over 30 minutes.
- Dilute 20-mg (4-ml) or 40-mg (8-ml) continuous infusion dose with 250 ml of D₅W before use. Gently invert the bag several times to mix thoroughly. Infuse immediately over 24 hours. If infusion is interrupted for any reason, discard any remaining solution 24 hours after mixing.
- Monitor neurologic status and serum sodium level closely during therapy because rapid increase in serum sodium level (more than 12 mEq/L/24 hr) may result in serious neurologic impairment. If serum sodium level rises faster than expected, stop infusion temporarily and notify prescriber. If it keeps rising, expect conivaptan to be discontinued. If hyponatremia persists or recurs and patient has no neurologic abnormalities, drug may be resumed at a reduced rate.

- Monitor vital signs, and assess patient regularly for hypovolemia. If patient develops hypovolemia or hypotension while receiving conivaptan, stop infusion, notify prescriber, and provide supportive care, as prescribed. After hypovolemia and hypotension have been corrected, drug may be resumed at a reduced rate.
- Store ampules in cardboard container, protected from light, until ready for use.

PATIENT TEACHING

- Instruct patient to report any infusion site discomfort immediately.
- Tell patient that frequent laboratory tests will be performed to monitor his serum sodium level and volume status.

cortisone acetate

Cortisone Acetate-ICN (CAN), Cortone (CAN), Cortone Acetate

Class and Category

Chemical class: Glucocorticoid

Therapeutic class: Anti-inflammatory, corticosteroid replacement, immunosuppressant

Pregnancy category: Not rated

Indications and Dosages

➤ *To treat allergic and inflammatory disorders, collagen disorders, congenital adrenal hyperplasia, dermatologic disorders, edema (from systemic lupus erythematosus or nephrotic syndrome), GI disorders, hematologic disorders, multiple sclerosis (acute exacerbations), neoplastic diseases, primary or secondary adrenocortical insufficiency, respiratory disorders, rheumatic disorders, trichinosis with myocardial or neurologic involvement, and tuberculous meningitis*

TABLETS

Adults and adolescents. *Initial:* 25 to 300 mg before 9 a.m. daily. *Maintenance:* Dosage adjusted based on patient response.

Children. 2.5 to 10 mg/kg daily before 9 a.m. For adrenocortical insufficiency, 0.7 mg/kg/day before 9 a.m.

I.M. INJECTION

Adults and adolescents. *Initial:* 25 to 300 mg daily. *Maintenance:* Dosage adjusted based on patient response.

Children. 0.83 to 5 mg/kg every 12 to 24 hr.

For adrenocortical insufficiency, 0.7 mg/kg daily or every third day, or 0.23 to 0.35 mg/kg daily.

Route	Onset	Peak	Duration
P.O.	Rapid	2 hr	1.25–1.5 days
I.M.	Slow	20–48 hr	1.25–1.5 days

Mechanism of Action

Binds to intracellular glucocorticoid receptors and suppresses inflammatory and immune responses by:

- inhibiting neutrophil and monocyte accumulation at the inflammation site and suppressing their phagocytic and bactericidal activity
- stabilizing lysosomal membranes
- suppressing the antigen response of macrophages and helper T cells
- inhibiting synthesis of cellular mediators of inflammatory response, such as cytokines, interleukins, and prostaglandins.

Contraindications

Hypersensitivity to cortisone or its components, idiopathic thrombocytopenic purpura (parenteral form), live-virus vaccine administration, systemic fungal infection

Interactions

DRUGS

anticholinesterases: Possibly antagonized anticholinesterase effects in myasthenia gravis

barbiturates: Decreased cortisone effectiveness, increased cortisol clearance

digitalis glycosides: Possibly digitalis toxicity

estrogens, oral contraceptives: Increased cortisone effects and risk of toxicity

hydantoin, rifampin: Increased metabolism and decreased effects of cortisone

isoniazid: Decreased blood isoniazid level

neuromuscular blockers: Possibly enhanced blockade of neuromuscular blockers, leading to increased or prolonged respiratory depression or apnea

oral anticoagulants: Possibly obstructed anticoagulant effects

potassium-wasting diuretics: Possibly hypokalemia

salicylates: Decreased effectiveness and blood level of salicylates

somatrem: Decreased growth-promoting effect

Adverse Reactions

CNS: Ataxia, behavior changes, depression, dizziness, euphoria, fatigue, headache, increased ICP with papilledema, insomnia, lassitude, malaise, mood swings, paresthesia, seizures, steroid psychosis, syncope, vertigo

CV: Arrhythmias (from hypokalemia), fat embolism, heart failure, hypertension, hypotension, thromboembolism, thrombophlebitis

EENT: Exophthalmos, glaucoma, increased intraocular pressure, nystagmus, posterior subcapsular cataracts

ENDO: Adrenal insufficiency during stress, Cushing's syndrome, diabetes mellitus, growth suppression in children, hyperglycemia, negative nitrogen balance from protein catabolism

GI: Abdominal distention, hiccups, increased appetite, nausea, pancreatitis, peptic ulcer, ulcerative esophagitis, vomiting

GU: Glycosuria, menstrual irregularities, perineal burning or tingling

HEME: Leukocytosis

MS: Arthralgia; aseptic necrosis of femoral and humeral heads; compression fractures; muscle atrophy, weakness, and twitching; myalgia; osteoporosis; spontaneous fractures; steroid myopathy; tendon rupture

SKIN: Acne; diaphoresis; ecchymosis; erythema; hirsutism; hyperpigmentation; hypopigmentation; necrotizing vasculitis; petechiae; purpura; rash; scarring; sterile abscesses; striae; subcutaneous fat atrophy; thin, fragile skin; urticaria

Other: Anaphylaxis, hypocalcemia, hypokalemia, hypokalemic alkalosis, impaired wound healing, masking of infection, metabolic alkalosis, suppressed skin test reaction, weight gain

Nursing Considerations

- Use cortisone cautiously in patients with ocular herpes simplex because corneal perforation may occur.
- Expect prescriber to order baseline ophthalmologic examination before therapy starts because prolonged use of cortisone may result in glaucoma, increased intraocular pressure, and damage to optic nerve.
- Assess patient for signs and symptoms of infection before giving cortisone because drug may mask them. Be aware that new

infections may develop during therapy because of risk of immunosuppression. If a new infection develops, expect to administer appropriate antibiotics.

- Obtain serum electrolyte levels before therapy, as ordered, and monitor results often during therapy to detect electrolyte imbalances. Increased calcium excretion, potassium depletion, and sodium and water retention may occur with large doses of cortisone. Anticipate the need for potassium and calcium supplementation and sodium restriction, if indicated.
- Keep in mind that prescriber will order lowest effective dose.
- To avoid peptic ulcer formation from cortisone, expect patient to receive concurrent antacid or antihistamine therapy.

WARNING Be aware that live-virus vaccines shouldn't be given during cortisone therapy because patient may become immunosuppressed and develop the viral infection.

WARNING Assess for adrenal suppression or insufficiency (fatigue, hypotension, lassitude, nausea, vomiting, and weakness) in patient exposed to stress or receiving prolonged cortisone therapy. Notify prescriber immediately if patient has evidence of this life-threatening adverse reaction.

- Watch for signs and symptoms of steroid psychosis (confusion, delirium, euphoria, insomnia, mood swings, personality changes, severe depression), which may develop 15 to 30 days after starting drug. Be prepared to stop drug if such signs occur. If stopping isn't possible, expect to administer a psychotropic drug.
- Watch for cushingoid signs, such as acne, buffalo hump, central obesity, ecchymosis, moon face, striae, and weight gain. Notify prescriber at once if they occur.
- Expect to taper oral cortisone dosage slowly to prevent withdrawal syndrome (abdominal or back pain, anorexia, dizziness, fever, headache, and syncope).

PATIENT TEACHING

- Instruct patient to take oral cortisone exactly as prescribed, every morning before 9 a.m. Advise him to take it with food if GI distress occurs.
- Caution patient not to stop drug abruptly because doing so may lead to adrenal insufficiency, withdrawal symptoms, or both.

- Inform patient about adrenal insufficiency and need for possible dosage increases during stress. Advise him to notify prescriber immediately if signs or symptoms develop or if he's exposed to stress.
- Caution patient to avoid exposure to people with infections because cortisone can cause immunosuppression. Also, teach him to recognize and immediately report signs and symptoms of infection.
- Teach patient to recognize and report adverse reactions, including Cushing's syndrome.
- Urge patient receiving long-term cortisone therapy to carry medical identification.
- Recommend regular eye examinations.
- Urge patient to keep follow-up appointments with prescriber, which may include laboratory tests, to evaluate effects of therapy.

cromolyn sodium (disodium cromoglycate, sodium cromoglycate)

Apo-Cromolyn (CAN), Gastrocrom, Intal Syncroner (CAN), Nalcrom (CAN), Nasalcrom, Novo-cromolyn (CAN)

Class and Category

Chemical class: Disodium chromoglycate

Therapeutic class: Antiasthmatic, anti-inflammatory

Pregnancy category: B

Indications and Dosages

➤ *To prevent bronchial asthma attacks*

AEROSOL (METERED-DOSE INHALER)

Adults and children over age 5. 2 metered sprays (1.6 to 2 mg) every 4 to 6 hr.

Maximum: 16 sprays (12.8 to 16 mg) daily.

CAPSULES FOR INHALATION

Adults and children over age 2. 1 capsule (20 mg) every 4 to 6 hr. *Maximum:* 8 capsules (160 mg) daily.

SOLUTION FOR NEBULIZATION

Adults and children over age 2. 20 mg every 4 to 6 hr. *Maximum:* 160 mg daily.

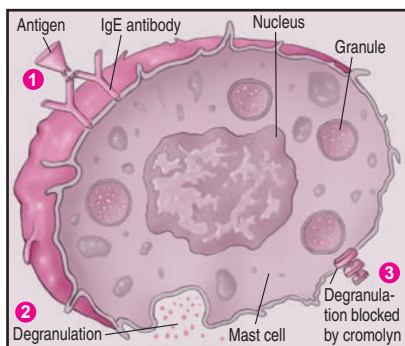

➤ *To prevent bronchospasm caused by environmental exposure or exercise*

AEROSOL (METERED-DOSE INHALER)

Adults and children over age 5. 2 metered

Mechanism of Action

In asthma, inflammation results when antigen reexposure causes mast cells to degranulate and release histamine and chemical mediators. Cromolyn helps reduce inflammation by preventing degranulation. After exposure to an antigen, mast cells become sensitized to it and immunoglobulin E (IgE) antibodies appear on their surfaces. When the antigen returns, it attaches to IgE (1 in the illustration) and triggers events that lead to degranulation (2). By preventing granules from opening on the cells' surfaces (3), cromolyn blocks release of histamine and chemical mediators.

sprays (1.6 to 2 mg) as a single dose at least 10 to 15 min (no longer than 1 hr) before exposure or exercise. *Maximum:* 16 sprays (12.8 to 16 mg) daily.

CAPSULES FOR INHALATION

Adults and children over age 2. 1 capsule (20 mg) as single dose inhaled at least 10 to 15 min (no longer than 1 hr) before exposure or exercise. *Maximum:* 8 capsules (160 mg) daily.

SOLUTION FOR NEBULIZATION

Adults and children over age 2. *Initial:* 20 mg inhaled 10 to 15 min (no longer than 1 hr) before exposure or exercise. Repeated p.r.n. during prolonged exercise. *Maximum:* 160 mg daily.

➔ *To treat allergic rhinitis*

NASAL SOLUTION

Adults and children over age 2. 1 spray (5.2 mg) in each nostril at regular intervals t.i.d. or q.i.d. *Maximum:* 1 spray (5.2 mg) in each nostril 6 times daily.

➔ *To prevent systemic mastocytosis*

CAPSULES, ORAL CONCENTRATE

Adults and adolescents. 200 mg q.i.d., 30 min before meals and at bedtime.

Children ages 2 to 12. 100 mg q.i.d., 30 min before meals and at bedtime. *Maximum:* 40 mg/kg/day.

Children under age 2. 5 mg/kg q.i.d. *Maximum:* 40 mg/kg daily.

Contraindications

Arrhythmias, coronary artery disease (aerosol); hypersensitivity to cromolyn or its components, status asthmaticus (all forms);

nasal polyps (nasal solution)

Route	Onset	Peak	Duration
Aerosol	Minutes	Unknown	Up to 2 hr
Nasal solution	1 wk	1–4 wk	Unknown
Nebulizer solution	Minutes	Unknown	3–6 hr

Adverse Reactions

CNS: Dizziness, headache, neuritis

EENT: Burning eyes, hoarseness, laryngeal edema, nasal congestion, and swollen parotid glands (all forms); increased sneezing, nasal stinging, and throat irritation (nasal solution); taste perversion (aerosol)

GI: Anorexia, diarrhea (capsules and oral concentrate), nausea, vomiting

GU: Dysuria, urinary frequency

MS: Arthralgia, joint swelling

RESP: Cough, wheezing

SKIN: Rash, urticaria

Nursing Considerations

WARNING Be aware that cromolyn sodium shouldn't be used to relieve acute asthma attack or severe bronchospasm; it should be used only for prevention.

- Don't give cromolyn sodium through handheld nebulizer. Instead, administer via power-operated nebulizer with a face mask or mouthpiece.
- Evaluate patient for effective inhalation; patient must be able to inhale adequately for nebulizer solution to be effective.

- Thoroughly mix oral concentrate or capsule contents into half a glass of hot water (not fruit juice, milk, or food), and let cool before administering.
- Give drug at regular intervals to maximize effectiveness.

PATIENT TEACHING

- Teach patient how to use power-operated nebulizer; warn against using handheld nebulizer.
- Advise patient to use cromolyn sodium 10 to 15 minutes before exercising or exposure to other precipitating factors.
- Instruct patient to thoroughly mix oral concentrate with hot water (not fruit juice, milk, or food) and let it cool before drinking.
- Inform patient that nasal spray may cause minor nasal irritation.
- Explain that cromolyn sodium may take up to 1 month to reach full therapeutic effects.

crotamiton

Eurax

Class and Category

Chemical class: Synthetic chloroformate salt
Therapeutic class: Antipruritic, scabicide
Pregnancy category: C

Indications and Dosages

↗ *To treat scabies*

CREAM, LOTION

Adults. 30 to 60 g (thin layer) massaged into skin from chin down and repeated in 24 hr. Applied p.r.n. to skin folds, creases, and areas of intense pruritus for up to 48 hr.

↗ *To relieve pruritus caused by scabies*

CREAM, LOTION

Adults. 30 to 60 g (thin layer) massaged gently into affected areas until drug is completely absorbed. Repeated p.r.n.

Mechanism of Action

Exerts a toxic effect on *Sarcoptes scabiei* by an unknown mechanism.

Contraindications

Abrasions, application to mucous membranes, breaks in skin, hypersensitivity to crotamiton or its components, inflammation

Adverse Reactions

SKIN: Contact dermatitis, irritation, pruritus, rash

Nursing Considerations

- Expect pruritus to continue for 4 to 6 weeks after treatment.

PATIENT TEACHING

- Advise patient to shake lotion bottle well before applying.
- Warn him to keep drug away from eyes, nose, mouth, and inflamed skin.
- Advise patient to use a topical corticosteroid for dermatitis and an antihistamine for pruritus, as prescribed.
- Instruct patient to change clothing and bed linens the morning after final application and to take a cleansing bath 48 hours after final application.
- Inform patient that pruritus may continue for 4 to 6 weeks after treatment.
- Advise patient to notify prescriber if skin irritation or rash occurs.

cyclizine hydrochloride

Marezine

cyclizine lactate

Marzine (CAN)

Class and Category

Chemical class: Piperazine derivative
Therapeutic class: Anticholinergic, antiemetic
Pregnancy category: B

Indications and Dosages

↗ *To prevent postoperative vomiting*

I.M. INJECTION

Adults and adolescents. 50 mg 15 to 30 min before surgery ends; then every 4 to 6 hr, p.r.n., for first few postoperative days.

Children ages 6 to 12. 25 mg 15 to 30 min before surgery ends; then t.i.d., p.r.n., for first few postoperative days.

Children up to age 6. 12.5 mg 15 to 30 min before surgery ends; then t.i.d., p.r.n., for first few postoperative days.

↗ *To prevent and treat motion sickness*

TABLETS

Adults and adolescents. 50 mg 30 min

before travel; then every 4 to 6 hr, p.r.n.

Maximum: 200 mg daily.

Children ages 6 to 12. 25 mg 30 min before travel; then every 6 to 8 hr, p.r.n. *Maximum:* 75 mg daily.

I.M. INJECTION

Adults and adolescents. 50 mg every 4 to 6 hr, p.r.n.

Children. 1 mg/kg t.i.d., p.r.n.

Route	Onset	Peak	Duration
P.O., I.M.	30–60 min	Unknown	4–6 hr

Mechanism of Action

May act centrally on the vomiting center by blocking chemoreceptor trigger zones.

Cyclizine also may reduce the sensitivity of the labyrinthine apparatus in the inner ear.

Contraindications

Hypersensitivity to cyclizine or its components, shock

Interactions

DRUGS

anticholinergics: Possibly potentiated anticholinergic effects

apomorphine: Possibly decreased emetic response of apomorphine

CNS depressants: Possibly potentiated CNS depression

ACTIVITIES

alcohol use: Possibly potentiated CNS depression

Adverse Reactions

CNS: Dizziness, drowsiness, euphoria, excitation, hallucinations, insomnia, nervousness, restlessness, seizures (in children), vertigo

CV: Hypotension, palpitations, tachycardia

EENT: Blurred vision; diplopia; dry mouth, nose, and throat; tinnitus

GI: Anorexia, constipation, diarrhea, nausea, vomiting

GU: Urinary frequency and hesitancy, urine retention

SKIN: Jaundice, rash, urticaria

Nursing Considerations

- Help patient with ambulation, and take safety precautions to prevent injury from falls if drowsiness or dizziness occurs.
- Don't schedule allergen skin tests until at least 5 days after stopping cyclizine; drug may interfere with test results.

PATIENT TEACHING

- Urge patient to avoid alcohol and other CNS depressants during cyclizine therapy.
- Advise patient to ask for help with ambulation if he feels drowsy or dizzy.

cyclobenzaprine hydrochloride

Flexeril

Class and Category

Chemical class: Tricyclic amine salt

Therapeutic class: Skeletal muscle relaxant

Pregnancy category: B

Indications and Dosages

↗ *As adjunct to rest and physical therapy for relief of muscle spasm associated with acute, painful musculoskeletal conditions*

TABLETS

Adults and adolescents. 5 mg t.i.d., increased as needed to 10 mg t.i.d.

Maximum: 30 mg daily for 3 wk.

DOSAGE ADJUSTMENT Dosage frequency reduced in elderly patients and those with hepatic impairment.

Route	Onset	Peak	Duration
P.O.	1 hr	1–2 wk	12–24 hr

Mechanism of Action

Acts in the brain stem to reduce or abolish tonic muscle hyperactivity. Because cyclobenzaprine doesn't act at the neuromuscular junction or directly on skeletal muscle, it relieves muscle spasm without disrupting muscle function.

Contraindications

Acute recovery phase of MI; age less than 12; arrhythmias, including heart block and other conduction disturbances; heart failure; hypersensitivity to cyclobenzaprine or its components; hyperthyroidism; MAO inhibitor use within 14 days

Interactions

DRUGS

anticholinergics, antidyskinetics: Possibly potentiated anticholinergic effects of these drugs

CNS depressants, tricyclic antidepressants:

Possibly additive CNS depressant effects of these drugs, increased risk of adverse effects of antidepressants and cyclobenzaprine
guanadrel, guanethidine: Possibly decreased or blocked antihypertensive effects of these drugs

MAO inhibitors: Possibly hyperpyretic crisis, severe seizures, and death

ACTIVITIES

alcohol use: Possibly additive CNS depression

Adverse Reactions

CNS: Asthenia, confusion, depression, dizziness, drowsiness, fatigue, fever, headache, insomnia, irritability, nervousness, paresthesia, seizures, tremor, weakness
CV: Arrhythmias, including tachycardia; orthostatic hypotension; palpitations; vasodilation

EENT: Blurred vision, diplopia, dry mouth, transient vision loss, unpleasant taste

GI: Constipation, hiccups, indigestion, nausea, vomiting

GU: Libido changes, urinary frequency, urine retention

SKIN: Diaphoresis, facial flushing, pruritus, rash

Nursing Considerations

- Use cyclobenzaprine cautiously in patients with history of low seizure threshold.
- If possible, avoid giving drug to elderly patients because of its anticholinergic effects.
- To prevent falls, take safety precautions if patient is confused, dizzy, or weak.

PATIENT TEACHING

- Urge patient to avoid alcohol and other CNS depressants during therapy.
- Inform patient about possible lack of alertness and dexterity.
- Advise patient to ask for assistance with walking, driving, or hazardous activities if he experiences dizziness or weakness.

cycloserine

Seromycin

Class and Category

Chemical class: D-alanine analogue, *Streptomyces garyphalus* or *Streptomyces orchidaceus* derivative

Therapeutic class: Antitubercular
Pregnancy category: C

Indications and Dosages

➤ *To treat tuberculosis with other antituberculotics after failure of primary drugs, including ethambutol, isoniazid, pyrazinamide, rifampin, streptomycin*

CAPSULES

Adults and adolescents. 250 mg every 12 hr for 2 wk; then every 6 to 8 hr for 2 wk. Dosage increased gradually to maintain blood cycloserine level below 30 mcg/ml. *Maximum*: 1 g daily.

Children. 10 to 20 mg/kg daily in divided doses every 12 hr. *Maximum*: 1 g daily.

Mechanism of Action

Inhibits bacterial cell wall synthesis in gram-positive organisms, including *Mycobacterium tuberculosis*. In early stages of bacterial cell wall synthesis, cycloserine inhibits two enzymes that help form peptidoglycan, which is needed to make the cell membrane rigid and protective.

Contraindications

Chronic alcoholism, depression, hypersensitivity to cycloserine or its components, psychosis, renal disease, seizure disorder, severe anxiety

Interactions

DRUGS

ethionamide: Possibly increased risk of seizures

isoniazid: Possibly increased risk of adverse CNS effects

phenytoin: Possibly increased blood phenytoin level

pyridoxine: Possibly anemia or peripheral neuritis

ACTIVITIES

alcohol use: Possibly increased risk of seizures

Adverse Reactions

CNS: Aggression, anxiety, coma, confusion, depression, dizziness, drowsiness, headache, irritability, lethargy, memory loss, nervousness, nightmares, psychosis, restlessness, seizures, suicidal tendencies, tremor, vertigo
CV: Heart failure

HEME: Leukocytosis, megaloblastic anemia

MS: Dysarthria, hyperreflexia

SKIN: Dermatitis, photosensitivity

Other: Folic acid deficiency, vitamin B₁₂ deficiency

Nursing Considerations

- Monitor blood cyclosporine level, as appropriate. Blood level should be maintained at 25 to 30 mcg/ml.
- Monitor mental status, mood, and affect for aggression or depression.
- Monitor CBC to detect blood dyscrasias.
- To prevent injury from falls, take safety precautions if adverse CNS reactions, such as dizziness or drowsiness, develop.

PATIENT TEACHING

- Urge patient to avoid alcohol while taking cyclosporine.
- Instruct patient to seek help immediately if he has suicidal thoughts.
- Advise patient to avoid driving and to ask for assistance with walking or hazardous activities if he develops adverse CNS reactions, such as dizziness and drowsiness.
- Tell patient to contact prescriber if symptoms haven't improved after 2 to 3 weeks.
- Emphasize the importance of complying with drug therapy because effective treatment may take years to complete.

cyclosporine (cyclosporin A)

Neoral, Sandimmune, SangCya

Class and Category

Chemical class: Tolyptocladium inflatum

Gams- or Cyliandrocarpon lucidum

Booth-derived polypeptide

Therapeutic class: Antipsoriatic, antirheumatic, immunosuppressant

Pregnancy category: C

Indications and Dosages

↗ *To prevent or treat organ rejection in kidney, liver, and heart allogenic transplantation*

CAPSULES, MODIFIED CAPSULES, MODIFIED ORAL SOLUTION, ORAL SOLUTION

Adults and children. *Initial:* 12 to 15 mg/kg daily in divided doses every 12 hr starting 4 to 12 hr before surgery and continuing 1 to 2 wk afterward. Then, dosage reduced by 5% every wk to maintenance dose.

Maintenance: 5 to 10 mg/kg daily in divided doses every 12 hr.

I.V. INFUSION

Adults. 2 to 6 mg/kg daily starting 4 to 12 hr before surgery and continuing afterward until patient can tolerate oral form of drug.

↗ *To treat severe rheumatoid arthritis*

MODIFIED CAPSULES, MODIFIED ORAL SOLUTION

Adults. 2.5 mg/kg daily in divided doses every 12 hr, increased by 0.5 to 0.75 mg/kg daily after 8 wk and again after 12 wk.

Maximum: 4 mg/kg daily.

↗ *To treat psoriasis*

MODIFIED CAPSULES, MODIFIED ORAL SOLUTION

Adults. *Initial:* 2.5 mg/kg daily in divided doses b.i.d., increased by 0.5 mg/kg daily after 4 wk. Then dosage increased every 2 wk, if needed. *Maximum:* 4 mg/kg daily.

Mechanism of Action

Causes immunosuppression by inhibiting the proliferation of T lymphocytes, the production and release of lymphokines, and the release of interleukin-2.

Contraindications

Abnormal renal function, neoplastic diseases, and uncontrolled hypertension in patients with psoriasis or rheumatoid arthritis (modified capsules and oral solution); hypersensitivity to cyclosporine, its components, or polyoxyethylated castor oil (I.V. infusion)

Interactions

DRUGS

ACE inhibitors, angiotensin II receptor antagonists, potassium-sparing diuretics, potassium supplements: Increased risk of hyperkalemia

allopurinol, amiodarone, azithromycin, bromocriptine, clarithromycin, colchicine, danazol, diltiazem, erythromycin, fluconazole, hormonal contraceptives, imatinib, itraconazole, ketoconazole, methylprednisolone, metoclopramide, nefazodone, nifedipine, oral contraceptives, quinupristin and dalfo-pristin, verapamil, voriconazole: Increased cyclosporine level

amphotericin B, azapropazon, cimetidine, ciprofloxacin, colchicine, co-trimoxazole, fibric acid derivatives (bezafibrate, fenofibrate), gentamicin, ketoconazole, melphalan, NSAIDs, ranitidine, tacrolimus, tobramycin, vancomycin: Increased risk of nephrotoxicity

atorvastatin, fluvastatin, lovastatin, pravastatin, simvastatin: Risk of myotoxicity

bosentan, carbamazepine, nafcillin, octreotide, orlistat, oxcarbazepine, phenobarbital, phenytoin, rifampin, St. John's wort, sulfonpyrazone, terbinafine, ticlopidine:

Decreased blood cyclosporine level and therapeutic response

colchicine: Possibly colchicine toxicity, such as myopathy and neuropathy

digoxin: Increased blood digoxin level and risk of digitalis toxicity

indinavir, nelfinavir, ritonavir, saquinavir:

Possibly increased blood cyclosporine level

methotrexate: Increased blood methotrexate level and risk of renal dysfunction

methylprednisolone (high dose): Increased risk of seizures

other immunosuppressants: Possibly excessive immunosuppression

prednisolone: Increased prednisolone level

repaglinide: Possibly increased repaglinide level and risk of hypoglycemia

sirolimus: Increased blood sirolimus level

vaccines (killed or live virus): Possibly suppressed immune response and increased adverse effects of vaccine

FOODS

Grapefruit, grapefruit juice: Increased risk of nephrotoxicity

Potassium-rich foods: Increased risk of hyperkalemia

Adverse Reactions

CNS: Altered level of consciousness, confusion, headache, intracranial hypertension, loss of motor function, paresthesia, psychiatric disturbances, seizures, tremor

CV: Chest pain, hypertension

EENT: Gingival hyperplasia, optic disc edema, oral candidiasis, visual impairment

ENDO: Gynecomastia

GI: Diarrhea, nausea, pancreatitis, vomiting

GU: Albuminuria, hematuria, nephropathy associated with BK virus, proteinuria, renal failure

HEME: Anemia, leukopenia, thrombocytopenia

SKIN: Acne, cancer, flushing, hirsutism, rash

Other: Anaphylaxis, hyperkalemia, hypomagnesemia, life-threatening infections, lymphoma and other malignancies

Nursing Considerations

- Be aware that capsules and oral solution aren't interchangeable with modified cap-

sules and modified oral solution. Modified forms have greater bioavailability.

- Prepare I.V. infusion by diluting each milliliter of concentrate in 20 to 100 ml of normal saline solution or D₅W. Use glass containers because of possible leaching of diethylhexylphthalate from polyvinyl chloride bags into cyclosporine solution.

- Administer I.V. infusion over 2 to 6 hr. If needed, drug may be infused over 24 hr.

WARNING Closely monitor patient for anaphylaxis, at least during first 30 minutes of I.V. administration. Make sure emergency equipment and drugs are immediately available.

WARNING Be aware that rapid I.V. infusion may cause acute nephrotoxicity.

- Don't draw blood to measure cyclosporine level through same I.V. tubing used to administer drug, even if line was flushed after administration. Blood level may be falsely elevated.

- Discard diluted solution after 24 hours.

- Be aware that oral solution contains alcohol and shouldn't be administered to patient who drinks heavily or has a history of alcohol dependence.

- Don't add water to oral solution because it will alter drug's effectiveness.

- Avoid giving oral cyclosporine with grapefruit juice, which may raise trough level, increasing risk of nephrotoxicity.

- Monitor blood pressure, especially in patients with a history of hypertension, because drug can worsen this condition. Expect to decrease dosage if hypertension develops.

- Monitor liver and renal function tests, as ordered, to detect decreased function.

- Although uncommon, cyclosporine may cause neurotoxicity, especially after liver transplantation. Watch for evidence of encephalopathy (impaired consciousness, loss of motor function, psychiatric disturbance, seizures, visual disturbance).

- Be aware that cyclosporine use may result in increased serum cholesterol levels.

- Be aware that St. John's wort may decrease blood cyclosporine level.

- Store capsules at 77° F (25° C) in prepackaged foil wrap to protect them from light.

- Expect about 50% of patients treated for psoriasis to relapse about 4 months after therapy stops.

WARNING Watch for evidence of infection (such as fever, pain, cough, malaise) because patients receiving immunosuppressants such as cyclosporine are at increased risk for viral, bacterial, fungal, and parasitic infection. Watch for both generalized and localized infections, including worsening of pre-existing infections, and be aware that these infections may become life-threatening. Activation of latent viral infections may also occur and include BK virus–associated nephropathy that can lead to decreased renal function and renal graft loss.

PATIENT TEACHING

- Instruct patient to take drug at same time each day and in same relation to type and timing of food intake to help increase compliance and maintain steady blood level.
- Advise patient to mix oral solution in a glass—not plastic—container with room-temperature orange or apple juice to improve flavor. Caution him to avoid grapefruit juice because it alters drug metabolism.
- Instruct patient to use syringe supplied by manufacturer to ensure accurate measurement of oral solution dose and to wipe—not rinse—syringe after use to prevent cloudiness.
- Advise patient not to stop taking drug without consulting prescriber.
- Instruct patient to avoid virus vaccines during therapy and people who have received such vaccines. Or, suggest wearing a protective mask when he's around them.
- Caution patient to avoid people who have infections during therapy because cyclosporine causes immunosuppression.
- Advise good dental hygiene because of risk of gingival hyperplasia.
- Advise patient to discard oral solution after it has been opened for 2 months.
- Inform patient with rheumatoid arthritis that drug effects may not appear for 4 to 6 weeks.
- Caution patient to avoid excessive exposure to ultraviolet light.

D

daclizumab (dacliximab)

Zenapax

Class and Category

Chemical class: Monoclonal antibody
Therapeutic class: Immunosuppressant
Pregnancy category: C

Indications and Dosages

➤ *To prevent acute organ rejection after kidney transplantation*

I.V. INFUSION

Adults and children. 1 mg/kg given in five doses. Dose 1 given no more than 24 hr before transplantation; doses 2 through 5 given at 14-day intervals.

Mechanism of Action

Inhibits interleukin-2–mediated activation of lymphocytes, which prevents WBCs from attacking the transplanted kidney. Drug also reduces the body’s infection-fighting ability.

Contraindications

Hypersensitivity to daclizumab or its components

Adverse Reactions

CNS: Anxiety, chills, depression, dizziness, fatigue, fever, headache, insomnia, prickly sensation, tremor, weakness

CV: Chest pain, edema, hypertension, hypotension, tachycardia, thrombosis

EENT: Blurred vision, pharyngitis, rhinitis

ENDO: Hyperglycemia

GI: Abdominal distention and pain, constipation, diarrhea, flatulence, gastritis, heartburn, hemorrhoids, indigestion, nausea, vomiting

GU: Dysuria, hematuria, hydronephrosis, oliguria, renal insufficiency, renal tubular necrosis, urine retention

HEME: Bleeding

MS: Arthralgia, back pain, leg cramps, myalgia

RESP: Atelectasis, cough, crackles, dyspnea, hypoxia, lung congestion, pleural effusion,

pulmonary edema

SKIN: Acne, diaphoresis, hirsutism, impaired wound healing, night sweats, pruritus, rash

Other: Dehydration, fluid overload, injection site pain and redness, lymphocele

Nursing Considerations

- Dilute calculated dose of daclizumab in 50 ml of normal saline solution. Gently invert bag to mix. To prevent foaming, don’t shake it.
- Use room temperature solution within 4 hours or refrigerate it for up to 24 hours. Discard unused solution.
- Because daclizumab’s compatibility with other drugs isn’t known, don’t add or simultaneously infuse other drugs through same I.V. line.
- Monitor blood glucose level for increases during therapy.

WARNING Although daclizumab seldom causes severe hypersensitivity reactions, keep drugs to treat such a reaction nearby for immediate use.

PATIENT TEACHING

- Urge patient to complete the course of therapy and return for follow-up visits.

dalfampridine

Ampyra

Class and Category

Chemical: Aminopyridine

Therapeutic: Potassium channel blocker

Pregnancy category: C

Indications and Dosages

➤ *To improve walking in patients with multiple sclerosis*

TABLETS

Adults. 10 mg twice daily

Route	Onset	Peak	Duration
P.O.	1–2 hr	3–4 hr	10–11 hr

Mechanism of Action

May improve walking in multiple sclerosis patients by blocking potassium channels. When potassium channels are blocked, there is increased conduction of action potentials in demyelinated axons resulting in improved muscle action.

Contraindications

History of seizures, hypersensitivity to dalfampridine or its components, moderate or severe renal impairment (creatinine clearance of 50 ml/min/1.73 m² or less)

Interactions**DRUGS**

other aminopyridine agents: Increased risk of adverse reactions

Adverse Reactions

CNS: Asthenia, balance disorder, confusion, dizziness, headache, insomnia, paresthesia, seizures

EENT: Nasopharyngitis, pharyngolaryngeal pain

GI: Constipation, dyspepsia, nausea

GU: UTI

MS: Back pain, multiple sclerosis relapse

Nursing Considerations

- Check patient's creatinine clearance, as ordered, before starting dalfampridine.
- Use dalfampridine cautiously in patients with mild renal failure (creatinine clearance 51 to 80 ml/min/1.73 m²) because seizures may occur. If they do, expect drug to be discontinued.
- Drug shouldn't be taken with compounded 4-AP, 4-aminopyridine, or fampridine because the risk of seizures may increase.
- Monitor patient's ability to walk to determine drug's effectiveness.

PATIENT TEACHING

- Tell patient to space dalfampridine doses about 12 hours apart.
- Instruct patient, especially one with mild renal impairment, to notify prescriber and stop dalfampridine if seizures occur.
- Review signs and symptoms of UTI (pain on urination, frequency or urgency with urination, cloudy appearance to urine) and tell patient to report any such effects to the prescriber.

dalteparin sodium (tedelparin)

Fragmin

Class and Category

Chemical class: Low-molecular-weight heparin

Therapeutic class: Anticoagulant, anti-thrombotic

Pregnancy category: B

Indications and Dosages

↗ *To prevent ischemic complications in patients who receive aspirin as part of treatment for unstable angina and non-Q-wave MI*

SUBCUTANEOUS INJECTION

Adults. 120 international units/kg every 12 hr with aspirin (75 to 165 mg daily) until patient is stable, usually 5 to 8 days. *Maximum:* 10,000 international units/dose.

↗ *To prevent blood clots in patients undergoing hip replacement surgery*

SUBCUTANEOUS INJECTION

Adults. Initial: 2,500 international units 1 to 2 hr before surgery, repeated in 8 to 12 hr and again 8 to 12 hr later.

Maintenance: 5,000 international units every morning for 5 to 10 days postoperatively or until patient is fully ambulatory.

Alternate: 5,000 international units the evening before surgery; then 5,000 international units daily (starting the next evening) for 5 to 10 days or until patient is fully ambulatory.

↗ *To prevent blood clots in patients undergoing abdominal surgery who are at risk for thromboembolic complications*

SUBCUTANEOUS INJECTION

Adults. 2,500 international units daily, starting 1 to 2 hr before surgery and repeated for 5 to 10 days. For patients at high risk (those with cancer), 5,000 international units the evening before surgery, repeated daily for 5 to 10 days; or 2,500 international units 1 to 2 hr before surgery followed by 2,500 international units 12 hr later and then 5,000 international units daily for 5 to 10 days.

↗ *To prevent blood clots in patients with severe mobility restrictions during acute illness*

SUBCUTANEOUS INJECTION

Adults. 5,000 international units daily.

↗ *To treat symptomatic venous thromboembolism and prevent recurrence in patients with cancer*

SUBCUTANEOUS INJECTION

Adults. 200 international units/kg (not to exceed 18,000 international units) once daily for 30 days. Then 150 international units/kg once daily for 5 more mo.

Mechanism of Action

Binds to and accelerates the activity of antithrombin III, thus inhibiting thrombin and blocking the formation of fibrin clots.

Incompatibilities

Don't mix dalteparin with other drugs.

Contraindications

Active major bleeding; hypersensitivity to low-molecular-weight heparins, heparin, or pork products; thrombocytopenia associated with positive tests for antiplatelet antibodies in the presence of dalteparin

Interactions

DRUGS

NSAIDs, oral anticoagulants, platelet aggregation inhibitors, thrombolytics: Possibly increased risk of hemorrhage and spinal or epidural hematoma

Adverse Reactions

GI: Elevated liver enzymes

HEME: Hemorrhage, thrombocytopenia

SKIN: Alopecia, bullous eruption, necrosis, pruritus, rash

Other: Anaphylaxis, injection site hematoma and pain

Nursing Considerations

- Use dalteparin with extreme caution in patients with a history of heparin-induced thrombocytopenia; those at increased risk for hemorrhage (such as those who use a platelet inhibitor or have bacterial endocarditis, bleeding disorders, active ulcerative GI disease, uncontrolled hypertension, or hemorrhagic stroke); and those with recent brain, eye, or spinal surgery.
- Use drug cautiously in patients with bleeding diathesis, diabetic retinopathy, platelet defects, recent GI bleeding, severe hepatic or renal insufficiency, or thrombocytopenia.
- Before giving first dose, tell Jewish or Islamic patients that drug comes from porcine intestine.
- Risk factors for thromboembolic events include age over 40, cancer, history of deep vein thrombosis or pulmonary embolism, obesity, and planned use of anesthesia for more than 30 minutes.
- Don't give drug by I.M. or I.V. injection.
- With patient seated or supine, administer drug deep into subcutaneous tissue in U-shaped area around navel, upper outer

thigh, or upper outer quadrant of buttocks. If using area around navel or on thigh, lift skin fold with thumb and forefinger while giving injection. Insert entire length of needle at a 45- to 90-degree angle. Rotate sites daily.

- Routine coagulation tests and dosage adjustments usually aren't required.

WARNING Monitor patient receiving dalteparin and epidural or spinal anesthesia or spinal puncture because spinal hematomas can occur, causing long-term or permanent paralysis. Watch for evidence of neurologic impairment, such as changes in sensory or motor function. If present, notify prescriber immediately; patient needs urgent care to minimize effect of hematoma. Use of indwelling epidural catheters, concurrent use of other drugs that affect hemostasis, a history of traumatic or repeated epidural or spinal punctures, or a history of spinal deformity or spinal surgery increases the risk of spinal or epidural hematoma in patients receiving dalteparin.

PATIENT TEACHING

- If therapy will continue at home, teach patient or caregiver to select injection sites, give subcutaneous injections, and rotate sites daily. Tell patient to discard drug if it's discolored or contains particles. Review safe handling and disposal of syringes and needles.
- Teach patient to store drug at room temperature, away from moisture and heat.
- Urge patient to report adverse reactions, especially bleeding, and to seek help immediately if signs of thromboembolism develop, such as severe dyspnea (pulmonary embolism) or neurologic deficits (cerebral embolism).
- Stress the importance of follow-up visits.

danaparoid sodium

Orgaran

Class and Category

Chemical class: Glycosaminoglycan heparinoid, low-molecular-weight heparin

Therapeutic class: Anticoagulant, antithrombotic

Pregnancy category: B

Indications and Dosages

↗ *To prevent deep vein thrombosis after hip replacement surgery*

SUBCUTANEOUS INJECTION

Adults. 750 anti-factor Xa units b.i.d. (first dose 1 to 4 hr preoperatively; second dose no sooner than 2 hr after surgery) for 7 to 14 days, as indicated.

Mechanism of Action

Inhibits thrombin generation in coagulation pathway, thus preventing fibrin formation and clotting.

Contraindications

Active major bleeding (including hemorrhagic stroke); hypersensitivity to low-molecular-weight heparins, heparin, or pork products; severe hemorrhagic disorders, such as hemophilia and thrombocytopenic purpura; sulfite sensitivity; type II thrombocytopenia associated with positive laboratory tests for antiplatelet antibodies in the presence of danaparoid

Interactions

DRUGS

NSAIDs, oral anticoagulants, platelet aggregation inhibitors: Possibly increased risk of bleeding

Adverse Reactions

CNS: Asthenia, dizziness, fever, headache, insomnia

CV: Chest pain, edema

GI: Abdominal pain, constipation, nausea, vomiting

GU: Urine retention, UTI

HEME: Anemia, excessive bleeding

MS: Arthralgia, myalgia

SKIN: Pruritus, rash

Other: Anaphylaxis, injection site pain

Nursing Considerations

- Use danaparoid with extreme caution in patients at increased risk for hemorrhage (such as those with severe uncontrolled hypertension, acute bacterial endocarditis, bleeding disorders, active ulcerative GI disease, severe renal dysfunction, or non-hemorrhagic stroke); those with a postoperative indwelling epidural catheter; and those with recent had brain, eye, or spinal surgery.
- Before administering first dose, inform Jewish and Islamic patients that drug comes from porcine intestinal mucosa.

- Don't give drug by I.M. or I.V. injection.
- Administer drug with patient lying down. Use a 25G or 26G needle to minimize tissue trauma. Select site on left or right anterolateral or posterolateral abdominal wall. Hold skin fold gently between thumb and forefinger, and insert entire length of needle deep into subcutaneous tissue at a 45- to 90-degree angle. Don't pinch or rub site afterward. Rotate sites.
- Expect to monitor results of CBC and fecal occult blood tests during therapy. Typical coagulation tests, such as PT, APTT, clotting time, whole blood clotting time, and thrombin time, aren't useful for monitoring drug's anticoagulant effect.

PATIENT TEACHING

- If therapy must continue at home, teach patient or caregiver how to give subcutaneous injections. Review injection sites, and instruct her to rotate them daily. Tell her to discard drug if it's discolored or contains particles. Review safe handling and disposal of syringes and needles.
- Teach patient to store drug at room temperature, away from moisture and heat.
- Instruct patient to consult prescriber before using aspirin, ibuprofen, indomethacin, ketoprofen, naproxen, and other NSAIDs because they may increase the risk of bleeding.
- Advise patient to stop taking drug and seek help immediately if she experiences severe dizziness, fever, rash, wheezing, or prolonged or unexplained bleeding and pain at the injection site.

dantrolene sodium

Dantrium, Dantrium Intravenous

Class and Category

Chemical class: Hydantoin derivative, imidazolidinedione sodium salt

Therapeutic class: Antispastic, malignant hyperthermia therapy adjunct

Pregnancy category: C (parenteral), Not rated (oral)

Indications and Dosages

↗ *To treat chronic spastic conditions caused by severe chronic disorders, such as cerebral palsy, stroke, multiple sclerosis, and spinal cord injury*

CAPSULES

Adults and adolescents. *Initial:* 25 mg daily for 7 days. Then dosage increased to 25 mg/day every 4 to 7 days until desired response occurs or dosage reaches 100 mg q.i.d.

Maximum: 400 mg daily.

Children. *Initial:* 0.5 mg/kg b.i.d. for 7 days. Then increased by 0.5 mg/kg daily every 4 to 7 days until desired response occurs or dosage reaches 3 mg/kg q.i.d. *Maximum:* 400 mg daily.

↗ *To prevent malignant hyperthermia before surgery*

CAPSULES

Adults and children. 4 to 8 mg/kg daily in divided doses t.i.d. or q.i.d. 1 or 2 days before surgery, with last dose given 3 to 4 hr before surgery.

I.V. INFUSION

Adults and children. *Initial:* 2.5 mg/kg 60 to 75 min before anesthesia and infused over 1 hr. Additional individualized doses given as needed during surgery.

↗ *To treat malignant hyperthermic crisis*

I.V. INJECTION

Adults and adolescents. *Initial:* 1 mg/kg by rapid bolus; repeated, p.r.n., until symptoms subside or cumulative dose of 10 mg/kg has been reached and if symptoms reappear.

↗ *To treat postmalignant hyperthermic crisis*

CAPSULES

Adults and children. 4 to 8 mg/kg daily in divided doses q.i.d. for 1 to 3 days.

I.V. INJECTION

Adults and children. *Initial:* Individualized dosage beginning with 1 mg/kg or more as needed if oral therapy can't be used.

Maximum: 10 mg/kg total dose.

Route	Onset	Peak	Duration
P.O.	1 wk*	Unknown	Unknown

Mechanism of Action

Acts directly on skeletal muscle to reduce the force of reflex muscle contraction. This in turn reduces hyperreflexia, spasticity, involuntary movements, and clonus, probably by preventing calcium release from the sarcoplasmic reticulum of skeletal muscle

* For spasticity; unknown for malignant hyperthermia.

cells. Blocked calcium release also inhibits the activation of acute catabolism associated with malignant hyperthermic crisis syndrome.

Incompatibilities

Don't administer parenteral dantrolene with acidic solutions, including D₅W and normal saline solution.

Contraindications

For oral drug only: Active hepatic disease (such as cirrhosis and hepatitis), conditions in which spasticity helps maintain upright posture and improve balance or function, skeletal muscle spasms caused by rheumatic disorders

Interactions**DRUGS**

calcium channel blockers (especially verapamil): Possibly hyperkalemia, shock, life-threatening arrhythmias

hepatotoxic drugs: Increased risk of hepatotoxicity with long-term oral dantrolene use

sedatives: Possibly profound sedation

ACTIVITIES

alcohol use: Possibly increased CNS depression

Adverse Reactions

CNS: Chills, confusion, depression, dizziness, drowsiness, fatigue, fever, headache, insomnia, light-headedness, malaise, nervousness, seizures, slurred speech or other speech problems, weakness

CV: Heart failure (I.V.), labile blood pressure, pericarditis, phlebitis, tachycardia

EENT: Abnormal vision, altered taste, diplopia, lacrimation

GI: Abdominal cramps, anorexia, constipation, diarrhea, dysphagia, gastric irritation, GI bleeding, hepatitis, hepatotoxicity

GU: Crystalluria, dysuria, erectile dysfunction, hematuria, nocturia, urinary frequency, urinary incontinence, urine retention

MS: Backache, myalgia

RESP: Feeling of suffocation, pleural effusion

SKIN: Acne, diaphoresis, eczematoid eruption, erythema (I.V.), extravasation with tissue damage, hirsutism, pruritus, rash, urticaria

Nursing Considerations

• Use dantrolene cautiously in patients with impaired pulmonary function, especially

those with COPD, and in those with severe cardiac or hepatic dysfunction.

- Reconstitute drug with 60 ml sterile water for injection. Shake vial until clear. Store reconstituted solution at room temperature, protected from direct sunlight. Discard after 6 hours.
- To prevent precipitation, transfer reconstituted drug to a plastic I.V. bag, rather than a glass bottle, for infusion.
- Because drug has a high pH, infuse into a central vein, if possible, to avoid tissue damage from extravasation.
- Monitor blood pressure and heart rate often during administration to detect tachycardia and blood pressure changes.
- Notify prescriber about persistent diarrhea with oral therapy; drug may need to be stopped.
- Monitor results of liver function tests—especially ALT, AST, alkaline phosphatase, and total bilirubin levels—to detect hepatotoxicity. Expect to stop drug after 45 days if benefits aren't sufficient because risk of hepatotoxicity increases with dose and time, especially for women and patients over age 35.

PATIENT TEACHING

- Advise patient to take dantrolene with food if gastric irritation develops.
- Tell patient that drug may weaken muscles used for walking and climbing stairs.
- Explain drug's sedating effects. Caution patient to avoid sedatives (unless prescribed), including alcohol.
- Advise patient to report yellow skin or sclerae, itching, anorexia, and fatigue.
- If patient misses a dose, tell her to wait until the next scheduled dose if more than 2 hours have passed since the missed dose. Instruct her not to double the dose.
- Caution patient not to stop taking drug without consulting prescriber. Gradual dosage reduction may be required, especially after long-term use.

daptomycin

Cubicin

Class and Category

Chemical class: Cyclic lipopeptide

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat complicated skin and skin structure infections caused by Staphylococcus aureus (including methicillin-resistant isolates), Streptococcus pyogenes, Streptococcus agalactiae, Streptococcus dysgalactiae subspecies Equisimilis, and Enterococcus faecalis (vancomycin-susceptible isolates only)*

I.V. INFUSION

Adults. 4 mg/kg administered over 30 min daily for 7 to 14 days. *Maximum:* 6 mg/kg I.V. every 24 hr.

DOSE ADJUSTMENT For patients with creatinine clearance less than 30 ml/min/1.73 m², 4 or 6 mg/kg (depending on infection type) once every 48 hr.

➤ *To treat Staphylococcus aureus bloodstream infections, including right-sided infective endocarditis, caused by methicillin-susceptible and methicillin-resistant isolates*

I.V. INFUSION

Adults. 6 mg/kg administered over 30 min daily for 2 to 6 wk. *Maximum:* 6 mg/kg I.V. every 24 hr.

DOSE ADJUSTMENT For patients with creatinine clearance less than 30 ml/min/1.73 m², dosage is 4 or 6 mg/kg (depending on infection) once every 48 hr.

Mechanism of Action

Binds to bacterial membranes to cause rapid depolarization of membrane potential. This loss of membrane potential inhibits protein, DNA, and RNA synthesis, which results in bacterial cell death.

Contraindications

Hypersensitivity to daptomycin or its components

Interactions

DRUGS

HMG-CoA reductase inhibitors: Possibly increased CK level and increased risk of myopathy

Adverse Reactions

CNS: Anxiety, asthenia, confusion, dizziness, fever, headache, insomnia, peripheral neuropathy

CV: Cardiac failure, chest pain, hypertension, hypotension, peripheral edema, supraventricular tachycardia

EENT: Pharyngolaryngeal pain, oral can-

diidiasis, sore throat

ENDO: Hyperglycemia, hypoglycemia

GI: Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, dysphagia, elevated liver enzymes, GI hemorrhage, nausea, pseudomembranous colitis, vomiting

GU: Renal failure, UTI, vaginal candidiasis

HEME: Anemia, eosinophilia, increased INR, leukocytosis, thrombocytopenia, thrombocytosis

MS: Arthralgia, back or limb pain, elevated myoglobin level, myopathy, rhabdomyolysis, osteomyelitis

RESP: Cough, dyspnea, pleural effusion, pneumonia, pulmonary eosinophilia, shortness of breath

SKIN: Cellulitis, diaphoresis, erythema, pruritus, rash, urticaria, vesiculobullous rash

Other: Anaphylaxis, bacteremia, elevated alkaline phosphatase level, elevated serum sodium bicarbonate level, fungal infection, hyperkalemia, hypokalemia, hypomagnesemia, injection site reactions, sepsis

Nursing Considerations

- Obtain blood samples for culture and sensitivity testing before starting daptomycin.
- Reconstitute daptomycin powder by slowly transferring 10 ml normal saline for injection into vial and pointing needle toward wall of vial to minimize foaming. Then gently rotate vial until all powder is wet. Don't agitate or shake vial. Let vial stand undisturbed for 10 minutes, and then gently rotate or swirl contents for a few minutes, as needed, to obtain a completely reconstituted solution.
- Further dilute reconstituted daptomycin solution with normal saline for injection, and give by I.V. infusion over 30 minutes. Reconstituted drug is stable in infusion bag for 12 hours at room temperature or 48 hours refrigerated.
- Daptomycin may cause a significant false increase in PT and INR. If this occurs during daptomycin therapy, draw blood sample just before next daptomycin dose and evaluate other causes of the increase.
- Monitor patient closely for diarrhea, which may herald pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber. If pseudomembranous colitis develops, expect to discontinue drug and give fluids,

electrolytes, protein, and antibiotic effective against *C. difficile*.

- Monitor patient for evidence of superinfection, and inform prescriber if present. Expect to stop drug and provide care.
- Assess patient for muscle pain or weakness, especially of distal limbs. Expect to monitor CK level weekly or more often in patients recently or currently taking an HMG-CoA reductase inhibitor. Expect to stop daptomycin, as ordered, if patient has myopathy or marked rise in CK level.
- Monitor patient's BUN and serum creatinine levels closely, especially if renal insufficiency is already present.

PATIENT TEACHING

- Inform patient that diarrhea may occur 2 months or more after daptomycin therapy stops. If severe or prolonged, advise patient to notify prescriber as soon as possible; additional treatment may be needed.
- Urge patient to immediately report muscle pain, tenderness, or weakness and other symptoms of myopathy.

darbepoetin alfa

Aranesp

Class and Category

Chemical class: 165-amino acid glycoprotein identical to human erythropoietin

Therapeutic class: Antianemic

Pregnancy category: C

Indications and Dosages

➤ *To treat anemia from chronic renal failure*

I.V. OR SUBCUTANEOUS INJECTION

Adults. *Initial:* 0.45 mcg/kg as a single dose every wk. *Maintenance:* Dosage individualized and increased monthly to maintain a hemoglobin level not to exceed 12 g/dl.

DOSAGE ADJUSTMENT Dosage reduced by about 25% if hemoglobin level increases and approaches 12 g/dl. If it continues to increase, doses temporarily withheld until hemoglobin level begins to decrease; then therapy is restarted at a dose about 25% below previous dose. Dosage reduced by about 25% if hemoglobin level increases by more than 1 g/dl in a 2-wk period. Dosage increased by about 25% of previous dose if hemoglobin level increases less than 1 g/dl

over 4 wk but only if serum ferritin level is 100 mcg/L or greater and serum transferrin saturation is 20% or greater. Further increases made at 4-wk intervals until specified hemoglobin level is obtained.

DOSAGE ADJUSTMENT For conversion from epoetin alfa to darbepoetin alfa, dosage administered every wk for patient who previously received epoetin alfa 2 to 3 times/wk and once every 2 wk for patient who previously received epoetin alfa once/wk. For conversion from epoetin alfa, 6.25 mcg/wk darbepoetin alfa given every wk for patients who received less than 2,500 units/wk of epoetin alfa; 12.5 mcg/wk darbepoetin alfa every wk for patients who received 2,500 to 4,999 units/wk of epoetin alfa; 25 mcg/wk darbepoetin alfa every wk for patients who received 5,000 to 10,999 units/wk of epoetin alfa; 40 mcg/wk darbepoetin alfa every wk for patients who received 11,000 to 17,999 units/wk of epoetin alfa; 60 mcg/wk darbepoetin alfa every wk for patients who received 18,000 to 33,999 units/wk of epoetin alfa; 100 mcg/wk darbepoetin alfa every wk for patients who received 34,000 to 89,999 units/wk of epoetin alfa; 200 mcg/wk darbepoetin alfa every wk for patients who received 90,000 or more units/wk of epoetin alfa.

↗ *To treat chemotherapy-induced anemia in patients with nonmyeloid malignancies and hemoglobin level less than 10 g/dl*

SUBCUTANEOUS INJECTION

Adults. *Initial:* 2.25 mcg/kg as a single dose every wk. *Maintenance:* Dosage individualized to maintain a target hemoglobin level.

DOSAGE ADJUSTMENT Dosage increased to 4.5 mcg/kg if hemoglobin level increases less than 1.0 g/dl after 6 wk of therapy. If it increases more than 1.0 g/dl over 2 wk or it exceeds 12 g/dl, dosage reduced by about 25%. If hemoglobin level exceeds 13 g/dl, doses temporarily withheld until it falls to 12 g/dl. Then therapy is restarted at a dose about 25% less than last dose given.

Route	Onset	Peak	Duration
I.V., SubQ	2–6 wk	Unknown	Unknown

Mechanism of Action

Stimulates release of reticulocytes from the bone marrow into the bloodstream, where they develop into mature RBCs.

Incompatibilities

Don't mix darbepoetin alfa with any other drug.

Contraindications

Hypersensitivity to human albumin or products made from mammal cells; uncontrolled hypertension

Adverse Reactions

CNS: Asthenia, dizziness, fatigue, fever, headache, seizures, stroke, transient ischemic attack

CV: Acute MI, angina, arrhythmias, cardiac arrest, chest pain, congestive heart failure, hypertension, hypotension, peripheral edema, vascular access hemorrhage, vascular access thrombosis

GI: Abdominal pain, constipation, diarrhea, nausea, vomiting

MS: Arthralgia, back pain, limb pain, muscle spasm, myalgia

RESP: Bronchitis, cough, dyspnea, pneumonia, pulmonary embolism, upper respiratory tract infection

SKIN: Pruritus, rash, urticaria

Other: Dehydration, fluid overload, infection, flulike symptoms, injection site pain, sepsis

Nursing Considerations

- Before starting darbepoetin alfa therapy, expect to correct folic acid or vitamin B₁₂ deficiencies because these conditions may interfere with drug's effectiveness.
- Darbepoetin alfa shouldn't be given to cancer patients when a cure is anticipated because drug may decrease survival rate and increase tumor progression in patients with certain types of cancers, such as breast, non-small cell lung, head and neck, lymphoid, and cervical cancers.
- To ensure effective drug response, expect to obtain serum ferritin level and transferrin saturation before and during therapy, as ordered. If serum ferritin level is less than 100 mcg/L or serum transferrin saturation is less than 20%, expect to begin supplemental iron therapy.
- Don't shake vial during preparation to avoid denaturing drug and rendering it biologically inactive.
- Discard drug if you see particulate matter or discoloration.
- Don't dilute drug before giving it.

- Needle cover on prefilled syringe contains dry natural rubber and may cause allergic reaction in those with latex sensitivity.
- Discard unused portion of drug because it contains no preservatives.
- Monitor patient closely for hypertension during therapy. Expect to reduce dosage or withhold drug if blood pressure is poorly controlled with antihypertensive and dietary measures.
- Monitor hemoglobin level weekly, as ordered, until hemoglobin stabilizes and maintenance dosage has been achieved. Then monitor hemoglobin level regularly, as ordered. After each dosage adjustment, expect to check hemoglobin level weekly for 4 weeks until it stabilizes in response to dosage change.

WARNING If hemoglobin level increases more than about 1 g/dl during any 2-week period or it exceeds 12 g/dl, the risk of cardiac arrest, seizures, stroke, worsened hypertension, congestive heart failure, vascular thrombosis, vascular ischemia, vascular infarction, acute MI, fluid overload with peripheral edema, tumor progression, and shortened survival increases. Expect to decrease dosage if this occurs.

- Expect to discontinue darbepoetin in cancer patients if hemoglobin level hasn't increased after 8 weeks or if patient continues to need transfusions despite therapy.
- Institute seizure precautions according to facility policy.
- For patients with chronic renal failure who aren't receiving dialysis, expect to give lower doses than those given to patients receiving dialysis. Also, monitor renal function test results and fluid and electrolyte balance in these patients for signs of declining renal function. If patient starts dialysis, monitor hemoglobin and blood pressure closely and expect maintenance dosage to be adjusted, as needed.
- Store drug at 2° to 8° C (36° to 46° F). Don't freeze, and do protect from light.

PATIENT TEACHING

- Advise patient that the risk of seizures is highest during the first 90 days of therapy. Discourage her from engaging in hazardous activities during this time.
- Stress the importance of complying with the dosage regimen and keeping follow-up medical and laboratory appointments.

- Advise patient to follow up with her prescriber for blood pressure monitoring.
- Encourage patient to eat adequate quantities of iron-rich foods.
- If patient will self-administer darbepoetin, teach her and her caregiver the proper administration technique.
- Caution patient and her caregiver not to reuse needles, syringes, or drug product. Thoroughly instruct them in proper needle and syringe disposal using a puncture-resistant container.
- Explain that needle cover on prefilled syringe contains dry natural rubber and may cause allergic reaction in those with latex sensitivity.
- Review possible adverse reactions, and urge patient to notify prescriber if she experiences chest pain, headache, rash, seizures, shortness of breath, or swelling.

darifenacin

Enblex

Class and Category

Chemical class: Muscarinic receptor antagonist

Therapeutic class: Bladder antispasmodic

Pregnancy category: C

Indications and Dosages

➤ *To treat overactive urinary bladder with symptoms of urge incontinence, including urgency and frequency*

E.R. TABLETS

Adults. *Initial:* 7.5 mg daily, increased to 15 mg daily after 2 wk as needed.

DOSE ADJUSTMENT For patients with moderate hepatic impairment and those taking potent CYP3A4 inhibitors (such as clarithromycin, itraconazole, ketoconazole, nefazodone, nelfinavir, and ritonavir) daily dosage should not exceed 7.5 mg.

Route	Onset	Peak	Duration
P.O.	Unknown	7 hr	Unknown

Mechanism of Action

Antagonizes effect of acetylcholine on muscarinic receptors in detrusor muscle, decreasing muscle spasms that cause inappropriate bladder emptying. This action increases bladder capacity and volume,

which relieves sensations of urgency and frequency and enhances bladder control.

Contraindications

Gastric retention, hypersensitivity to darifenacin or its components, uncontrolled narrow-angle glaucoma, urine retention, and patients at risk for these conditions

Interactions

DRUGS

anticholinergics: Increased frequency and severity of anticholinergic adverse reactions
flecainide, thioridazine, tricyclic antidepressants: Risk of toxicity with these drugs
potent CYP3A4 inhibitors (such as clarithromycin, itraconazole, ketoconazole, nefazodone, nelfinavir, and ritonavir): Decreased metabolism and increased effects of darifenacin, possibly increasing the risk of adverse reactions

Adverse Reactions

CNS: Asthenia, confusion, dizziness, hallucinations

CV: Hypertension, palpitations, peripheral edema

EENT: Abnormal vision, dry eyes or mouth, pharyngitis, rhinitis, sinusitis

GI: Abdominal pain, constipation, diarrhea, indigestion, nausea, vomiting

GU: Urine retention, UTI, vaginitis

MS: Arthralgia, back pain

RESP: Bronchitis

SKIN: Dry skin, pruritus, rash

Other: Angioedema, flulike symptoms, hypersensitivity reactions, weight gain

Nursing Considerations

- Use darifenacin cautiously in patients with significant bladder outflow obstruction; they have increased risk of urine retention.
- Use darifenacin cautiously in patients with severe constipation, ulcerative colitis, or myasthenia gravis because it may decrease GI motility. Also use drug cautiously in obstructive GI disorders because it increases the risk of gastric retention.

PATIENT TEACHING

- Tell patient to swallow tablets with liquid and not to crush, split, or break them.
- Advise patient to avoid exercising in hot weather because darifenacin decreases sweating, increasing the risk of heatstroke.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.

decitabine

Dacogen

Class and Category

Chemical class: Analogue of natural nucleoside 2'-deoxycytidine
Therapeutic class: Antineoplastic
Pregnancy category: D

Indications and Dosages

↗ **To treat myelodysplastic syndromes (MDS) including secondary MDS of all French-American-British subtypes and intermediate 1 and 2 and high-risk International Prognostic Scoring System groups**

I.V. INFUSION

Adults. 15 mg/m² over 3 hr, repeated every 8 hr for 3 days with cycle repeated every 6 wk for at least four cycles.

DOSAGE ADJUSTMENT For hematologic recovery that requires more than 6 wk but less than 8 wk, doses delayed for up to 2 wk and temporarily reduced to 11 mg/m² every 8 hr. For recovery that requires more than 8 wk but less than 10 wk, doses delayed up to 2 more wk and reduced to 11 mg/m² every 8 hr, maintained or increased in subsequent cycles as clinically indicated.

Mechanism of Action

Inhibits DNA methyltransferase after phosphorylation and direct incorporation into DNA, resulting in hypomethylation of the DNA and cellular differentiation. In neoplastic cells, hypomethylation may restore normal function to genes essential for controlling cellular differentiation and proliferation. In rapidly dividing cells, decitabine also may cause cell death by forming covalent adducts between DNA methyltransferase and decitabine-saturated DNA.

Contraindications

Hypersensitivity to decitabine or its components

Adverse Reactions

CNS: Anxiety, confusion, dizziness, fatigue, fever, headache, hypoesthesia, insomnia, lethargy, malaise, rigors

CV: Chest discomfort or pain, hypotension, peripheral edema

EENT: Bleeding gums, blurred vision, lip or

tongue ulceration, oral mucous petechiae, oral candidiasis, pharyngitis, postnasal drip, sinusitis, stomatitis

ENDO: Hyperglycemia

GI: Abdominal distention, abdominal pain, anorexia, ascities, constipation, decreased appetite, diarrhea, dysphagia, dyspepsia, gastroesophageal reflux disease, hyperbilirubinemia, nausea, vomiting

GU: Dysuria, urinary frequency, UTI

HEME: Anemia, leukopenia, neutropenia, thrombocytopenia, thrombocythemia

MS: Arthralgia, back or limb pain, myalgia

RESP: Decreased breath sounds, cough, crackles, hypoxia, pneumonia, pulmonary edema

SKIN: Alopecia, cellulites, ecchymosis, erythema, hematoma, pallor, petechiae, pruritus, rash, urticaria

Other: Bacteremia; candidal infection; dehydration; facial edema; hyperkalemia; hypoalbuminemia; hypokalemia; hypomagnesemia; hyponatremia; injection site swelling, pain, and redness; lymphadenopathy

Nursing Considerations

- Use cautiously in patients with liver or renal impairment.
- Follow facility protocols for preparing and handling antineoplastic drugs and for disposing of used equipment.
- Reconstitute with 10 ml sterile water using aseptic technique; each milliliter contains about 5 mg of decitabine. Immediately after reconstitution, further dilute with normal saline solution, dextrose 5%, or lactated Ringer's solution to a final concentration of 0.1 to 1 mg/ml. Use within 15 minutes. If delay is expected, reconstitute drug using cold dilution solution and store in refrigerator for up to 7 hours.
- Monitor CBC—including hematocrit, platelet count, and WBC with differential—as well as electrolyte, liver enzyme, and serum creatinine levels before and intermittently during decitabine therapy, as ordered.
- If patient develops leukopenia, look for evidence of infection, such as fever. Expect to obtain appropriate specimens for culture and sensitivity testing.

WARNING Monitor patient closely for non-hematologic toxicities, such as active or uncontrolled infection, serum creatinine

level greater than 2 mg/dl, or serum glutamic pyruvic transaminase or total bilirubin 2 or more times the upper limit of normal. If present, notify prescriber and expect decitabine therapy to be withheld until resolved.

PATIENT TEACHING

- Advise male patients not to father a child during decitabine therapy and for 2 months after. Also urge female patients to use contraception to avoid pregnancy during therapy and to notify prescriber immediately if pregnancy occurs.
- Urge patient to have needed dental work completed before starting decitabine therapy, if possible, or to defer such work until blood counts return to normal because decitabine can delay healing and cause gingival bleeding. Teach patient proper oral hygiene, and advise him to use a soft-bristled toothbrush.
- If patient develops bone marrow depression, instruct him to avoid people with infections and to report fever, cough, or lower back or side pain; they may indicate infection.
- Stress the need to avoid accidental cuts from sharp objects, such as razor blades or fingernail clippers, because excessive bleeding or infection may occur.
- Advise patient with stomatitis to eat bland, soft foods served cold or at room temperature to decrease irritation.
- Stress the need to comply with the dosage regimen and to keep follow-up medical and laboratory appointments.

deferasirox

Exjade

Class and Category

Chemical class: Benzoic acid

Therapeutic class: Iron chelator

Pregnancy category: B

Indications and Dosages

➤ To treat chronic iron overload caused by blood transfusions

TABLETS

Adults and children age 2 and over. *Initial:* 20 mg/kg/day, increased by 5 to 10 mg/kg every 3 to 6 mo. *Maximum:* 30 mg/kg/day.

Mechanism of Action

Binds iron with high affinity and removes it in feces. Deferasirox is a tridentate ligan.

Route	Onset	Peak	Duration
P.O.	Unknown	1.5–4 hr	Unknown

Contraindications

Hypersensitivity to deferasirox or its components, hearing impairment

Interactions

DRUGS

aluminum-containing antacids, phenobarbital, phenytoin, rifampicin, ritonavir: Possibly decreased effectiveness of deferasirox

anticoagulants, corticosteroids, NSAIDs, oral bisphosphonates: Increased risk of GI ulceration or hemorrhage

cyclosporine, hormonal contraceptives, midazolam, simvastatin: Possibly decreased effectiveness of these drugs

iron chelators: Possibly combined effect

paclitaxel, repaglinide: Increased plasma levels and effects of these drugs

FOODS

food: Increased bioavailability of deferasirox

Adverse Reactions

CNS: Dizziness, fatigue, fever, headache, hyperactivity, insomnia

EENT: Acute tonsillitis, cataracts, decreased hearing, ear infection, elevated intraocular pressure, high-frequency hearing loss, lens opacities, nasopharyngitis, pharyngolaryngeal pain, pharyngitis, retinal disturbances, rhinitis

GI: Abdominal pain, diarrhea, elevated liver enzymes, gallstones, hepatic failure, hepatitis, nausea, pancreatitis, upper GI ulceration and hemorrhage, vomiting

GU: Acute renal failure, glycosuria, increased creatinine, proteinuria, renal tubulopathy

HEME: Agranulocytosis, neutropenia, thrombocytopenia

MS: Arthralgia, back pain

RESP: Bronchitis, cough, respiratory tract infection

SKIN: Leukocytoclastic vasculitis, purpura, rash, urticaria

Other: Anaphylaxis, angioedema, drug fever, influenza

Nursing Considerations

- Because deferasirox can cause renal failure,

obtain baseline assessment of patient's renal function by collecting blood samples to measure serum creatinine level twice before starting deferasirox. When therapy starts, monitor serum creatinine level, as ordered, especially in elderly patients, patients taking other drugs that depress renal function, and patients with increased risk of complications, pre-existing renal conditions, or comorbid conditions. For patients at increased risk for renal failure, expect to monitor serum creatinine level weekly for first month of therapy and monthly thereafter. Report increased serum creatinine level, and expect deferasirox dosage to be decreased.

- Because deferasirox may cause hepatic abnormalities and failure, obtain baseline assessment of hepatic function before therapy starts by collecting blood samples to measure liver enzymes and bilirubin level. When therapy starts, monitor these levels every 2 weeks for first month and then monthly thereafter. Notify prescriber about elevations, and expect to decrease dose for severe or persistent elevations.
- Obtain auditory and ophthalmic testing (including slit lamp examination and dilated funduscopy) before deferasirox therapy begins and yearly thereafter, as ordered, because drug infrequently causes auditory or visual disturbances.
- Monitor patient's blood counts regularly, as ordered, because deferasirox can cause cytopenias. If cytopenia occurs, expect drug to be discontinued until blood counts return to normal.
- Especially in the first month of therapy, assess patient closely for hypersensitivity reactions, such as anaphylaxis or angioedema. Notify prescriber immediately if present, and expect drug to be discontinued. Provide care, as needed.
- Inspect patient's skin regularly for rash. If it occurs and becomes severe, drug may be withheld temporarily.
- Watch for evidence of GI ulceration and hemorrhage, especially if patient takes drugs that increase the risk of ulceration and bleeding, such as NSAIDs, corticosteroids, oral bisphosphonates, or anticoagulants. Notify prescriber of suspected GI ulceration or hemorrhage, and prepare patient for further evaluation and treat-

ment, as prescribed.

PATIENT TEACHING

- Instruct patient to take deferasirox 30 minutes before eating. Tell her to completely disperse the tablet in water, orange juice, or apple juice; drink the suspension immediately; and then add liquid to any remaining residue and drink again.
- Tell patient to avoid taking aluminum-based antacids at the same time as deferasirox and to seek prescriber advice before taking other drugs, including OTC preparations such as NSAIDs, because of potential interactions.
- Advise her to report any hearing or visual disturbances.
- If patient has diarrhea or vomiting, tell her to notify prescriber and to stay hydrated.
- Caution her to avoid hazardous activities, such as driving, if she becomes dizzy.

demeclocycline hydrochloride

Declomycin

Class and Category

Chemical class: Tetracycline derivative

Therapeutic class: Antibiotic

Pregnancy category: D

Indications and Dosages

➤ *To treat Rocky Mountain spotted fever, typhus infections, Q fever, and rickettsialpox and tick fevers caused by Rickettsiae; psittacosis (ornithosis), lymphogranuloma venereum, granuloma inguinale, and Mycoplasma pneumoniae or Borrelia recurrentis infections; infections caused by gram-negative organisms, such as Bacteroides species, Bartonella bacilliformis, Brucella species, Campylobacter fetus, Francisella tularensis, Haemophilus ducreyi, Vibrio cholerae, and Yersinia pestis; infections caused by susceptible strains of Acinetobacter calcoaceticus, Enterobacter aerogenes, Escherichia coli, Haemophilus influenzae (respiratory tract infections), Herellea species, Klebsiella species (respiratory tract infections and UTIs), and Shigella species; infections caused by susceptible*

strains of Staphylococcus aureus (skin and soft-tissue infections) and Streptococcus species; infections caused by Actinomyces species, Bacillus anthracis, Clostridium species, Fusobacterium fusiforme, Listeria monocytogenes, Treponema pallidum, and Treponema pertenuis; and acute intestinal amebiasis

CAPSULES, TABLETS

Adults and adolescents. 150 mg every 6 hr or 300 mg every 12 hr.

Children ages 8 to 12. 6 to 12 mg/kg daily in divided doses every 6 to 12 hr.

➤ *To treat gonorrhoea*

CAPSULES, TABLETS

Adults and adolescents. 600 mg followed by 300 mg every 12 hr for 4 days for total dose of 3,000 mg.

Mechanism of Action

Binds with ribosomal subunits of susceptible bacteria and alters the cytoplasmic membrane, inhibiting bacterial protein synthesis and rendering organism ineffective.

Contraindications

Hypersensitivity to demeclocycline or other tetracyclines

Interactions

DRUGS

antacids, calcium supplements, cholestyramine, choline, colestipol, iron supplements, magnesium-containing laxatives, magnesium salicylate, sodium bicarbonate: Decreased demeclocycline absorption

digoxin: Possibly increased blood digoxin level and risk of digitalis toxicity

methoxyflurane: Increased nephrotoxicity
oral anticoagulants: Increased anticoagulation
oral contraceptives: Decreased contraceptive effectiveness

penicillins: Decreased bactericidal action of penicillins

vitamin A: Possibly benign intracranial hypertension

FOODS

milk, other dairy products: Decreased drug absorption

Adverse Reactions

CNS: Dizziness, headache, light-headedness, vertigo

EENT: Tinnitus, vision changes

GI: Abdominal cramps, diarrhea, nausea,

pseudomembranous colitis, vomiting
GU: Elevated BUN level, nephrogenic diabetes insipidus

HEME: Eosinophilia, hemolytic anemia, neutropenia, thrombocytopenia

SKIN: Photosensitivity, pruritus, rash, urticaria

Other: Anaphylaxis, angioedema

Nursing Considerations

- Expect to monitor renal and liver function tests during demeclocycline therapy.

WARNING Watch for nephrogenic diabetes insipidus during long-term therapy.

- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold demeclocycline and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

PATIENT TEACHING

- Stress importance of completing therapy as prescribed, even if symptoms improve.
- Advise patient not to take demeclocycline within 3 hours of other drugs or dairy products; its absorption may decrease.
- Instruct patient to avoid taking antacids because of impaired drug absorption.
- Advise patient to avoid direct sunlight, use sunscreen, and wear protective clothing outdoors; among tetracyclines, demeclocycline causes the most photosensitivity.
- Urge patient to immediately report edema, rash, or other hypersensitivity reactions.
- Urge patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.
- Tell patient to avoid hazardous activities if light-headed, dizzy, or vertigo occurs.
- Instruct woman of childbearing age to notify prescriber if she may be pregnant; drug may need to be discontinued.

desipramine hydrochloride

Norpramin, Pertofrane (CAN)

Class and Category

Chemical class: Dibenzazepine derivative

Therapeutic class: Antidepressant

Pregnancy category: C

Indications and Dosages

↗ **To treat depression**

TABLETS

Adults. *Initial:* 100 to 200 mg daily as single dose or divided doses. Increased gradually to 300 mg daily, if needed. *Maximum:* 300 mg daily.

Adolescents. *Initial:* 25 to 50 mg daily in divided doses. Increased gradually, if needed. *Maximum:* 100 mg daily.

Children ages 6 to 12. *Initial:* 10 to 30 mg daily, or 1 to 5 mg/kg, in divided doses.

DOSAGE ADJUSTMENT For elderly patients, initial dosage decreased to 25 to 50 mg daily in divided doses; increased gradually, if needed,, to maximum of 150 mg daily.

Route	Onset	Peak	Duration
P.O.	2–3 wk	Unknown	Unknown

Mechanism of Action

Blocks serotonin and norepinephrine reuptake by adrenergic nerves, which normally release these neurotransmitters from their storage sites when activated by a nerve impulse. By blocking reuptake, this tricyclic antidepressant increases serotonin and norepinephrine levels at nerve synapses, which may elevate mood and reduce depression.

Contraindications

Acute recovery phase of MI; hypersensitivity to desipramine, other tricyclic antidepressants, or their components; MAO inhibitor therapy within 14 days

Interactions

DRUGS

activated charcoal: Prevention of desipramine absorption, reduced effects

barbiturates: Decreased blood desipramine level, increased CNS depression

bupropion, haloperidol, H₂-receptor antagonists, valproic acid: Increased blood level and adverse effects of desipramine

carbamazepine: Increased blood carbamazepine level, decreased blood desipramine level

cimetidine: Increased blood desipramine level and anticholinergic effects (dry mouth, urine retention, blurred vision)

clonidine: Increased risk of hypertensive crisis

dicumarol: Increased anticoagulant effect

grepafloxacin, quinolones, sparfloxacin:

Increased risk of arrhythmias, including

torsades de pointes

guanethidine: Antagonized antihypertensive effect of guanethidine

levodopa: Delayed levodopa absorption, increased risk of hypotension

MAO inhibitors: Increased risk of life-threatening adverse effects, such as hyperpyretic or hypertensive crisis and severe seizures

phenothiazines: Increased desipramine level, risk of inhibited phenothiazine metabolism and neuroleptic malignant syndrome

quinidine: Increased blood quinidine level

rifamycins: Decreased desipramine effects

selective serotonin reuptake inhibitors:

Increased desipramine effects

sympathomimetics: Possibly arrhythmias, possibly increased or decreased vasopressor effects of sympathomimetics

ACTIVITIES

alcohol use: Possibly increased CNS or respiratory depression, hypotension, alcohol effects

Adverse Reactions

CNS: Agitation, akathisia, anxiety, ataxia, confusion, delusions, disorientation, dizziness, drowsiness, extrapyramidal reactions, fatigue, headache, hypomania, insomnia, lack of coordination, nervousness, nightmares, paresthesia, peripheral neuropathy, psychosis exacerbation, restlessness, seizures, sleep disturbance, stroke, suicidal ideation (children and teens), tremor, weakness

CV: Arrhythmias, including heart block; hypertension; hypotension; palpitations

EENT: Black tongue, blurred vision, dry mouth, mydriasis, stomatitis, taste perversion, tinnitus

ENDO: Breast enlargement and galactorrhea (women), gynecomastia (men), hyperglycemia, hypoglycemia, syndrome of inappropriate ADH secretion

GI: Abdominal cramps, anorexia, constipation, diarrhea, elevated liver function test results, elevated pancreatic enzyme levels, epigastric distress, hepatitis, ileus, increased appetite, nausea, vomiting

GU: Acute renal failure, impotence, libido changes, nocturia, painful ejaculation, testicular swelling, urinary frequency and hesitancy, urine retention

HEME: Agranulocytosis, eosinophilia, thrombocytopenia

SKIN: Acne, alopecia, dermatitis, diaphoresis, dry skin, flushing, petechiae, photosensitivity, pruritus, purpura, rash, urticaria

Other: Angioedema, drug fever, weight gain

Nursing Considerations

- Use desipramine with extreme caution in patients with cardiovascular disease, glaucoma, seizure disorder, thyroid disease, or urine retention or with a family history of sudden death, cardiac arrhythmias, or conduction disturbances.

WARNING Desipramine increases risk of suicidal ideation in children and teens; monitor them closely for evidence.

WARNING Expect drug to produce sedation and possibly to lower seizure threshold. Take safety and seizure precautions.

Seizures may precede arrhythmias and death in some patients. Alert prescriber immediately if seizure activity occurs.

- Monitor blood glucose level often.

- Be prepared to obtain blood sample for leukocyte and differential counts if patient develops fever during therapy.

- Expect to discontinue drug as soon as possible before elective surgery because of its possible adverse cardiovascular effects.

PATIENT TEACHING

WARNING Urge parents to watch child or teen closely and to report abnormal thinking or behavior, aggression, or hostility.

- Urge patient to use sunscreen outdoors and to avoid sunlamps and tanning beds.

- Instruct patient to notify prescriber immediately about a fast and pounding heartbeat, fainting, severe agitation or restlessness, and strange behavior or thoughts.

- Caution patient not to stop drug abruptly; doing so may cause dizziness, headache, hyperthermia, irritability, malaise, nausea, sleep disturbances, and vomiting.

- Advise against drinking alcohol because of increased risk of adverse CNS reactions.

- Advise patient to avoid hazardous activities until drug's CNS effects are known.

- Urge diabetic patient to monitor blood glucose level often.

desmopressin acetate

DDAVP Injection, DDAVP Nasal Spray, DDAVP Rhinal Tube, DDAVP Rhinyle

Nasal Solution (CAN), DDAVP Tablets, Octostim (CAN), Stimate, Stimate Nasal Spray

Class and Category

Chemical class: Synthetic ADH analogue
Therapeutic class: Antidiuretic, antihemorrhagic
Pregnancy category: B

Indications and Dosages

↗ *To manage primary nocturnal enuresis*

TABLETS

Adults and children age 6 and over. *Initial:* 0.2 mg at bedtime, increased as needed. *Maximum:* 0.6 mg daily.

↗ *To control symptoms of central diabetes insipidus*

TABLETS

Adults and children age 6 and over. *Initial:* 0.05 mg b.i.d., increased as needed. *Usual:* 0.1 to 0.8 mg in divided doses b.i.d. or t.i.d. *Maximum:* 1.2 mg daily.

I.V. INFUSION, I.M. OR SUBCUTANEOUS INJECTION

Adults. 2 to 4 mcg daily in divided doses b.i.d. Dosage adjusted as needed.

NASAL SOLUTION

Adults and adolescents. 0.1 to 0.4 ml daily (10 to 40 mcg daily) as a single dose or in divided doses b.i.d. or t.i.d. Dosage adjusted as needed. If daily dose is divided, each dose adjusted separately.

Children ages 3 months to 12 years.

0.25 mcg/kg daily as a single dose or in divided doses b.i.d. Dosage adjusted as needed. If daily dose is divided, each dose adjusted separately.

↗ *To prevent or manage bleeding episodes in hemophilia A or mild to moderate type I von Willebrand's disease*

I.V. INFUSION

Adults and children weighing more than 10 kg (22 lb). 0.3 mcg/kg diluted in 50 ml of normal saline solution and infused over 15 to 30 min. If used preoperatively, given 30 min before procedure.

Children weighing 10 kg or less. 0.3 mcg/kg diluted in 10 ml normal saline solution and infused over 15 to 30 min. If used preoperatively, given 30 min before procedure.

NASAL SOLUTION (STIMATE NASAL SPRAY)

Adults and children weighing more than 50 kg (110 lb). 150 mcg in each nostril.

If used preoperatively, given 2 hr before procedure.

Adults and children weighing 50 kg or less. 150 mcg in one nostril. If used preoperatively, given 2 hr before procedure.

Route	Onset	Peak	Duration
P.O.	1 hr*	4–7 hr*	8–12 hr*
I.V.	15–30 min†	30–60 min†	3 hr‡
Nasal	In 1 hr*	1–5 hr*	8–20 hr*

Mechanism of Action

Exerts an antidiuretic effect similar to that of vasopressin by increasing cellular permeability of renal collecting ducts and distal tubules, thus enhancing water reabsorption, reducing urine flow, and increasing osmolality. As an antihemorrhagic, drug increases blood level of clotting factor VIII (antihemophilic factor) and activity of von Willebrand factor (factor VII_{VWF}). It also may increase platelet aggregation and adhesion at injury sites by directly affecting blood vessel walls.

Contraindications

Hypersensitivity to desmopressin or its components, moderate to severe renal impairment (creatinine clearance below 50 ml/min/1.73 m²), previous or current hyponatremia

Interactions

DRUGS

carbamazepine, chlorpromazine, lamotrigine, NSAIDs, opioid analgesics, selective serotonin reuptake inhibitors, tricyclic antidepressants:

Possibly increased risk of water intoxication with hyponatremia

demeclocycline, lithium: Possibly decreased antidiuretic effect of desmopressin

imipramine, oxybutinin: Increased risk of hyponatremic seizures

vasopressor drugs: Possibly potentiated vasopressor effect of desmopressin

Adverse Reactions

CNS: Asthenia, chills, dizziness, headache, stroke

CV: Hypertension (with high doses), MI,

* For antidiuretic effect.

† For antihemorrhagic effect.

‡ For von Willebrand disease; 4 to 20 hr for mild hemophilia A.

thrombosis, transient hypotension

EENT: Conjunctivitis, epistaxis, lacrimation, nasal congestion (nasal form), ocular edema, pharyngitis, rhinitis

GI: Nausea

GU: Vulvar pain (parenteral form)

SKIN: Flushing

Other: Anaphylaxis, hyponatremia, injection site pain and redness; water intoxication

Nursing Considerations

- Use desmopressin cautiously in patients with conditions associated with fluid and electrolyte imbalance, such as cystic fibrosis, heart failure, and renal disorders; these patients are prone to hyponatremia.
- Also use cautiously in patients with habitual or psychogenic polydipsia; they may be more likely to drink excessive water, raising the risk of hyponatremia.
- Nasal cavity scarring, edema, and other abnormalities may cause erratic absorption and require a different administration route.
- Check blood pressure often during therapy.

WARNING Monitor patient closely for evidence of hyponatremia, such as headache, nausea, vomiting, restlessness, fatigue, lethargy, depressed reflexes, and changes in mental status. If left undetected, seizures, coma, and respiratory arrest may occur. Monitor patient's serum sodium level, and notify prescriber of abnormalities.

PATIENT TEACHING

- To prevent hyponatremia and water intoxication in a child or an elderly patient, urge family to restrict patient's fluids as prescribed.
- Tell patient to refrigerate nasal solution.
- Teach patient to prime nasal spray pump (only once) and spray dose into one or both nostrils, as prescribed, while inhaling briskly. Instruct her to clean tip of sprayer with hot water and dry it with clean tissue. Advise her to keep track of doses given and to discard bottle after 50 doses.
- Instruct patient who uses Stimate Nasal Spray to prime pump before first use by pressing down four times. Advise her to discard pump after 25 or 50 doses, depending on bottle, because delivery of an accurate dose can't be assured.
- For nasal tube, teach patient to draw prescribed amount of solution into calibrated plastic tube, insert one end of tube into a

nostril and the other end into her mouth, and gently blow into tube to deposit solution deep into nasal cavity. Caution her not to let drug drain into her mouth.

- Teach patient or caregiver how to administer subcutaneous injection, if appropriate.
- Urge patient to report adverse reactions.

dexamethasone

Decadron, Decadron Elixir, Deronil (CAN), Dexamethasone Intensol, Dexasone (CAN), Dexone, Hexadrol, Oradexon (CAN)

dexamethasone acetate

Cortastat LA, Dalalone D.P., Dalalone L.A., Decadron-LA, Decaject L.A., Dexacen LA-8, Dexacorten-LA, Dexasone L.A., Dexone LA, Solurex LA

dexamethasone sodium phosphate

Cortastat, Dalalone, Decadrol, Decadron Respihaler, Decaject, Dexacen-4, Dexacorten, Dexacort Turbinaire, Dexasone, Dexone, Hexadrol Phosphate, Primethasone, Solurex

Class and Category

Chemical class: Synthetic adrenocortical steroid

Therapeutic class: Anti-inflammatory, diagnostic aid, immunosuppressant

Pregnancy category: C

Indications and Dosages

➤ To treat endocrine disorders, such as congenital adrenal hyperplasia, hypercalcemia associated with cancer, and nonsuppurative thyroiditis; acute episodes or exacerbations of rheumatic disorders; collagen diseases, such as systemic lupus erythematosus and acute rheumatic carditis; severe dermatologic diseases; severe allergic conditions, such as seasonal or perennial allergic rhinitis, bronchial asthma, serum sickness, and drug hypersensitivity reactions; respiratory diseases, such as symptomatic sar-

coidosis, Löffler's syndrome, berylliosis, fulminating or disseminated pulmonary tuberculosis, and aspiration pneumonitis; hematologic disorders, such as idiopathic thrombocytopenic purpura and secondary thrombocytopenia in adults, autoimmune hemolytic anemia, aplastic crisis, and congenital hypoplastic anemia; tuberculous meningitis and trichinosis with neurologic or myocardial involvement

- ↗ *To manage leukemias and lymphomas in adults and acute leukemia in children; to induce diuresis or remission of proteinuria in idiopathic nephrotic syndrome without uremia or nephrotic syndrome caused by systemic lupus erythematosus*
- ↗ *To provide palliative therapy during acute exacerbations of GI diseases, such as ulcerative colitis and regional enteritis*

ELIXIR, ORAL SOLUTION, TABLETS, I.V. OR I.M. INJECTION

Adults. Highly individualized dosage based on severity of disorder. *Usual:* 0.75 to 9 mg/day as a single dose or in divided doses.

ELIXIR, ORAL SOLUTION, TABLETS

Children. Highly individualized based on severity of disorder. *Usual:* 83.3 to 333.3 mcg/kg daily in divided doses t.i.d. or q.i.d.

I.M. INJECTION

Children. Highly individualized based on severity of disorder. *Usual:* 27.76 to 166.65 mcg/kg every 12 to 24 hr.

- ↗ *To manage adrenocortical insufficiency*

ELIXIR, ORAL SOLUTION, TABLETS, I.V. OR I.M. INJECTION

Adults. 0.5 to 9 mg daily as a single dose or in divided doses.

ELIXIR, ORAL SOLUTION, TABLETS

Children. 23.3 mcg/kg daily in divided doses t.i.d.

I.M. INJECTION

Children. 23.3 mcg/kg daily in divided doses t.i.d. given every third day; alternatively, 7.76 to 11.65 mcg/kg daily.

- ↗ *To test for Cushing's syndrome*

ELIXIR, ORAL SOLUTION, TABLETS

Adults. 0.5 mg every 6 hr for 48 hr followed by collection of 24-hr urine specimen to determine 17-hydroxycorticosteroid level. Or, 1 mg at 11 p.m. followed by plasma cortisol test performed at 8 a.m. the next day.

- ↗ *To distinguish Cushing's syndrome relat-*

ed to pituitary corticotropin excess from Cushing's syndrome from other causes

ELIXIR, ORAL SOLUTION, TABLETS

Adults. 2 mg every 6 hr for 48 hr followed by collection of 24-hr urine specimen to determine 17-hydroxycorticosteroid level.

- ↗ *To decrease cerebral edema*

ELIXIR, ORAL SOLUTION, TABLETS

Adults. 2 mg every 8 to 12 hr as maintenance after parenteral form has controlled initial symptoms.

I.V. OR I.M. INJECTION

Adults. 10 mg I.V. followed by 4 mg I.M. every 6 hr. Decreased after 2 to 4 days, if needed, gradually tapering off over 5 to 7 days unless inoperable or recurring brain tumor is present. If such a tumor is present, dosage gradually decreased after 2 to 4 days to maintenance dosage of 2 mg I.M. every 8 to 12 hr and switched to P.O. regimen as soon as possible.

- ↗ *To treat unresponsive shock*

I.V. INFUSION AND INJECTION

Adults. 20 mg as a single dose followed by 3 mg/kg over 24 hr as a continuous infusion; 40 mg as a single dose followed by 40 mg every 2 to 6 hr, as needed; or 1 mg/kg as a single dose. All regimens used no more than 3 days.

- ↗ *To decrease localized inflammation*

INTRA-ARTICULAR INJECTION

Adults. 2 to 4 mg for large joint; 0.8 to 1 mg for small joint; 2 to 3 mg for bursae; 0.4 to 1 mg for tendon sheaths.

SOFT-TISSUE INJECTION

Adults. 2 to 6 mg; 1 to 2 mg for ganglia.

INTRALESIONAL INJECTION

Adults. 0.8 to 1.6 mg/injection site.

- ↗ *To decrease inflammation in allergic conditions or nasal polyps (except in sinuses)*

NASAL AEROSOL

Adults and children age 12 and over.

2 sprays (0.2 mg) in each nostril b.i.d. or t.i.d. *Maximum:* 12 sprays (1.2 mg) daily.

Children ages 6 to 12. 1 or 2 sprays (0.1 to 0.2 mg) in each nostril b.i.d. *Maximum:* 8 sprays (0.8 mg) daily.

Mechanism of Action

Binds to intracellular glucocorticoid receptors and suppresses inflammatory and immune responses by:

- inhibiting neutrophil and monocyte accu-

- modulation at inflammation site and suppressing phagocytic and bactericidal action
- stabilizing lysosomal membranes
- suppressing antigen response of macrophages and helper T cells
- inhibiting synthesis of inflammatory response mediators, such as cytokines, interleukins, and prostaglandins.

Contraindications

Administration of live-virus vaccine to patient or family member, hypersensitivity to dexamethasone or its components (including sulfites), idiopathic thrombocytopenic purpura (I.M. administration), systemic fungal infections

Interactions

DRUGS

aminoglutethimide, antacids, barbiturates, carbamazepine, hydantoins, mitotane, rifampin: Decreased dexamethasone effects
amphotericin B (parenteral), carbonic anhydrase inhibitors: Risk of hypokalemia
anticholinesterases: Decreased anticholinesterase effectiveness in myasthenia gravis
aspirin, NSAIDs: Increased risk of adverse GI effects
cholestyramine: Increased dexamethasone clearance
cyclosporine: Increased activity of both drugs, possibly resulting in seizures
digoxin: Increased risk of digitalis toxicity related to hypokalemia
ephedrine: Decreased half-life and increased clearance of dexamethasone
erythromycin, indinavir: Increased clearance and decreased levels of these drugs
estrogens, ketoconazole, macrolide antibiotics: Decreased dexamethasone clearance
isoniazid: Decreased blood isoniazid level
neuromuscular blockers: Possibly potentiated or counteracted neuromuscular blockade
oral anticoagulants: Altered coagulation times, requiring reduced anticoagulant dosage
oral contraceptives: Increased half-life and concentration of dexamethasone
phenytoin: Increased risk of seizures
potassium-wasting diuretics: Increased potassium loss and risk of hypokalemia
salicylates: Decreased blood level and effectiveness of salicylates
somatrem: Possibly inhibition of somatrem's growth-promoting effect

thalidomide: Increased risk of toxic epidermal necrolysis
theophyllines: Altered effects of either drug
toxoids, vaccines: Decreased antibody response

ACTIVITIES

alcohol use: Increased risk of GI bleeding

Adverse Reactions

CNS: Depression, emotional lability, euphoria, fever, headache, increased ICP with papilledema, insomnia, light-headedness, malaise, neuritis, neuropathy, paresthesia, psychosis, seizures, syncope, tiredness, vertigo, weakness
CV: Arrhythmias, bradycardia, edema, fat embolism, heart failure, hypercholesterolemia, hyperlipidemia, hypertension, myocardial rupture, tachycardia, thromboembolism, thrombophlebitis, vasculitis
EENT: Cataracts, glaucoma, vision changes (all forms); epistaxis, loss of smell and taste, nasal burning and dryness, oral candidiasis, perforated nasal septum, pharyngitis, rebound nasal congestion, rhinorrhea, sneezing (nasal aerosol)
ENDO: Cushingoid symptoms, decreased iodine uptake, growth suppression in children, hyperglycemia, menstrual irregularities, secondary adrenocortical and pituitary unresponsiveness
GI: Abdominal distention, bloody stools, elevated liver function test results, heartburn, hepatomegaly, increased appetite, indigestion, intestinal perforation, melena, nausea, pancreatitis, peptic ulcer with possible perforation, ulcerative esophagitis, vomiting
GU: Glycosuria, increased or decreased number and motility of spermatozoa, perineal irritation, urinary frequency
HEME: Leukocytosis, leukopenia
MS: Aseptic necrosis of femoral and humeral heads; muscle atrophy, spasms, or weakness; myalgia; osteoporosis; pathologic fracture of long bones; tendon rupture (intra-articular injection); vertebral compression fracture
RESP: Bronchospasm
SKIN: Acne, allergic dermatitis, diaphoresis, ecchymosis, erythema, hirsutism, necrotizing vasculitis, petechiae, subcutaneous fat atrophy, striae, thin and fragile skin, urticaria
Other: Aggravated or masked signs of infection, anaphylaxis, angioedema, hypernatremia, hypocalcemia, hypokalemia,

hypokalemic alkalosis, impaired wound healing, metabolic acidosis, sodium and fluid retention, suppressed skin test reaction, weight gain

Nursing Considerations

- Use dexamethasone cautiously in patients with congestive heart failure, hypertension, or renal insufficiency because drug can cause sodium retention, which may lead to edema and hypokalemia.
- Also use cautiously in patients who have had intestinal surgery and in those with peptic ulcer, diverticulitis, or ulcerative colitis because of the risk of perforation.
- Give once-daily dose of dexamethasone in the morning to coincide with the body's natural cortisol secretion.
- Give oral drug with food to decrease GI distress.
- Be aware that dosage forms with a concentration of 24 mg/ml are for I.V. use only.
- Shake I.M. solution before injecting deep into large muscle mass.

WARNING Avoid subcutaneous injection; it may cause atrophy and sterile abscess.

- Inject undiluted I.V. dose directly into I.V. tubing of infusing compatible solution over 30 seconds or less, as prescribed.

WARNING Don't give acetate form by I.V. injection.

- Shake nasal aerosol container well, and hold it upright about 6" (15 cm) from area being treated. Keep spray out of patient's eyes, and advise her not to inhale it.
- Expect to taper drug rather than stopping it abruptly; prolonged use can cause adrenal suppression.
- Monitor fluid intake and output and daily weight, and watch for crackles, dyspnea, peripheral edema, and steady weight gain.
- Evaluate growth if patient is a child.
- Test stool for occult blood.
- Monitor results of hematology studies and blood glucose, serum electrolyte, cholesterol, and lipid levels. Dexamethasone may cause hyperglycemia, hypernatremia, hypocalcemia, hypokalemia, or leukopenia. It also may increase serum cholesterol and lipid levels, and it may decrease iodine uptake by the thyroid.
- Assess patient for evidence of osteoporosis, Cushing's syndrome, and other systemic effects during long-term use.
- Monitor neonate for signs of hypoadrenocorticism if mother received dexamethasone during pregnancy.

Be aware that some preparations contain benzyl alcohol, which may cause a fatal toxic syndrome in neonates and immature infants.

- Watch for hypersensitivity reactions after giving acetate or sodium phosphate form; both may contain bisulfites or parabens, to which some people are allergic.

PATIENT TEACHING

- Instruct patient not to store drug in damp or hot places and to protect liquid form from freezing.
- Instruct patient to take once-daily oral dose in the morning with food to help prevent GI distress.
- Caution against consuming alcohol during dexamethasone therapy because it increases the risk of GI bleeding.
- Advise patient to follow a low-sodium, high-potassium, high-protein diet, if prescribed, to help minimize weight gain, which is common with dexamethasone therapy. Instruct her to inform prescriber if she's on a special diet.
- Instruct patient not to stop drug abruptly.
- Advise patient to notify prescriber if condition recurs or worsens after dosage is reduced or therapy stops.
- Urge patient to have regular eye examinations during long-term use.
- Advise patient on long-term therapy to carry medical identification and to notify all health care providers that she takes dexamethasone.
- Instruct patient (especially a child) to avoid close contact with anyone who has chickenpox or measles and to notify prescriber immediately if exposure occurs.
- Advise patient and family members to avoid live-virus vaccinations during therapy unless prescriber approves.
- Inform diabetic patient that drug may affect her blood glucose level.
- If drug is injected into a joint, instruct patient to avoid putting excessive pressure on it and to notify prescriber if it becomes red or swollen.
- Tell patient to notify prescriber about anorexia, depression, light-headedness, malaise, muscle pain, nausea, vomiting, and early hyperadrenocorticism (abdominal distention, amenorrhea, easy bruising, extreme weakness, facial hair, increased

appetite, moon face, weight gain). Tell patient and family about possible changes in appearance.

- Urge patient to notify prescriber about illness, surgery, or changes in stress level.

dexchlorpheniramine maleate

Dexchlor, Polaramine, Polaramine Repetabs

Class and Category

Chemical class: Propylamine derivative

Therapeutic class: Antihistamine

Pregnancy category: B

Indications and Dosages

↗ *To treat allergic conjunctivitis; transfusion reaction; dermatographism; mild, uncomplicated allergic skin reactions, such as urticaria and angioedema; perennial and seasonal allergic rhinitis; and vasomotor rhinitis and as adjunct to treat anaphylaxis*

E.R. TABLETS

Adults and adolescents. 4 to 6 mg daily at bedtime or every 8 to 10 hr, p.r.n.

SYRUP, TABLETS

Adults and adolescents. 2 mg every 4 to 6 hr, p.r.n.

Children ages 6 to 12. 1 mg every 4 to 6 hr or 150 mcg/kg in divided doses q.i.d., p.r.n.

Children ages 2 to 6. 0.5 mg every 4 to 6 hr, p.r.n.

Route	Onset	Peak	Duration
P.O.	15–60 min*	Unknown*	4–8 hr*

Mechanism of Action

Binds to central and peripheral H₁ receptors, competing with histamine for these sites and preventing histamine from reaching its site of action. By blocking histamine, dexchlorpheniramine:

- inhibits respiratory, vascular, and GI smooth-muscle contraction, which prevents wheezing
- decreases capillary permeability, which

- reduces itching, flares, and wheals
- decreases lacrimal and salivary gland secretions, reducing nasal secretions, itching, sneezing, and watery eyes.

Contraindications

Angle-closure glaucoma; benign prostatic hyperplasia; bladder neck obstruction; hypersensitivity to dexchlorpheniramine or other antihistamines; lower respiratory tract disorders, such as asthma; MAO inhibitor use within 14 days; pyloroduodenal obstruction; stenosing peptic ulcer

Interactions

DRUGS

anticholinergics: Potentiated anticholinergic effects

CNS depressants: Increased CNS depression

MAO inhibitors: Possibly severe hypotension and prolonged and intensified anticholinergic and sedative effects of dexchlorpheniramine

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Ataxia, confusion, dizziness, drowsiness, euphoria, excitement, headache, insomnia, irritability, nervousness, neuritis, nightmares, paresthesia, restlessness, vertigo, weakness

CV: Hypotension, palpitations, tachycardia

EENT: Acute labyrinthitis, blurred vision, dry mouth, tinnitus, vision changes

GI: Anorexia, constipation, diarrhea, indigestion, nausea, vomiting

GU: Urinary hesitancy, urine retention

RESP: Tenacious bronchial secretions

SKIN: Diaphoresis, photosensitivity, rash

Nursing Considerations

- Use dexchlorpheniramine cautiously in elderly patients and those with CV disease, hyperthyroidism, increased intraocular pressure, prostatic hypertrophy, or renal disease.
- Monitor patient for adverse reactions, especially in elderly patients and children.
- Watch for evidence of overdose, including clumsiness; drowsiness; dry mouth, nose, or throat; dyspnea; flushed or red face; hallucinations; insomnia; light-headedness; seizures; and unsteadiness.

PATIENT TEACHING

- Inform patient that drug provides tempo-

* For syrup and tablets; unknown for E.R. tablets.

rary relief of symptoms.

- Advise patient to take drug with food, water, or milk to reduce GI irritation. Inform her that she can crush regular (not E.R.) tablets and mix with food or fluid.
- For E.R. tablets, tell patient not to break, crush, or chew them before swallowing.
- Urge patient to take missed dose as soon as possible unless it's almost time for next dose.
- Because drug may cause drowsiness, caution patient to avoid hazardous activities until its CNS effects are known.
- Instruct her to avoid prolonged sun exposure and to use a sunscreen.
- Suggest that patient use sugarless candy or gum, ice chips, or saliva substitute to relieve dry mouth. If dryness lasts longer than 2 weeks, urge her to notify prescriber.
- Caution patient to avoid alcohol and CNS depressants, such as sedatives, sleeping pills, and tranquilizers, during therapy.
- If patient takes high doses of aspirin, urge her to inform prescriber because antihistamines may mask adverse reactions to aspirin overdose, such as tinnitus.
- Inform patient that drug needs to be discontinued 3 to 4 days before skin tests for allergies are performed.

dexamethylphenidate hydrochloride

Focalin, Focalin XR

Class, Category, and Schedule

Chemical class: *d*-threo-enantiomer of methylphenidate

Therapeutic class: CNS stimulant

Pregnancy category: C

Controlled substance schedule: II

Indications and Dosages

➤ *To treat attention deficit hyperactivity disorder (ADHD)*

TABLETS

Adults and children age 6 and over who are new to methylphenidate. 2.5 mg b.i.d. at least 4 hr apart, increased weekly by 2.5 to 5 mg. *Maximum:* 10 mg b.i.d.

Adults and children age 6 and over who take methylphenidate. Half of racemic methylphenidate dosage. *Maximum:* 10 mg

b.i.d. at least 4 hr apart.

DOSE ADJUSTMENT Drug stopped if no improvement within 1 mo after appropriate dosage adjustments. Dosage decreased or drug stopped for paradoxical aggravation of symptoms or adverse reactions.

E.R. CAPSULES, E.R. TABLETS

Adults who are new to methylphenidate.

10 mg daily, increased after 1 wk as needed to 20 mg daily.

Children age 6 and over who are new to methylphenidate. 5 mg daily, increased weekly as needed by 5-mg increments.

Maximum: 20 mg daily.

Adults and children age 6 and over who take methylphenidate. Half of racemic methylphenidate dosage. *Maximum:* 20 mg daily.

Mechanism of Action

May block reuptake of norepinephrine and dopamine into presynaptic neurons in cerebral cortex, which increases availability of norepinephrine and dopamine in extraneuronal space.

Contraindications

Diagnosis or family history of Tourette's syndrome; glaucoma; hypersensitivity to dexamethylphenidate, methylphenidate, or their components; marked anxiety, tension, and agitation; motor tics; use within 14 days of MAO inhibitor

Interactions

DRUGS

anticoagulants (oral), anticonvulsants, antidepressants (tricyclic and selective serotonin reuptake inhibitors): Possibly decreased metabolism of these drugs

antihypertensives: Decreased therapeutic effect of these drugs

dopamine and other vasopressors: Increased therapeutic effect of these drugs

MAO inhibitors: Increased adverse effects, risk of hypertensive crisis

Adverse Reactions

CNS: Cerebral arteritis or occlusion, dizziness, drowsiness, dyskinesia, fever, headache, insomnia, motor or vocal tics, nervousness, seizures, Tourette's syndrome, toxic psychosis

CV: Angina, arrhythmias, hypertension, hypotension, increased or decreased pulse rate, palpitations, tachycardia

EENT: Accommodation abnormality, blurred vision

GI: Abdominal pain, anorexia, nausea

HEME: Thrombocytopenic purpura

MS: Arthralgia

SKIN: Erythema multiforme, exfoliative dermatitis, necrotizing vasculitis, rash, urticaria

Other: Weight loss (prolonged therapy)

Nursing Considerations

WARNING Be aware that dexmethylphenidate may induce CNS stimulation, mania, and psychosis and may worsen behavior disturbances and thought disorders. Use drug cautiously in children with psychosis or mania. Be aware that withdrawal symptoms may occur with long-term use.

- Also know that dexmethylphenidate should be used cautiously in patients with serious structural cardiac abnormalities, cardiomyopathy, serious heart rhythm abnormalities, or other serious cardiac problems because drug may increase risk of sudden death from these conditions.
- Monitor blood pressure and pulse rate to detect hypertension and excessive stimulation. Notify prescriber if signs appear.
- Dexmethylphenidate shouldn't be used to treat severe depression or to prevent or treat normal fatigue.

WARNING Monitor patient for signs of physical or psychological dependence. Use drug cautiously in patients with a history of drug abuse, including alcoholism.

- Monitor CBC and differential and platelet counts, as ordered, during prolonged therapy.
- Expect to stop drug if seizures occur. Drug may lower seizure threshold, especially in patients with a history of seizures or EEG abnormalities.
- Monitor children on long-term dexmethylphenidate therapy for signs of growth suppression, which has been noted during long-term use of stimulants.
- Dosages of drugs affected by dexmethylphenidate, such as anticoagulants and antihypertensives, may need adjustment.

PATIENT TEACHING

- Tell patient that extended-release capsules should either be taken whole, without being chewed, crushed, or divided, or capsule contents should be sprinkled on a small amount of applesauce.

- Urge patient to notify prescriber if she has excessive nervousness, fever, insomnia, nausea, palpitations, or rash while taking dexmethylphenidate.
- Caution patient with seizure disorder that drug may cause seizures.
- Advise patient to protect drug from light and moisture.
- Teach patient (or parent) to watch for improvement in signs and symptoms of ADHD, such as decreased impulsiveness and increased attention. Stress the need for continued follow-up care, and suggest participation in an ADHD program.

dexrazoxane

Zincard

Class and Category

Chemical class: Piperazinedione

Therapeutic class: Cardioprotective agent, chelating agent

Pregnancy category: C

Indications and Dosages

↗ *To prevent or reduce severity of cardiomyopathy related to doxorubicin therapy in women with metastatic breast cancer*

I.V. INJECTION

Adults. *Initial:* 500 mg/m² for every 50 mg/m² of doxorubicin every 3 wk.

DOSE ADJUSTMENT In patients with hyperbilirubinemia, dosage proportionately reduced (depending on severity) to maintain a dexrazoxane-to-doxorubicin ratio of 10:1. If creatinine clearance is less than 40 ml/min/1.73 m², dosage decreased 50%.

Mechanism of Action

Rapidly enters cardiac cells and acts as an intracellular heavy metal chelator. In cardiac tissues, anthracyclines, such as doxorubicin, form complexes with iron or copper, damaging cardiac cell membranes and mitochondria. Dexrazoxane combines with intracellular iron and protects against anthracycline-induced free radical damage to the myocardium. It also prevents conversion of ferrous ions back to ferric ions for use by free radicals.

Incompatibilities

Don't mix dexrazoxane in same I.V. line with other drugs.

Contraindications

Hypersensitivity to dexrazoxane or its components; use with chemotherapy regimens that do not contain an anthracycline, such as daunorubicin, doxorubicin, epirubicin, idarubicin, or mitoxantrone

Interactions

bone marrow depressants: Possibly enhanced bone marrow depression

Adverse Reactions

HEME: Myelosuppression (granulocytopenia, leukopenia, thrombocytopenia)

Other: Injection site pain

Nursing Considerations

WARNING Use gloves when preparing reconstituted solution. If dexrazoxane powder or solution contacts your skin or mucosa, immediately and thoroughly wash with soap and water.

- To reconstitute, mix with 25 or 50 ml of 0.167 molar sodium lactate, supplied by manufacturer, to produce 10 mg/ml. Give reconstituted solution by slow I.V. push, or further dilute with normal saline solution or D₅W to 1.3 to 5 mg/ml, as prescribed, for rapid I.V. infusion.
- Dexrazoxane may interfere with tumor response to doxorubicin, especially if given at start of fluorouracil-doxorubicin-cyclophosphamide therapy.
- Monitor patient with immunosuppression or decreased bone marrow reserves from prior chemotherapy or radiation therapy to prevent worsening of her condition. Notify prescriber if condition deteriorates.

PATIENT TEACHING

- Inform patient that dexrazoxane protects the heart from damage by myelosuppression and that she'll be given the drug by a health care professional in the hospital or clinic before receiving chemotherapy.
- Inform patient that dexrazoxane and chemotherapy may make her feel generally unwell, but urge her to continue treatment unless prescriber tells her to stop.
- Instruct patient to report chills, fever, mouth sores, pain at injection site, sore throat, unusual bleeding or bruising, unusual tiredness or weakness, and vomiting. Dosage may need to be changed or therapy stopped.
- Inform patient that drug may worsen symptoms of bone marrow suppression

caused by anthracycline chemotherapy, including increased risk of infection.

- Teach patient importance of avoiding injury and infection during dexrazoxane therapy. For example, advise her to use a soft-bristled toothbrush to prevent damage to teeth and gums; to avoid people with colds, flu, or bronchitis; and to avoid anyone who has recently had oral polio vaccine because of the increased risk of infection from live virus.

dextrose (d-glucose)

B-D Glucose, Glucose, Insta-Glucose, Insulin Reaction

glucose

2.5% Dextrose Injection, 5% Dextrose Injection, 10% Dextrose Injection, 20% Dextrose Injection, 25% Dextrose Injection, 50% Dextrose Injection, 60% Dextrose Injection, 70% Dextrose Injection

Class and Category

Chemical class: Monosaccharide

Therapeutic class: Antidiabetic, nutritional supplement

Pregnancy category: C

Indications and Dosages

↗ *To treat insulin-induced hypoglycemia*

CHEWABLE TABLETS, ORAL GEL

Adults and children. *Initial:* 10 to 20 g. Repeated in 10 to 20 min, if needed, based on serum glucose level.

I.V. INFUSION OR INJECTION

Adults and children. *Initial:* 20 to 50 ml of 50% solution given at 3 ml/min.

Maintenance: 10% to 15% solution by continuous infusion until blood glucose level reaches therapeutic range.

Infants and neonates. 2 ml/kg of 10% to 25% solution until blood glucose level reaches therapeutic range.

↗ *To replace calories*

I.V. INFUSION

Adults and children. Individualized dosage of 2.5%, 5%, or 10% solution, based on need for fluids or calories and given by peripheral I.V. line. Or 10% to 70% solu-

tion given by central vein, if needed, typically with amino acids or other solutions.

Route	Onset	Peak	Duration
P.O.	10–20 min	40 min	Unknown
I.V.	2–3 min	Unknown	Unknown

Mechanism of Action

Prevents protein and nitrogen loss, promotes glycogen deposition, prevents or decreases ketosis, and, in large amounts, acts as an osmotic diuretic. Dextrose is readily metabolized and undergoes oxidation to carbon dioxide and water. The oral form—glucose—is absorbed directly into the bloodstream from the intestines and is distributed, used, or stored in the liver.

Incompatibilities

Don't give dextrose through same infusion set as blood or blood products because pseudoagglutination of RBCs may occur.

Contraindications

For all solutions: Diabetic coma with excessively elevated blood glucose level

For concentrated solutions: Anuria, alcohol withdrawal syndrome in dehydrated patient, glucose-galactose malabsorption syndrome, hepatic coma, hypersensitivity to corn or corn products, intracranial or intraspinal hemorrhage, overhydration

Interactions

DRUGS

corticosteroids, corticotropin: Increased risk of fluid and electrolyte imbalance if dextrose solution contains sodium ions

Adverse Reactions

CNS: Confusion, fever

GU: Glycosuria

Other: Dehydration; hyperosmolar coma; hypervolemia; hypovolemia; injection site extravasation with tissue necrosis, infection, phlebitis, and venous thrombosis

Nursing Considerations

- Use dextrose cautiously in patients with renal impairment because solutions contain aluminum that could be toxic in prolonged parenteral therapy.
- Give highly concentrated dextrose solution by central venous catheter—not by subcutaneous or I.M. route.

WARNING Rapid or excessive delivery of

dextrose solution in a very low–birth-weight infant may increase serum osmolality and cause intracerebral hemorrhage.

- Assess infusion site regularly for signs of infiltration, such as pain or swelling.
- Assess patient for glucosuria by using a urine reagent strip or collecting a urine sample and reviewing urinalysis results.
- When discontinuing a concentrated solution, expect to give a 5% to 10% dextrose infusion to avoid rebound hypoglycemia.
- Monitor patient for signs of hypervolemia, such as jugular vein distention and crackles.

PATIENT TEACHING

- Advise patient to swallow oral dextrose; it isn't absorbed from the buccal cavity.
- Instruct patient to monitor her blood glucose level as directed.
- Stress importance of reporting discomfort, pain, or signs of infection at I.V. site.

dezacine

Dalgan

Class and Category

Chemical class: Aminotetralin, synthetic opioid

Therapeutic class: Analgesic

Pregnancy category: C

Indications and Dosages

↗ *To relieve pain*

I.V. INJECTION

Adult. Initial: 5 mg followed by 2.5 to 10 mg every 2 to 4 hr, p.r.n. **Maximum:** 120 mg daily.

I.M. INJECTION

Adult. Initial: 10 mg followed by 5 to 20 mg every 3 to 6 hr, p.r.n. **Maximum:** 20 mg/dose, 120 mg daily.

Route	Onset	Peak	Duration
I.V.	In 15 min	30 min	2–4 hr
I.M.	In 30 min	1–2 hr	2–4 hr

Mechanism of Action

Binds with opiate receptors at many CNS sites, affecting perception of and emotional response to pain.

Contraindications

Hypersensitivity to dezacine or its components

Interactions**DRUGS**

CNS depressants, general anesthetics, hypnotics, sedatives, tranquilizers: Increased CNS depressant effects

opioids: Possibly decreased therapeutic opioid effects and withdrawal symptoms in patient receiving long-term opioid therapy

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Dizziness, sedation, vertigo

GI: Nausea, vomiting

Other: Injection site redness and swelling

Nursing Considerations

- Use dezocine cautiously and in low doses in elderly patients and those who have common bile duct, hepatic, renal, or respiratory disease.
- Discard solution if it contains precipitate.
- Monitor blood pressure, pulse, and respiratory rate often after giving first dose, especially if given by I.V. route.

WARNING Avoid giving dezocine to opioid-dependent patient. Doing so may precipitate withdrawal symptoms because dezocine can antagonize opioid effects.

- Assess patient for pain relief often, and document findings.

PATIENT TEACHING

- Instruct patient to notify prescriber if pain isn't relieved within 1 hour.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.

diazepam

Apo-Diazepam (CAN), Diastat, Diazepam Intensol, Dizac, Novo-Dipam (CAN), Valium, Vivol (CAN)

Class, Category, and Schedule

Chemical class: Benzodiazepine

Therapeutic class: Anticonvulsant, anxiolytic, sedative-hypnotic, skeletal muscle relaxant

Pregnancy category: D

Controlled substance schedule: IV

Indications and Dosages

↗ *To relieve anxiety*

ORAL SOLUTION, TABLETS

Adults. 2 to 10 mg b.i.d. to q.i.d.

DOSAGE ADJUSTMENT Dosage reduced to

2 to 2.5 mg daily or b.i.d. and increased gradually as needed and tolerated for elderly or debilitated patients.

Children age 6 months and over. Initial: 1 to 2.5 mg t.i.d. or q.i.d. Increased gradually as needed and tolerated.

I.V. OR I.M. INJECTION

Adults. 2 to 5 mg every 3 to 4 hr, p.r.n., for moderate anxiety; 5 to 10 mg every 3 to 4 hr, p.r.n., for severe anxiety.

Children. Individualized dosage. **Maximum:** 0.25 mg/kg given over 3 min, repeated after 15 to 30 min if needed, and after another 15 to 30 min if needed.

↗ *To treat symptoms of acute alcohol withdrawal*

ORAL SOLUTION, TABLETS

Adults. 10 mg t.i.d. or q.i.d. during first 24 hr. Then 5 mg t.i.d. or q.i.d., if needed.

I.V. OR I.M. INJECTION

Adults. 10 mg and then 5 to 10 mg in 3 to 4 hr, if needed.

↗ *To provide muscle relaxation, to provide sedation*

ORAL SOLUTION, TABLETS

Adults. 2 to 10 mg t.i.d. or q.i.d.

DOSAGE ADJUSTMENT Dosage reduced to 2 to 2.5 mg once or twice daily and increased gradually as needed and tolerated for elderly or debilitated patients.

Children age 6 months and over. Initial: 1 to 2.5 mg t.i.d. or q.i.d. Increased gradually as needed and tolerated.

I.V. OR I.M. INJECTION

Adults. 2 to 5 mg every 3 to 4 hr, p.r.n., for moderate anxiety; 5 to 10 mg every 3 to 4 hr, p.r.n., for severe anxiety.

Children. Individualized dosage. **Maximum:** 0.25 mg/kg given over 3 min, repeated after 15 to 30 min if needed, and after another 15 to 30 min if needed.

↗ *To treat seizures*

ORAL SOLUTION, TABLETS

Adults. 2 to 10 mg b.i.d. to q.i.d.

DOSAGE ADJUSTMENT Dosage reduced to 2 to 2.5 mg once or twice daily and increased gradually as needed and tolerated for elderly or debilitated patients.

Children age 6 months and over. Initial: 1 to 2.5 mg t.i.d. or q.i.d. Increased gradually as needed and tolerated.

↗ *To treat status epilepticus and severe recurrent seizures*

I.V. INJECTION

Adults. 5 to 10 mg repeated every 10 to 15 min, as needed, up to a cumulative dose of 30 mg. Regimen repeated, if needed, in 2 to 4 hr. (Use I.M. route if I.V. access is impossible.)

Children age 5 and over. 1 mg repeated every 2 to 5 min, as needed, up to a cumulative dose of 10 mg. Regimen repeated, if needed, in 2 to 4 hr.

Children ages 1 month to 5 years. 0.2 to 0.5 mg repeated every 2 to 5 min, as needed, up to a cumulative dose of 5 mg. Regimen repeated, if needed, in 2 to 4 hr.

RECTAL GEL

Adults and adolescents. 0.2 mg/kg rounded up to next available unit dose (or rounded down for elderly or debilitated patient). Repeated in 4 to 12 hr, if needed.

Children ages 6 to 12. 0.3 mg/kg rounded up to next available unit dose. Repeated in 4 to 12 hr, if needed.

Children ages 2 to 6. 0.5 mg/kg rounded up to next available unit dose. Repeated in 4 to 12 hr, if needed.

↗ *To provide preoperative sedation*

I.V. OR I.M. INJECTION

Adults. 5 to 10 mg 30 min before surgery.

↗ *To reduce anxiety before cardioversion*

I.V. INJECTION

Adults. 5 to 15 mg 5 to 10 min before procedure.

↗ *To reduce anxiety before endoscopic procedures*

I.V. INJECTION

Adults. Up to 20 mg titrated to desired sedation and given immediately before procedure.

I.M. INJECTION

Adults. 5 to 10 mg 30 min before procedure.

↗ *To treat tetanus*

I.V. OR I.M. INJECTION

Adults and children age 5 and over. *Initial:* 5 to 10 mg repeated every 3 to 4 hr, if needed. Sometimes larger doses for adults.

DOSAGE ADJUSTMENT Initial dose reduced to 2 to 5 mg and increased gradually as needed and tolerated for debilitated patients.

Children ages 1 month to 5 years. 1 to 2 mg repeated every 3 to 4 hr, as needed.

Mechanism of Action

May potentiate effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptors in limbic and cor-

tical areas of CNS. GABA inhibits excitatory stimulation, which helps control emotional behavior. Limbic system contains a dense area of benzodiazepine receptors, which may explain drug's antianxiety effects. Diazepam suppresses spread of seizure activity caused by seizure-producing foci in cortex, thalamus, and limbic structures.

Incompatibilities

Don't mix diazepam injection with aqueous solutions. Don't mix diazepam emulsion for I.M. injection with morphine or glycopyrrolate or administer it through an infusion set that contains polyvinyl chloride.

Contraindications

Acute angle-closure glaucoma, hypersensitivity to diazepam or its components, untreated open-angle glaucoma

Interactions

DRUGS

antacids: Altered rate of diazepam absorption

anticonvulsants: Decreased effectiveness of these drugs

cimetidine, disulfiram, fluoxetine, fluvoxamine, isoniazid, itraconazole, ketoconazole, metoprolol, omeprazole, oral contraceptives, propoxyphene, propranolol, valproic acid:

Decreased diazepam metabolism, increased blood level and risk of adverse effects

CNS depressants: Increased CNS depression

digoxin: Increased serum digoxin level and risk of digitalis toxicity

levodopa: Decreased antidyskinetic effect of levodopa

phenytoin: Decreased metabolic elimination of phenytoin, increased risk of adverse reactions

probenecid: Faster onset or more prolonged effects of diazepam

ranitidine: Delayed elimination and increased blood level of diazepam

rifampin: Decreased blood diazepam level

theophyllines: Antagonized sedative effect of diazepam

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Anterograde amnesia, anxiety, ataxia, confusion, depression, dizziness, drowsiness, fatigue, headache, insomnia, lethargy, light-headedness, paradoxical reactions, psychi-

atric effects, sedation, sleepiness, slurred speech, suicidal ideation, tremor, vertigo
CV: Hypotension, palpitations, tachycardia
EENT: Blurred vision, diplopia, dry mouth, increased salivation

GI: Anorexia, constipation, diarrhea, elevated liver enzymes, jaundice, nausea, vomiting
GU: Libido changes, urinary incontinence, urine retention

HEME: Neutropenia

MS: Dysarthria, muscle weakness

RESP: Respiratory depression

SKIN: Dermatitis

Other: Physical and psychological dependence

Nursing Considerations

- Use diazepam with extreme caution in patients with a history of alcohol or drug abuse because it can cause physical and psychological dependence, and in patients with hepatic disorders such as hepatic fibrosis and hepatitis because of potentially significant increase in drug's half-life.
- Use diazepam cautiously in patients with hepatic or renal impairment. Severe hepatic impairment is a contraindication to use.
- Expect to give a lower diazepam dose to patient with chronic respiratory insufficiency because of the risk of respiratory depression.
- Mix concentrated oral solution (Intensol) with liquid or semisolid food. Use supplied calibrated dropper to measure doses.
- Protect diazepam injection from light. Don't use solution that's more than slightly yellow or that contains precipitate.
- Give I.M. injection into deltoid muscle for rapid, complete absorption. Using other sites may cause slow, erratic absorption.
- Before administering emulsion form, ask if patient is allergic to soybeans because this form contains soybean oil.
- For an infant or a child, administer I.V. injection slowly over 3 minutes in a dose not to exceed 0.25 mg/kg.
- Give emulsion form within 6 hours of opening ampule because it contains no preservatives and allows rapid microbial growth. Use polyethylene-lined or glass infusion sets and polyethylene or polypropylene plastic syringes for administration. Don't use a filter with a pore size less than 5 microns because a smaller size may break down the emulsion.

- Don't mix emulsion form with anything other than its emulsion base. Otherwise, it may become unstable and increase the risk of serious adverse reactions.

- Monitor patient for adverse reactions, especially if she has hypoalbuminemia, which increases the risk of sedation.

WARNING Watch for signs of physical and psychological dependence (strong desire or need to continue taking diazepam, need to increase dose to maintain drug effects, and posttherapy withdrawal symptoms, such as abdominal cramps, insomnia, irritability, nervousness, and tremor).

- Monitor patient closely for increase in frequency or severity of grand mal seizures when diazepam is used with standard anticonvulsant therapy. Dosage of other anticonvulsants may need to be increased.
- Avoid abrupt withdrawal of diazepam, as ordered, when used as part of the patient's seizure control regimen because a transient increase in frequency or severity of seizures may occur.
- Monitor severely depressed patient or one with depression-related anxiety for suicidal tendencies, particularly when therapy starts and dosage changes; depression may worsen temporarily during these times.
- Watch for psychiatric and paradoxical reactions to diazepam, especially in children and the elderly. If reactions occur, notify prescriber and expect drug to be discontinued.
- Monitor patient for decreased drug effectiveness, especially with prolonged use.
- Check patient's blood counts and liver function periodically, as ordered, because prolonged diazepam therapy rarely causes neutropenia and jaundice.

PATIENT TEACHING

- Instruct patient not to take more drug, more often, or for a longer time than prescribed. Warn her that physical and psychological dependence can occur, and teach her to recognize the signs.
- Advise patient not to take drug to relieve everyday stress.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to avoid CNS depressants and alcohol during therapy.
- Instruct patient not to stop taking drug abruptly without prescriber's supervision.

If patient has a history of seizures, warn that abrupt withdrawal may trigger them.

- Instruct patient to mix Diazepam Intensol with water, soda, or a similar beverage; applesauce; or pudding just before taking it. Caution her not to save the mixture for later. Tell her to use calibrated dropper that's provided to measure each dose.
- Teach patient how to self-administer a rectal form, if prescribed.
- Instruct female patient of childbearing age to notify prescriber immediately if she is or could be pregnant because diazepam therapy will need to be discontinued.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.

diazoxide

Hyperstat, Proglycem

Class and Category

Chemical class: Benzothiadiazine derivative

Therapeutic class: Antihypertensive, antihypoglycemic

Pregnancy category: C

Indications and Dosages

↗ *To manage hypoglycemia caused by hyperinsulinism*

CAPSULES, ORAL SUSPENSION

Adults and children. *Initial:* 1 mg/kg every 8 hr. *Maintenance:* 3 to 8 mg/kg daily in 2 or 3 equal doses given every 8 or 12 hr.

Maximum: 15 mg/kg daily.

Infants and neonates. *Initial:* 3.3 mg/kg every 8 hr. *Maintenance:* 8 to 15 mg/kg daily in 2 or 3 equal doses given every 8 or 12 hr.

↗ *To treat severe hypertension in hospitalized patients*

I.V. INJECTION

Adults and children. *Initial:* 1 to 3 mg/kg by rapid bolus, repeated every 5 to 15 min until diastolic pressure falls below 100 mm Hg. Repeated in 4 hr and again in 24 hr, if needed, until oral antihypertensive therapy begins. *Maximum:* 150 mg/dose, 1.2 g daily.

Mechanism of Action

Directly affects smooth muscle cells of peripheral arteries and arterioles, causing them to dilate. This action decreases

peripheral resistance, which helps reduce blood pressure. Diazoxide also inhibits insulin release from the pancreas, stimulates catecholamine release, and increases hepatic glucose release.

Route	Onset	Peak	Duration
P.O.	In 1 hr	Unknown	8 hr
I.V.	1 min	2–5 min	2–12 hr

Contraindications

Acute aortic dissection; hypersensitivity to diazoxide, thiazides, other sulfonamide derivatives, or their components; treatment of compensatory hypertension, as occurs with aortic coarctation

Interactions

DRUGS

allopurinol, colchicine, probenecid, sulfipyrazone: Increased serum uric acid level

antihypertensives: Additive hypotensive effects

beta blockers: Increased hypotensive effects of diazoxide

diuretics, especially thiazides: Potentiated hyperglycemic, hyperuricemic, and antihypertensive effects of diazoxide

estrogens, NSAIDs, sympathomimetics:

Antagonized diazoxide hypotensive effects

insulin, oral antidiabetics: Possibly decreased effectiveness of these drugs

oral anticoagulants: Increased anticoagulation

peripheral vasodilators, ritodrine (I.V.):

Additive, possibly severe, hypotensive effects

Adverse Reactions

CNS: Anxiety, apprehension, cerebral ischemia, dizziness, euphoria, headache, insomnia, light-headedness, malaise, somnolence, weakness

CV: Bradycardia, chest pain, hypotension, palpitations, tachycardia, transient hypertension

EENT: Blurred vision, dry mouth, increased salivation, taste perversion, tinnitus, transient hearing loss

ENDO: Transient hyperglycemia

GI: Abdominal pain, anorexia, constipation, diarrhea, ileus, nausea, vomiting

MS: Gout

SKIN: Diaphoresis, flushing, pruritus, rash, sensation of warmth

Other: Extravasation with injection site cellulitis and pain; fluid and sodium retention

Nursing Considerations

- Use diazoxide cautiously in patients with uncompensated heart failure (can cause fluid retention and heart failure) and patients with impaired cardiac or cerebral circulation in whom abrupt blood pressure drop, mild tachycardia, and decreased blood perfusion may be harmful.
- Give I.V. drug undiluted over 10 to 30 seconds. Don't give it I.M. or subcutaneously.
- Keep patient supine during I.V. injection and for 1 hour afterward.
- Monitor blood pressure throughout treatment to check for hypertension. Before monitoring ends, measure patient's standing blood pressure if she's ambulatory.
- Assess I.V. site often for extravasation; drug is alkaline and can irritate tissue.
- Expect to adjust dosage if patient switches from oral suspension to capsules; suspension causes a higher blood diazoxide level.
- If diabetic patient receives I.V. diazoxide to treat hypertension, watch for evidence of hyperglycemia because parenteral form commonly causes transient hyperglycemia.
- Monitor blood glucose level of all patients who receive oral diazoxide to see if drug has raised blood glucose level to normal.

PATIENT TEACHING

- Tell patient who receives I.V. diazoxide that she'll be on bed rest until taking oral drug.
- Advise patient to protect oral suspension from light.
- Tell patient to take oral drug on a regular schedule and not to skip or double doses.
- Urge patient to monitor blood glucose level if she takes oral drug for hypoglycemia.
- Caution patient not to take antidiabetic drugs unless prescribed.
- Advise patient to notify prescriber if she has signs of hyperglycemia, such as increased urinary frequency, increased thirst, and fruity breath.

dichloralphenazone

(all contain 325 mg of acetaminophen, 100 mg of dichloralphenazone, and 65 mg of isometheptene mucate)

Amidrine, I.D.A., Iso-Acetozone, Isocom, Midchlor, Midrin, Migquin, Migragap, Migratine, Migrazone, Migrend, Migrex, Mitride

Class and Category

Chemical class: Sympathomimetic amine

Therapeutic class: Analgesic

Pregnancy category: Not rated

Indications and Dosages

↗ *To relieve tension headache*

CAPSULES

Adults. 1 to 2 caps every 4 hr. *Maximum:* 8 capsules daily.

↗ *To relieve migraine headache*

CAPSULES

Adults. 2 caps followed by 1 cap every hr until relief occurs. *Maximum:* 5 capsules every 12 hr.

Route	Onset	Peak	Duration
P.O.	30–60 min	1–3 hr	3–4 hr

Mechanism of Action

Dichloralphenazone reduces emotional reaction to pain through mild sedative effect. Acetaminophen raises pain threshold by acting on hypothalamus. Isometheptene constricts dilated cranial and cerebral arterioles through sympathomimetic action, reducing stimuli for vascular headaches.

Contraindications

Heart disease, hepatic disease, hypersensitivity to acetaminophen or isometheptene, MAO inhibitor therapy within 14 days, severe renal disease, uncontrolled glaucoma, uncontrolled hypertension

Interactions

DRUGS

CNS depressants: Additive sedative effects
hepatic enzyme inducers, other hepatotoxic drugs: Increased risk of hepatotoxicity
MAO inhibitors: Increased risk of severe hypertension and hyperpyrexia

ACTIVITIES

alcohol use: Additive sedative effects, increased risk of hepatotoxicity

Adverse Reactions

CNS: Dizziness, drowsiness

SKIN: Rash

Nursing Considerations

- Because dichloralphenazone has vasoconstrictive and sympathomimetic actions, assess patients with peripheral vascular disease or recent angina pectoris or MI for signs and symptoms indicating aggrava-

tion or deterioration of these conditions.

- Institute safety precautions to prevent injury from falls.

PATIENT TEACHING

WARNING Caution patient not to take dichloralphenazone within 14 days of an MAO inhibitor; doing so can cause severe hypertension or hyperpyrexia.

- Advise patient to take drug only after a headache or migraine warning sign occurs. Too-frequent use may make drug less effective and may worsen headaches.
- Instruct patient to lie down in a quiet, dark room after taking drug.
- Because of possible dizziness or drowsiness, caution patient to avoid hazardous activities until drug's CNS effects are known.
- Caution patient to avoid alcohol and CNS depressants during therapy because they increase dizziness, drowsiness, and the risk of hepatotoxicity.
- Advise patient to notify prescriber if drug becomes less effective or if headaches occur more often.
- Teach patient how to read drug labels and avoid taking too much acetaminophen, which can cause hepatic or renal damage.
- Explain that decreasing dichloralphenazone dose may prevent dizziness or rash.
- Instruct patient to store drug away from heat, moisture, and direct light.

dichlorphenamide

Daranide

Class and Category

Chemical class: Sulfonamide derivative

Therapeutic class: Antiglaucoma drug

Pregnancy category: C

Indications and Dosages

➤ To manage chronic open-angle glaucoma, secondary glaucoma, and acute angle-closure glaucoma (preoperatively)

TABLETS

Adults. *Initial:* 100 to 200 mg followed by 100 mg every 12 hr. *Maintenance:* 25 to 50 mg once daily to t.i.d.

Mechanism of Action

Inhibits the enzyme carbonic anhydrase, which normally is in renal proximal tubule

cells, choroid plexes of the brain, and ciliary processes of the eyes. In eyes, enzyme inhibition decreases aqueous humor secretion, which reduces intraocular pressure.

Route	Onset	Peak	Duration
P.O.	30–60 min	2–4 hr	6–12 hr

Contraindications

Adrenocortical insufficiency, hepatic insufficiency, hyperchloremic acidosis, hypersensitivity to dichlorphenamide or sulfa drugs, hypokalemia, hyponatremia, renal failure, severe obstructive pulmonary disease

Interactions

DRUGS

diflunisal: Increased adverse effects of dichlorphenamide, significantly decreased intraocular pressure

salicylates: Increased risk of dichlorphenamide toxicity, including CNS depression and metabolic acidosis

Adverse Reactions

CNS: Depression, disorientation, dizziness, drowsiness, lassitude, paresthesia

CV: Arrhythmias

EENT: Metallic taste, pharyngitis

ENDO: Hyperglycemia

GI: Anorexia, diarrhea, hepatic dysfunction, nausea, vomiting

GU: Phosphaturia, renal calculi, renal colic, urinary frequency

HEME: Hemolytic anemia, leukopenia, pancytopenia, thrombocytopenia

SKIN: Photosensitivity

Other: Hyperchloremia, hyperuricemia, weight loss

Nursing Considerations

- Use dichlorphenamide cautiously in patients with emphysema, pulmonary obstruction, or severe respiratory acidosis.
- Monitor serum potassium level often (especially in elderly patients and those taking digoxin) because diuresis may cause hypokalemia.

PATIENT TEACHING

- Instruct patient to take dichlorphenamide with food or full glass of water to decrease GI distress.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.

WARNING Urge patient to immediately

report evidence of blood dyscrasias, such as fever, numbness or tingling, rash, sore throat, and unusual bleeding or bruising.

- Advise patient to avoid prolonged exposure to sunlight, to apply sunscreen, and to wear protective clothing outdoors.
- Instruct patient to take a missed dose as soon as she remembers it, unless it's almost time for the next dose.
- Tell patient to store drug at room temperature and protect from moisture and heat.

diclofenac potassium

Cataflam, Voltaren Rapide (CAN), Zipsor

diclofenac sodium

Apo-Diclo (CAN), Novo-Difenac (CAN), Nu-Diclo (CAN), Voltaren, Voltaren SR (CAN)

Class and Category

Chemical class: Phenylacetic acid derivative

Therapeutic class: Analgesic, anti-inflammatory

Pregnancy category: B

Indications and Dosages

↗ *To relieve pain and inflammation in rheumatoid arthritis*

DELAYED-RELEASE TABLETS, TABLETS

Adults. *Initial:* 150 to 200 mg daily in divided doses t.i.d. or q.i.d. *Maintenance:* 75 to 100 mg/ day, divided, t.i.d.

Maximum: 225 mg daily.

E.R. TABLETS

Adults. *Initial:* 75 or 100 mg daily, morning or evening, or 75 mg b.i.d., morning and evening.

RECTAL SUPPOSITORIES

Adults. 50 or 100 mg as substitute for last P.O. dose of day.

↗ *To relieve pain and inflammation in osteoarthritis*

DELAYED-RELEASE TABLETS, TABLETS

Adults. 100 to 150 mg daily in divided doses b.i.d. or t.i.d. *Maximum:* 150 mg daily.

↗ *To relieve pain in patients with ankylosing spondylitis*

DELAYED-RELEASE TABLETS, TABLETS

Adults. 100 to 125 mg daily in 4 or 5 divided doses.

↗ *To relieve pain and dysmenorrhea*

TABLETS

Adults. 50 mg t.i.d., p.r.n.; if needed, 100 mg for first dose only.

DOSAGE ADJUSTMENT Dosage reduced, if needed, for elderly patients and those with serious renal dysfunction.

↗ *To relieve mild to moderate acute pain*

CAPSULES

Adults. 25 mg four times daily.

Route	Onset	Peak	Duration
P.O.*	30 min	Unknown	8 hr

Mechanism of Action

Blocks the activity of cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate inflammatory response and cause local pain, swelling, and vasodilation. By blocking cyclooxygenase and inhibiting prostaglandins, diclofenac reduces inflammatory symptoms. This mechanism also relieves pain because prostaglandins promote pain transmission from periphery to spinal cord.

Contraindications

Active GI bleeding or ulcers; asthma attacks, rhinitis, or urticaria from aspirin or other NSAIDs; hypersensitivity to diclofenac or NSAIDs; treatment of perioperative pain after coronary artery bypass grafting

Interactions

DRUGS

acetaminophen: Increased risk of adverse renal effects with long-term concurrent use
anticoagulants, thrombolytics: Prolonged PT, increased risk of bleeding

antihypertensives: Decreased antihypertensive effectiveness

aspirin, other NSAIDs, salicylates: Increased GI irritability and bleeding, decreased diclofenac effectiveness

beta blockers: Impaired antihypertensive effect

cefamandole, cefoperazone, cefotetan, plicamycin, valproic acid: Increased risk of hypoprothrombinemia

cimetidine: Altered blood diclofenac level
colchicine, corticotropin (long-term use), glucocorticoids, potassium supplements:

* For tablets; unknown for delayed-release and E.R. tablets.

Increased GI irritability and bleeding
cyclosporine, gold compounds, nephrotoxic drugs: Increased risk of nephrotoxicity
digoxin: Increased blood digoxin level
insulin, oral antidiabetics: Decreased effects of these drugs
lithium: Increased risk of lithium toxicity
loop diuretics: Decreased diuretic effects
methotrexate: Increased risk of methotrexate toxicity
phenytoin: Increased blood phenytoin level
potassium-sparing diuretics: Increased risk of hyperkalemia
probenecid: Increased diclofenac toxicity

FOODS

food: Delayed absorption of delayed-release tablets

ACTIVITIES

alcohol use: Increased risk of GI irritability and bleeding

Adverse Reactions

CNS: Aseptic meningitis, cerebral hemorrhage, dizziness, drowsiness, headache

CV: Bradycardia and other arrhythmias, hypotension, vasculitis

EENT: Glaucoma, hearing loss, tinnitus

ENDO: Hypoglycemia

GI: Abdominal pain, constipation, diarrhea, dysphagia, elevated liver function test results, esophageal ulceration, flatulence, GI bleeding or ulceration, hepatic failure, hepatitis, indigestion, jaundice, nausea, perforation of stomach or intestine

GU: Acute renal failure, interstitial nephritis

HEME: Agranulocytosis, aplastic anemia, eosinophilia, leukocytosis, leukopenia, pancytopenia, porphyria, thrombocytopenia

SKIN: Erythema multiforme, exfoliative dermatitis, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, angioedema, fluid retention, hyperkalemia, hyperuricemia, hyponatremia, lymphadenopathy

Nursing Considerations

- Use diclofenac with extreme caution and for shortest possible time in patients with a history of GI bleeding or ulcer disease because NSAIDs increase risk of GI bleeding and ulceration.
- Don't substitute one form of oral diclofenac for another. Different formulations aren't bioequivalent.
- Be aware that serious GI tract ulceration

and bleeding, as well as perforation of stomach or intestine, can occur without warning or symptoms. Elderly patients are at greater risk. Monitor patient for signs of GI irritation and ulceration, especially if patient has a predisposing condition (such as a history of GI bleeding); takes an oral corticosteroid, anticoagulant, or NSAID (long-term); smokes; is an alcoholic; is over age 60; has poor general health; or tests positive for *Helicobacter pylori*. To minimize risk, give diclofenac with food. If patient develops GI distress, withhold drug and notify prescriber immediately.

- Use diclofenac cautiously in patients with hypertension, and monitor blood pressure closely; drug can cause or worsen hypertension.
- Assess patient for hypotension. If patient takes a potassium-sparing diuretic, check for elevated serum potassium level.

WARNING Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs such as diclofenac increase the risk for such events.

- Report signs of bleeding, such as bleeding gums, bloody or cloudy urine, ecchymoses, melena, and petechiae.
- Monitor BUN and serum creatinine levels in elderly patients, patients taking ACE inhibitors or diuretics, and patients with heart failure or impaired renal or hepatic function. These patients may have an increased risk of renal failure.
- Assess patient's skin routinely for rash or other signs of hypersensitivity reaction; drug may cause serious skin reactions without warning. At first sign of reaction, stop drug and notify prescriber.
- Because severe hepatic reactions may occur during diclofenac therapy, monitor liver function test results and serum uric acid level. Liver enzyme elevations usually occur within 2 months of starting drug and should be reported promptly because dosage may need adjustment. Also monitor patient for evidence of hepatic dysfunction (diarrhea, fatigue, flulike symptoms, jaundice, lethargy, nausea, pruritus, right upper quadrant tenderness).
- Report weight gain of more than 1 kg (2 lb) in 24 hours because it suggests fluid retention.

PATIENT TEACHING

- Advise patient not to chew, crush, or dissolve tablet, but to swallow it whole.
- Instruct patient to take diclofenac with food to minimize GI distress.
- To decrease risk of esophageal ulceration, instruct patient not to lie down for 15 to 30 minutes after taking drug.
- Warn patient to avoid hazardous activities until diclofenac's CNS effects are known.
- Urge patient to notify prescriber about ringing or buzzing in ears, impaired hearing, dizziness, or GI distress or bleeding.
- Advise patient to consult prescriber before taking aspirin or other OTC analgesics or drinking alcohol.
- Explain that diclofenac may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention for signs and symptoms such as chest pain, shortness of breath, weakness, and slurred speech.
- Tell patient that diclofenac also may increase risk of serious adverse GI reactions; stress need to seek immediate medical attention for such evidence as epigastric or abdominal pain, indigestion, black or tarry stools, and vomiting blood or material that looks like coffee grounds.
- Alert patient about possibly serious skin reactions and need to seek immediate medical attention for such as problems as blisters, fever, itching, rash, and other signs of hypersensitivity.
- Urge patient to promptly report adverse effects (nausea, fatigue, lethargy, diarrhea, pruritus, jaundice, right upper quadrant discomfort, flulike symptoms).

dicloxacillin sodium

Dycill, Dynapen, Pathocil

Class and Category

Chemical class: Isoxazolyl penicillin derivative

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

↗ *To treat mild to moderate upper respiratory tract and localized skin and soft-tissue infections caused by penicillinase-producing staphylococci*

CAPSULES, ORAL SOLUTION

Adults and children weighing 40 kg (88 lb) or more. 125 mg every 6 hr.

Children weighing less than 40 kg.

12.5 mg/kg daily divided into four equal doses and given every 6 hr.

↗ *To treat severe infections, such as lower respiratory tract or disseminated infections, caused by penicillinase-producing staphylococci*

CAPSULES, ORAL SOLUTION

Adults and children weighing 40 kg or more. 250 mg every 6 hr, or higher doses, if needed. *Maximum:* 6 g daily.

Children over age 1 month weighing less than 40 kg. 25 mg/kg daily divided into 4 equal doses and given every 6 hr, or higher doses if needed.

Mechanism of Action

Inhibits cell wall synthesis in susceptible bacteria, which assemble rigid, cross-linked cell walls in several steps. Dicloxacillin affects final cross-linking by inactivating penicillin-binding protein (the enzyme needed to link cell wall strands). This action inhibits cell wall synthesis and causes cell lysis and death.

Contraindications

Hypersensitivity to dicloxacillin, other penicillins, beta-lactamase inhibitors (such as piperacillin/tazobactam), cephalosporins, imipenem, or their components

Interactions

DRUGS

hepatotoxic drugs: Increased risk of hepatotoxicity

methotrexate: Decreased methotrexate clearance and increased risk of toxicity

oral contraceptives: Decreased contraceptive action

probenecid: Increased and prolonged blood dicloxacillin level

tetracyclines: Decreased dicloxacillin effectiveness

FOODS

all foods: Possibly delayed absorption

Adverse Reactions

CNS: Dizziness, fatigue, fever, insomnia

EENT: Black "hairy" tongue, dry mouth, glossitis, laryngeal edema, laryngospasm, stomatitis, taste perversion

GI: Abdominal pain, anorexia, diarrhea, flatulence, nausea, pseudomembranous

colitis, transient hepatitis, vomiting

GU: Nephropathy, vaginitis

MS: Prolonged muscle relaxation

SKIN: Dermatitis, erythema multiforme, pruritus, rash, urticaria, vesicular eruptions

Other: Anaphylaxis, serum sicknesslike reaction, superinfection

Nursing Considerations

- Before dicloxacillin therapy begins, expect to obtain body fluid and tissue samples for culture and sensitivity tests, as ordered, and review the results, if possible. Also check for history of sensitivity to cephalosporins, penicillins, and other substances.
- If diarrhea develops, notify prescriber; it could be the development of pseudomembranous colitis.

PATIENT TEACHING

- Instruct patient to take drug 1 hour before or 2 hours after meals.
- Instruct patient to take drug around the clock, not to miss a dose, and to complete the entire prescription unless directed otherwise by prescriber.
- Advise patient to take oral solution with a cold beverage but not acidic juice, such as orange juice. Explain that solution is effective for 7 days at room temperature and for 14 days if refrigerated.
- Caution patient not to open capsules and mix contents with food or liquids because an unpleasant taste and decreased drug absorption will result.
- Instruct parent to shake oral solution thoroughly and measure doses with a calibrated device for accuracy.
- Advise patient to notify prescriber if she experiences adverse GI reactions or signs of hypersensitivity or superinfection.
- If patient takes an oral contraceptive, advise her to use an additional form of contraception during therapy.
- Instruct patient to store drug away from heat, moisture, and direct light and to refrigerate—but not freeze—oral solution.

dicumarol

Class and Category

Chemical class: Coumarin derivative

Therapeutic class: Anticoagulant

Pregnancy category: X

Indications and Dosages

➤ *To prevent and treat pulmonary embolus, thromboembolus, and venous thrombus; to prevent thromboembolism related to atrial fibrillation and mechanical heart valves*

TABLETS

Adults. *Initial:* 200 to 300 mg on the first day. *Maintenance:* 25 to 200 mg daily.

DOSAGE ADJUSTMENT Dosage reduced for elderly patients and those with hepatic or renal impairment.

Route	Onset	Peak	Duration
P.O.	1–5 days	Unknown	5–6 days

Mechanism of Action

Prevents coagulation by interfering with the liver's ability to synthesize vitamin K–dependent clotting factors. This in turn depletes clotting factors II (prothrombin), VII, IX, and X. Normally, clots result from a cascade of proteolytic reactions that involve several clotting factors, including vitamin K–dependent factors. These clotting factors must be converted to an activated form before the clotting cascade can continue. By depleting vitamin K–dependent clotting factors, dicumarol interferes with the clotting cascade and prevents coagulation.

Contraindications

Active bleeding; aneurysm; ascorbic acid deficiency; bacterial endocarditis; blood dyscrasia; continuous tube drainage of small intestine; diverticulitis; eclampsia or preclampsia; emaciation; hemophilia; hemorrhagic tendency; history of bleeding diathesis or warfarin-induced necrosis; leukemia; major regional lumbar block anesthesia; malnutrition; pericardial effusion; pericarditis; polyarthritis; pregnancy; prostatectomy; recent surgery on brain, eye, GI tract, or prostate; recovery from spinal puncture; severe hepatic or renal impairment; stroke; surgery resulting in large, open surfaces; threatened abortion; thrombocytopenic purpura; uncontrolled or malignant hypertension; visceral cancer; vitamin K deficiency

Interactions

DRUGS

acetaminophen, androgens, beta blockers, chlorpropamide, clofibrate, corticosteroids,

cyclophosphamide, dextrothyroxine, disulfiram, erythromycin, fluconazole, gemfibrozil, glucagon, hydantoins, influenza virus vaccine, isoniazid, ketoconazole, miconazole, moricizine, propoxyphene, quinolones, streptokinase, sulfonamides, tamoxifen, thioamines, thyroid drugs, urokinase: Increased effects of dicumarol and risk of bleeding

Adverse Reactions

CNS: Fever, malaise

ENDO: Adrenal hemorrhage

GI: Abdominal cramps and distention, anorexia, diarrhea, flatulence, nausea, vomiting

GU: Menorrhagia, priapism

HEME: Hemorrhage, leukopenia

SKIN: Alopecia, pruritus, rash, urticaria

Other: Allergic reaction, purple toes syndrome

Nursing Considerations

- Use dicumarol cautiously in elderly patients and those with hepatic or renal impairment.
- Monitor results of serial PT and INR tests, and expect to adjust dosage accordingly.
- If patient also receives heparin, expect heparin therapy to continue until INR reaches desired level: 2 to 3 times the control value for pulmonary embolus, thromboembolus, or venous thrombus; or 3 to 4.5 times the control value for thromboembolism related to atrial fibrillation or mechanical valves.
- If PT or INR are prolonged, withhold one dicumarol dose, as prescribed, and, to reverse anticoagulation, give vitamin K. If patient has severe bleeding, expect to give blood to offset vitamin K's delayed onset.
- Assess patient for signs of hemorrhage, such as ecchymosis, epistaxis, gingival bleeding, hematuria, and melena.
- To reduce bleeding, apply pressure to I.M. or venipuncture sites for up to 5 minutes.

PATIENT TEACHING

- Instruct patient to take dicumarol at the same time every day.
- Inform patient that drug's full effects may not occur for 2 to 7 days.
- Instruct patient to have frequent coagulation tests, as prescribed.
- Advise patient to stabilize her intake of foods high in vitamin K. Urge her to consult prescriber before starting a weight-loss diet, altering eating habits, or taking

new vitamins or other nutritional supplements; these activities may alter her vitamin K intake.

- Caution patient to avoid activities that may cause bleeding. Advise the use of a soft toothbrush and an electric razor.
- Urge patient to consult prescriber before taking OTC drugs, including herbs; they may affect anticoagulant effect.
- Instruct patient to take a missed dose as soon as she remembers unless it's nearly time for the next dose. Urge her to report missed doses to prescriber.
- Caution patient to immediately notify prescriber if signs of bleeding occur, such as abdominal pain or swelling; back pain; bloody or black stools; bloody urine; coughing up blood; joint pain, swelling, or stiffness; severe or continuing headache; and vomiting blood or material that looks like coffee grounds.
- Urge patient to carry medical identification and tell all health care providers that she takes dicumarol.
- Explain that coagulation will gradually return to normal after therapy stops. Remind patient to keep watching for bleeding.

dicyclomine hydrochloride

Bentyl, Bentlyl (CAN), Formulex (CAN), Spasmoban (CAN)

Class and Category

Chemical class: Tertiary amine

Therapeutic class: Anticholinergic, antispasmodic

Pregnancy category: Not rated

Indications and Dosages

↗ *To control diarrhea and GI tract spasms*

CAPSULES, TABLETS

Adults and adolescents. 10 to 20 mg t.i.d. or q.i.d., increased as needed and tolerated. *Maximum:* 160 mg daily.

Children ages 6 to 12. 10 mg t.i.d. or q.i.d.

E.R. TABLETS

Adults and adolescents. 30 mg b.i.d.

SYRUP

Adults and adolescents. 10 to 20 mg t.i.d. or q.i.d., increased as needed and tolerated.

Maximum: 60 mg daily.

Children ages 2 to 13. 10 mg t.i.d. or q.i.d.

Children ages 6 months to 2 years. 5 to 10 mg t.i.d. or q.i.d.

I.M. INJECTION

Adults. 20 mg every 4 to 6 hr. Dosage adjusted as needed and tolerated.

Mechanism of Action

Inhibits acetylcholine's muscarinic actions at postganglionic parasympathetic receptors in smooth muscles, secretory glands, and the CNS. These actions relax smooth muscles and diminish GI, GU, and biliary tract secretions.

Contraindications

Adhesions between iris and lens, angle-closure glaucoma, GI obstruction, hemorrhagic shock, hepatic disease, hiatal hernia, hypersensitivity to any anticholinergic, ileus, intestinal atony in elderly or debilitated patients, myasthenia gravis, myocardial ischemia, obstructive uropathy, renal disease, severe ulcerative colitis, tachycardia, toxic megacolon

Interactions

DRUGS

adsorbent antidiarrheals, antacids:

Decreased dicyclomine absorption
amantadine, anticholinergics, phenothiazines, tricyclic antidepressants: Increased dicyclomine effects

antimyoasthenics: Reduced intestinal motility

atenolol: Increased atenolol effects

cyclopropane: Risk of ventricular arrhythmias
haloperidol: Decreased antipsychotic effect of haloperidol

ketoconazole: Decreased ketoconazole absorption

metoclopramide: Decreased effect of metoclopramide on GI motility

opioid analgesics: Increased risk of ileus, severe constipation, and urine retention
potassium chloride, especially wax-matrix preparations: Possibly GI ulceration

urinary alkalinizers (antacids that contain calcium or magnesium, carbonic anhydrase inhibitors, citrates, sodium bicarbonate):

Delayed excretion and increased risk of adverse effects of dicyclomine

Adverse Reactions

CNS: Agitation, dizziness, drowsiness, dyskinesia, excitement, fever, insomnia, lethar-

gy, light-headedness (I.M. use), nervous-

ness, paresthesia, syncope

CV: Palpitations, tachycardia

EENT: Blurred vision, cycloplegia, dry mouth, loss of taste, mydriasis, nasal congestion, photophobia

GI: Constipation, dysphagia, heartburn, ileus, vomiting

GU: Impotence, urine retention

SKIN: Decreased sweating, flushing, pruritus

Other: Heatstroke; injection site pain, redness, and swelling

Nursing Considerations

- Assess patient for tachycardia before giving dicyclomine; heart rate may increase.
- Don't give drug by I.V. route.
- Watch for symptoms of hypersensitivity, such as agitation and pruritus. They usually resolve within 48 hours of stopping drug.
- During long-term use, assess patient for chronic constipation and fecal impaction, and take corrective measures, as prescribed.

PATIENT TEACHING

- Instruct patient to store dicyclomine in a tightly sealed container at room temperature, protected from moisture and direct light. Advise her not to refrigerate syrup.
- Inform patient that dicyclomine relieves symptoms but doesn't cure the disorder.
- For best results, instruct patient to take drug 30 to 60 minutes before eating.
- Advise patient not to take an antacid or an anti-diarrheal within 2 hours of dicyclomine.
- Inform patient that blurred vision, dizziness, or drowsiness may occur.
- To prevent constipation, advise patient to eat high-fiber foods and drink at least eight glasses of water daily.

WARNING Urge patient to avoid getting overheated during exercise or in hot weather because heatstroke may result. Inform patient that hot baths or saunas may cause dizziness or fainting.

- Instruct patient to change position slowly to avoid light-headedness.
- Inform patient that stopping drug abruptly may cause dizziness and vomiting.
- Tell patient to take a missed dose as soon as she remembers unless it's nearly time for the next dose. Caution against doubling the dose.

diflunisal

Apo-Diflunisal (CAN), Dolobid, Novo-Diflunisal (CAN)

Class and Category

Chemical class: Difluorophenyl, salicylic acid derivative

Therapeutic class: Analgesic, anti-inflammatory

Pregnancy category: C (first trimester), Not rated (later trimesters)

Indications and Dosages

➤ *To relieve mild to moderate pain*

TABLETS

Adults. 1 g followed by 0.5 g every 8 to 12 hr. *Maximum:* 1.5 g daily.

➤ *To reduce inflammation in osteoarthritis or rheumatoid arthritis*

TABLETS

Adults. 0.5 to 1 g daily in divided doses b.i.d. *Maximum:* 1.5 g daily.

DOSAGE ADJUSTMENT Dosage reduced for elderly patients and those who use diuretics; who could be harmed by prolonged bleeding time; or who have compromised cardiac function, conditions that cause fluid retention, hepatic or renal impairment, hypertension, or upper GI disease.

Route	Onset	Peak	Duration
P.O.*	1 hr	2–3 hr	8–12 hr

Mechanism of Action

Blocks the activity of cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate the inflammatory response and cause local vasodilation, swelling, and pain. By blocking cyclooxygenase and inhibiting prostaglandins, this NSAID reduces inflammatory symptoms. This mechanism also relieves pain because prostaglandins promote pain transmission from the periphery to the spinal cord.

Contraindications

Asthma attacks, rhinitis, or urticaria precipitated by aspirin or other NSAIDs; hypersensitivity to diflunisal; treatment of perioperative pain after coronary artery bypass graft surgery

* For analgesia; unknown for anti-inflammatory effects.

Interactions

DRUGS

acetaminophen: Increased risk of adverse renal effects with long-term use of both drugs

antacids: Decreased blood diflunisal level

antihypertensives: Decreased antihypertensive effects

aspirin, other NSAIDs, salicylates: Increased GI irritability and bleeding, decreased diflunisal effectiveness

beta blockers: Impaired antihypertensive effects of beta blocker

cefamandole, cefoperazone, cefotetan, plicamycin, valproic acid: Increased risk of hypoprothrombinemia

colchicine, corticotropin (long-term use), glucocorticoids, potassium supplements:

Increased GI irritability and bleeding

cyclosporine, gold compounds, nephrotoxic drugs: Increased risk of nephrotoxicity

digoxin: Increased blood digoxin level

heparin, oral anticoagulants, thrombolytics: Prolonged PT, increased risk of bleeding

hydrochlorothiazide: Increased blood hydrochlorothiazide level

insulin, oral antidiabetics: Increased hypoglycemic effects

loop diuretics: Decreased loop diuretic effectiveness

methotrexate: Increased risk of methotrexate toxicity

phenytoin: Increased blood phenytoin level

probenecid: Increased diflunisal toxicity

ACTIVITIES

alcohol use: Increased GI irritability and bleeding

Adverse Reactions

CNS: Aseptic meningitis, cerebral hemorrhage, dizziness, drowsiness, headache, insomnia

CV: Vasculitis

EENT: Tinnitus

ENDO: Hypoglycemia

GI: Abdominal pain, constipation, diarrhea, esophageal irritation, GI bleeding or ulceration, hepatic failure, hepatitis, indigestion, jaundice, nausea, perforation of stomach or intestine, vomiting

GU: Acute renal failure, interstitial nephritis

HEME: Agranulocytosis, aplastic anemia, leukopenia, pancytopenia, thrombocytopenia

SKIN: Erythema multiforme, exfoliative

dermatitis, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, angioedema, hyponatremia

Nursing Considerations

- Use diflunisal with extreme caution and for shortest time possible in patients with a history of GI bleeding or ulcer disease because NSAIDs such as diflunisal increase the risk.
- Serious GI tract ulceration and bleeding, as well as perforation of stomach or intestine, can occur without warning or symptoms. Elderly patients are at greater risk. To minimize risk, give diflunisal with food. If patient has GI distress, withhold drug and notify prescriber immediately.
- Use diflunisal cautiously in patients with hypertension, and monitor blood pressure closely during therapy; drug can cause or worsen hypertension.
- Use drug cautiously in elderly patients, those with renal dysfunction, and those who should avoid prolonged bleeding time.

WARNING Monitor patient closely for thrombotic events, including stroke and MI, because NSAIDs such as diflunisal increase the risk of these events.

- Monitor BUN and serum creatinine levels in elderly patients, patients taking ACE inhibitors or diuretics, and patients with heart failure or impaired hepatic or renal function. These patients may have an increased risk of renal failure.
- Assess patient's skin routinely for rash or other signs of hypersensitivity reaction; drug may cause serious skin reactions without warning. At first sign of reaction, stop drug and notify prescriber.
- Assess type, location, and intensity of pain before and 1 to 2 hours after giving drug.
- Assess patient carefully because long-term or high-dose therapy may mask fever.

PATIENT TEACHING

- Teach patient not to crush or chew diflunisal tablets.
- Instruct patient to take tablet with a full glass of water and not to lie down for 30 minutes afterward to avoid esophageal irritation.
- Inform patient that drug will start working in about 1 week but that full effects may not occur for several weeks.

- Explain that diflunisal may increase the risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention for such signs and symptoms as chest pain, shortness of breath, slurred speech, and weakness.
- Tell patient that diflunisal also may increase risk of serious adverse GI reactions; stress need to seek immediate medical attention for signs and symptoms such as abdominal or epigastric pain, black or tarry stools, indigestion, and vomiting blood or material that resembles coffee grounds.
- Alert patient about possibly serious skin reactions and the need to seek immediate medical attention for such as problems as blisters, fever, itching, rash, and other signs of hypersensitivity.
- Caution patient to avoid acetaminophen, alcohol, aspirin, and other salicylates during diflunisal therapy, unless directed otherwise by prescriber.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to tell health care providers about diflunisal therapy before surgery, including dental surgery. Therapy should stop for 1 week before procedure.

digoxin

Lanoxicaps, Lanoxin, Lanoxin Elixir Pediatric, Lanoxin Injection, Lanoxin Injection Pediatric, Novo-Digoxin (CAN)

Class and Category

Chemical class: Digitalis glycoside
Therapeutic class: Antiarrhythmic, cardiotonic
Pregnancy category: C

Indications and Dosages

➤ To treat heart failure, atrial flutter, atrial fibrillation, and paroxysmal atrial tachycardia with rapid digitalization

CAPSULES, I.V. INJECTION

Adults. *Loading:* 10 to 15 mcg/kg in 3 divided doses every 6 to 8 hr, with first dose equal to 50% of total dose. *Maintenance:* 125 to 350 mcg daily once or twice daily.

Children over age 10. *Loading:* 8 to 12 mcg/kg in 3 or more divided doses, with first dose equal to 50% of total dose. Subsequent

doses given every 6 to 8 hr. *Maintenance:* 2 to 3 mcg/kg once daily.

Children ages 6 to 10. *Loading:* 15 to 30 mcg/kg in 3 or more divided doses, with first dose equal to 50% of total dose.

Subsequent doses given every 6 to 8 hr.

Maintenance: 4 to 8 mcg/kg daily in 2 divided doses.

Children ages 2 to 5. *Loading:* 25 to 35 mcg/kg in 3 or more divided doses, with first dose equal to 50% of total dose. Subsequent doses given every 6 to 8 hr. *Maintenance:* 6 to 9 mcg/kg daily in 2 divided doses.

Infants ages 1 to 24 months. *Loading:* 30 to 50 mcg/kg in 3 or more divided doses, with first dose equal to 50% of total dose.

Subsequent doses every 6 to 8 hr.

Maintenance: 7.5 to 12 mcg/kg daily in 2 divided doses.

Full-term neonates. *Loading:* 20 to 30 mcg/kg in 3 or more divided doses, with first dose equal to 50% of total dose. Subsequent doses given every 6 to 8 hr. *Maintenance:* 5 to 8 mcg/kg daily in 2 divided doses.

Premature neonates. *Loading:* 15 to 25 mcg/kg in 3 or more divided doses, with first dose equal to 50% of total dose.

Subsequent doses given every 6 to 8 hr.

Maintenance: 4 to 6 mcg/kg daily in 2 divided doses.

ELIXIR, TABLETS

Adults. *Loading:* 10 to 15 mcg/kg total dose given in 3 divided doses every 6 to 8 hr, with first dose equal to 50% of total dose.

Maintenance: 125 to 500 mcg daily.

Children over age 10. *Loading:* 10 to 15 mcg/kg total given in 3 divided doses every 6 to 8 hr, with first dose equal to 50% of total dose. *Maintenance:* 2.5 to 5 mcg/kg daily.

Children ages 5 to 10. *Loading:* 20 to 35 mcg/kg in 3 divided doses every 6 to 8 hr. *Maintenance:* 5 to 10 mcg/kg daily in 2 divided doses.

Children ages 2 to 5. *Loading:* 30 to 40 mcg/kg in 3 divided doses every 6 to 8 hr.

Maintenance: 7.5 to 10 mcg/kg daily in 2 divided doses.

Infants ages 1 to 24 months. *Loading:* 35 to 60 mcg/kg in 3 divided doses every 6 to 8 hr. *Maintenance:* 10 to 15 mcg/kg daily in 2 divided doses.

Full-term neonates. *Loading:* 25 to 35 mcg/kg in 3 divided doses every 6 to 8 hr.

Maintenance: 6 to 10 mcg/kg daily in 2 divided doses.

Premature neonates. *Loading:* 20 to 30 mcg/kg in 3 divided doses every 6 to 8 hr.

Maintenance: 5 to 7.5 mcg/kg daily in 2 divided doses.

DOSAGE ADJUSTMENT Dosage carefully adjusted for patients who are elderly or debilitated or have implanted pacemakers because toxicity may develop at doses tolerated by most patients.

Route	Onset	Peak	Duration
P.O.	30–120 min	6–8 hr	3–4 days
I.V.	5–30 min	1–5 hr	3–4 days

Mechanism of Action

Increases the force and velocity of myocardial contraction, resulting in positive inotropic effects. Digoxin produces antiarrhythmic effects by decreasing the conduction rate and increasing the effective refractory period of the AV node.

Contraindications

Hypersensitive carotid sinus syndrome, hypersensitivity to digoxin, presence or history of digitalis toxicity or idiosyncratic reaction to digoxin, ventricular fibrillation, ventricular tachycardia unless heart failure occurs unrelated to digoxin therapy

Interactions

DRUGS

adsorbent antidiarrheals, such as kaolin and pectin; bulk laxatives; cholestyramine; colestipol; oral neomycin; sulfasalazine: Inhibited digoxin absorption

amiodarone, propafenone: Elevated blood digoxin level, possibly to toxic level

antacids: Inhibited digoxin absorption
antiarrhythmics, pancuronium, parenteral calcium salts, rauwolfia alkaloids, sympathomimetics: Increased risk of arrhythmias

diltiazem, verapamil: Increased blood digoxin level, possibly excessive bradycardia

edrophonium: Excessive slowing of heart rate

erythromycin, neomycin, tetracycline:

Possibly increased blood digoxin level

hypokalemia-causing drugs, potassium-wasting diuretics: Increased risk of digitalis toxicity from hypokalemia

indomethacin: Decreased renal clearance

and increased blood level of digoxin
magnesium sulfate (parenteral): Possibly cardiac conduction changes and heart block
quinidine, quinine: Increased blood digoxin level

spironolactone: Increased half-life and risk of adverse effects of digoxin

succinylcholine: Increased risk of digoxin-induced arrhythmias

sucralfate: Decreased digoxin absorption

FOODS

high-fiber food: Inhibited digoxin absorption

Adverse Reactions

CNS: Confusion, depression, drowsiness, extreme weakness, headache, syncope

CV: Arrhythmias, heart block

EENT: Blurred vision, colored halos around objects

GI: Abdominal discomfort or pain, anorexia, diarrhea, nausea, vomiting

Other: Electrolyte imbalances

Nursing Considerations

- Give parenteral digoxin undiluted, or dilute with a fourfold or greater volume of sterile water for injection, normal saline solution, or D₅W for I.V. administration. Once diluted, give immediately. Discard if solution is markedly discolored or contains precipitate.
- Before giving each dose, take patient's apical pulse and notify prescriber if it's below 60 beats/minute (or other specified level).
- Monitor patient closely for signs of digitalis toxicity, such as altered mental status, arrhythmias, heart block, nausea, vision disturbances, and vomiting. If they appear, notify prescriber, check serum digoxin level as ordered, and expect to withhold drug until level is known. Monitor ECG tracing continuously.
- If patient has acute or unstable chronic atrial fibrillation, assess for drug effectiveness. Ventricular rate may not normalize even when serum drug level falls within therapeutic range; raising the dosage probably won't produce a therapeutic effect and may lead to toxicity.
- Frequently obtain ECG tracings as ordered in elderly patients because of their smaller body mass and reduced renal clearance. Elderly patients, especially those with coronary insufficiency, are more suscepti-

ble to arrhythmias—particularly ventricular fibrillation—if digitalis toxicity occurs.

- Monitor patient's serum potassium level regularly because hypokalemia predisposes to digitalis toxicity and serious arrhythmias. Also monitor potassium level often when giving potassium salts because hyperkalemia in patients receiving digoxin can be fatal.

PATIENT TEACHING

- Stress importance of taking digoxin exactly as prescribed. Warn about possible toxicity from taking too much and decreased effectiveness from taking too little.
- Instruct patient to take digoxin at same time each day to help increase compliance.
- Teach patient how to take her pulse, and instruct her to do so before each dose. Urge her to notify prescriber if pulse falls below 60 beats/minute or suddenly increases.
- Inform patient that small, white 0.25-mg tablets can easily be confused with other drugs. Caution against carrying digoxin in anything other than its original labeled container.
- Emphasize need to use special dropper supplied with elixir to ensure accurate dose measurement.
- Instruct patient to take a missed dose as soon as she remembers if within 12 hours of scheduled dose. If not, urge her to notify prescriber immediately.
- Urge patient to notify prescriber if she experiences adverse reactions, such as GI distress or pulse changes.
- Instruct patient to carry medical identification that indicates her need for digoxin.
- Advise patient to consult prescriber before using other drugs, including OTC products.

digoxin immune Fab (ovine)

Digibind

Class and Category

Chemical class: Digoxin-specific antigen-binding fragments

Therapeutic class: Digitalis glycoside antidote

Pregnancy category: C

Indications and Dosages

➤ *To treat acute toxicity from a known amount of digoxin elixir or tablets*

I.V. INJECTION

Adults and children. Individualized dosage based on amount ingested. Dose (mg) = dose ingested (mg) multiplied by 0.8 and then divided by 0.5, multiplied by 38, and rounded up to next whole vial.

➤ *To treat acute toxicity from a known amount of digoxin capsules, digitoxin tablets, or I.V. injection of digoxin or digitoxin*

I.V. INJECTION

Adults and children. Individualized dosage based on amount ingested. Dose (mg) = dose ingested (mg) divided by 0.5, then multiplied by 38 and rounded up to next whole vial.

➤ *To treat acute toxicity from an unknown amount of digoxin or digitoxin during long-term therapy*

I.V. INJECTION

Adults and children. Individualized dosage for digoxin toxicity: dose (mg) = serum digoxin level (ng/ml) multiplied by body weight (kg), then divided by 100, and then multiplied by 38. Individualized dosage for digitoxin toxicity: dose (mg) = serum digitoxin level (ng/ml) multiplied by body weight (kg) and then divided by 1,000, multiplied by 38, and rounded up to next whole vial.

DOSAGE ADJUSTMENT Higher dose administered, as prescribed, if the dose based on ingested amount differs substantially from the dose based on serum digoxin or digitoxin level. Dose repeated after several hours, if needed.

Route	Onset	Peak	Duration
I.V.	15–30 min	Unknown	8–12 hr

Mechanism of Action

Binds with digoxin or digitoxin molecules. The resulting complex is excreted through the kidneys. As the free serum digoxin level declines, tissue-bound digoxin enters the serum and also is bound and excreted.

Contraindications

Hypersensitivity to digoxin immune Fab

Adverse Reactions

CV: Increased ventricular rate (in atrial fib-

rillation), worsening of heart failure or low cardiac output

Other: Allergic reaction (difficulty breathing, urticaria), febrile reaction, hypokalemia

Nursing Considerations

- Expect each 38-mg vial of purified digoxin immune Fab to bind about 0.5 mg of digoxin or digitoxin.
- To reconstitute for I.V. use, dissolve 38 mg in 4 ml of sterile water for injection to yield 9.5 mg/ml. Mix gently. Further dilute with normal saline solution to proper volume for I.V. infusion. For very small doses, reconstituted 38-mg vial may be diluted with 34 ml of normal saline solution to yield 1 mg/ml.

WARNING Before giving digoxin immune Fab to high-risk patient, test for allergic reaction as prescribed by diluting 0.1 ml of reconstituted drug in 9.9 ml sodium chloride for injection and then injecting 0.1 ml (9.5 mcg/0.1 ml) intradermally. After 20 minutes, observe for an urticarial wheal surrounded by erythema. Alternatively, perform a scratch test by placing one drop of 9.5 mcg/0.1 ml dilution on patient's skin and making a 1/4" scratch through the drop with a sterile needle. Inspect site in 20 minutes. Test is considered positive if it produces a wheal surrounded by erythema. If test causes a systemic reaction, apply tourniquet above test site, notify prescriber, and prepare to respond to anaphylaxis. Be aware that if a skin or systemic reaction occurs, additional drug shouldn't be given unless essential; if more of the drug must be given, expect prescriber to pretreat patient with corticosteroids and diphenhydramine. Prescriber should be on standby to treat anaphylaxis.

- For an infant, reconstitute digoxin immune Fab as ordered and administer with a tuberculin syringe.
- When administering to a child, watch for fluid volume overload.
- When giving a large dose, expect a faster onset but watch closely for febrile reaction.
- Give I.V. infusion through a 0.22-micron membrane filter over 30 minutes. Keep in mind that drug may be given by rapid I.V. injection if cardiac arrest is imminent.
- Monitor serum potassium level often, especially during first few hours of thera-

py. Potassium level may drop rapidly.

PATIENT TEACHING

- Inform patient of the purpose of digoxin immune Fab and how it will be given.
- Advise patient to notify you immediately if she experiences adverse reactions, especially difficulty breathing and urticaria.

dihydroergotamine mesylate

D.H.E. 45, Dihydroergotamine-Sandoz (CAN), Migranal

Class and Category

Chemical class: Semisynthetic ergot alkaloid

Therapeutic class: Antimigraine

Pregnancy category: X

Indications and Dosages

↗ *To treat acute migraine with or without aura*

I.V. INJECTION

Adults. 1 mg, repeated in 1 hr, if needed.

Maximum: 6 mg/wk.

I.M. INJECTION

Adults. 1 mg at first sign of headache,

repeated every hr up to 3 mg, if needed.

Maximum: 3 mg/24 hr, 6 mg/wk.

NASAL SPRAY

Adults. 1 spray (0.5 mg) in each nostril, repeated in 15 min for a total dose of 2 sprays in each nostril or 2 mg. *Maximum:* 3 mg/24 hr, 4 mg/wk.

Route	Onset	Peak	Duration
I.V.	In 5 min	15 min– 2 hr	About 8 hr
I.M.	15–30 min	15 min– 2 hr	3–4 hr
Nasal	In 30 min	30–60 min	Unknown

Mechanism of Action

Produces intracranial and peripheral vasoconstriction by binding to all known 5-hydroxytryptamine₁ (5-HT₁) receptors, alpha₁- and alpha₂-adrenergic receptors, and dopaminergic receptors. Activation of 5-HT₁ receptors on intracranial blood vessels probably constricts large intracranial arteries and closes arteriovenous anastomoses to relieve migraine headache.

Activation of 5-HT₁ receptors on sensory nerves in the trigeminal system also may inhibit the release of pro-inflammatory neuropeptides.

Peripherally, dihydroergotamine causes vasoconstriction by stimulating alpha-adrenergic receptors. At therapeutic doses, it inhibits norepinephrine reuptake, increasing vasoconstriction. Drug constricts veins more than arteries, increasing venous return while decreasing venous stasis and pooling.

Contraindications

Coronary artery disease, including vasospasm; hemiplegic or basilar migraine; hypersensitivity to dihydroergotamine or other ergot alkaloids; malnutrition; peripheral vascular disease or after vascular surgery; pregnancy; sepsis; severe hepatic or renal impairment; severe pruritus; uncontrolled hypertension; use of macrolide antibiotics or protease inhibitors; use within 24 hours of 5-HT₁ agonist, ergotamine-containing or ergot-type drug, or methysergide

Interactions

DRUGS

beta blockers: Possibly peripheral vasoconstriction and peripheral ischemia, increased risk of gangrene

macrolides, protease inhibitors: Possibly increased risk of vasospasm, acute ergotism with peripheral ischemia

nitrates: Decreased antianginal effects of nitrates

other ergot drugs, including ergoloid mesylates, ergonovine, methylergonovine, methysergide, and sumatriptan: Increased risk of serious adverse effects from nasal dihydroergotamine

systemic vasoconstrictors: Risk of severe hypertension

ACTIVITIES

smoking: Possibly increased ischemic response to ergot therapy

Adverse Reactions

CNS: Anxiety, confusion, dizziness, fatigue, headache, paresthesia, somnolence, weakness

CV: Bradycardia, chest pain, peripheral vasospasm (calf or heel pain with exertion, cool and cyanotic hands and feet, leg weakness, weak or absent pulses), tachycardia

EENT: Abnormal vision; dry mouth; epis-

taxis, nasal congestion or rhinitis, and sore nose (nasal spray); miosis; pharyngitis; sinusitis; taste perversion

GI: Diarrhea, nausea, vomiting

MS: Muscle stiffness

SKIN: Localized edema of face, feet, fingers, and lower legs; sensation of heat or warmth; sudden diaphoresis

Nursing Considerations

WARNING Monitor patient for signs of dihydroergotamine overdose, such as abdominal pain, confusion, delirium, dizziness, dyspnea, headache, nausea, pain in legs or arms, paresthesia, seizures, and vomiting.

- Assess patient's peripheral pulses, skin sensation, warmth, and capillary refill. After giving nasal dihydroergotamine, monitor patient for signs of widespread blood vessel constriction and adverse reactions caused by decreased circulation to many body areas.

PATIENT TEACHING

- Instruct patient to use nasal spray when headache pain—not aura—begins.
- Teach her to prime spray pump by squeezing it four times.
- Advise patient to wait 15 minutes between each set of nasal sprays.
- Encourage patient to lie down in a quiet, dark room after using drug.
- Instruct patient to use more dihydroergotamine if headache returns or worsens but not to exceed maximum prescribed amount or frequency.
- Remind patient to take drug only as needed, not on a daily basis.
- Instruct patient to discard residual nasal spray in an open ampule after 8 hours.
- If patient has a headache different from her usual migraines, caution her not to use dihydroergotamine and to notify prescriber.
- Inform patient that nasal drug won't relieve pain other than throbbing headaches.
- Advise patient to avoid alcohol, which can cause or worsen headaches, and to avoid smoking, which may cause an ischemic response.
- Warn patient about possible dizziness during or after a migraine for which she took dihydroergotamine.

dihydrotachysterol

DHT, DHT Intensol, Hytakerol

Class and Category

Chemical class: Sterol derivative, vitamin D analogue

Therapeutic class: Antihypocalcemic, antihypoparathyroid

Pregnancy category: C

Indications and Dosages

↗ *To treat hypocalcemic and idiopathic tetany*

CAPSULES, ORAL SOLUTION, TABLETS

Adults and adolescents. *Initial:* 0.75 to 2.5 mg daily for 3 days for acute cases; 0.25 to 0.5 mg daily for 3 days for less acute cases. *Maintenance:* 0.25 mg/wk to 1 mg daily, as needed to maintain normal serum calcium level.

↗ *To treat hypoparathyroidism*

CAPSULES, ORAL SOLUTION, TABLETS

Adults and adolescents. *Initial:* 0.75 to 2.5 mg daily for several days. *Maintenance:* 0.2 to 1 mg daily.

Children. *Initial:* 1 to 5 mg daily for 4 days; then continued or decreased to one-quarter the dose. *Maintenance:* 0.5 to 1.5 mg daily.

Route	Onset	Peak	Duration
P.O.	Several hr	Unknown	Up to 9 wk

Mechanism of Action

Stimulates intestinal calcium absorption and mobilizes bone calcium when parathyroid hormone and renal tissue fail to raise the serum calcium level.

Contraindications

Hypercalcemia, hypersensitivity to vitamin D, hypervitaminosis D, malabsorption syndrome, renal dysfunction

Interactions

DRUGS

aluminum-containing antacids: Possibly increased serum aluminum level, leading to toxicity

barbiturates, phenytoin: Decreased half-life and therapeutic effects of vitamin D

calcium-containing drugs, thiazide diuretics: Risk of hypercalcemia in patients with hypoparathyroidism
cholestyramine, colestipol, mineral oil:

Decreased vitamin D absorption
digitalis glycosides: Possibly hypercalcemia; possibly potentiated effects of digitalis glycosides, resulting in arrhythmias
magnesium-containing antacids: Risk of hypermagnesemia, especially in patients with chronic renal failure
phosphorus-containing drugs: Increased risk of hyperphosphatemia
vitamin D analogues: Increased risk of vitamin D toxicity

Adverse Reactions

Other: Vitamin D toxicity (long-term, high-dose therapy)

Nursing Considerations

- After thyroid surgery, expect to give 0.25 mg once daily with 6 g of oral calcium lactate until danger of tetany has passed.
- Monitor serum calcium level regularly to determine dosage schedule and detect or prevent hypercalcemia. The difference between therapeutic and toxic doses may be small.
- Watch closely for signs of vitamin D toxicity: abdominal cramps, amnesia, anorexia, ataxia, coma, constipation, depression, diarrhea, disorientation, hallucinations, headache, hypotonia, lethargy, nausea, syncope, tinnitus, vertigo, vomiting, and weakness. Renal impairment may cause albuminuria, polydipsia, and polyuria. Delayed treatment can result in death from cardiac and renal failure caused by widespread calcification of soft tissues, including the heart, blood vessels, kidneys, and lungs.
- If toxicity occurs, notify prescriber and expect to stop dihydrotachysterol immediately. Place patient on bed rest, administer fluids and a laxative, and give low-calcium diet as ordered. For hypercalcemic crisis with dehydration, prepare to give I.V. normal saline solution and a loop diuretic (such as furosemide or ethacrynic acid) to increase urinary calcium excretion.

PATIENT TEACHING

- Stress importance of not exceeding prescribed dihydrotachysterol dosage because of the risk of vitamin D toxicity.
- If patient detects signs of toxicity, caution her not to take the next dose and to notify prescriber immediately.

- Advise patient to drop solution directly into her mouth or to mix it with fruit juice, cereal, or other food.
- Tell patient to take a missed dose as soon as she remembers unless it's nearly time for next dose. Warn her not to double it.
- Advise patient to avoid OTC drugs and dietary supplements that contain aluminum, calcium, phosphorus, or vitamin D, unless directed by prescriber. Also advise her to avoid antacids that contain magnesium.
- Urge patient to keep follow-up appointments and to have her serum calcium level measured periodically.

diltiazem hydrochloride

Apo-Diltiaz (CAN), Cardizem, Cardizem CD, Cardizem LA, Cardizem SR, Dilacor XR, Novo-Diltiazem (CAN), Nu-Diltiaz (CAN)

Class and Category

Chemical class: Benzothiazepine derivative
Therapeutic class: Antianginal, antiarrhythmic, antihypertensive
Pregnancy category: C

Indications and Dosages

↗ *To treat Prinzmetal's (variant) angina and chronic stable angina*

TABLETS

Adults and adolescents. *Initial:* 30 mg t.i.d. or q.i.d. before meals and at bedtime, increased every 1 or 2 days as appropriate. *Maximum:* 360 mg daily in divided doses t.i.d. or q.i.d.

E.R. TABLETS

Adults and adolescents. *Initial:* 180 mg daily, increased every 7 to 14 days as needed. *Maximum:* 360 mg daily.

↗ *To control hypertension*

E.R. CAPSULES

Adults and adolescents. *Initial:* 180 to 240 mg daily, adjusted after 14 days as appropriate. *Maximum:* 360 mg daily.

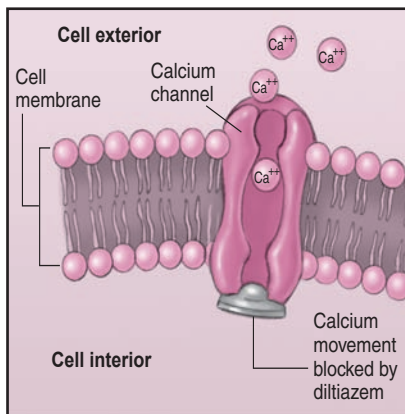

S.R. CAPSULES

Adults and adolescents. *Initial:* 60 to 120 mg b.i.d., adjusted after 14 days as appropriate. *Maximum:* 360 mg daily.

Mechanism of Action

Diltiazem inhibits calcium movement into coronary and vascular smooth-muscle cells by blocking slow calcium channels in cell membranes, as shown. This action decreases intracellular calcium, which:

- inhibits smooth-muscle cell contractions
- decreases myocardial oxygen demand by relaxing coronary and vascular smooth muscle, reducing peripheral vascular resistance and systolic and diastolic blood pressures
- slows AV conduction time and prolongs AV nodal refractoriness
- interrupts the reentry circuit in AV nodal reentrant tachycardias.

TABLETS

Adults and adolescents. Initial: 30 mg t.i.d. or q.i.d. before meals and at bedtime, increased every 1 or 2 days as appropriate. *Maximum:* 360 mg daily in divided doses t.i.d. or q.i.d.

E.R. TABLETS

Adults. Initial: 180 to 240 mg daily, adjusted after 14 days, as needed. *Maximum:* 540 mg daily.

➤ *To treat atrial fibrillation, atrial flutter, and paroxysmal supraventricular tachycardia*

I.V. INFUSION OR INJECTION

Adults and adolescents. 0.25 mg/kg given by bolus over 2 min. If response is inadequate after 15 min, 0.35 mg/kg given by bolus over 2 min. Then 10 mg/hr for continued reduction of heart rate after bolus, increased by 5 mg/hr, as needed. *Maximum:* 15 mg/hr for up to 24 hr.

Route	Onset	Peak	Duration
P.O.	30–60 min	In 2 wk	Unknown
P.O. (E.R.)	2–3 hr	In 2 wk	Unknown
P.O. (S.R.)	Unknown	In 2 wk	Unknown
I.V.	In 3 min	2–7 min	30 min–10 hr*

Incompatibilities

Don't give diltiazem through same I.V. line as acetazolamide, acyclovir, aminophylline,

*For infusion; 1 to 3 hr for injection.

ampicillin sodium/sulbactam sodium, cefamandole, cefoperazone, diazepam, furosemide, heparin, hydrocortisone sodium succinate, methylprednisolone sodium succinate, mezlocillin, nafcillin, phenytoin, rifampin, or sodium bicarbonate.

Contraindications

Acute MI; cardiogenic shock; Lown-Ganong-Levine or Wolff-Parkinson-White syndrome, second- or third-degree AV block, and sick sinus syndrome, unless artificial pacemaker is in place; pulmonary edema; systolic blood pressure below 90 mm Hg; ventricular tachycardia (wide complex)

Interactions

DRUGS

anesthetic: Additive hypotension; possibly decreased cardiac contractility, conductivity, and automaticity
benzodiazepines: Increased risk of prolonged sedation
beta blockers: Possibly increased risk of adverse cardiovascular effects
buspirone: Increased effects and risk of buspirone toxicity
carbamazepine, cyclosporine, lovastatin, quinidine, theophyllines: Decreased hepatic clearance and increased serum levels of these drugs, leading to toxicity
cimetidine: Decreased diltiazem metabolism, increased blood diltiazem level
digoxin: Increased blood digoxin level
lithium: Possibly neurotoxicity

NSAIDs: Possibly antagonized antihypertensive effect of diltiazem

prazosin: Possibly increased risk of hypotension

procainamide: Possibly increased risk of prolonged QT interval

quinidine: Increased risk of adverse quinine effects

rifampin: Decreased blood diltiazem level to undetectable amounts

Adverse Reactions

CNS: Abnormal gait, amnesia, asthenia, depression, dizziness, dream disturbances, extrapyramidal reactions, fatigue, hallucinations, headache, insomnia, nervousness, paresthesia, personality change, somnolence, syncope, tremor, weakness

CV: Angina, atrial flutter, AV block (first-, second-, and third-degree), bradycardia, bundle-branch block, heart failure, hypotension, palpitations, peripheral edema, PVCs, sinus arrest, sinus tachycardia, 12-lead ECG abnormalities, ventricular fibrillation, ventricular tachycardia

EENT: Amblyopia, dry mouth, epistaxis, eye irritation, gingival bleeding and hyperplasia, gingivitis, nasal congestion, retinopathy, taste perversion, tinnitus

ENDO: Hyperglycemia

GI: Anorexia, constipation, diarrhea, elevated liver function test results, indigestion, nausea, thirst, vomiting

GU: Acute renal failure, impotence, nocturia, polyuria, sexual dysfunction

HEME: Hemolytic anemia, leukopenia, prolonged bleeding time, thrombocytopenia

MS: Arthralgia, muscle spasms, myalgia

RESP: Cough, dyspnea

SKIN: Alopecia, diaphoresis, erythema multiforme, exfoliative dermatitis, flushing, leukocytoclastic vasculitis, petechiae, photosensitivity, pruritus, purpura, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Angioedema, hyperuricemia, weight gain

Nursing Considerations

- Use diltiazem cautiously in patients with impaired hepatic or renal function, and monitor liver and renal function, as appropriate; drug is metabolized mainly in the liver and excreted by the kidneys.

WARNING Monitor patient's blood pressure,

pulse rate, and heart rate and rhythm by continuous ECG as appropriate during therapy. Keep emergency equipment and drugs available.

- Assess patient for signs and symptoms of heart failure.
- If patient takes digoxin, watch for digitalis toxicity (nausea, vomiting, halo vision, elevated serum digoxin level).
- Administer sublingual nitroglycerin, as prescribed, during diltiazem therapy.
- Expect to discontinue drug if adverse skin reactions, usually transient, persist.

PATIENT TEACHING

- Explain that regular tablets can be crushed but that capsules and E.R. tablets must be swallowed whole.

WARNING Tell patient that stopping drug suddenly may have life-threatening effects.

- Advise patient to monitor blood pressure and pulse rate regularly and to report significant changes to prescriber.
- Urge patient to report chest pain, difficulty breathing, dizziness, fainting, irregular heartbeat, rash, or swollen ankles.
- Instruct patient to maintain good oral hygiene, perform gum massage, and see a dentist every 6 months to prevent gingival bleeding and hyperplasia and gingivitis.

dimenhydrinate

Dinate, Dramanate, Gravol (CAN), Hydrate

Class and Category

Chemical class: Ethanolamine derivative

Therapeutic class: Antiemetic, antivertigo

Pregnancy category: B

Indications and Dosages

↗ To treat nausea, vomiting, dizziness, or vertigo associated with motion sickness

CHEWABLE TABLETS, ORAL SOLUTION, SYRUP, TABLETS

Adults and adolescents. 50 to 100 mg every 4 to 6 hr, p.r.n. *Maximum:* 400 mg/24 hr.

Children ages 6 to 12. 25 to 50 mg every 6 to 8 hr, p.r.n. *Maximum:* 150 mg/24 hr.

Children ages 2 to 6. 12.5 to 25 mg every 6 to 8 hr, p.r.n. *Maximum:* 75 mg/24 hr.

I.M. INJECTION

Adults and adolescents. 50 mg every 4 hr, p.r.n.

Children. 1.25 mg/kg or 37.5 mg/m² every 6 hr, p.r.n. *Maximum:* 300 mg daily.

I.V. INFUSION OR INJECTION

Adults and adolescents. 50 mg in 10 ml of normal saline solution administered slowly, over at least 2 min, every 4 hr, p.r.n.

Children. 1.25 mg/kg or 37.5 mg/m² in 10 ml of normal saline solution administered slowly, over at least 2 min, every 6 hr, p.r.n. *Maximum:* 300 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	3–6 hr
I.M.	20–30 min	Unknown	3–6 hr
I.V.	Immediate	Unknown	3–6 hr

Mechanism of Action

May inhibit vestibular stimulation and labyrinthine stimulation and function by acting on the otolith system and, with larger doses, on the semicircular canals.

Contraindications

Age less than 1 month, hypersensitivity to dimenhydrinate or its components

Interactions

DRUGS

aminoglycosides, other ototoxic drugs:

Masked symptoms of ototoxicity
anticholinergics, drugs with anticholinergic activity: Potentiated anticholinergic effects of dimenhydrinate

apomorphine: Possibly decreased emetic response to apomorphine in treatment of poisoning

barbiturates, other CNS depressants: Possibly increased CNS depression

MAO inhibitors: Increased anticholinergic and CNS depressant effects of dimenhydrinate

ACTIVITIES

alcohol use: Possibly increased CNS depression

Adverse Reactions

CNS: Confusion, drowsiness, hallucinations, nervousness, paradoxical stimulation

CV: Hypotension, palpitations, tachycardia

EENT: Blurred vision, diplopia, dry eyes, dry mouth, nasal congestion

GI: Anorexia, constipation, diarrhea, epigastric discomfort, nausea, vomiting

GU: Dysuria

HEME: Hemolytic anemia

RESP: Thickening of bronchial secretions, wheezing

SKIN: Photosensitivity, rash, urticaria

Other: Anaphylaxis

Nursing Considerations

WARNING Be aware that I.V. dimenhydrinate shouldn't be administered to premature or full-term neonates. Some I.V. preparations may contain benzyl alcohol, which can cause a fatal toxic syndrome characterized by CNS, respiratory, circulatory, and renal impairment and metabolic acidosis.

WARNING Be aware that the 50-mg/ml concentration of dimenhydrinate is intended for I.M. use. For I.V. use, the solution must be diluted further with at least 10 ml of diluent, such as D₅W or normal saline solution, for each milliliter of dimenhydrinate.

- Monitor patients with prostatic hyperplasia, stenosing peptic ulcer, pyloroduodenal obstruction, bladder neck obstruction, angle-closure glaucoma, bronchial asthma, or cardiac arrhythmias for worsening of these conditions caused by anticholinergic effects.
- Monitor elderly patients for increased sensitivity to dimenhydrinate, such as excessive drowsiness, confusion, and restlessness.
- Assess patients, especially children and elderly patients, for evidence of paradoxical stimulation, such as nightmares, unusual excitement, nervousness, restlessness, or irritability.
- Store parenteral drug at 15° to 30° C (59° to 86° F); don't freeze.

PATIENT TEACHING

- Because dimenhydrinate may cause drowsiness, instruct patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to inform health care providers about dimenhydrinate therapy, especially if she's being evaluated for medical conditions that are affected by this drug, such as appendicitis.
- Instruct patient to avoid alcohol, sedatives, and tranquilizers while taking dimenhydrinate.
- Encourage patient to use sunscreen to prevent photosensitivity reactions.

diphenhydramine hydrochloride

Allerdryl (CAN), Banophen, Benadryl, Benadryl Allergy, Diphenhist CapTabs, Genahist, Hyrexin, Nytol QuickCaps, Siladryl, Sleep-Eze D Extra Strength, Unisom SleepGels Maximum Strength

Class and Category

Chemical class: Ethanolamine derivative
Therapeutic class: Antianaphylactic adjunct, antidyskinetic, antiemetic, antihistamine, antitussive (syrup), antivertigo, sedative-hypnotic
Pregnancy category: B

Indications and Dosages

↗ *To treat hypersensitivity reactions, such as perennial and seasonal allergic rhinitis, vasomotor rhinitis, allergic conjunctivitis, uncomplicated allergic skin eruptions, and transfusion reactions*

CAPSULES, TABLETS

Adults and adolescents. 25 to 50 mg every 4 to 6 hr, p.r.n. *Maximum:* 300 mg daily.

Children ages 6 to 12. 12.5 to 25 mg every 4 to 6 hr. *Maximum:* 150 mg daily.

Children up to age 6. 6.25 to 12.5 mg every 4 to 6 hr.

ELIXIR

Adults and adolescents. 25 to 50 mg every 4 to 6 hr, p.r.n. *Maximum:* 300 mg daily.

Children. 1.25 mg/kg every 4 to 6 hr. *Maximum:* 300 mg daily.

I.V. OR I.M. INJECTION

Adults and adolescents. 10 to 50 mg every 4 to 6 hr up to 100 mg/dose, if needed. *Maximum:* 400 mg daily.

Children. 1.25 mg/kg every 4 to 6 hr. *Maximum:* 300 mg daily.

↗ *To treat sleep disorders*

CAPSULES, TABLETS

Adults and adolescents. 50 mg 20 to 30 min before bedtime.

↗ *To provide antitussive effects*

ELIXIR

Adults and adolescents. 25 mg every 4 hr. *Maximum:* 100 mg/24 hr.

Children ages 6 to 12. 12.5 mg every 4 to 6 hr. *Maximum:* 75 mg daily.

Children ages 2 to 6. 6.25 mg every 4 to 6 hr. *Maximum:* 25 mg daily.

↗ *To prevent motion sickness or treat vertigo*

CAPSULES, ELIXIR, TABLETS

Adults and adolescents. 25 to 50 mg every 4 to 6 hr, p.r.n. *Maximum:* 300 mg daily.

Children. 1 to 1.5 mg/kg every 4 to 6 hr, p.r.n. *Maximum:* 300 mg daily.

I.V. OR I.M. INJECTION

Adults and adolescents. *Initial:* 10 mg. Increased to 20 to 50 mg every 2 to 3 hr, if needed. *Maximum:* 100 mg/dose, 400 mg daily.

Children. 1 to 1.5 mg/kg I.M. every 4 to 6 hr, p.r.n. *Maximum:* 300 mg daily.

↗ *To treat symptoms of Parkinson's disease and drug-induced extrapyramidal reactions in elderly patients who can't tolerate more potent antidyskinetic drugs*

CAPSULES, ELIXIR, TABLETS

Adults. 25 mg t.i.d. increased gradually to 50 mg q.i.d., if needed. *Maximum:* 300 mg daily.

I.V. OR I.M. INJECTION

Adults and adolescents. 10 to 50 mg q.i.d., as needed. *Maximum:* 100 mg/dose, 400 mg daily.

Route	Onset	Peak	Duration
P.O.	15–60 min	1–3 hr	6–8 hr
I.V.	Immediate	1–3 hr	6–8 hr
I.M.	30 min	1–3 hr	6–8 hr

Mechanism of Action

Binds to central and peripheral H₁ receptors, competing with histamine for these sites and preventing it from reaching its site of action. By blocking histamine, diphenhydramine produces antihistamine effects, inhibiting respiratory, vascular, and GI smooth-muscle contraction; decreasing capillary permeability, which reduces wheals, flares, and itching; and decreasing salivary and lacrimal gland secretions.

Diphenhydramine produces antidyskinetic effects, possibly by inhibiting acetylcholine in the CNS. It also produces antitussive effects by directly suppressing the cough center in the medulla oblongata in the brain. Diphenhydramine's antiemetic and antivertigo effects may be related to its ability to bind to CNS muscarinic receptors and depress vestibular stimulation and labyrinthine function. Its sedative effects are related to its CNS depressant action.

Contraindications

Bladder neck obstruction, hypersensitivity to diphenhydramine or its components, lower respiratory tract symptoms (including asthma), MAO inhibitor therapy, narrow-angle glaucoma, pyloroduodenal obstruction, stenosing peptic ulcer, symptomatic benign prostatic hyperplasia

Interactions

DRUGS

apomorphine: Possibly decreased emetic response in treatment of poisoning
barbiturates, other CNS depressants: Possibly increased CNS depression

MAO inhibitors: Increased anticholinergic and CNS depressant effects of diphenhydramine

ACTIVITIES

alcohol use: Possibly increased CNS depression

Adverse Reactions

CNS: Confusion, dizziness, drowsiness

CV: Arrhythmias, palpitations, tachycardia

EENT: Blurred vision, diplopia

GI: Epigastric distress, nausea

HEME: Agranulocytosis, hemolytic anemia, thrombocytopenia

RESP: Thickened bronchial secretions

SKIN: Photosensitivity

Nursing Considerations

- Expect to give parenteral form of diphenhydramine only when oral ingestion isn't possible.
- Keep elixir container tightly closed. Protect elixir and parenteral forms from light.
- Expect to discontinue drug at least 72 hours before skin tests for allergies because drug may inhibit cutaneous histamine response, thus producing false-negative results.

PATIENT TEACHING

- Instruct patient to take diphenhydramine at least 30 minutes before exposure to situations that may cause motion sickness.
- Advise her to take drug with food to minimize GI distress.
- Urge patient to avoid alcohol while taking diphenhydramine.
- Instruct her to use sunscreen to prevent photosensitivity reactions.
- Advise patient to avoid taking other OTC drugs that contain diphenhydramine to prevent additive effects.

dipyridamole

**Apo-Dipyridamole FC (CAN),
Apo-Dipyridamole SC (CAN),
Novo-Dipiradol (CAN), Persantine**

Class and Category

Chemical class: Pyrimidine

Therapeutic class: Coronary vasodilator, diagnostic aid, platelet aggregation inhibitor

Pregnancy category: B

Indications and Dosages

↗ *To prevent thromboembolic complications of cardiac valve replacement*

TABLETS

Adults. 75 to 100 mg q.i.d. with coumarin or indanedione derivative anticoagulant.

↗ *To aid diagnosis during thallium perfusion imaging of myocardium*

I.V. INFUSION

Adults. 0.57 mg/kg in 50 ml of D₅W infused over 4 min. *Maximum*: 60 mg.

Route	Onset	Peak	Duration
I.V.	Unknown	3.8–8.7 min*	Unknown

Mechanism of Action

May increase the intraplatelet level of adenosine, which causes coronary vasodilation and inhibits platelet aggregation. Dipyridamole also may increase the intraplatelet level of cyclic adenosine monophosphate (cAMP) and may inhibit formation of the potent platelet activator stimulant thromboxane A₂, which decreases platelet activation. Vasodilation and increased blood flow occur preferentially in nondiseased coronary vessels, which results in redistribution of blood away from significantly diseased vessels. These changes in perfusion are observed during thallium imaging studies.

Contraindications

Asthma (I.V.), hypersensitivity to dipyridamole or its components, hypotension, unstable angina pectoris

* After start of infusion, for increased velocity of coronary artery blood flow.

Interactions

DRUGS

adenosine: Potentiated effects of adenosine
cefamandole, cefoperazone, cefotetan, plitacemylin, valproic acid: Possibly hypoprothrombinemia and increased risk of bleeding
heparin, NSAIDs, thrombolytics: Possibly increased risk of bleeding
theophylline: Reversal of coronary vasodilation caused by dipyridamole, possibly false-negative thallium imaging result

Adverse Reactions

CNS: Dizziness, headache

CV: Angina, arrhythmias, ECG changes (specifically, ST-segment and T-wave changes)

GI: Abdominal pain, diarrhea, nausea, vomiting

RESP: Dyspnea

SKIN: Flushing, pruritus, rash

Nursing Considerations

- Protect I.V. form of dipyridamole from direct light and freezing.
- Monitor blood pressure, pulse rate and rhythm, and breath sounds every 10 to 15 minutes during I.V. infusion.
- Keep parenteral aminophylline available to relieve adverse reactions to dipyridamole infusion.
- At therapeutic doses, expect adverse reactions to be minimal and transient. They typically resolve with long-term use.

PATIENT TEACHING

- Urge patient to take dipyridamole at least 1 hour before or 2 hours after meals for faster absorption. If she experiences GI distress, advise her to take drug with meals or milk.
- Advise patient to take drug at evenly spaced intervals.
- Inform patient that drug commonly is taken with other anticoagulants.
- Urge her to keep appointments for coagulation tests.
- Instruct patient to seek immediate emergency treatment if chest pain occurs.
- Caution patient to consult prescriber before taking aspirin and other OTC NSAIDs because of the possible increased risk of bleeding.
- Advise patient to notify all health care providers about dipyridamole use.

dirithromycin

Dynabac

Class and Category

Chemical: Semisynthetic macrolide

Therapeutic: Antibiotic

Pregnancy category: C

Indications and Dosages

➤ *To treat acute bacterial exacerbations and secondary bacterial infections in patients with bronchitis caused by Moraxella catarrhalis or Streptococcus pneumoniae, and uncomplicated skin and soft-tissue infections caused by methicillin-susceptible Staphylococcus aureus*

TABLETS

Adults and adolescents. 500 mg daily for 7 days.

➤ *To treat streptococcal pharyngitis*

TABLETS

Adults and adolescents. 500 mg daily for 10 days.

➤ *To treat community-acquired pneumonia caused by Legionella pneumophila, Mycoplasma pneumoniae, or S. pneumoniae*

TABLETS

Adults and adolescents. 500 mg daily for 14 days.

Mechanism of Action

Binds with the 50S ribosomal subunit of the 70S ribosome in susceptible bacteria. This action inhibits RNA-dependent protein synthesis in bacterial cells, causing them to die.

Contraindications

Concurrent use of astemizole, cisapride, or pimozide; hypersensitivity to dirithromycin, erythromycin, other macrolide antibiotics, or their components; known, potential, or suspected bacteremia

Interactions

DRUGS

antacids, H₂-receptor antagonists: Increased dirithromycin absorption
astemizol, terfenadine: Possibly life-threatening arrhythmias
theophylline: Possibly increased serum theophylline level

Adverse Reactions**CNS:** Dizziness, headache, weakness**GI:** Abdominal pain, diarrhea, nausea, pseudomembranous colitis, vomiting**SKIN:** Pruritus, rash, urticaria**Nursing Considerations**

- Use dirithromycin cautiously in patients with impaired hepatic function. Monitor liver function test results as indicated because drug is metabolized in liver.

PATIENTTEACHING

- Instruct patient to take dirithromycin at the same time each day with food or within 1 hour of eating.
- Caution patient not to cut, chew, or crush tablets.
- Advise patient to store drug at room temperature in a dry place.
- Instruct patient to complete the full course of prescribed therapy, even if she feels better before drug is gone.
- Advise patient to notify prescriber immediately if GI problems persist.

disopyramide

Rythmodan (CAN)

disopyramide phosphate

Norpace, Norpace CR, Rythmodan-LA (CAN)

Class and Category*Chemical class:* Substituted pyramide derivative*Therapeutic class:* Class IA antiarrhythmic*Pregnancy category:* C**Indications and Dosages**

↗ *To rapidly control ventricular arrhythmias*

CAPSULES

Adults. *Loading:* 300 mg (200 mg if patient weighs less than 50 kg [110 lb]). If no response within 6 hr, 200 mg given every 6 hr. If no response within 48 hr, drug discontinued or dosage carefully increased to 250 to 300 mg every 6 hr.

↗ *To treat ventricular arrhythmias*

CAPSULES

Adults. 400 to 800 mg daily in divided

doses every 6 hr, limited to 400 mg daily if patient weighs less than 50 kg. *Maximum:* 800 mg daily.

Children ages 12 to 18. 6 to 15 mg/kg daily in divided doses every 6 hr.

Children ages 4 to 12. 10 to 15 mg/kg daily in divided doses every 6 hr.

Children ages 1 to 4. 10 to 20 mg/kg daily in divided doses every 6 hr.

Children under age 1. 10 to 30 mg/kg daily in divided doses every 6 hr.

DOSAGE ADJUSTMENT Initial dosage reduced to 100 mg every 6 to 8 hr for adults with cardiomyopathy or possible cardiac decompensation. In renal insufficiency, dosage reduced to 100 mg every 6 hr if creatinine clearance exceeds 40 ml/min/1.73 m² or hepatic function is impaired; to 100 mg every 8 hr if clearance is 30 to 40 ml/min/1.73 m²; to 100 mg every 12 hr if clearance is 15 to 29 ml/min/1.73 m²; and to 100 mg every 24 hr if clearance is less than 15 ml/min/1.73 m².

E.R. CAPSULES, E.R. TABLETS

Adults. 400 to 800 mg daily in divided doses every 12 hr, limited to 200 mg every 12 hr if patient weighs less than 50 kg. *Maximum:* 800 mg daily.

Mechanism of Action

Inhibits sodium influx through fast channels of myocardial cell membranes, thus increasing recovery period after repolarization. Disopyramide decreases automaticity in the His-Purkinje system and conduction velocity in atria, ventricles, and accessory pathways. It prolongs QRS and QT intervals in normal sinus rhythm and atrial arrhythmias. Drug has a potent negative inotropic effect. It also acts as an anticholinergic and increases peripheral vascular resistance.

Contraindications

Cardiogenic shock, congenital QT-interval prolongation, hypersensitivity to disopyramide or its components, second- or third-degree AV block (without pacemaker), sick sinus syndrome

Interactions**DRUGS**

antiarrhythmics: Widened QRS complex, prolonged QT interval, risk of arrhythmias, serious negative inotropic effects

anticholinergics: Possibly additive anti-

cholinergic effects

cisapride: Possibly increased risk of prolonged QT interval

clarithromycin, erythromycin: Increased blood disopyramide level

digoxin: Increased serum digoxin level

hydantoin, rifampin: Decreased blood disopyramide level

insulin, oral antidiabetic drugs: Possibly intensified antidiabetic effects

quinidine: Increased blood disopyramide level, decreased quinidine level, or both

verapamil: Widened QRS complex, prolonged QT interval, possibly death

Adverse Reactions

CNS: Depression, dizziness, fatigue, fever, headache, insomnia, nervousness, syncope

CV: Chest pain; conduction disturbances; edema; heart failure (new or worsened); hypercholesterolemia; hypertriglyceridemia; hypotension; palpitations; proarrhythmias, including torsades de pointes; ventricular fibrillation; ventricular tachycardia

EENT: Blurred vision; dry eyes, mouth, nose, and throat

ENDO: Gynecomastia, hypoglycemia

GI: Abdominal distention, anorexia, constipation, diarrhea, vomiting

GU: Impotence, urinary frequency and urgency, urine retention

HEME: Reversible agranulocytosis (rare), thrombocytopenia

MS: Muscle weakness

RESP: Dyspnea

SKIN: Decreased sweating, pruritus, rash, reversible cholestatic jaundice

Other: Hypokalemia, lupus erythematosus-like symptoms

Nursing Considerations

WARNING Because of disopyramide's anticholinergic activity, avoid using drug in patients with glaucoma, myasthenia gravis, or urine retention.

- Use disopyramide cautiously and expect to reduce dosage in patients with impaired hepatic or renal function. Monitor hepatic and renal function, as ordered. Be aware that E.R. form shouldn't be given to patients with severe renal insufficiency.
- When changing from immediate-release to E.R. form, expect to start maintenance schedule 6 hours after last immediate-release dose.

- At therapeutic doses in hemodynamically uncompromised patients, expect drug to reduce cardiac output without decreasing resting sinus rate or affecting blood pressure. Keep in mind, however, that 2 mg/kg given I.V. over 3 minutes can increase heart rate and total peripheral resistance.
- Monitor heart rate and rhythm by continuous ECG.
- Assess serum electrolyte levels, especially potassium level, because drug may be ineffective in hypokalemia and its toxic effects enhanced in hyperkalemia.
- If patient takes quinidine, expect to start disopyramide 6 to 12 hours after last dose of quinidine. If patient takes procainamide, expect to start disopyramide 3 to 6 hours after the last dose of procainamide. A loading dose may not be required in either case.

PATIENT TEACHING

- Warn patient not to stop taking disopyramide abruptly; doing so may cause life-threatening cardiac problems.
- Advise patient to take a missed dose as soon as possible after she remembers, unless it's nearly time for the next dose. Caution her against doubling the dose. Urge her to notify prescriber if she misses more than one dose.
- Instruct patient to store drug at room temperature in a dry place.
- Instruct patient to check her pulse rate regularly and report significant changes.
- Urge patient to report blurred vision, constipation, difficulty urinating, dizziness, dry mouth, and trouble breathing.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to rise slowly from a lying or sitting position to reduce dizziness.
- Urge patient to avoid becoming overheated during hot weather or exercise because of risk of heatstroke.

disulfiram

Antabuse

Class and Category

Chemical class: Thiuram derivative

Therapeutic class: Alcohol abuse deterrent

Pregnancy category: Not rated

Indications and Dosages

↗ *As adjunct to maintain sobriety in treatment of chronic alcoholism*

TABLETS

Adults. *Initial:* Up to 500 mg daily for 1 to 2 wk. *Maintenance:* 125 to 500 mg daily. *Maximum:* 500 mg daily.

Route	Onset	Peak	Duration
P.O.	1–2 hr	Unknown	Up to 14 days

Mechanism of Action

Interferes with the enzyme responsible for hepatic oxidation of acetaldehyde to acetate, which occurs during alcohol catabolism. Ingestion of even a small amount of alcohol after taking disulfiram raises the blood acetaldehyde level to 5 to 10 times normal. Disulfiram doesn't alter the rate of alcohol elimination. Its major metabolite, diethyldithiocarbamate, inhibits norepinephrine synthesis and may be responsible for the drug's hypotensive effect.

Contraindications

Alcohol intoxication; coronary artery occlusion; hypersensitivity to disulfiram, its components, rubber, pesticides, or fungicides; psychosis; recent use of alcohol, alcohol-containing preparations, metronidazole, or paraldehyde; severe myocardial disease

Interactions

DRUGS

alfentanil: Decreased plasma clearance and prolonged duration of action of alfentanil
amoxicillin-clavulanate, bacampicillin: Possibly disulfiram-alcohol reaction
ascorbic acid: Possibly interference with disulfiram-alcohol reaction
CNS depressants: Possibly increased CNS depressant effects of either drug
isoniazid: Increased risk of additive neurotoxic effect of disulfiram; possibly increased adverse CNS effects
metronidazole: Risk of CNS toxicity, resulting in confusion and psychosis
oral anticoagulants: Possibly increased anticoagulant effects
paraldehyde: Decreased paraldehyde metabolism, increased blood paraldehyde level
phenytoin: Possibly increased blood phenytoin level and risk of phenytoin toxicity
tricyclic antidepressants: Possibly temporary delirium

FOODS

caffeine: Possibly increased cardiovascular and CNS effects of caffeine

ACTIVITIES

alcohol use: Disulfiram-alcohol reaction (if within 14 days of disulfiram therapy)

Adverse Reactions

CNS: Drowsiness, headache, peripheral neuropathy, psychotic reaction, tiredness
EENT: Blurred vision, garlic or metallic taste, optic atrophy, optic neuritis
GU: Impotence
SKIN: Rash

Nursing Considerations

- Disulfiram is given only to patients who are highly motivated to stop drinking and who are receiving psychotherapy or substance abuse counseling.
- Alcohol content of patient's other drugs should be checked before starting therapy.

WARNING Never give drug to patient without her knowledge or who is intoxicated.

- If needed, crush tablet and mix with fluids before administration.
- Don't give drug within 14 days of patient's ingestion of alcohol-containing substance.
- Expect alcohol ingestion during disulfiram therapy to produce a severe reaction that lasts from 30 minutes to several hours. Symptoms may include angina, anxiety, blurred vision, confusion, diaphoresis, dyspnea, heart failure, hypotension, nausea, palpitations, sinus tachycardia, syncope, thirst, throbbing headache, throbbing in neck, vertigo, vomiting, and weakness. A deep sleep usually follows.

WARNING Ingestion of three or more alcoholic beverages with a disulfiram dose greater than 500 mg daily may cause respiratory depression, arrhythmias, and cardiac arrest.

- If patient takes phenytoin, monitor blood phenytoin level before and during disulfiram therapy, and adjust dosage of either drug as prescribed. Interactions may not occur if disulfiram therapy starts before phenytoin therapy. A subtherapeutic phenytoin level may result if disulfiram therapy stops.
- If patient takes an oral anticoagulant, monitor PT before and during disulfiram therapy, and adjust anticoagulant dosage as prescribed. Drug interactions may not

occur if disulfiram therapy starts before warfarin therapy. If disulfiram therapy stops, be prepared to adjust warfarin dosage to avoid loss of hypoprothrombinemic effects.

- Expect some adverse reactions, such as drowsiness, headache, and impotence, to subside over time or with a brief dosage reduction.
- Because one-fifth of a disulfiram dose may stay in the body for 1 week or longer, alcohol ingestion may continue to produce unpleasant symptoms for up to 2 weeks after therapy stops.
- Expect therapy to last months to years, depending on patient's ability to abstain from alcohol.

PATIENT TEACHING

- Teach patient's household and family members about precautions needed and risks associated with disulfiram therapy.
- Explain that drug doesn't cure alcoholism but does help deter alcohol consumption.
- If patient reports daytime drowsiness, advise her to take drug in the evening.
- Warn patient to avoid alcohol-containing substances, such as vinegar, cough syrup, and sauces, during therapy because a disulfiram-alcohol reaction may occur after ingesting as little as 15 ml of 100-proof alcohol. Urge her to avoid alcohol-containing liniments and lotions as well.
- Teach patient what to expect if disulfiram-alcohol reaction occurs. Inform her that a deep sleep usually follows the reaction.
- Advise patient that a reaction can occur up to 14 days after therapy stops and that a severe reaction may cause respiratory depression, arrhythmias, and cardiac arrest.
- Instruct patient to carry medical identification that indicates drug, describes possible reactions, and lists someone to notify in case of emergency.

dobutamine hydrochloride

Dobutrex

Class and Category

Chemical class: Synthetic catecholamine

Therapeutic class: Cardiac stimulant

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat low cardiac output and heart failure*

I.V. INFUSION

Adults. 2.5 to 10 mcg/kg/min as continuous infusion adjusted according to hemodynamic response.

Children. 5 to 20 mcg/kg/min as continuous infusion adjusted according to hemodynamic response.

Route	Onset	Peak	Duration
I.V.	1–2 min	Unknown	Under 5 min

Mechanism of Action

Mainly stimulates beta₁-adrenergic receptors, and mildly stimulates beta₂- and alpha₁-adrenergic receptors. Beta₁-receptor stimulation produces a positive inotropic effect on the myocardium, increasing cardiac output by boosting myocardial contractility and stroke volume. Increased myocardial contractility raises coronary blood flow and myocardial oxygen consumption. Systolic blood pressure typically rises as a result of increased stroke volume. Other hemodynamic effects include decreased systemic vascular resistance, which reduces afterload, and decreased ventricular filling pressure, which reduces preload.

Incompatibilities

Don't combine dobutamine with cefamandole, cefazolin, hydrocortisone sodium succinate, cephalothin, penicillin, sodium ethacrylate, and sodium heparin because of incompatibility. Don't mix dobutamine with alkaline solutions, such as sodium bicarbonate, because of possible physical incompatibility. Don't use diluents that contain sodium bisulfite or ethanol.

Contraindications

Hypersensitivity to dobutamine or its components, idiopathic hypertrophic subaortic stenosis

Interactions

DRUGS

beta blockers: Possibly increased alpha-adrenergic activity and peripheral resistance
bretylum: Potentiated vasopressor activity, possibly arrhythmias

cyclopropane, halothane: Possibly serious arrhythmias

guanethidine: Decreased hypotensive effect of guanethidine, possibly resulting in severe hypertension

thyroid hormones: Increased cardiovascular effects of thyroid hormones or dobutamine

tricyclic antidepressants: Possibly potentiated cardiovascular and vasopressor effects of dobutamine, resulting in arrhythmias, hyperpyrexia, or severe hypertension

Adverse Reactions

CNS: Fever, headache, nervousness, restlessness

CV: Angina, bradycardia, hypertension, hypotension, palpitations, PVCs, tachycardia

GI: Nausea, vomiting

RESP: Dyspnea

SKIN: Extravasation with tissue necrosis and sloughing, rash

Other: Hypokalemia

Nursing Considerations

- Avoid giving dobutamine to patients with uncorrected hypovolemia. Expect prescriber to order whole blood or plasma volume expanders to correct hypovolemia. Also avoid giving dobutamine to patients with acute MI because it can intensify or extend myocardial ischemia.
- Use drug cautiously in patients allergic to sulfites because drug may cause anaphylactic-like signs and symptoms; commercially available dobutamine injections contain sodium bisulfite. Also use drug cautiously in patients with atrial fibrillation because drug increases AV conduction. Keep in mind that patient should be adequately digitalized before administration.
- Dilute concentrate with at least 50 ml compatible I.V. solution. A common dilution is 500 mg (40 ml from 250-ml bag) in 210 ml D₅W or normal saline solution to yield 2,000 mcg/ml. Or dilute 1,000 mg (80 ml from 250-ml bag) in 170 ml D₅W or normal saline solution to yield 4,000 mcg/ml. Adjust maximum concentration according to patient's fluid requirements as prescribed. Don't exceed 5,000 mcg/ml. Discard solution after 24 hours.
- Inspect parenteral solution for particles and discoloration before administering it.
- Give I.V. drug using an infusion pump.
- Monitor blood pressure often during therapy,

preferably by continuous intraarterial monitoring; systolic increase of 10 to 20 mm Hg may indicate dobutamine-induced increase in cardiac output.

- If hypotension develops, expect to reduce dosage or discontinue drug.
 - Monitor heart rate and rhythm continuously for PVCs, which may result from drug's stimulatory effect on heart's conduction system, and sinus tachycardia, which results from positive chronotropic effect of beta stimulation and may increase heart rate by 5 to 15 beats/minute.
 - Monitor hemodynamic parameters, such as central venous pressure, pulmonary artery wedge pressure, and cardiac output, as indicated, to assess drug's effectiveness.
- WARNING** Monitor serum potassium level to check for hypokalemia, a rare result of beta₂ stimulation that causes electrolyte imbalance.
- Monitor urine output hourly, as appropriate, to check for improved renal blood flow.
 - Dobutamine isn't indicated for long-term treatment of heart failure because it may not be effective and may increase the risk of hospitalization and death.

PATIENT TEACHING

- Explain the need for frequent hemodynamic monitoring.

docusate calcium (dioctyl calcium sulfosuccinate)

Albert Docusate (CAN), DC Softgels, Docucal-P, Doxidan (CAN), Pro-Cal-Sof, Sulfolax, Surfak

docusate potassium (dioctyl potassium sulfosuccinate)

Diocto-K, Kasof

docusate sodium (dioctyl sodium sulfosuccinate)

Afko-Lube, Afko-Lube Lax, Bilax, Colace, Colax, Correctol Stool Softener Soft Gels, Dialose, Diocto, Dioeze,

DOK, D.O.S. Softgels, Ex-Lax Light Formula (CAN), Modane Soft, Regulax SS, Silace

Class and Category

Chemical class: Anionic surfactant

Therapeutic class: Laxative, stool softener

Pregnancy category: C

Indications and Dosages

➤ *To treat constipation*

CAPSULES (DOCUSATE CALCIUM)

Adults and adolescents. 240 mg at bedtime until bowel movements are normal.

Children age 6 and over. 50 to 150 mg at bedtime.

CAPSULES, LIQUID, SYRUP, TABLETS (DOCUSATE SODIUM)

Adults and adolescents. 50 to 500 mg at bedtime.

Children ages 6 to 12. 40 to 120 mg at bedtime.

Children ages 3 to 6. 20 to 60 mg at bedtime.

Children under age 3. 10 to 40 mg at bedtime.

CAPSULES, TABLETS (DOCUSATE POTASSIUM)

Adults and adolescents. 100 mg t.i.d. until bowel movements are normal.

Children age 6 and over. 100 mg at bedtime.

Route	Onset	Peak	Duration
P.O.	24–72 hr	Unknown	Unknown

Mechanism of Action

Acts as a surfactant that softens stool by decreasing surface tension between oil and water in feces. This action lets more fluid penetrate stool, forming a softer fecal mass.

Contraindications

Fecal impaction; hypersensitivity to docusate salts or their components; intestinal obstruction; nausea, vomiting, or other symptoms of appendicitis; undiagnosed abdominal pain

Interactions

DRUGS

mineral oil: Increased mineral oil absorption, increased risk of toxicity

tetracycline: Decreased tetracycline absorption

Adverse Reactions

CNS: Dizziness, syncope

CV: Palpitations

GI: Abdominal cramps and distention, diarrhea, nausea, perianal irritation, vomiting

MS: Muscle weakness

Nursing Considerations

WARNING Expect long-term or excessive use of docusate to cause dependence on laxatives for bowel movements, electrolyte imbalances, osteomalacia, steatorrhea, and vitamin and mineral deficiencies.

- Assess for laxative abuse syndrome, especially in women with depression, personality disorders, or anorexia nervosa.

PATIENT TEACHING

- Tell patient not to use docusate when she has abdominal pain, nausea, or vomiting.
- Advise patient to take docusate with a full glass of water or milk.
- To help prevent constipation, encourage patient to increase fiber intake, exercise regularly, and drink 6 to 8 glasses (240 ml/glass) of water daily.
- Instruct patient to notify prescriber about rectal bleeding; symptoms of electrolyte imbalances, such as dizziness, light-headedness, muscle cramping, and weakness; and unrelieved constipation.

dofetilide

Tikosyn

Class and Category

Chemical class: Methanesulfonanilide derivative

Therapeutic class: Class III antiarrhythmic

Pregnancy category: C

Indications and Dosages

➤ *To convert symptomatic atrial fibrillation or flutter to normal sinus rhythm or to maintain normal sinus rhythm in patients converted from symptomatic atrial fibrillation or flutter*

CAPSULES

Adults. *Initial:* 500 mcg b.i.d. for patients with creatinine clearance above 60 ml/min/1.73 m². *Maintenance:* Dosage based on QTc interval. If, 2 to 3 hr after initial dose, QTc interval increase is 15% of baseline or less, initial dose given b.i.d. *Maximum:* 500 mcg b.i.d.

DOSAGE ADJUSTMENT Initial dose reduced to 250 mcg b.i.d. if creatinine clearance is 40 to 60 ml/min/1.73 m² and to 125 mcg b.i.d. if clearance is 20 to 39 ml/min/1.73 m², as prescribed. If, 2 to 3 hr after initial dose, QTc interval has increased by at least 15% or is more than 500 milliseconds (msec) (550 msec in patients with ventricular conduction abnormalities), dosage decreased by 50%, as prescribed. However, for patients receiving lowest initial dose of 125 mcg b.i.d., dosage reduced to 125 mcg daily, as prescribed. During next four doses (given every 2 to 3 hr, as prescribed), if QTc interval increases to more than 500 msec (550 msec in patients with ventricular conduction abnormalities), expect to discontinue drug, as prescribed.

Route	Onset	Peak	Duration
P.O.	Unknown	2 hr	4 hr

Mechanism of Action

Selectively blocks potassium channels in myocardial cell membranes involved in cardiac repolarization. By blocking potassium channels, dofetilide prolongs ventricular refractoriness (widens QT interval), effective refractory period, and action potential duration. These actions terminate or prevent reentrant tachyarrhythmias, such as atrial fibrillation, atrial flutter, and ventricular tachycardia.

Contraindications

Cardiac conduction disturbances without an artificial pacemaker; congenital or acquired QT prolongation syndrome; concurrent therapy with cimetidine, hydrochlorothiazide, ketoconazole, trimethoprim, or verapamil; hypersensitivity to dofetilide or its components; severe renal impairment (creatinine clearance less than 20 ml/min/1.73 m²)

Interactions

DRUGS

amiloride, cimetidine, co-trimoxazole, ketoconazole, megestrol, metformin, triam-terene, trimethoprim: Possibly increased blood dofetilide level

azole antifungals, diltiazem, nefazodone, norfloxacin, protease inhibitors, quinine, selective serotonin reuptake inhibitors, zafirlukast: Possibly increased blood dofetilide level and

risk of dofetilide toxicity
bepidil, cisapride, macrolide antibiotics, phenothiazines, tricyclic antidepressants: Possibly prolonged QT interval
class I and III antiarrhythmics, especially amiodarone: Possibly prolonged QT interval and increased risk of dofetilide-induced proarrhythmias
diuretics (potassium-depleting): Increased risk of torsades de pointes in patients with hypokalemia or hypomagnesemia
hydrochlorothiazide, verapamil: Possibly increased blood dofetilide level and increased risk of torsades de pointes

FOODS

grapefruit juice: Increased dofetilide level

ACTIVITIES

marijuana use: Increased dofetilide level

Adverse Reactions

CNS: Cerebral ischemia, dizziness, facial or flaccid paralysis, headache, insomnia, paresthesia, slurred speech, stroke, syncope

CV: AV block, bradycardia, cardiac arrest, chest pain, edema, MI, tachycardia, ventricular arrhythmias (including torsades de pointes and ventricular tachycardia)

GI: Abdominal pain, diarrhea, hepatic dysfunction, nausea

MS: Back pain, muscle weakness

RESP: Cough, dyspnea, respiratory tract infection

SKIN: Jaundice, rash

Other: Angioedema, flulike symptoms, weight gain

Nursing Considerations

WARNING If patient has previously received amiodarone, be aware that dofetilide shouldn't be started until blood amiodarone level is less than 0.3 mcg/ml or until amiodarone has been withdrawn for at least 3 months.

- Evaluate and document QTc interval before and during dofetilide therapy.
- Place patient on continuous ECG monitoring for at least 3 days, as ordered, during dofetilide therapy.

WARNING If patient does not convert to normal sinus rhythm within 24 hours of starting dofetilide, expect possible synchronized electrical cardioversion.

- Be prepared to reevaluate renal function and QTc interval every 3 months, as ordered, during dofetilide therapy.

- When switching to dofetilide from class I or class III antiarrhythmics, or after withdrawing antiarrhythmic treatment, monitor continuous ECG for at least 30 hours, as ordered.
- If patient requires a drug that may interact with dofetilide, expect to discontinue dofetilide, as prescribed, for 2 or more days before starting the other drug.

WARNING Monitor laboratory test results for hypokalemia or hypomagnesemia, especially in patients taking diuretics, because of the increased risk of dofetilide-induced torsades de pointes.

- Monitor women often for adverse reactions, including prolonged QTc interval and torsades de pointes; they have 12% to 18% lower renal clearance of drug than men and therefore a greater risk of adverse reactions.

PATIENT TEACHING

- Advise patient to swallow dofetilide capsules with water.
- Instruct patient to avoid drinking grapefruit juice while taking this drug.
- Inform patient that she may be hospitalized for at least 3 days if dofetilide dosage is increased.
- Teach patient to measure pulse rate and blood pressure during dofetilide therapy.
- Urge patient to report chest discomfort, fluttering, or palpitations immediately.
- Advise patient to consult prescriber before using any OTC drugs, nutritional supplements, or herbal products.
- Instruct patient to keep follow-up appointments to monitor heart rhythm.

dolasetron mesylate

Anzemet

Class and Category

Chemical class: Carboxylate monomethanesulfonate

Therapeutic class: Antiemetic

Pregnancy category: B

Indications and Dosages

➤ *To prevent nausea and vomiting due to chemotherapy*

ORAL SOLUTION, TABLETS

Adults and children over age 16. 100 mg within 1 hr before chemotherapy.

Children ages 2 to 16. 1.8 mg/kg within 1 hr before chemotherapy. *Maximum:* 100 mg.

I.V. INJECTION

Adults and children over age 16. 1.8 mg/kg or 100 mg as a single dose within 30 min before chemotherapy.

Children ages 2 to 16. 1.8 mg/kg as a single dose within 30 min before chemotherapy. *Maximum:* 100 mg.

➤ *To prevent postoperative nausea and vomiting*

ORAL SOLUTION, TABLETS

Adults and children over age 16. 100 mg within 2 hr before surgery.

Children ages 2 to 16. 1.2 mg/kg within 2 hr before surgery. *Maximum:* 100 mg.

I.V. INJECTION

Adults and children over age 16. 12.5 mg 15 min before end of anesthesia.

Children ages 2 to 16. 0.35 mg/kg 15 min before end of anesthesia. *Maximum:* 12.5 mg/dose.

➤ *To treat postoperative nausea and vomiting*

I.V. INJECTION

Adults and children over age 16. 12.5 mg as single dose as soon as symptoms develop.

Children ages 2 to 16. 0.35 mg/kg as single dose as soon as symptoms develop. *Maximum:* 12.5 mg/dose.

Mechanism of Action

With its active metabolite hydrodolasetron, prevents activation of serotonin 5-HT₃ receptors located peripherally on vagal nerve terminals and centrally in chemoreceptor trigger zone, thereby decreasing the vomiting reflex.

Contraindications

Hypersensitivity to dolasetron or components

Interactions

DRUGS

atenolol: Possibly decreased dolasetron clearance

cimetidine: Possibly increased blood dolasetron level

rifampin: Possibly decreased blood dolasetron level

Adverse Reactions

CNS: Headache

CV: Cardiac arrest, hypertension, hypotension, MI, ventricular fibrillation and tachy-

cardia, wide-complex tachycardia

GI: Diarrhea

SKIN: Rash

Other: Injection site pain

Nursing Considerations

- Expect to give up to 100 mg of donepezil I.V. in 30 seconds or to dilute it in normal saline solution, D₅W, dextrose 5% in half-normal (0.45) saline solution, or lactated Ringer's solution and infuse for up to 15 minutes, as prescribed.
- Flush I.V. line with compatible solution before and after drug administration.
- Expect to prepare an oral solution of donepezil for patients unable to swallow tablets by diluting injection solution with apple or apple-grape juice.

WARNING Assess patient for ECG changes, including prolonged PR, QTc, and QT intervals and widened QRS complex.

PATIENT TEACHING

- For children or patients who have trouble swallowing, explain that oral solution can be prepared by diluting injection form of drug with apple or apple-grape juice.
- Inform patient that oral solution may be refrigerated for up to 48 hours but should be discarded after 2 hours at room temperature.

donepezil hydrochloride

Aricept

Class and Category

Chemical class: Piperidine derivative

Therapeutic class: Antidementia

Pregnancy category: C

Indications and Dosages

➤ To treat dementia of Alzheimer's type

ORAL SOLUTION, TABLETS

Adults. *Initial:* 5 mg at bedtime. After 4 to 6 wk, dosage increased to 10 mg at bedtime, as indicated. *Maximum:* 10 mg daily.

Mechanism of Action

Reversibly inhibits acetylcholinesterase and improves acetylcholine's concentration at cholinergic synapses. Raising acetylcholine level in the cerebral cortex may improve cognition. Donepezil becomes less effective

as Alzheimer's disease progresses and number of intact cholinergic neurons declines.

Contraindications

Hypersensitivity to donepezil, piperidine derivatives, or their components

Interactions

DRUGS

anticholinergics: Possibly interference with activity of these drugs
carbamazepine, dexamethasone, phenobarbital, phenytoin, rifampin: Increased donepezil elimination rate
cholinergic agonists, neuromuscular blockers: Possibly synergistic effects of these drugs
ketoconazole, quinidine: Inhibited donepezil metabolism
NSAIDs: Possibly increased gastric acid secretion and increased risk of GI bleeding

Adverse Reactions

CNS: Abnormal gait, agitation, anxiety, asthenia, depression, dizziness, dream disturbances, fatigue, fever, headache, hostility, insomnia, nervousness, seizures, somnolence, syncope, tremor
CV: Abnormal ECG, bradycardia, chest pain, edema, heart failure, hypertension, hypotension
EENT: Pharyngitis
ENDO: Hyperglycemia
GI: Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, gastroenteritis, fecal incontinence, nausea, vomiting
GU: Cystitis, glycosuria, hematuria, urinary frequency or incontinence, UTI
HEME: Anemia, hemorrhage
MS: Arthralgia, back pain, elevated creatine kinase level, muscle spasms
RESP: Bronchitis, increased cough, pneumonia
SKIN: Ecchymosis, eczema, pruritus, rash, ulceration
Other: Angioedema, dehydration, elevated alkaline phosphatase or lactate dehydrogenase level, flu syndrome, weight loss

Nursing Considerations

- Use donepezil cautiously in patients with bladder obstruction because drug's weak peripheral cholinergic effect could obstruct outflow.
- Use drug cautiously in patients with asthma, COPD, or other pulmonary disorders because it has weak affinity for peripheral

cholinesterase, which may increase bronchoconstriction and bronchial secretions.

- If patient has cardiac disease, monitor heart rate and rhythm for bradycardia, which may result from increased vagal tone caused by drug's inhibition of peripheral cholinesterase. Reduced heart rate may be especially significant if patient has sick sinus syndrome, bradycardia, or other supraventricular arrhythmia.
- Take safety precautions if patient is dizzy or has other adverse CNS reactions.

PATIENT TEACHING

- Advise patient to take donepezil just before going to bed.
- Inform her that drug may be taken with or without food.
- Instruct patient to avoid hazardous activities, such as driving, until drug's CNS effects are known. Urge her to take safety precautions to prevent falling if she has adverse reactions, such as dizziness.
- If patient has a history of peptic ulcer disease or gastric irritation, explain that drug may aggravate these conditions by increasing gastric acid secretion.
- Caution patient to avoid NSAIDs during therapy because of risk of GI bleeding. Urge her to notify prescriber immediately if she notices black, tarry stools.

dopamine hydrochloride

Intropin, Revimine (CAN)

Class and Category

Chemical class: Catecholamine

Therapeutic class: Cardiac stimulant, vasopressor

Pregnancy category: C

Indications and Dosages

➤ *To correct hypotension that's unresponsive to adequate fluid volume replacement or occurs as part of shock syndrome caused by bacteremia, chronic cardiac decompensation, drug overdose, MI, open-heart surgery, renal failure, trauma, or other major systemic illnesses; to improve low cardiac output*

I.V. INFUSION

Adults. 0.5 to 3 mcg/kg/min for vasodila-

tion of renal arteries; 2 to 10 mcg/kg/min for positive inotropic effects and increased cardiac output; 10 mcg/kg/min, increased gradually according to patient's response, for increased systolic and diastolic blood pressures.

DOSE ADJUSTMENT Initial dosage reduced to 10% of usual amount if patient has taken MAO inhibitor in previous 2 to 3 wk.

Children. 1 to 5 mcg/kg/min increased gradually in increments of 2.5 to 5 mcg/kg/min to achieve desired results.

Maximum: 20 mcg/kg/min.

Route	Onset	Peak	Duration
I.V.	In 5 min	Unknown	Up to 10 min

Mechanism of Action

Stimulates dopamine₁ (D₁) and dopamine₂ (D₂) postsynaptic receptors. D₁ receptors mediate vasodilation in renal, mesenteric, coronary, and cerebral blood vessels. D₂ receptors inhibit norepinephrine release. In higher doses, dopamine also stimulates alpha₁ and alpha₂ receptors, causing vascular smooth-muscle contraction.

At doses of 0.5 to 3 mcg/kg/min, this naturally occurring catecholamine mainly affects dopaminergic receptors in renal, mesenteric, coronary, and cerebral vessels, resulting in vasodilation, increased renal blood flow, improved GFR, and increased urine output. At doses of 2 to 10 mcg/kg/min, dopamine stimulates beta₁-adrenergic receptors, increasing cardiac output while maintaining dopaminergic-induced vasodilation. At doses of 10 mcg/kg/min or more, alpha-adrenergic agonism takes over, causing increased peripheral vascular resistance and renal vasoconstriction.

Incompatibilities

Don't add dopamine to 5% sodium bicarbonate, alkaline I.V. solutions, oxidizing agents, or iron salts.

Contraindications

Pheochromocytoma, uncorrected ventricular fibrillation, ventricular tachycardia, and other tachyarrhythmias

Interactions

DRUGS

alpha blockers, haloperidol, loxapine, phenothiazines, thioxanthenes: Antagonized

peripheral vasoconstriction with high doses of dopamine

anesthetics, such as chloroform, enflurane, halothane, isoflurane, and methoxyflurane:

Increased risk of severe atrial and ventricular arrhythmias

antihypertensives, diuretics used as antihypertensives: Possibly decreased antihypertensive effects of these drugs

beta blockers: Antagonized beta receptor-mediated inotropic effects of dopamine

digitalis glycosides: Possibly increased risk of arrhythmias and additive inotropic effects

diuretics: Possibly increased diuretic effects of dopamine or diuretic

doxapram: Possibly increased vasopressor effects of dopamine or doxapram

ergot alkaloids: Enhanced peripheral vasoconstriction

guanadrel, guanethidine: Possibly decreased hypotensive effects of these drugs and

potentiated vasopressor response to dopamine, resulting in hypertension and

arrhythmias

levodopa: Increased risk of arrhythmias

MAO inhibitors: Prolonged and intensified cardiac stimulation and vasopressor effect

maprotiline, tricyclic antidepressants:

Possibly potentiated cardiovascular and vasopressor effects of dopamine, resulting in arrhythmias, hyperpyrexia, or severe hypertension

mecamylamine, methyl dopa: Possibly decreased hypotensive effects of these drugs and enhanced vasopressor effect of

dopamine

methylphenidate: Possibly potentiated vasopressor effect of dopamine

nitrates: Possibly decreased antianginal effects of nitrates; possibly decreased vasopressor effect of dopamine, resulting in

hypotension

oxytocic drugs: Possibly severe hypertension

phenoxybenzamine: Possibly antagonized peripheral vasoconstriction of dopamine, causing hypotension and tachycardia

phenytoin: Possibly sudden bradycardia and hypotension

rauwolfia alkaloids: Possibly decreased hypotensive effects of these drugs

sympathomimetics: Possibly increased adverse cardiovascular and other effects

thyroid hormones: Increased risk of coronary insufficiency

Adverse Reactions

CNS: Headache

CV: Angina, bradycardia, hypertension, hypotension, palpitations, peripheral vasoconstriction, sinus tachycardia, ventricular arrhythmias

GI: Nausea, vomiting

RESP: Dyspnea

SKIN: Extravasation with tissue necrosis

Nursing Considerations

- If possible, avoid giving dopamine to patients with occlusive vascular disease, such as atherosclerosis, Buerger's disease, diabetic endarteritis, or Raynaud's disease, because of risk of decreased peripheral circulation.
- Use drug cautiously in patients with cardiac disease, particularly coronary artery disease, because dopamine increases myocardial oxygen demand. Also use drug cautiously in patients allergic to sulfites, which are contained in some forms of dopamine.
- Inspect parenteral solution for particles and discoloration before administration.
- Dilute dopamine concentrate with a compatible I.V. solution before administering. Typical dilution is 400 mg in 250 ml to yield 1.6 mg/ml. Don't exceed 3.2 mg/ml.
- If patient has hypovolemia, ensure adequate fluid resuscitation before giving drug.
- Give drug by I.V. infusion using an infusion pump.

WARNING When infusion rate exceeds 20 mcg/kg/min, monitor patient for excessive vasoconstriction and loss of renal vasodilating effects. Avoid using an infusion rate above 50 mcg/kg/min.

- If you must infuse more than 20 mcg/kg/min of dopamine to maintain blood pressure, expect to infuse norepinephrine as prescribed.
- To avoid extravasation and tissue necrosis, administer infusion through a central catheter. If you must give drug via peripheral line, inspect site often for signs of extravasation and necrosis. If you detect such signs, start a new I.V. line for dopamine infusion, discontinue previous I.V. line, and notify prescriber immediately.
- If drug extravasates, expect to give 5 to 10 mg phentolamine diluted in 10 to 15 ml

normal saline solution, as prescribed. Phentolamine infiltrates directly into area to antagonize vasoconstriction and minimize sloughing and tissue necrosis.

- Titrate dopamine gradually to minimize hypotension, especially after a high infusion rate.
- Monitor blood pressure continuously with an intra-arterial line, as indicated.
- Place patient on continuous ECG monitoring, and assess heart rate and rhythm for arrhythmias.
- Monitor patient's hemodynamic parameters, such as central venous pressure, pulmonary artery wedge pressure, and cardiac output, as indicated, to assess effectiveness of dopamine therapy.
- Monitor urine output hourly as appropriate to assess patient for improved renal blood flow.

PATIENT TEACHING

- Explain the need for frequent hemodynamic monitoring.

doripenem

Doribax

Class and Category

Chemical class: Carbapenem

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat complicated intra-abdominal infections caused by Escherichia coli, Klebsiella pneumoniae, Pseudomonas aeruginosa, Bacteroides caccae, B. fragilis, B. thetaiotaomicron, B. uniformis, B. vulgatus, Streptococcus intermedius, S. constellatus, and Peptostreptococcus micros and complicated UTIs, including pyelonephritis caused by E. coli, K. pneumoniae, Proteus mirabilis, P. aeruginosa, and Acinetobacter baumannii*

I.V. INFUSION

Adults. 500 mg infused over 1 hr every 8 hr for 5 to 14 days. May switch to oral therapy if improvement after 3 days.

DOSAGE ADJUSTMENT For patients with impaired renal function or creatinine clearance of 30 to 50 ml/min/1.73 m², dosage reduced to 250 mg infused over 1 hr every

8 hr. For creatinine clearance of 10 to 30 ml/min/1.73 m², dosage reduced to 250 mg infused over 1 hr every 12 hr.

Route	Onset	Peak	Duration
I.V.	Unknown	1 hr	8 hr

Mechanism of Action

Inhibits cell wall synthesis in susceptible bacteria. Doripenem inactivates multiple penicillin-binding proteins essential in cell wall synthesis to cause cell death.

Incompatibilities

Don't mix doripenem with other drugs or add to solutions containing other drugs because of potential for incompatibility.

Contraindications

History of anaphylactic reactions to beta-lactams; hypersensitivity to doripenem, its components or other carbapenems

Interactions

DRUGS

divalproex sodium, valproic acid: Decreased effectiveness of valproic acid with possible loss of seizure control

probenecid: Increased plasma concentrations of doripenem

Adverse Reactions

CNS: Headache, seizure

CV: Phlebitis

EENT: Oral candidiasis

GI: Diarrhea, liver enzyme elevation, nausea

GU: Vaginitis

HEME: Leukopenia, neutropenia

SKIN: Dermatitis, erythema, erythema multiforme, macular or papular eruptions, pruritus, rash, Stevens Johnson Syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis

Nursing Considerations

- Use cautiously in patients with a history of hypersensitivity to cephalosporins or penicillins because cross sensitivity may occur.
- Constitute vial with 10 ml sterile water for injection or normal saline solution, and gently shake to form a suspension. Withdraw suspension using a syringe with a 21G needle and add it to an infusion bag containing 100 ml normal saline solution or 5% dextrose. Gently shake until clear. If administering reduced dosage of 250 mg,

remove 55 ml of prepared solution from infusion bag and discard before infusion.

- Be aware that upon constitution, suspension in the vial must be diluted within 1 hour. Once drug is diluted in infusion solution, drug stored at room temperature must be used within 8 hours if mixed in normal saline solution and within 4 hours if mixed in 5% dextrose. If infusion solution is refrigerated, it must be used within 24 hours or discarded.
- Monitor patient closely for evidence of hypersensitivity, especially if patient has multiple allergies, because serious and occasionally fatal hypersensitivity reactions have occurred in patients receiving beta-lactam antibiotics. If an allergic reaction occurs, discontinue drug immediately, notify prescriber, and expect to administer emergency treatment such as epinephrine, oxygen, I.V. fluids, I.V. antihistamines, corticosteroids, and pressor amines, as ordered, and provide airway management.
- Assess patient's bowel pattern daily; severe diarrhea may be caused by *Clostridium difficile*. If suspected, expect to stop drug and provide treatment as prescribed.

PATIENT TEACHING

- Instruct patient to report any evidence of allergic reaction, such as rash, hives, itching or trouble breathing.
- Advise patient to report diarrhea if severe or persistent.

doxapram hydrochloride

Dopram

Class and Category

Chemical class: Pyrrolidinone derivative

Therapeutic class: Respiratory stimulant

Pregnancy category: B

Indications and Dosages

↗ *To stimulate respiration in COPD-related acute respiratory insufficiency*

I.V. INFUSION

Adults and adolescents. 1 to 2 mg/min titrated according to respiratory response. *Maximum:* 3 mg/min for up to 2 hr.

↗ *To treat respiratory depression after anesthesia*

I.V. INFUSION

Adults and adolescents. 5 mg/min until desired response occurs and then reduced to 1 to 3 mg/min. *Maximum:* Cumulative dose of 4 mg/kg or 300 mg.

I.V. INJECTION

Adults and adolescents. 0.5 to 1 mg/kg, repeated every 5 min, if needed. *Maximum:* 1.5 mg/kg as a single dose or 2 mg/kg every 5 min.

Route	Onset	Peak	Duration
I.V.	20–40 sec	1–2 min	5–12 min

Mechanism of Action

Activates peripheral carotid, aortic, and other chemoreceptors to stimulate respiration, resulting in increased tidal volume and respiratory rate. Doxapram also may increase respiratory rate and tidal volume by directly stimulating the respiratory center in the medulla oblongata.

Incompatibilities

To avoid precipitation and gas formation, don't mix doxapram with alkaline solutions, such as aminophylline, sodium bicarbonate, or 2.5% thiopental.

Contraindications

Age less than 1 month; cerebral edema; head injury; hypersensitivity to doxapram or its components; mechanical disorders of ventilation, including acute bronchial asthma, flail chest, muscle paresis, obstruction, pneumothorax, and pulmonary fibrosis; pulmonary embolism; seizure disorder; severe cardiovascular disorder; severe hypertension; stroke; uncompensated heart failure

Interactions

DRUGS

chloroform, cyclopropane, enflurane, halothane, isoflurane, methoxyflurane, trichloroethylene: Possibly adverse myocardial effects if doxapram given within 10 minutes of these drugs

CNS stimulants: Possibly excessive CNS stimulation, with arrhythmias, insomnia, irritability, nervousness, or seizures

MAO inhibitors, sympathomimetics:

Additive vasopressor effects

skeletal muscle relaxants: Masked residual effects of muscle relaxants

Adverse Reactions

CNS: Disorientation, dizziness, headache
CV: Arrhythmias, including sinus tachycardia; hypertension
GI: Diarrhea, hiccups, nausea, vomiting
GU: Urine retention
RESP: Bronchospasm, cough, dyspnea
SKIN: Diaphoresis
Other: Injection site pain, redness, swelling, and thrombophlebitis

Nursing Considerations

- Avoid giving doxapram to patients receiving mechanical ventilation.
- Maintain a patent airway, and assess for optimal oxygenation before giving drug.
- Monitor I.V. insertion site for extravasation and signs of thrombophlebitis or local skin irritation.
- If hypertension or dyspnea develops suddenly, stop infusion as directed.
- Assess patient for early signs and symptoms of overdose, including enhanced deep tendon reflexes, skeletal muscle hyperactivity, and tachycardia.

PATIENT TEACHING

- Explain the need for frequent pulse and blood pressure monitoring.

doxazosin mesylate

Cardura, Cardura-1 (CAN),
 Cardura-2 (CAN), Cardura-4 (CAN)

Class and Category

Chemical class: Quinazoline derivative
Therapeutic class: Antihypertensive, benign prostatic hyperplasia therapeutic agent
Pregnancy category: C

Indications and Dosages

↗ *To manage hypertension*

TABLETS

Adults. *Initial:* 1 mg daily. Doubled every 1 to 2 wk, if needed to achieve desired blood pressure. *Maximum:* 16 mg daily.

↗ *To treat benign prostatic hyperplasia (BPH)*

TABLETS

Adults. *Initial:* 1 mg daily. Doubled every 1 to 2 wk, if needed, based on signs and symptoms. *Maximum:* 8 mg daily.

Mechanism of Action

Competitively inhibits alpha₁-adrenergic

receptors in the sympathetic nervous system, causing peripheral vasodilation and reduced peripheral vascular resistance. This action increases heart rate and decreases blood pressure, especially when the patient stands. Doxazosin also relaxes smooth muscle of the bladder neck, prostate, and prostate capsule, which reduces urethral resistance and pressure and urinary outflow resistance.

Route	Onset	Peak	Duration
P.O.	1–2 hr*	2–6 hr†	24 hr†

Contraindications

Hypersensitivity to doxazosin, prazosin, terazosin, or their components

Interactions

DRUGS

antihypertensives, diuretics, phosphodiesterase-5 inhibitors: Enhanced hypotensive effects

cimetidine: Possibly increased blood doxazosin level

dopamine: Antagonized vasopressor effect of high-dose dopamine

ephedrine, metaraminol, methoxamine, phenylephrine: Possibly decreased vasopressor effects of these drugs

epinephrine: Possibly severe hypotension and tachycardia

NSAIDs: Possibly loss of hypotensive activity from sodium or fluid accumulation

Adverse Reactions

CNS: Dizziness, drowsiness, headache, nervousness, restlessness, vertigo
CV: Arrhythmias, including sinus tachycardia; first-dose orthostatic hypotension; palpitations; peripheral edema
EENT: Intraoperative floppy iris syndrome, rhinitis

GI: Nausea

RESP: Dyspnea

Nursing Considerations

- Don't give drug to hypotensive patients.
- Use doxazosin cautiously in patients with hepatic disease (because normal dosage may cause exaggerated effects) and in elderly patients (because hypotensive response may be more pronounced).

* For hypertension; in 2 wk for BPH.

† For hypertension; unknown for BPH.

WARNING Monitor patient for orthostatic hypotension (which may cause syncope) early in therapy, especially after exercise and in patients with hypovolemia.

- Monitor blood pressure for 2 to 6 hours after first dose and with each increase because orthostatic hypotension commonly occurs at this time. Adjust dose as prescribed, based on standing blood pressure.
- Carefully monitor patients with renal disease for exaggerated effects, such as first-dose orthostatic hypotension.
- Monitor urination, checking for difficulty urinating and urine retention, to assess drug's effects on BPH.

PATIENT TEACHING

- Inform patient that she may take doxazosin in the morning or evening and with food, if desired.
- Instruct patient to change position slowly to minimize orthostatic hypotension.
- Advise patient to avoid standing for long periods, exercising, using alcohol, and going outside in hot weather; these activities may worsen orthostatic hypotension.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.

doxepin hydrochloride

Novo-Doxepin (CAN), Sinequan, Triadapin (CAN)

Class and Category

Chemical class: Dibenzoxepin derivative

Therapeutic class: Antidepressant

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat mild to moderate depression or anxiety*

CAPSULES, ORAL SOLUTION

Adults and adolescents. 75 to 150 mg daily at bedtime. *Maximum:* 150 mg daily.

↗ *To treat mild to moderate depression or anxiety with organic disease*

CAPSULES, ORAL SOLUTION

Adults and adolescents. 25 to 50 mg daily.

↗ *To treat severe depression or anxiety*

CAPSULES, ORAL SOLUTION

Adults and adolescents. 50 mg t.i.d., gradually increased to 300 mg daily, as indicated.

Mechanism of Action

May block serotonin and norepinephrine reuptake by adrenergic nerves. In this way, the tricyclic antidepressant raises serotonin and norepinephrine levels at nerve synapses, which may elevate mood and reduce depression.

Route	Onset	Peak	Duration
P.O.	2–3 wk	Unknown	Unknown

Incompatibilities

Don't mix doxepin solution with carbonated beverages or grape juice.

Contraindications

Acute recovery phase of MI; concurrent use of MAO inhibitor; glaucoma; hypersensitivity to doxepin, other tricyclic antidepressants, or their components; urine retention

Interactions

DRUGS

amantadine, anticholinergics, antidyskinetics, antihistamines: Possibly intensified anticholinergic effects, causing confusion, hallucinations, and nightmares

anticonvulsants: Possibly lowered seizure threshold and decreased effects of these drugs

antithyroid drugs: Possibly increased risk of agranulocytosis

barbiturates, carbamazepine: Increased doxepin metabolism, decreased blood doxepin level, possibly lowered seizure threshold

bupropion, clozapine, cyclobenzaprine, haloperidol, loxapine, maprotiline, molindone, phenothiazines, thioxanthenes: Possibly prolonged and intensified sedative and anticholinergic effects of either drug, possibly increased risk of seizures

cimetidine, flecainide, phenothiazines, propafenone, quinidine, selective serotonin reuptake inhibitors, tricyclic antidepressants: Increased blood doxepin level from inhibited systemic clearance, resulting in increased risk of toxicity

clonidine, guanadrel, guanethidine: Increased risk of hypertension, especially during second week of doxepin therapy

CNS depressants: Possibly potentiated CNS depression, hypotension, and respiratory depression

corticosteroids: Possibly worsened depression

direct-acting sympathomimetics, such as epinephrine and norepinephrine: Potentiated effects of these drugs

disulfiram: Possibly transient delirium

fluoxetine: Possibly increased blood doxepin level

MAO inhibitors: Possibly hyperpyrexia, hypertension, seizures, and death

oral anticoagulants: Possibly increased anticoagulant effects of these drugs

pimozide: Increased risk of arrhythmias

probucol: Possibly prolonged QT interval, increased risk of ventricular tachycardia

thyroid hormones: Possibly increased therapeutic and toxic effects of both drugs

tolazamide: Possibly severe hypoglycemia

ACTIVITIES

alcohol use: Possibly enhanced CNS depression, hypotension, and respiratory depression

Adverse Reactions

CNS: Confusion, delirium, dream disturbances, drowsiness, fatigue, hallucinations, headache, nervousness, parkinsonism, restlessness, sedation, seizures, suicidal ideation (children and teens), tremor

CV: ECG changes, orthostatic hypotension, palpitations

EENT: Blurred vision, dry mouth, taste perversion

GI: Constipation, diarrhea, heartburn, ileus, increased appetite, nausea, vomiting,

GU: Decreased libido, ejaculation disorders

SKIN: Diaphoresis, jaundice

Other: Weight gain

Nursing Considerations

- If desired, mix oral solution in 120 ml of water; milk; or orange, grapefruit, tomato, or pineapple juice.
- Expect to observe adverse reactions within a few hours after giving drug.
- Evaluate patient for therapeutic response, such as decreased anxiety, apprehension, depression, fear, guilt, somatic symptoms, and worry; increased energy; and more restful sleep.

WARNING Monitor children and teens closely for evidence of suicidal thinking and behavior because doxepin increases the risk in these groups.

- Keep in mind that abrupt withdrawal of doxepin after prolonged therapy can cause cholinergic rebound effects, including

diarrhea, nausea, and vomiting.

- Plan to discontinue drug, as prescribed, several days before elective surgery to avoid hypertension.
- Monitor elderly patients for parkinsonism, especially with high-dose therapy.
- Be alert for seizures. Patients with seizure disorder may need increased anticonvulsant dosage to maintain seizure control.
- For patients with asthma or sulfite sensitivity, doxepin tablets may aggravate asthma or cause allergic reactions because they contain sulfites.
- Follow diabetic patient's serum glucose level closely; drug may alter glucose metabolism.
- If patient takes a thyroid hormone, be alert for increased responses to both drugs and, possibly, exaggerated drug-induced effects, such as arrhythmias and CNS stimulation. Untreated hypothyroidism prevents adequate response to therapy.

PATIENT TEACHING

WARNING Alert parents to watch their child or teen closely for abnormal thinking or behavior and increased aggression or hostility. Stress importance of notifying prescriber about unusual changes.

- Instruct patient to avoid alcohol during doxepin therapy because mental alertness may decrease.
- Advise diabetic patient to measure serum glucose level more often than usual.

doxercalciferol

Hectorol

Class and Category

Chemical class: Fat-soluble vitamin D analogue

Therapeutic class: Antihyperparathyroid drug

Pregnancy category: B

Indications and Dosages

➤ To reduce elevated intact parathyroid hormone (iPTH) serum level when managing secondary hyperparathyroidism in patients undergoing chronic hemodialysis

CAPSULES

Adults. *Initial:* 10 mcg 3 times/wk (about

every other day) before, during, or after dialysis. *Maintenance:* If iPTH level is decreased by 50% and above 300 picograms (pg)/ml, dosage increased by 2.5 mcg at 8-wk intervals, as needed. If iPTH level is 150 to 300 pg/ml, initial dosage maintained. If iPTH level is less than 100 pg/ml, drug stopped for 1 wk and then restarted at a dose at least 2.5 mcg less than previous dose. *Maximum:* 20 mcg 3 times/wk for a total of 60 mcg/wk.

➤ *To reduce elevated iPTH blood level when managing secondary hyperparathyroidism in patients with stage 3 or 4 chronic renal disease*

CAPSULES

Adults. 1 mcg daily. *Maintenance:* If iPTH level exceeds 70 pg/ml for stage 3 or 110 pg/ml for stage 4, dosage increased by 0.5 mcg at 2-wk intervals, as needed. If iPTH level is 35 to 70 pg/ml for stage 3 or 70 to 110 pg/ml for stage 4, dosage is maintained. If iPTH level is less than 35 pg/ml for stage 3 or less than 70 pg/ml for stage 4, drug is stopped for 1 wk and then restarted at a dose at least 0.5 mcg lower than previous dose. *Maximum:* 3.5 mcg daily.

Mechanism of Action

Undergoes hepatic conversion to an active metabolite (1,25-dihydroxyvitamin D₂ [1,25-dihydroxyergocalciferol]), which increases intestinal absorption of dietary calcium and renal tubular reabsorption of urinary calcium. Together with parathyroid hormone, doxercalciferol also mobilizes calcium from bone. These effects serve to maintain blood calcium levels in patients with chronic renal failure, which in turn prevents hyperparathyroidism.

In patients with renal failure, decreased metabolic activation of vitamin D in the kidneys leads to chronic hypocalcemia. The parathyroid gland compensates by increasing PTH secretion, but renal failure prevents it from achieving a normal serum calcium level. Thus, secondary hyperparathyroidism develops. Because doxercalciferol doesn't require renal conversion to form its active metabolite, it can regulate the serum calcium level and thus suppress PTH secretion and reduce its serum level in patients with chronic renal failure. An elevated PTH level in these patients leads to metabolic bone disease, such as renal osteodystrophy.

Contraindications

Evidence of vitamin D toxicity, hypersensitivity to doxercalciferol or its components, risk or history of hypercalcemia or hyperphosphatemia

Interactions

DRUGS

antacids that contain magnesium: Possibly additive drug effects and increased risk of hypermagnesemia

cholestyramine, mineral oil, orlistat, other drugs that affect lipid absorption: Possibly decreased doxercalciferol absorption

glutethimide, phenobarbital: Possibly increased doxercalciferol metabolism and risk of adverse reactions

erythromycin, ketoconazole: Possibly inhibited doxercalciferol metabolism and decreased effectiveness

vitamin D and its analogues: Possibly additive effects, resulting in increased adverse effects, such as hypercalcemia

Adverse Reactions

CNS: Depression, dizziness, headache, insomnia, malaise, paresthesia

CV: Bradycardia, chest pain, peripheral edema

EENT: Rhinitis

ENDO: Oversuppression of iPTH

GI: Anorexia, constipation, indigestion, nausea, vomiting

HEME: Anemia

MS: Hypertonia

RESP: Cough, dyspnea

SKIN: Pruritus

Other: Dehydration, hypercalcemia, hypercalciuria, hyperphosphatemia, weight gain

Nursing Considerations

WARNING Be aware that patients who take vitamin D should not also take doxercalciferol because they may develop severe vitamin D toxicity and hypercalcemia.

- Be alert for signs and symptoms of vitamin D toxicity and hypercalcemia in patients receiving high-dose or long-term doxercalciferol therapy. Early signs and symptoms include bone pain, constipation, dry mouth, headache, metallic taste, myalgia, nausea, somnolence, vomiting, and weakness. Late signs and symptoms include albuminuria, anorexia, arrhythmias, azotemia, conjunctivitis (calcific), decreased libido, elevated AST and ALT

levels, elevated BUN level, generalized vascular calcification, hypercholesterolemia, hypertension, hyperthermia, irritability, mild metabolic acidosis, nephrocalcinosis, nocturia, pancreatitis, photophobia, polydipsia, polyuria, pruritus, rhinorrhea, and weight loss.

- Keep emergency equipment readily available in case patient develops toxicity.
- Expect to monitor patient's blood iPTH, calcium, and phosphorus levels before starting drug and weekly early in therapy.
- For patients with renal failure who are having hemodialysis, oral calcium-based or other non-aluminum-containing phosphate binders and a low-phosphate diet typically are used to control serum phosphorus level. An elevated serum phosphorus level worsens secondary hyperparathyroidism and may decrease doxercalciferol's effectiveness in reducing blood iPTH level.
- After doxercalciferol therapy starts, expect to decrease dosage of phosphate binders to correct persistent mild hypercalcemia. Expect to increase dosage to correct persistent mild hyperphosphatemia.
- Avoid giving magnesium-containing antacids with doxercalciferol if patient receives long-term hemodialysis because doing so may lead to hypermagnesemia.

PATIENT TEACHING

- Urge patient who takes doxercalciferol to follow strict low-phosphorus diet and to take calcium supplement, as prescribed, to maintain serum calcium level. Stress that diet and calcium-based phosphate binder should provide 1.5 to 2 g of calcium daily.
- Explain importance of periodic follow-up blood work to measure drug effectiveness. Tell the patient that it may take several months to reach optimal PTH suppression.
- Warn patient not to take other forms of vitamin D with doxercalciferol and to ask prescriber before taking any OTC drug.
- Advise patient to contact prescriber immediately if early signs or symptoms of toxicity, such as headache or nausea, develop.

doxycycline calcium

(contains 50 mg of base per 5 ml of oral suspension)

Vibramycin

doxycycline hyclate

(contains 50 or 100 mg of base per capsule, 100 mg of base per delayed-release capsule, 100 mg of base per tablet, and 100 or 200 mg of base per injection vial)

Alti-Doxycycline (CAN),
Apo-Doxy (CAN), Doryx,
Doxycin (CAN), Vibramycin, Vibra-Tabs

doxycycline monohydrate

(contains 50 or 100 mg of base per capsule and 25 mg of base per 5 ml of oral suspension)

Monodox, Vibramycin

Class and Category

Chemical class: Oxytetracycline derivative

Therapeutic class: Antibiotic

Pregnancy category: D

Indications and Dosages

↗ *To treat cutaneous, GI, or inhalation anthrax*

CAPSULES, DELAYED-RELEASE CAPSULES, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults, adolescents, and children weighing more than 45 kg (99 lb). 100 mg (base)

every 12 hr for 60 days.

Children weighing less than 45 kg. 2.2 mg/kg (base) every 12 hr for 60 days.

↗ *To treat inflammatory lesions (papules and pustules) of rosacea*

Adults. 40 mg once daily in morning

↗ *To treat endocervical, rectal, and urethral infections caused by Chlamydia trachomatis*

CAPSULES, DELAYED-RELEASE CAPSULES, ORAL SUSPENSION, TABLETS

Adults and children over age 8 weighing more than 45 kg. 100 mg (base) b.i.d. for 7 days. *Maximum:* 300 mg (base) daily.

Children weighing 45 kg or less. 2.2 mg (base)/kg b.i.d. on day 1 and then 2.2 to 4.4 mg (base)/kg daily or 1.1 to 2.2 mg (base)/kg b.i.d.

I.V. INFUSION

Adults and children over age 8 weighing more than 45 kg. 200 mg (base) once daily or 100 mg (base) every 12 hr on day 1 and then 100 to 200 mg (base) once daily or

50 to 100 mg (base) every 12 hr. *Maximum:* 300 mg (base) daily.

Children weighing 45 kg or less. 4.4 mg (base)/kg once daily or 2.2 mg (base)/kg every 12 hr on day 1 and then 2.2 to 4.4 mg (base)/kg once daily or 1.1 to 2.2 mg (base)/kg every 12 hr.

↗ *To treat epididymo-orchitis caused by C. trachomatis or Neisseria gonorrhoeae or nongonococcal urethritis caused by C. trachomatis or Ureaplasma urealyticum*

CAPSULES, DELAYED-RELEASE CAPSULES, ORAL SUSPENSION, TABLETS

Adults and children over age 8 weighing more than 45 kg. 100 mg (base) b.i.d. for at least 10 days. *Maximum:* 300 mg (base)/day.

Children weighing 45 kg or less. 2.2 mg (base)/kg b.i.d. on day 1 and then 2.2 to 4.4 mg (base)/kg once daily or 1.1 to 2.2 mg (base)/kg b.i.d.

I.V. INFUSION

Adults and children over age 8 weighing more than 45 kg. 200 mg (base) once daily or 100 mg (base) every 12 hr on day 1 and then 100 to 200 mg (base) once daily or 50 to 100 mg (base) every 12 hr. *Maximum:* 300 mg (base) daily.

Children weighing 45 kg or less. 4.4 mg (base)/kg once daily or 2.2 mg (base)/kg every 12 hr on day 1 and then 2.2 to 4.4 mg (base)/kg once daily or 1.1 to 2.2 mg (base)/kg every 12 hr.

↗ *To prevent malaria*

CAPSULES, DELAYED-RELEASE CAPSULES, ORAL SUSPENSION, TABLETS

Adults and children over age 8 weighing more than 45 kg. 100 mg (base) daily starting 1 to 2 wk before travel, continued daily during travel, and then daily for 4 wk after travel ends. *Maximum:* 300 mg (base) daily.

Children over age 8. 2 mg (base)/kg daily starting 1 to 2 days before travel, continued daily during travel, and daily for 4 wk after travel ends. *Maximum:* 100 mg (base) daily.

↗ *To treat early syphilis in penicillin-allergic patients*

CAPSULES, DELAYED-RELEASE CAPSULES, ORAL SUSPENSION, TABLETS

Adults and children over age 8 weighing more than 45 kg. 100 mg (base) b.i.d. for 2 wk. *Maximum:* 600 mg (base) daily.

Children weighing 45 kg or less. 2.2 mg (base)/kg b.i.d. on day 1 and then 2.2 to 4.4 mg (base)/kg once daily or 1.1 to 2.2 mg

(base)/kg b.i.d.

I.V. INFUSION

Adults and children over age 8 weighing more than 45 kg. 150 mg (base) every 12 hr for at least 10 days. *Maximum:* 300 mg (base) daily.

Children weighing 45 kg or less. 4.4 mg (base)/kg once daily or 2.2 mg (base)/kg every 12 hr on day 1 and then 2.2 to 4.4 mg (base)/kg once daily or 1.1 to 2.2 mg (base)/kg every 12 hr.

↗ *To treat syphilis of more than 1 year's duration in penicillin-allergic patients*

CAPSULES, DELAYED-RELEASE CAPSULES, ORAL SUSPENSION, TABLETS

Adults and children over age 8 weighing more than 45 kg. 100 mg (base) b.i.d. for 4 wk. *Maximum:* 300 mg (base) daily.

I.V. INFUSION

Adults and children over age 8 weighing more than 45 kg. 150 mg (base) every 12 hr for at least 10 days. *Maximum:* 300 mg (base) daily.

Children weighing 45 kg or less. 4.4 mg (base)/kg once daily or 2.2 mg (base)/kg every 12 hr on day 1 and then 2.2 to 4.4 mg (base)/kg once daily or 1.1 to 2.2 mg (base)/kg every 12 hr.

↗ *To treat all other infections caused by susceptible organisms*

CAPSULES, DELAYED-RELEASE CAPSULES, ORAL SUSPENSION, TABLETS

Adults and children over age 8 weighing more than 45 kg. 100 mg (base) every 12 hr on day 1 and then 100 mg (base) once daily or 50 mg (base) b.i.d. For severe infections, 100 mg (base) continued every 12 hr. *Maximum:* 300 mg (base) daily.

Children weighing 45 kg or less. 2.2 mg (base)/kg b.i.d. on day 1 and then 2.2 to 4.4 mg (base)/kg once daily or 1.1 to 2.2 mg (base)/kg b.i.d.

I.V. INFUSION

Adults and children over age 8 weighing more than 45 kg. 200 mg (base) once daily or 100 mg (base) every 12 hr on day 1 and then 100 to 200 mg (base) once daily or 50 to 100 mg (base) every 12 hr. *Maximum:* 300 mg (base) daily.

Children weighing 45 kg or less. 4.4 mg (base)/kg once daily or 2.2 mg (base)/kg every 12 hr on day 1 and then 2.2 to 4.4 mg (base)/kg once daily or 1.1 to 2.2 mg (base)/kg every 12 hr.

Mechanism of Action

Exerts a bacteriostatic effect against a wide variety of gram-positive and gram-negative organisms. Doxycycline is more lipophilic than other tetracyclines, which allows it to pass more easily through the bacterial lipid bilayer, where it binds reversibly to 30S ribosomal subunits. Bound doxycycline blocks the binding of aminoacyl transfer RNA to messenger RNA, thus inhibiting bacterial protein synthesis.

Contraindications

Hypersensitivity to any tetracycline

Interactions

DRUGS

antacids that contain aluminum, calcium, magnesium, or zinc; calcium supplements; choline and magnesium salicylates; iron salts; laxatives that contain magnesium: Decreased doxycycline absorption and effects
barbiturates, carbamazepine, phenytoin: Increased clearance and decreased effects of doxycycline

cholestyramine, colestipol: Decreased doxycycline absorption

digoxin: Increased bioavailability of digoxin, possibly leading to digitalis toxicity

oral anticoagulants: Possibly increased hypoprothrombinemic effects of these drugs

oral contraceptives: Decreased effectiveness of estrogen-containing oral contraceptives, increased risk of breakthrough bleeding

penicillins: Inhibited bactericidal action

penhtrane: Possibly increased risk of fatal renal toxicity

sodium bicarbonate: Altered doxycycline absorption from increased gastric pH

FOODS

dairy products, other foods high in calcium or iron: Decreased doxycycline absorption

Adverse Reactions

CNS: Paresthesia

CV: Phlebitis

EENT: Black “hairy” tongue, glossitis, hoarseness, oral candidiasis, pharyngitis, stomatitis, tooth discoloration

GI: Anorexia; bulky, loose stools; diarrhea; dysphagia; enterocolitis; epigastric distress; esophageal ulceration; hepatotoxicity; nausea; pseudomembranous colitis; rectal candidiasis; vomiting

GU: Anogenital lesions, dark yellow or brown urine, elevated BUN level, vaginal

candidiasis

HEME: Eosinophilia, hemolytic anemia, neutropenia, thrombocytopenia, thrombocytopenic purpura

SKIN: Dermatitis, photosensitivity, rash, urticaria

Other: Anaphylaxis, injection site phlebitis

Nursing Considerations

- Avoid giving doxycycline to breastfeeding women because of the risk of enamel hypoplasia, inhibited linear skeletal growth, oral and vaginal candidiasis, photosensitivity reactions, and tooth discoloration in breastfeeding infant.
- Avoid giving drug to children under age 8, if possible; it may cause discoloration and enamel hypoplasia of developing teeth.
- Use oral suspension cautiously in patients allergic to sulfites because it contains sodium metabisulfite.
- Expect to adjust dosage for patients who have hepatic disease to avoid drug accumulation.

WARNING Don't give doxycycline by I.M. or subcutaneous route.

- Give doxycycline without regard to meals. Food and milk may delay absorption, but they don't significantly reduce it.
- Observe patient often for injection site phlebitis, a common adverse reaction to I.V. administration.
- Monitor liver function test results as appropriate to detect hepatotoxicity.
- Expect oral or parenteral doxycycline to increase risk of oral, rectal, or vaginal candidiasis—especially in elderly or debilitated patients and those on prolonged therapy—by changing the normal balance of microbial flora.
- Monitor patient closely for diarrhea, which may indicate pseudomembranous colitis. If diarrhea occurs, notify prescriber and expect to withhold doxycycline. Expect to treat pseudomembranous colitis with fluids, electrolytes, protein, and an antibiotic effective against *Clostridium difficile*.

PATIENT TEACHING

- Instruct patient not to take doxycycline just before bed because it may not dissolve properly when she's recumbent and may cause esophageal burning and ulceration.
- Instruct patient taking doxycycline for rosacea to take the capsule in the morning

- on an empty stomach.
- Advise patient to avoid dairy products; foods high in calcium or iron; antacids containing aluminum, calcium, or magnesium; bismuth subsalicylate; and iron-containing products during therapy.
- Caution patient not to take bismuth subsalicylate while taking doxycycline because doxycycline absorption will be reduced.
- Instruct patient to drink plenty of fluids while taking doxycycline to reduce the risk of esophageal burning and ulceration.
- Inform patient that her urine may become dark yellow or brown during therapy.
- Advise patient to avoid sun exposure and ultraviolet light as much as possible during therapy and to use sunscreen or sunblock as needed. If patient develops phototoxicity, such as skin eruption, tell her to stop drug and notify prescriber.
- Advise patients who take an oral contraceptive to use an additional contraceptive method during therapy.
- If patient is being treated for a sexually transmitted disease, explain that her partner may need treatment as well.
- Tell patient to notify prescriber immediately about anorexia, epigastric distress, nausea, or vomiting during therapy.
- Urge patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.
- Alert female patients that doxycycline may increase risk of vaginal candidiasis. Tell her to notify prescriber if she develops vaginal itching or discharge.
- Advise patient taking doxycycline for malaria prevention to start taking drug 1 to 2 days before traveling to the region and continue for 4 weeks after leaving the area. Note that the total length of therapy shouldn't exceed 4 months.

dronabinol

(delta-9-tetrahydrocannabinol, THC)

Marinol

Class, Category, and Schedule

Chemical class: Synthetic tetrahydrocannabinol

Therapeutic class: Antiemetic, appetite

stimulant

Pregnancy category: C

Controlled substance schedule: II

Indications and Dosages

↗ *To prevent nausea and vomiting caused by chemotherapy and unresponsive to other antiemetics*

CAPSULES

Adults. 5 mg/m² 1 to 3 hr before and 2 to 4 hr after chemotherapy, increased by 2.5 mg/m², p.r.n. *Maximum:* 15 mg/m²/dose or a total of 4 to 6 doses daily.

↗ *To stimulate appetite in cancer and AIDS patients*

CAPSULES

Adults. *Initial:* 2.5 mg b.i.d. before lunch and supper, increased p.r.n. *Maximum:* 20 mg daily in divided doses.

DOSAGE ADJUSTMENT Dosage reduced to 2.5 mg before supper or at bedtime for patients who can't tolerate 5 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	24 hr or longer*

Mechanism of Action

May exert antiemetic effect by inhibiting the vomiting control mechanism in the medulla oblongata. As the main psychoactive substance in marijuana (*Cannabis sativa* L.), dronabinol's effects may be mediated by cannabinoid receptors in neural tissues.

Contraindications

Hypersensitivity to dronabinol, its components, sesame oil, or marijuana

Interactions

DRUGS

anticholinergics, antihistamines: Possibly increased risk of tachycardia
apomorphine: Possibly potentiated CNS depression, possibly decreased emetic response with prior use of dronabinol
CNS stimulants (such as amphetamines), and CNS depressants (such as benzodiazepines): Additive CNS effects
sympathomimetics: Possibly enhanced hypertension, tachycardia, and other adverse cardiovascular effects

* For appetite stimulant effects; unknown for antiemetic effects.

ACTIVITIES

alcohol use: Additive CNS depressant effects

Adverse Reactions

CNS: Amnesia, anxiety, ataxia, confusion, delusions, depression, dizziness, drowsiness, euphoria, fatigue, hallucinations, irritability, mood changes, nervousness, seizures, sleep disturbance

CV: Orthostatic hypotension, palpitations, sinus tachycardia

GI: Nausea, vomiting

Other: Physical and psychological dependence

Nursing Considerations

WARNING Dronabinol shouldn't be discontinued abruptly; if it is, withdrawal syndrome may occur.

- Use cautiously in patients with history of seizures because drug may lower seizure threshold. Notify prescriber of seizures immediately, and expect to stop drug.
- Patients under age 45 may tolerate drug better than those over age 45.
- Watch for adverse reactions that mimic psychosis, such as hallucinations and, possibly, acute anxiety, especially at high doses.
- Anticipate higher risk of cardiovascular reactions, such as increased heart rate and blood pressure changes (especially orthostatic hypotension), at higher doses.

WARNING Expect tolerance to drug to develop over time, especially if patient has smoked marijuana.

- Be aware that short-term, low-dose therapy doesn't typically lead to physical and psychological dependence, which may occur with long-term, high-dose therapy.
- Expect drug to alter REM sleep pattern, even after therapy stops.

PATIENT TEACHING

- Caution patient not to stop drug abruptly because withdrawal symptoms may occur.
- Urge patient not to use alcohol while taking dronabinol because it may enhance CNS depression.
- Instruct patient to rise slowly to sitting or standing position to minimize effects of orthostatic hypotension.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Inform patient that sleep pattern may be adversely affected during therapy and for sometime afterward.

dronedarone

Multaq

Class and Category

Chemical class: Benzofuran derivative

Therapeutic class: Antiarrhythmic

Pregnancy category: X

Indications and Dosages

➤ *To reduce risk of cardiovascular hospitalization in patients with paroxysmal or persistent atrial fibrillation or flutter, with a recent episode of atrial fibrillation or flutter and associated cardiovascular risk factors (i.e., age over 70 years or presence of hypertension, diabetes, prior cerebrovascular accident, left atrial diameter 50 mm or more or left ventricular ejection fraction less than 40%), who are in sinus rhythm or who will be cardioverted*

TABLETS

Adults. 400 mg twice daily, with morning and evening meals

Route	Onset	Peak	Duration
P.O.	Unknown	3–6 hr	Unknown

Mechanism of Action

Although specific effect on heart rhythm is unknown, dronedarone possesses properties of all four Vaughn-Williams antiarrhythmic classes.

Contraindications

Bradycardia less than 50 beats/minute; concurrent use of drugs or herbal products that prolong QT interval, such as class I and III antiarrhythmics, phenothiazine antipsychotics, oral macrolide antibiotics (selected), and tricyclic antidepressants; concurrent use of strong CYP3A inhibitors, such as clarithromycin, cyclosporine, ketoconazole, itraconazole, nefazodone, ritonavir, telithromycin, and voriconazole; hypersensitivity to dronedarone or its components; nursing mothers; NYHA Class IV heart failure or NYHA Class II–III heart failure with a recent decompensation requiring hospitalization or referral to a specialized heart failure clinic; pregnancy; QTc Bazett interval of 500 ms or greater or a PR interval greater than 280 ms; second- or third-

degree atrioventricular block or sick sinus syndrome (except when used in with a functioning pacemaker); severe hepatic impairment (Child-Pugh Class C)

Interactions

DRUGS

calcium channel blockers: Possibly increased dronedarone effects on conduction
calcium channel blockers, such as diltiazem, nifedipine, and verapamil; CYP3A substrates with narrow therapeutic range, such as sirolimus and tacrolimus; CYP2D6 substrates, such as beta blockers, selective serotonin reuptake agents, and tricyclic antidepressant; statins, such as simvastatin: Increased effects of these drugs with possibly increased risk of adverse reactions

class I and III antiarrhythmics, macrolide antibiotics, phenothiazines, tricyclic antidepressants: Possibly increased QT interval
CYP3A inducers, such as carbamazepine, phenobarbital, phenytoin, rifampin, St. John's wort: Decreased dronedarone effects

CYP3A inhibitors, such as clarithromycin, cyclosporine, ketoconazole, itraconazole, nefazodone, ritonavir, telithromycin, and voriconazole: Increased dronedarone effects
digoxin and other P-gP substrates: Increased effect of these drugs with risk of toxicity; increased risk of adverse GI reactions
diltiazem, verapamil: Increased dronedarone effect

potassium-depleting diuretics: Increased risk of hypokalemia and hypomagnesemia

FOODS

grapefruit juice: Increased dronedarone effects

Adverse Reactions

CNS: Astenia

CV: Bradycardia, heart failure, prolonged QT interval

GI: Abdominal pain, diarrhea, dyspepsia, nausea, vomiting

GU: Increased serum creatinine levels

SKIN: Allergic dermatitis, dermatitis, eczema, photosensitivity, pruritus, rash

Nursing Considerations

- Check that patient has stopped taking any drug contraindicated with dronedarone, as prescribed, before giving first dose.
- Monitor patient for evidence of heart failure, such as weight gain, dependent edema, or increasing shortness of breath.

If present, notify prescriber; dronedarone may need to be discontinued.

- Monitor patient's PR and QT interval, as ordered, to see if conduction is delayed. If so, notify prescriber immediately. Dronedarone will need to be stopped.
- Monitor patient's serum creatinine levels, as ordered. Elevation may occur rapidly, plateau after 7 days, and usually is reversible after therapy stops. However, if serum creatinine level increases, be aware that this increased value should be used as the patient's new baseline.

PATIENT TEACHING

- Inform patient that dronedarone must be taken with a meal.
- Warn patient that dronedarone should not be taken with grapefruit juice.
- Urge patient to contact prescriber if he develops evidence of heart failure, such as weight gain, dependent edema, or increasing shortness of breath, because dronedarone may need to be discontinued.
- Inform women of childbearing age of need for contraception if sexually active because drug is contraindicated during pregnancy and breastfeeding. If pregnancy occurs, she should notify prescriber immediately.
- Tell patient to inform all prescribers that he is taking dronedarone and to check with prescriber before taking any newly prescribed drug, OTC product, or herbal product with dronedarone.

droperidol

Inapsine

Class and Category

Chemical class: Butyrophenone derivative

Therapeutic class: Antiemetic

Pregnancy category: C

Indications and Dosages

↗ **To reduce nausea and vomiting after surgery or diagnostic procedures when other treatments are ineffective**

I.V. OR I.M. INJECTION

Adults and adolescents. Dosage individualized up to a maximum initial dose of 2.5 mg I.M. or slow I.V. Additional 1.25 mg may be given to achieve desired effect if potential benefit outweighs risk.

Children ages 2 to 12. Dosage individual-

ized to a maximum initial dose of 0.1 mg/kg. Additional dose may be given to achieve desired effect if potential benefit outweighs risk.

DOSE ADJUSTMENT Initial dosage reduced for elderly, debilitated, or critically ill patients because of the increased risk of hypotension and excessive sedation.

Route	Onset	Peak	Duration
I.V., I.M.	3–10 min	In 30 min	2–4 hr

Mechanism of Action

Produces sedation by blocking postsynaptic dopamine receptors in limbic system.

Droperidol may reduce nausea by blocking dopamine receptors in chemoreceptor trigger zone in reticular formation of the medulla oblongata. It also may produce antiemetic effects by attaching to postsynaptic gamma-amino-butyric acid (GABA) receptors in the chemoreceptor trigger zone.

Contraindications

Hypersensitivity to droperidol or its components, known or suspected prolonged QT interval (including congenital long-QT syndrome)

Interactions

DRUGS

amoxapine, haloperidol, loxapine, metoclopramide, metyrosine, molindone, olanzapine, phenothiazines, pimozide, rauwolfia alkaloids, risperidone, tacrine, thioxanthenes:

Possibly increased risk of severe extrapyramidal reactions

anesthetics: Possibly hypotension and peripheral vasodilation

antiarrhythmics (class I or III), antidepressants, antimalarials, benzodiazepines, diuretics, I.V. opioids, laxatives, MAO inhibitors, volatile anesthetics, and other drugs that prolong QT interval (such as some antihistamines): Increased risk of serious adverse effects of droperidol, such as prolonged QT interval and arrhythmias

antihypertensives: Possibly orthostatic hypotension

bromocriptine, levodopa: Possibly inhibited actions of these drugs

CNS depressants: Additive CNS depression

epinephrine: Possibly paradoxical reduction of blood pressure

propofol: Possibly decreased antiemetic effect of both drugs

ACTIVITIES

alcohol use: Additive CNS depression

Adverse Reactions

CNS: Anxiety, drowsiness, dystonia, restlessness

CV: Cardiac arrest, hypertension, hypotension, potentially fatal arrhythmias (such as torsades de pointes and ventricular tachycardia), prolonged QT interval, sinus tachycardia

EENT: Fixed upward position of eyeballs, laryngospasm

MS: Spasms of tongue, face, neck, and back muscles

RESP: Bronchospasm

Nursing Considerations

WARNING Use droperidol cautiously in patients over age 65 and in patients with alcoholism, bradycardia, heart failure, hypokalemia, hypomagnesemia, parkinsonism, or preexisting QT-interval prolongation because they're at increased risk for prolonged QT interval and potentially fatal adverse reactions. Patients who take drugs that prolong the QT interval, such as some antiarrhythmics and benzodiazepines, and patients who take drugs that may cause an electrolyte imbalance, such as diuretics and laxatives, are also at increased risk.

- Expect a 12-lead ECG to be performed on all patients before droperidol administration to verify the absence of prolonged QT interval. Monitor ECG continuously for 2 to 3 hours after administering drug. Also monitor serum electrolyte levels to detect electrolyte imbalances.
- Use droperidol cautiously in patients with cardiac disease, who may not be able to compensate for drug's hypotensive effect. Monitor vital signs, including blood pressure, frequently. Be aware that hypertension and tachycardia may occur in patients with a history of pheochromocytoma.
- Expect altered level of consciousness to last up to 12 hours after drug is given. Expect dosage to be reduced if patient is taking an opioid analgesic.
- If drug causes extrapyramidal reactions, such as restlessness, dystonia, and oculogyric crisis, expect to administer an anti-

cholinergic, such as benztropine or diphenhydramine. Be sure to maintain a patent airway and oxygenation.

- If patient develops severe hypotension, expect to give phenylephrine. If hypotension is related to hypovolemia, expect to administer fluids.

PATIENT TEACHING

- Advise patient to immediately report palpitations or faintness, which may indicate an abnormal cardiac rhythm.
- Instruct patient to ask for help with ambulation on first postoperative day because altered consciousness may last up to 12 hours.
- Caution patient to avoid drinking alcohol, taking CNS depressants, driving, and operating machinery for 24 hours after receiving droperidol.

drotrecogin alfa (activated) (recombinant human activated protein C)

Xigris

Class and Category

Chemical class: Serine protease glycoprotein

Therapeutic class: Anti-inflammatory, anti-thrombolytic

Pregnancy category: C

Indications and Dosages

➤ *To reduce risk of death in patients with severe sepsis in acute organ dysfunction*

I.V. INFUSION

Adults. 24 mcg/kg/hr for 96 hr.

Mechanism of Action

Interferes with a number of body responses to severe sepsis, including increased thrombin generation and fibrin formation, impaired fibrinolysis, and systemic inflammation. Drotrecogin alfa produces anti-thrombotic effect by inhibiting factors Va and VIIIa and indirect profibrinolytic effect by inhibiting plasminogen activator inhibitor-1 and limiting generation of activated thrombin-activatable fibrinolysis inhibitor.

Drotrecogin may produce anti-inflammatory effect by inhibiting produc-

tion of human tumor necrosis factor and other cytokines, preventing leukocyte adhesion to selectins, and limiting thrombin-induced inflammatory responses in the microvascular endothelium.

Incompatibilities

Don't infuse any drugs or solutions except D₅W, normal saline solution, lactated Ringer's solution, or dextrose and saline mixtures through drotrecogin alfa I.V. line.

Contraindications

Active internal bleeding; evidence of cerebral herniation; hemorrhagic stroke in the past 3 months; hypersensitivity to drotrecogin alfa or its components; intracranial or intraspinal surgery or severe head trauma in the past 2 months; intracranial neoplasm or lesion; presence of epidural catheter; trauma with an increased risk of life-threatening bleeding

Interactions

DRUGS

abciximab, eptifibatide, and other glycoprotein IIb/IIIa inhibitors; aspirin and other platelet inhibitors; heparin; oral anticoagulants; thrombolytics: Increased risk of bleeding

Adverse Reactions

CNS: Intracranial hemorrhage

CV: Intrathoracic bleeding

GI: GI, intra-abdominal, or retroperitoneal bleeding

GU: Genitourinary bleeding

HEME: Prolonged APTT

SKIN: Ecchymosis

Nursing Considerations

- Be aware that drotrecogin alfa is used only for patients with severe sepsis who are at high risk for death, as determined by an Acute Physiology and Chronic Health Evaluation (APACHE) II score, a method of assessing mortality risk. Patients with only single-organ dysfunction who are recovering from recent surgery may not be candidates for drotrecogin alfa despite an adequate APACHE II score.
- Reconstitute 5-mg and 20-mg vials by slowly adding 2.5 ml or 10 ml sterile water for injection, respectively, to yield 2 mg/ml. Gently swirl—don't shake—vial until powder is completely dissolved. Use

immediately or store for up to 3 hours at 59° to 86° F (15° to 30° C).

- Add reconstituted drug to normal saline solution by directing stream to side of bag to minimize agitation. Gently invert bag to mix; don't shake. Dilute to final concentration of 100 to 200 mg/ml if drug will be given by I.V. infusion pump or 100 to 1,000 mg/ml if by syringe pump. Infusion bag should not be transported by a mechanical delivery system, such as a tube delivery system, between pharmacy and nursing unit.
- Prime infusion set for 15 minutes at a flow rate of 5 ml/hour when infusing less than 200 mg/ml at less than 5 ml/hour. Use prepared I.V. solution within 12 hours.
- Give drotrecogin alfa through a dedicated I.V. line or lumen of a multilumen central venous catheter. Don't infuse any drugs or solutions except D₅W, normal saline solution, lactated Ringer's solution, or dextrose and saline mixtures through the same line.
- Be aware that total duration of the drotrecogin alfa infusion must equal 96 hours, even if you need to interrupt it for a period. For example, if you calculate that infusion should end on 5 p.m. Friday, but then have to stop to give the patient blood for 2 hours on Thursday, add those 2 hours to your estimated completion time, which would then be 7 p.m. Friday.

WARNING Monitor patient closely for bleeding; if it occurs, stop drotrecogin alfa infusion immediately and notify prescriber. Patients at increased risk include those with chronic severe hepatic disease, intracranial arteriovenous malformation or aneurysm, known bleeding diathesis, GI bleeding in previous 6 weeks, or ischemic stroke in previous 3 months; those receiving concurrent therapeutic heparin (15 units/kg/hour or more); those who have received thrombolytic therapy in previous 3 days, aspirin at more than 650 mg daily, other platelet inhibitors in previous 7 days, or oral anticoagulants or glycoprotein IIb/IIIa inhibitors in previous 7 days; those with any other condition in which bleeding would constitute a significant hazard or be difficult to manage because of its location; and those with a platelet count less than $30,000 \times 10^6/L$ or PT (as INR) greater than 3.0.

- Expect to discontinue drotrecogin alfa 2 hours before an invasive surgical or other procedure that poses a risk of bleeding and to resume administration immediately after uncomplicated, less-invasive procedures or 12 hours after major invasive procedures or surgery at the same rate of 24 mg/kg/hour, as prescribed.
- Be aware that drotrecogin alfa may prolong APTT during administration; PT may need to be used to monitor coagulopathy status during treatment.
- Before using drotrecogin alfa, refrigerate it at 36° to 46° F (2° to 8° C); don't freeze it. Protect from heat and direct sunlight.

PATIENT TEACHING

- Teach patient about adverse reactions to drotrecogin alfa, including bleeding from gums or nose and increased bruising. Instruct her to immediately report any signs of bleeding.
- Reassure patient that she'll be monitored closely throughout therapy.

duloxetine hydrochloride

Cymbalta

Class and Category

Chemical: Selective serotonin and norepinephrine reuptake inhibitor

Therapeutic: Antidepressant, neuropathic pain reliever

Pregnancy category: C

Indications and Dosages

↗ *To treat major depressive disorder*

E.R. CAPSULES

Adults. 20 mg b.i.d. Alternatively, 60 mg once daily or 30 mg b.i.d.

↗ *To relieve neuropathic pain associated with diabetic peripheral neuropathy*

E.R. CAPSULES

Adults. 60 mg daily.

↗ *To treat generalized anxiety disorder*

E.R. CAPSULES

Adults. *Initial:* 30 or 60 mg once daily, increased in 30-mg increments weekly, as needed. *Maximum:* 120 mg once daily.

↗ *To treat fibromyalgia*

E.R. CAPSULES

Adults. *Initial:* 30 mg daily for 1 wk; then

increased to 60 mg daily.

Mechanism of Action

Inhibits neuronal serotonin, norepinephrine, and dopamine reuptake to potentiate serotonergic and noradrenergic activity in the CNS. These activities may elevate mood and inhibit pain signals stemming from peripheral nerves adversely affected by chronically elevated serum glucose level.

Route	Onset	Peak	Duration
P.O.	Unknown	6 hr	Unknown

Contraindications

Hepatic insufficiency, hypersensitivity to duloxetine or its components, uncontrolled angle-closure glaucoma, use within 14 days of MAO inhibitor therapy

Interactions

DRUGS

amiodarone, celecoxib, cimetidine, erythromycin, fluoxetine, fluvoxamine, haloperidol, ketoconazole, methadone, paroxetine, quinidine, quinolones, ritonavir: Increased blood duloxetine level

amiodarone, amitriptyline, desipramine, flecainide, haloperidol, imipramine, methadone, nortriptyline, phenothiazines, propafenone, ritonavir, thioridazine:

Increased blood levels of these drugs

aspirin, NSAIDs, warfarin: Possibly increased risk of bleeding

CNS drugs: Increased effect of duloxetine
MAO inhibitors: Serious, sometimes fatal, autonomic instability, hyperthermia, myoclonus, rigidity

plasma protein binders (warfarin, phenytoin): Increased free concentration of these drugs and increased risk of adverse reactions

serotonergic drugs: Increased risk of serotonin syndrome

ACTIVITIES

alcohol use: Increased risk of hepatotoxicity

Adverse Reactions

CNS: Abnormal dreams, aggression, agitation, anger, anxiety, asthenia, chills, dizziness, extrapyramidal disorder, fatigue, fever, hallucinations, headache, insomnia, migraine, nervousness, neuroleptic malignant syndrome, parasthesia, restless legs syndrome, serotonin syndrome, somno-

lence, suicidal ideation, syncope, tremor, vertigo

CV: Hypertension, hypertensive crisis, orthostatic hypotension, palpitations, paresthesia, peripheral edema, supraventricular arrhythmia

EENT: Blurred vision, dry mouth, glaucoma, nasopharyngitis, pharyngitis, taste alteration

ENDO: Hot flashes, hyperglycemia

GI: Abdominal pain, anorexia, cholestatic jaundice, constipation, diarrhea, elevated liver enzymes, flatulence, hepatitis, hepatotoxicity, indigestion, jaundice, nausea, upper abdominal pain, vomiting

GU: Abnormal orgasm, decreased libido, erectile or ejaculatory dysfunction, urinary frequency, UTI

HEME: Bleeding episodes, leukopenia, thrombocytopenia

MS: Arthralgia, back pain, extremity pain, muscle cramp, myalgia

RESP: Cough, upper respiratory tract infection

SKIN: Diaphoresis, erythema multiforme, pruritus, rash, Stevens-Johnson syndrome, urticaria

Other: Anaphylaxis, angioedema, hyponatremia, weight loss

Nursing Considerations

- Avoid giving duloxetine to patients with severe renal impairment or end-stage renal disease that requires hemodialysis because blood drug levels increase significantly in these patients. Also avoid duloxetine in patients with hepatic insufficiency because drug is metabolized by the liver.
- Use duloxetine cautiously in patients with delayed gastric emptying because drug's enteric coating resists dissolution until it reaches an area where pH exceeds 5.5.
- Give duloxetine cautiously to patients with a history of mania, which it may activate. Also give cautiously to patients with a seizure disorder because drug effects aren't known in these patients.
- Obtain patient's baseline blood pressure before duloxetine therapy starts, and assess it periodically thereafter for changes. If orthostatic hypotension occurs during therapy, notify prescriber and anticipate that drug may need to be discontinued.
- Monitor patient's serum sodium level, especially if patient is elderly, is taking a

diuretic, or has volume depletion, because drug may lower serum sodium level.

- Monitor patient's hepatic function, as ordered, because drug may increase the risk of hepatotoxicity.
- If patient takes duloxetine for depression (especially if he's a child or an adolescent), watch closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.
- Avoid stopping duloxetine therapy abruptly, if possible, because withdrawal symptoms such as dizziness, nausea, headache, fatigue, paresthesia, vomiting, irritability, nightmares, insomnia, diarrhea, anxiety, hyperhidrosis, and vertigo may occur. Taper dosage gradually, as ordered.

WARNING Monitor patient for serotonin syndrome, characterized by agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. In its most severe form, serotonin syndrome can resemble neuroleptic malignant syndrome, which includes a high fever, muscle rigidity, autonomic instability with possible fluctuations in vital signs, and mental status changes.

PATIENT TEACHING

- Tell patient to take capsule whole and not to chew it, crush it, or sprinkle contents on food or liquids because doing so alters enteric coating and may affect drug absorption.
- Inform patient that full effect of duloxetine may take weeks to occur; stress the importance of continuing to take the drug as directed.
- Caution patient against excessive alcohol consumption while taking duloxetine because it may increase risk of hepatic dysfunction.
- Advise patient not to stop duloxetine abruptly because adverse reactions may occur. Explain that drug will be stopped gradually.
- Instruct patient to notify prescriber if any serious or troublesome adverse effects develop.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to rise from a lying or sitting position slowly to minimize drug's

effect on lowering blood pressure.

- If patient takes duloxetine for depression, urge caregivers to watch closely for evidence of suicidal tendencies, especially if patient is a child or an adolescent and especially when therapy starts or dosage changes.
- Instruct female patients of childbearing potential to notify prescriber if they are, could be, or wish to become pregnant; duloxetine therapy may cause adverse reactions in neonates exposed to it during the third trimester.

dutasteride

Avodart

Class and Category

Chemical class: Synthetic 4-azasteroid compound

Therapeutic class: Benign prostatic hyperplasia agent

Pregnancy category: X

Indications and Dosages

➤ To treat symptomatic benign prostatic hyperplasia (BPH); as adjunct with tamsulosin therapy to treat symptomatic BPH

CAPSULES

Adult men. 0.5 mg daily.

Contraindications

Children; women; hypersensitivity to dutasteride, its components, or other 5-alpha reductase inhibitors

Interactions

DRUGS

cimetidine, ciprofloxacin, diltiazem, ketoconazole, ritonavir, verapamil, and other CYP3A4 inhibitors: Risk of decreased dutasteride metabolism and enhanced effects

Adverse Reactions

CNS: Dizziness

ENDO: Gynecomastia, increased serum testosterone and thyroid-stimulating hormone levels

GU: Decreased ejaculatory volume, decreased libido, impotence

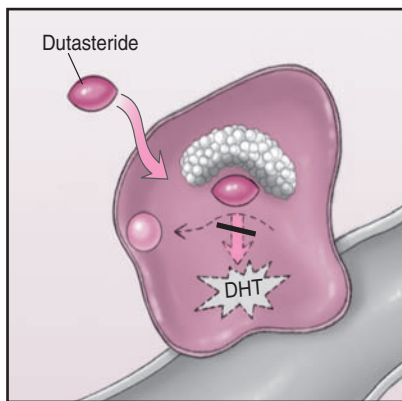

SKIN: Localized edema, pruritus, rash, serious skin reactions, urticaria

ENDO: Angioedema

Mechanism of Action

Dutasteride reduces prostate gland enlargement by inhibiting conversion of testosterone to its active metabolite, 5-alpha dihydrotestosterone (DHT). DHT is the main hormone that stimulates prostate cells to grow. As men age, they may become more sensitive to DHT, resulting in excessive growth of prostatic cells and enlargement of the prostate. This condition, benign prostatic hyperplasia, may cause urinary hesitancy, uri-

nary urgency, and nocturia. Two forms of the intracellular enzyme 5-alpha-reductase (5 α -R types 1 and 2) in liver, prostate, and skin, convert testosterone to DHT, as shown below left. Dutasteride, a dual 5 α -R inhibitor, deactivates both forms. When 5 α -R is inhibited by dutasteride, production of DHT is suppressed, as shown below right. With less circulating DHT, the prostate gland shrinks and symptoms improve.

Nursing Considerations

WARNING Be aware that dutasteride is absorbed through the skin. If you are female and pregnant or of childbearing age, do not handle dutasteride capsule when administering it to a patient.

- Patient should be evaluated for other urologic conditions, including prostate cancer, before dutasteride therapy starts.
- Expect patient to undergo a digital rectal examination of the prostate before and periodically during dutasteride therapy.
- Anticipate need to obtain a new baseline prostate-specific antigen (PSA) value after 3 to 6 months of dutasteride treatment because drug can decrease PSA concentration by 40% to 50%.

PATIENT TEACHING

WARNING Urge patient and female partners to use reliable contraceptive method during dutasteride therapy because semen of men who take drug can harm male fetuses. Caution women and children against handling capsules.

- Advise patient to inform prescriber if he has liver disease.
- Explain how to take drug properly, and advise patient to follow instructions that accompany drug. Instruct him to swallow capsule whole and to notify pharmacist if capsules are cracked or leaking.
- Inform patient that drug may decrease ejaculatory volume and libido and may cause impotence.
- Instruct patient to postpone blood donations for 6 months after final dose to avoid transmitting dutasteride to a pregnant woman during a blood transfusion.
- Urge patient to have periodic follow-up appointments.

dyphylline

Dilor, Lufyllin

Class and Category

Chemical class: Xanthine derivative

Therapeutic class: Bronchodilator
Pregnancy category: C

Indications and Dosages

➤ *To prevent or relieve bronchospasm from acute and chronic bronchial asthma, chronic bronchitis, and emphysema*

ELIXIR, TABLETS

Adults. Up to 15 mg/kg every 6 hr.

I.M. INJECTION

Adults. *Initial:* 500 mg. *Maintenance:* 250 to 500 mg every 2 to 6 hr, as needed.

Mechanism of Action

May cause bronchodilation by inhibiting phosphodiesterase enzymes. These enzymes normally inactivate cyclic adenosine monophosphate (cAMP) and cyclic guanosine monophosphate (cGMP), which are responsible for bronchial smooth-muscle relaxation. Drug also may foster calcium translocation, prostaglandin antagonism, catecholamine stimulation, and adenosine-receptor antagonism.

Contraindications

Hypersensitivity to dyphylline, xanthines, or their components; peptic ulcer disease; seizure disorder (unless controlled by anti-convulsant therapy)

Interactions

DRUGS

beta blockers: Possibly inhibited bronchodilation by dyphylline

ephedrine: Possibly increased frequency of insomnia, nausea, and nervousness

hydrocarbon inhalation anesthetics: Possibly increased risk of ventricular arrhythmias

probenecid: Possibly decreased renal excretion of dyphylline

sucralfate: Possibly adsorption of dyphylline if drugs given within 2 hours of each other

Adverse Reactions

CNS: Headache, insomnia, irritability, nervousness, seizures, tremor

CV: Arrhythmias, hypotension, tachycardia

GI: Diarrhea, gastroesophageal reflux, nausea, vomiting

GU: Increased diuresis

Nursing Considerations

- Inspect I.M. form of dyphylline for precipitate. If present, discard drug and obtain a new ampule.
- Give oral drug at least 1 hour after meals

for best absorption. However, if drug causes GI distress, give it with food if prescribed.

- Don't give parenteral drug by I.V. route.
- Evaluate for therapeutic response, including decreased respiratory rate and effort.
- Assess for signs of dyphylline toxicity, including seizures and ventricular tachycardia.

PATIENT TEACHING

- Instruct patient to take oral dyphylline with a full glass of water and on an empty stomach to promote absorption.
- Advise patient to consult prescriber about taking drug with food if she experiences GI distress.

E F

ecallantide

Kalbitor

Class and Category

Chemical class: 60-amino-acid protein

Therapeutic class: Kallikrein inhibitor replacement

Pregnancy category: C

Indications and Dosages

↗ *To treat acute attacks of hereditary angioedema in patients age 16 and older*

SUBCUTANEOUS INJECTION

Adults. 30 mg (3 ml) given in divided doses of 10 mg (1 ml) each and repeated, if needed, within 24 hr.

Route	Onset	Peak	Duration
P.O.	24–50 min	2–3 hr	Unknown

Mechanism of Action

Blocks conversion of kininogen to bradykinin by binding to plasma kallikrein. Without bradykinin, the inflammatory pathway is not initiated and signs and symptoms of angioedema are relieved.

The kallikrein-kinin system is a complex proteolytic cascade that initiates the inflammatory and coagulation pathways through conversion of kininogen to bradykinin by kallikrein. In hereditary angioedema, normal regulation of plasma kallikrein activity and the classical complement cascade is not present because of the absence of a kallikrein inhibitor. This allows kininogen to be converted to bradykinin unchecked, resulting in an excessive amount of bradykinin circulating in plasma. Bradykinin is a vasodilator that may be responsible for the symptoms of hereditary angioedema such as swelling, inflammation, and pain.

Contraindications

Hypersensitivity to ecallantide or its components

Adverse Reactions

CNS: Fatigue, fever, headache

EENT: Nasopharyngitis

GI: Diarrhea, nausea, upper abdominal pain, vomiting

RESP: Upper respiratory infection

SKIN: Pruritus

Other: Anaphylaxis; antibody formation to ecallantide; injection site reactions such as bruising, erythema, irritation, pain, pruritus, and urticaria

Nursing Considerations

- Ecallantide must be administered in a setting equipped to treat life-threatening hypersensitivity reactions.
- Refrigerate ecallantide and protect from light until time of administration.
- Using aseptic technique, withdraw 1 ml (10 mg) from 10-mg vial using a large-bore needle. Then, change needle on the syringe to a 27G subcutaneous needle. Repeat procedure for remaining two vials in dose pack.
- Give three injections of ecallantide subcutaneously into skin of abdomen, thigh, or upper arm. The injections may be in the same or different anatomic locations because there is no need for site rotation. However, the sites should be separated from each other by at least 5 cm (2 in). Also, don't use any site where signs and symptoms of the attack are located.

WARNING Monitor patient closely for hypersensitivity reactions, including anaphylaxis, especially within 1 hour of administration. Signs and symptoms may be similar to those of a hereditary angioedema attack. Immediately report chest pain, flushing, pharyngeal edema, pruritus, rhinorrhea, sneezing, nasal congestion, throat irritation, urticaria, wheezing, and hypotension, and be prepared to provide emergency supportive care, as ordered.

PATIENT TEACHING

- Explain that a dose requires three injections and that it may be repeated within 24 hours if needed.
- Stress importance of reporting any unusual signs and symptoms immediately after receiving ecallantide, such as wheezing, shortness of breath, cough, chest tightness, trouble breathing, dizziness, fainting, fast or weak heartbeat, nervousness, swelling of throat or tongue, throat tightness, hoarse voice, trouble swallowing, runny nose or sneezing, reddening of face, itching, hives or feeling warm.

E
F

eflornithine hydrochloride (alpha-difluoromethylornithine, DFMO)

Ornidyl

Class and Category

Chemical class: Difluoromethylornithine

Therapeutic class: Antiprotozoal

Pregnancy category: C

Indications and Dosages

↗ *To treat the meningoencephalitic stage of Trypanosoma brucei gambiense infection (sleeping sickness)*

I.V. INFUSION

Adults. 100 mg/kg given over at least 45 min every 6 hr for 14 days.

Route	Onset	Peak	Duration
I.V.	Unknown	4–6 hr	Unknown

Mechanism of Action

Inhibits the enzyme ornithine decarboxylase, which is needed for decarboxylation of ornithine. This process is the first step in polyamine synthesis, which is needed for protozoal cell division and differentiation.

Incompatibilities

Don't give eflornithine with any other drug.

Contraindications

Hypersensitivity to eflornithine or its components

Adverse Reactions

CNS: Asthenia, dizziness, headache, seizures

EENT: Hearing loss

GI: Abdominal pain, anorexia, diarrhea, vomiting

HEME: Anemia, eosinophilia, leukopenia, myelosuppression, thrombocytopenia

Other: Alopecia, facial edema

Nursing Considerations

- Plan to reduce eflornithine dosage as prescribed, based on renal function. Monitor creatinine clearance in patients with renal dysfunction.
- Before infusion, dilute eflornithine concentrate with sterile water for injection. Using strict aseptic technique, withdraw

the contents of a 100-ml vial and inject 25 ml into each of four I.V. diluent bags that contain 100 ml of sterile water. The resulting solution contains 40 mg/ml of eflornithine (5,000 mg of eflornithine in 125 ml total volume).

- Store bags of diluted eflornithine at 4° C (39° F) to reduce the risk of contamination. Use diluted drug within 24 hours.
- Expect to monitor the patient's CBC, including platelet count, before eflornithine treatment, twice weekly during treatment, and weekly after treatment stops until the patient's hematologic values return to baseline.
- Take infection-control and bleeding precautions because drug may cause myelosuppression. Adjust dosage or stop therapy as prescribed, based on severity.
- Take seizure precautions during eflornithine therapy.
- Consult prescriber about the need for serial audiography, if appropriate.
- Store undiluted vials of eflornithine at room temperature, and protect from freezing and light.

PATIENT TEACHING

- Stress need for follow-up visits because risk of relapse lasts 24 months after treatment.
- Teach patient how to follow infection-control and bleeding precautions if myelosuppression occurs.
- Warn patient about risk of seizures; advise against performing potentially hazardous activities during therapy.

eletriptan hydrobromide

Relpax

Class and Category

Chemical class: Serotonin 5-HT_{1D}-receptor agonist

Therapeutic class: Antimigraine agent

Pregnancy category: C

Indications and Dosages

↗ *To relieve acute migraine attacks with or without aura*

TABLETS

Adults. *Initial:* 20 or 40 mg as a single dose. Repeated in 2 hr, as needed and ordered.

Maximum: 40 mg as single dose, 80 mg daily.

Mechanism of Action

May stimulate 5-HT₁ receptors, causing selective vasoconstriction of inflamed and dilated cranial blood vessels in carotid circulation, which decreases carotid arterial blood flow and relieves acute migraines.

Contraindications

Bibasilar or hemiplegic migraine, cardiovascular disease (significant), cerebrovascular syndromes (stroke, transient ischemic attack), hepatic impairment (severe), hypersensitivity to eletriptan or components, ischemic bowel disease, ischemic or vasospastic coronary artery disease (CAD), peripheral vascular disease, uncontrolled hypertension, use within 24 hours of another serotonin 5-HT₁-receptor agonist or ergot-type drug, use within 72 hours of a potent CYP3A4 inhibitor

Interactions

DRUGS

clarithromycin, ketoconazole, itraconazole, nefazodone, nelfinavir, ritonavir, troleandomycin and other potent CYP3A4 inhibitors:

Increased metabolism of eletriptan and decreased blood eletriptan level
ergot-containing drugs, 5-HT₁-receptor agonists: Possibly additive or prolonged vasoconstrictive effects

fluoxetine, fluvoxamine, paroxetine, sertraline: Increased risk of weakness, hyperreflexia, and incoordination

Adverse Reactions

CNS: Asthenia, dizziness, headache, paresthesia, somnolence, tiredness, weakness

CV: Chest tightness, pain, or pressure; coronary artery vasospasm; hypertension, MI or myocardial ischemia (transient); ventricular fibrillation or tachycardia

EENT: Dry mouth, throat tightness

GI: Abdominal pain, cramps, discomfort, or pressure; dysphagia; indigestion; nausea

SKIN: Flushing

Other: Feeling of warmth, pain, or pressure

Nursing Considerations

- Ensure that patients who are at risk for CAD undergo a satisfactory CV evaluation before you administer the first dose of eletriptan and that they have a periodic re-evaluation of their cardiac status during

intermittent long-term therapy.

- Obtain an ECG immediately after first dose of drug in patients who have CV risk factors but who have had a satisfactory CV evaluation because of the drug's potential to cause coronary vasospasm.
- Evaluate patient for CV signs and symptoms after administration of eletriptan and notify prescriber if they occur. Expect drug to be withheld, as ordered, while patient undergoes an extensive CV workup, and discontinued if abnormalities are detected.
- Monitor patient's blood pressure during therapy because of drug's potential to increase blood pressure.

PATIENT TEACHING

- Advise patient to take eletriptan as soon as possible after onset of migraine symptoms.
- Urge patient to contact prescriber and avoid taking drug if headache symptoms aren't typical.
- Advise against exceeding prescribed dose.
- Instruct patient to seek emergency care for chest, jaw, or neck tightness after taking drug because these may indicate adverse CV reactions; subsequent doses may require ECG monitoring.
- Urge patient to report palpitations.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Advise yearly ophthalmic examinations during prolonged eletriptan therapy.
- Instruct patient to inform prescriber of all drugs he's taking, including OTC products and herbal remedies.

eltrombopag olamine

Promacta

Class and Category

Chemical class: Biphenyl hydrazone

Therapeutic class: Platelet formation inducer

Pregnancy category: C

Indications and Dosages

- *To treat thrombocytopenia in patients with chronic immune (idiopathic) thrombocytopenic purpura and an insufficient response to corticosteroids,*

*immunoglobulins, or splenectomy***TABLETS**

Adults. *Initial:* 50 mg daily, increased as needed to maintain a platelet count of $50 \times 10^9/L$. Platelet counts usually increase in 1 to 2 wk. *Maximum:* 75 mg daily.

DOSE ADJUSTMENT For patients of East Asian ancestry or patients with moderate to severe hepatic impairment, starting dose of 25 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	2–6 hr	Unknown

Mechanism of Action

Interacts with the transmembrane domain of the thrombopoietin receptor to signal cascades that induce proliferation and differentiation of megakaryocytes from bone marrow progenitor cells. This action increases platelet production, which is abnormally low in patients with thrombocytopenic purpura.

Contraindications

Hypersensitivity to eltrombopag or its components

Interactions**DRUGS**

acetaminophen, atorvastatin, benzylpenicillin, fluvastatin, methotrexate, nateglinide, NSAIDs, opioids, pravastatin, repaglinide, rifampin, rosuvastatin: Possibly increased risk of adverse reactions related to excessive exposure to these drugs
antacids and mineral supplements containing aluminum, calcium, iron, magnesium, selenium, or zinc: Decreased eltrombopag absorption

ciprofloxacin, fluvoxamine, gemfibrozil, omeprazole, rifampin, trimethoprim:

Increased risk of eltrombopag-induced adverse reactions

FOODS

all foods, especially dairy: Decreased absorption of eltrombopag

ACTIVITIES

smoking: Increased risk of eltrombopag-induced adverse reactions and possibly decreased eltrombopag efficacy

Adverse Reactions

CNS: Headache, paresthesia

EENT: Cataract, conjunctival hemorrhage

GI: Abdominal pain, dyspepsia, elevated liver enzymes, hepatotoxicity, nausea, vomiting

GU: Menorrhagia

HEME: Hemorrhage, thrombocytopenia

MS: Fatigue, myalgia

SKIN: Ecchymosis

Nursing Considerations

- Eltrombopag should be used only to treat chronic immune (idiopathic) thrombocytopenia purpura and not any other kind of thrombocytopenia because of the risk of hematologic malignancies.
- Eltrombopag can be used only through a restricted distribution program called, *Promacta Cares*. Patient, pharmacy, and prescriber must all be enrolled before therapy begins.
- Use cautiously in patients with hepatic impairment because drug may cause hepatotoxicity.
- Monitor liver enzymes and bilirubin level, as ordered, before starting eltrombopag, every 2 weeks during dosage adjustment, and monthly once dose is stable. If abnormalities occur, repeat testing within 3 to 5 days and then weekly until liver enzymes return to baseline. Expect to discontinue drug if alanine aminotransferase level increases to three or more times the upper normal limit, progresses or persists for 4 or more weeks, or is accompanied by an increase in direct bilirubin or clinical symptoms of liver injury.
- Obtain baseline CBC, including platelet count and peripheral blood smears, before starting eltrombopag therapy, weekly until stable, and monthly thereafter, as ordered, because thrombopoietin receptor agonists (the same class as eltrombopag) have caused bone marrow fibrosis.
- Patient should have a baseline eye examination, as ordered, before starting eltrombopag and periodically throughout therapy, because drug may cause cataracts.
- Dosage adjustments are based on platelet count response and are not used to normalize platelet counts in order to prevent or minimize thrombotic complications.
- Give eltrombopag 1 hour before or 2 hours after the patient has eaten. Separate doses of other drugs by at least 4 hours to prevent drug interactions.
- Do not administer more than one dose of

- eltrombopag within any 24-hour period.
- Expect to discontinue drug if improvement doesn't occur within 4 weeks at maximum dose of 75 mg daily.
 - Monitor patient for hematologic malignancies because eltrombopag stimulates thrombopoietin receptor on the surface of hematopoietic cells, which increases risk of malignancies.
 - Monitor patient for increased bleeding after stopping eltrombopag because thrombocytopenia may worsen, increasing bleeding risk, especially if patient is on anticoagulants or antiplatelet therapy. If bleeding occurs, obtain weekly CBC, including platelet count, for at least 4 weeks after therapy stops, and provide supportive care, as indicated and ordered.

PATIENT TEACHING

- Inform patient that, before eltrombopag therapy can begin, he must be enrolled in the *Promacta Cares* program, which provides comprehensive education about the drug.
- Urge patient to tell prescriber about all health conditions and all prescribed drugs, OTC drugs, herbs, and supplements taken.
- Instruct patient to take eltrombopag on an empty stomach with a full glass of water 1 hour before or 2 hours after a meal and to separate use of other drugs by at least 4 hours because food and certain drugs (such as antacids and iron and vitamin supplements) may interfere with eltrombopag absorption.
- Instruct patient to take drug at the same time every day because no more than one dose should be taken within any 24-hour period.
- Urge patient to report any adverse reactions to prescriber and to keep all appointments for blood work and follow-up.

enalapril maleate

Vasotec

enalaprilat

Vasotec I.V.

Class and Category

Chemical class: Dicarboxyl-containing ACE inhibitor

Therapeutic class: Antihypertensive
Pregnancy category: C (first trimester), D (later trimesters)

Indications and Dosages

↗ *To control hypertension*

TABLETS

Adults. *Initial:* 5 mg daily, increased after 1 to 2 wk, as needed. *Maintenance:* 10 to 40 mg once daily or in divided doses b.i.d.
Children. 0.08 mg/kg daily, titrated according to blood pressure response up to 5 mg daily. *Maximum:* 0.58 mg/kg/dose or 40 mg/dose.

I.V. INJECTION

Adults. 1.25 mg every 6 hr.

DOSAGE ADJUSTMENT Initial dose 2.5 mg P.O. or 0.625 mg I.V. for patients who have sodium and water depletion from diuretic therapy, are receiving diuretics, or have a creatinine clearance below 30 ml/min/1.73 m². If response to I.V. dose is inadequate after 1 hr, I.V. dose of 0.625 mg is repeated and therapy continued at 1.25 mg every 6 hr.

↗ *To treat heart failure*

TABLETS

Adults. *Initial:* 2.5 mg once or twice daily, increased after 1 to 2 wk, as needed. *Maintenance:* 5 to 40 mg once daily or in divided doses b.i.d.

↗ *To treat asymptomatic left ventricular dysfunction*

TABLETS

Adults. *Initial:* 2.5 mg b.i.d., increased to 20 mg daily in divided doses.

DOSAGE ADJUSTMENT Initial dosage reduced to 2.5 mg daily and, if possible, diuretic dosage reduced in patients who have a serum sodium level below 130 mEq/L or a serum creatinine level above 1.6 mg/dl.

Route	Onset	Peak	Duration
P.O.	1 hr	4–6 hr	About 24 hr
I.V.	15 min	1–4 hr	About 6 hr

Mechanism of Action

May reduce blood pressure by affecting the renin-angiotensin-aldosterone system. By inhibiting angiotensin-converting enzyme (ACE), enalapril:

- prevents conversion of angiotensin I to angiotensin II, a potent vasoconstrictor that also stimulates the adrenal cortex to

- secrete aldosterone
- may inhibit renal and vascular production of angiotensin II
- decreases the serum angiotensin II level and increases serum renin activity, which decreases aldosterone secretion and slightly increases serum potassium level and fluid loss
- decreases vascular tone and blood pressure
- inhibits aldosterone release, which reduces sodium and water reabsorption and increases their excretion, further reducing blood pressure.

Contraindications

History of angioedema from previous ACE inhibitor; hypersensitivity to enalapril, enalaprilat, or their components

Interactions

DRUGS

allopurinol, bone marrow depressants (such as amphotericin B and methotrexate), procainamide, systemic corticosteroids: Possibly increased risk of fatal neutropenia or agranulocytosis

cyclosporine, potassium-sparing diuretics, potassium supplements: Increased risk of hyperkalemia

diuretics, other antihypertensives: Additive hypotensive effects

lithium: Increased blood lithium level and lithium toxicity

NSAIDs: Possibly reduced antihypertensive effects of enalapril and enalaprilat

sodium aurothiomalate: Increased risk of nitritoid reactions, such as facial flushing, nausea, vomiting, and hypotension

sympathomimetics: Possibly reduced therapeutic effects of enalapril and enalaprilat

FOODS

potassium-containing salt substitutes: Increased risk of hyperkalemia

ACTIVITIES

alcohol use: Possibly additive hypotensive effect

Adverse Reactions

CNS: Ataxia, confusion, depression, dizziness, dream disturbances, fatigue, headache, insomnia, nervousness, peripheral neuropathy, somnolence, stroke, syncope, vertigo, weakness

CV: Angina, arrhythmias, cardiac arrest, hypotension, MI, orthostatic hypotension, palpitations, pulmonary embolism and

infarction, Raynaud's phenomenon

EENT: Blurred vision, conjunctivitis, dry eyes and mouth, glossitis, hoarseness, lacrimation, loss of smell, pharyngitis, rhinorrhea, stomatitis, taste perversion, tinnitus

ENDO: Gynecomastia

GI: Abdominal pain, anorexia, constipation, diarrhea, hepatic failure, hepatitis, ileus, indigestion, melena, nausea, pancreatitis, vomiting

GU: Flank pain, impotence, oliguria, renal failure, UTI

MS: Muscle spasms

RESP: Asthma, bronchitis, bronchospasm, cough, dyspnea, pneumonia, pulmonary edema, pulmonary infiltrates, upper respiratory tract infection

SKIN: Alopecia, diaphoresis, erythema multiforme, exfoliative dermatitis, flushing, pemphigus, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, herpes zoster, hyperkalemia

Nursing Considerations

- Use enalapril and enalaprilat cautiously in patients with impaired renal function. Avoid giving drug to children with a GFR less than 30 ml/min/1.73 m².
- For children who can't swallow tablets, consult with prescriber and pharmacist about preparing an oral suspension from tablets as directed by manufacturer.
- Administer each I.V. dose over at least 5 minutes.
- Measure patient's blood pressure immediately after first dose and frequently for at least 2 hours thereafter. If hypotension requires a dosage reduction, monitor blood pressure frequently for 2 hours after reduced dosage is administered and for another hour after blood pressure has stabilized.
- Monitor blood pressure regularly during therapy. If hypotension develops, place patient in a supine position and expect to give I.V. normal saline solution or other volume expander as prescribed.
- Monitor patient's heart rate and rhythm. Expect to obtain repeated 12-lead ECG tracings.
- Monitor laboratory test results to check hepatic and renal function, leukocyte count, and serum potassium level.

- Monitor patient closely for angioedema of the face, lips, tongue, glottis, larynx, and limbs. For angioedema of the face and lips, stop drug and give an antihistamine, as prescribed. If tongue, glottis, or larynx is involved, assess patient for airway obstruction and prepare to give epinephrine 1:1,000 (0.3 to 0.5 ml) subcutaneously and maintain a patent airway.

PATIENT TEACHING

- Advise patient to take enalapril or enalaprilat at the same time each day.
- Instruct patient not to split, crush, or chew tablets.
- Inform patient that light-headedness and fainting may occur, especially during first few days of therapy. Advise him to change position slowly and avoid hazardous activities until drug's CNS effects are known.
- Inform patient that diarrhea, excessive sweating, vomiting, and other conditions may cause dehydration, which can lead to dizziness, fainting, and very low blood pressure during therapy. Urge sufficient fluid intake to prevent dehydration and related adverse reactions. If diarrhea or vomiting is severe or prolonged, instruct patient to notify prescriber.
- Urge patient to immediately notify prescriber if angioedema and other adverse reactions, including persistent dry cough, occur.
- Advise patient to consult prescriber before using salt substitutes, potassium supplements, or other drugs (including OTC drugs) while taking drug.

WARNING Caution women of childbearing age that they should use a reliable form of contraception and should notify prescriber immediately if pregnancy is suspected because enalapril may cause fetal harm and should be discontinued.

enoxacin

Penetrex

Class and Category

Chemical class: Fluoroquinolone

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

↗ *To treat gonorrhea*

TABLETS

Adults. 400 mg as a single dose.

↗ *To treat uncomplicated UTI*

TABLETS

Adults. 200 mg every 12 hr for 7 days.

↗ *To treat complicated UTI*

TABLETS

Adults. 400 mg every 12 hr for 14 days.

DOSAGE ADJUSTMENT Dosage reduced by half in patients with creatinine clearance of 30 ml/min/1.73 m² or less.

Contraindications

History of tendinitis or tendon rupture, hypersensitivity to enoxacin or any quinolone antibiotic

Interactions

DRUGS

aluminum-, calcium-, or magnesium-containing antacids; didanosine (chewable or buffered tablets); ferrous sulfate; magnesium-containing laxatives; sucralfate; zinc:

Interference with enoxacin absorption, decreased blood enoxacin level

bismuth: Decreased enoxacin bioavailability (by about 25% if given with or up to 60 minutes after enoxacin)

cyclosporine: Possibly increased blood cyclosporine level

digoxin: Increased serum digoxin level and risk of digitalis toxicity

NSAIDs: Possibly increased risk of CNS stimulation and seizures

theophylline: Interference with theophylline metabolism, increased risk of theophylline toxicity

warfarin: Possibly increased anticoagulant effect and increased risk of bleeding

FOODS

caffeine: Decreased caffeine clearance, increased adverse effects of caffeine, increased blood enoxacin level

Adverse Reactions

CNS: Dizziness, drowsiness, hallucinations, headache, insomnia, nervousness, seizures, vertigo

EENT: Taste perversion

GI: Abdominal pain, diarrhea, indigestion, nausea, pseudomembranous colitis, vomiting

GU: Vaginitis

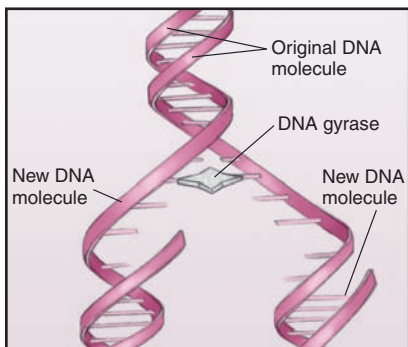

MS: Tendinitis, tendon rupture

SKIN: Photosensitivity, pruritus, rash

Other: Anaphylaxis

Mechanism of Action

Normally, the enzyme DNA gyrase is responsible for unwinding and supercoiling bacterial DNA before replication, as

shown at left. Enoxacin inhibits DNA gyrase, as shown at right, disrupting bacterial replication and causing cell death.

Nursing Considerations

- Be aware that enoxacin shouldn't be given to a patient under age 18 because it may cause arthropathy.
- Use drug cautiously in patients with a history of or susceptibility to seizures.
- Obtain a specimen for culture and sensitivity tests, as ordered, but expect to begin therapy before results are available.
- Monitor patient closely for signs and symptoms of anaphylaxis after first dose: shock, dyspnea, facial or laryngeal edema, loss of consciousness, paresthesia, pruritus, and urticaria. If they occur, stop enoxacin immediately, notify prescriber, and prepare to treat symptoms.
- Ask if patient has a history of seizures. Take seizure and safety precautions because drug may induce seizures and other adverse CNS reactions after a single dose.
- Report severe or prolonged diarrhea, which may indicate pseudomembranous colitis.
- Watch for pain, inflammation, and tendon rupture, especially in shoulders, hands, and ankles.
- If patient has gonorrhea, expect to obtain a serologic test for syphilis at diagnosis and 3 months after enoxacin therapy ends.

PATIENT TEACHING

- Stress the importance of taking the full course of enoxacin exactly as prescribed,

even if patient feels better before it's finished.

- Instruct patient to take drug at the same times each day—1 hour before or 2 hours after meals—with 8 oz of water.
- Urge patient to avoid potentially hazardous activities until CNS effects of enoxacin are known.
- Advise patient to notify prescriber if symptoms don't improve within a few days.
- Urge patient to drink plenty of fluids but to avoid caffeine during therapy.
- Caution patient not to take aluminum-, calcium-, or magnesium-containing antacids; bismuth; didanosine (chewable or buffered tablets), if prescribed; or products that contain iron or zinc for 8 hours before or 2 hours after taking enoxacin.
- Tell patient to avoid direct sunlight, to use sunscreen and wear protective clothing outdoors, and to report photosensitivity.
- Instruct patient to stop taking enoxacin and notify prescriber immediately if a rash or other allergic reaction develops.
- Instruct patient to take a missed dose as soon as he remembers, unless it's nearly time for the next. Warn against doubling the dose.
- Tell patient to report tendon pain or inflammation, to stop enoxacin, and to rest until tendinitis or tendon rupture is ruled out.

enoxaparin sodium

Lovenox

Class and Category

Chemical class: Low-molecular-weight heparin

Therapeutic class: Antithrombotic

Pregnancy category: B

Indications and Dosages

↗ *To prevent deep vein thrombosis (DVT) after hip or knee replacement and for continued prophylaxis after hospitalization for hip replacement*

SUBCUTANEOUS INJECTION

Adults. 30 mg every 12 hr, starting 12 to 24 hr after surgery for up to 14 days. Or, 40 mg daily, starting 9 to 15 hr after hip replacement surgery. *Prophylaxis:* 40 mg daily for 3 wk.

↗ *To prevent DVT after abdominal surgery for patients with thromboembolic risk factors (over age 40, obesity, general anesthesia lasting longer than 30 minutes, cancer, or a history of DVT or pulmonary embolism)*

SUBCUTANEOUS INJECTION

Adults. 40 mg daily, starting 2 hr before surgery and lasting 7 to 10 days.

↗ *To prevent ischemic complications of unstable angina and non-Q-wave MI*

SUBCUTANEOUS INJECTION

Adults. 1 mg/kg every 12 hr with 100 to 325 mg of aspirin daily for 2 to 8 days or until condition is stable.

DOSAGE ADJUSTMENT Dosage reduced to 30 mg daily if creatinine clearance is less than 30 ml/min/1.73 m² and patient is receiving drug as prophylaxis in abdominal, hip, or knee replacement surgery or is acutely ill. Reduced to 1 mg/kg daily if creatinine clearance is less than 30 ml/min/1.73 m² and drug is given with aspirin to prevent ischemic complications of unstable angina and non-Q-wave MI, with warfarin as inpatient treatment for acute DVT with or without pulmonary embolism, or with warfarin as outpatient treatment of acute DVT without pulmonary embolism.

↗ *To treat acute ST-segment-elevation MI (STEMI)*

I.V. INJECTION, THEN SUBCUTANEOUS INJECTION

Adults. 30 mg I.V. as a single dose, followed

by 1 mg/kg subcutaneously (maximum, 100 mg for first two doses). Then, 1 mg/kg subcutaneously every 12 hr.

DOSAGE ADJUSTMENT If patient also receives a thrombolytic, enoxaparin should be given 15 to 30 min before and 30 min after fibrinolytic therapy starts. If patient has percutaneous coronary intervention, give 0.3-mg/kg I.V. bolus if last enoxaparin dose was given more than 8 hr before balloon inflation.

Route	Onset	Peak	Duration
SubQ	Unknown	3–5 hr	Up to 24 hr

Mechanism of Action

Potentiates the action of antithrombin III, a coagulation inhibitor. By binding with antithrombin III, enoxaparin rapidly binds with and inactivates clotting factors (primarily thrombin and factor Xa). Without thrombin, fibrinogen can't convert to fibrin and clots can't form.

Incompatibilities

Don't mix enoxaparin with other I.V. fluids or drugs.

Contraindications

Active major bleeding; hypersensitivity to benzyl alcohol (if only the multidose vial is available), enoxaparin, heparin (including low-molecular-weight heparins), or pork products; thrombocytopenia and positive antiplatelet antibody test while taking low-molecular-weight heparins

Interactions

DRUGS

cefamandole, cefoperazone, cefotetan, plicamycin, valproic acid: Possibly increased risk of hemorrhage

NSAIDs; oral anticoagulants; platelet aggregation inhibitors, such as aspirin, dipyridamole, sulfipyrazone, and ticlopidine; thrombolytics, such as alteplase, anistreplase, streptokinase, and urokinase: Possibly increased risk of bleeding and of spinal or epidural hematoma

Adverse Reactions

CNS: Confusion, epidural or spinal hematoma, fever, paralysis, stroke

CV: Atrial fibrillation, congestive heart failure, hyperlipidemia, peripheral edema

EENT: Epistaxis

GI: Bloody stools, diarrhea, elevated liver function test results, hematemesis, melena, nausea, vomiting

GU: Hematuria, menstrual irregularities

HEME: Anemia, hemorrhage, thrombocytopenia

RESP: Dyspnea, pneumonia, pulmonary edema or embolism

SKIN: Cutaneous vasculitis, ecchymosis, persistent bleeding or oozing from mucous membranes or surgical wounds, pruritus, skin necrosis at injection site or distant from injection site, urticaria, vesiculobulbous rash

Other: Anaphylaxis; hyperkalemia; injection site erythema, hematoma, irritation, and pain

Nursing Considerations

- Use enoxaparin with extreme caution in patients with a history of heparin-induced thrombocytopenia or an increased risk of hemorrhage, as from bacterial endocarditis; congenital or acquired bleeding disorder; active ulcerative or angiodysplastic GI disease; hemorrhagic stroke; recent brain, spinal, or ophthalmologic surgery; or concurrent treatment with a platelet inhibitor.
- Use cautiously in those with bleeding diathesis, diabetic retinopathy, hepatic or renal impairment, recent GI ulceration or hemorrhage, or uncontrolled hypertension. Expect delayed elimination in elderly patients and those with renal insufficiency.
- Drug isn't recommended for patients with prosthetic heart valves, especially pregnant women, because of risk of prosthetic valve thrombosis. If enoxaparin is needed, monitor peak and trough anti-factor Xa levels often and adjust dosage as needed.
- Use multidose vials cautiously in pregnant women because benzyl alcohol may cross the placenta and cause fetal harm.
- Don't give drug by I.M. injection.

WARNING If patient is receiving enoxaparin with epidural or spinal anesthesia or spinal puncture, watch closely for development of spinal hematoma, which may cause long-term or permanent paralysis. If you see evidence of neurologic impairment, such as changes in sensory or motor function, notify prescriber immediately because urgent care is needed to minimize hematoma's effect. Risk of spinal or epidural hematoma during enoxaparin

therapy is increased by indwelling epidural catheters, concurrent use of other drugs that affect hemostasis, a history of traumatic or repeated epidural or spinal punctures, or a history of spinal deformity or spinal surgery.

- Expect to give drug with aspirin to patient with unstable angina, STEMI, and non-Q-wave MI. To minimize risk of bleeding after vascular procedures, give enoxaparin at recommended intervals.
- After percutaneous revascularization procedure, it is important to achieve hemostasis at the puncture site. A closure device may be removed right away; however, if a manual compression method is used, the sheath should be removed 6 hours after last enoxaparin dose. If enoxaparin therapy will continue, give next scheduled dose no sooner than 6 to 8 hours after sheath removal.
- Watch closely for bleeding. Notify prescriber immediately if platelet count falls below 100,000/mm³. Expect to stop drug and start treatment if patient has a thromboembolic event, such as a stroke.
- Test stool for occult blood, as ordered.
- Keep protamine sulfate nearby in case of accidental overdose.
- Check serum potassium level for elevation, especially in patients with renal impairment or concurrent use of potassium-sparing diuretics.

PATIENT TEACHING

- Advise patient to notify prescriber about adverse reactions, especially bleeding.
- Instruct patient to seek immediate help for evidence of thromboembolism, such as neurologic changes and severe shortness of breath.
- Stress the importance of complying with follow-up visits with prescriber.
- Teach patient or family member how to give enoxaparin at home, if needed. Show patient how to give by deep subcutaneous injection while lying down. Instruct him not to expel air bubble from a prefilled syringe to avoid losing some of the drug. Tell him to insert the entire needle into a skin fold held between the thumb and forefinger. Remind him to alternate injection sites between the left and right anterolateral abdominal wall.
- To minimize bruising, caution patient not

- to rub the site after giving the injection.
- Review safe handling and disposal of syringes and needles.

entacapone

Comtan

Class and Category

Chemical class: COMT inhibitor

Therapeutic class: Antidyskinetic

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to manage symptoms of Parkinson's disease*

TABLETS

Adults. 200 mg with each dose of carbidopa and levodopa. *Maximum:* 1,600 mg daily.

Mechanism of Action

Inhibits peripheral catechol-O-methyltransferase (COMT), the major metabolizing enzyme for levodopa. During levodopa metabolism, COMT causes the formation of a levodopa metabolite that reduces the effectiveness of levodopa. By inhibiting COMT, entacapone leads to higher sustained blood levels of levodopa and its increased availability for diffusion into the CNS, where it is converted to dopamine. By replenishing dopamine stores, entacapone increases dopaminergic stimulation in the brain and reduces the symptoms of Parkinson's disease. Carbidopa is given with levodopa because it inhibits the peripheral distribution of levodopa, making more levodopa available for transport to the brain.

Contraindications

Hypersensitivity to entacapone or its components, use within 14 days of nonselective MAO inhibitor therapy

Interactions

DRUGS

ampicillin, chloramphenicol, cholestyramine, erythromycin, probenecid, rifampin:

Decreased biliary excretion of entacapone
apomorphine, bitolterol, dobutamine, dopamine, epinephrine, isoetharine, isoproterenol, methyl dopa, norepinephrine: Possibly increased heart rate, arrhythmias, and excessive changes in blood pressure
MAO inhibitors (nonselective): Possibly

inhibited entacapone metabolism

Adverse Reactions

CNS: Agitation, anxiety, asthenia, dizziness, dyskinesia, fatigue, hallucinations, hyperkinesia, hypokinesia, somnolence

EENT: Dry mouth

GI: Abdominal pain, constipation, diarrhea, indigestion, gastritis, nausea

GU: Brown-orange urine

MS: Back pain

RESP: Dyspnea

SKIN: Diaphoresis, purpura

Other: Intense urges to perform certain acts, such as gambling or sex

Nursing Considerations

WARNING Be aware that entacapone should not be discontinued abruptly because doing so may precipitate signs and symptoms resembling those of neuroleptic malignant syndrome, such as fever, muscle rigidity, altered level of consciousness, confusion, and elevated creatine kinase level. Patients may also experience a rapid reemergence of parkinsonian symptoms.

- Monitor patient for drug-induced diarrhea during first 4 to 12 weeks of therapy.
- Help patient with activities as needed because drug may increase risk of orthostatic hypotension or syncope.
- Watch for worsening dyskinesia because entacapone potentiates dopaminergic adverse effects of levodopa.
- Drug may be taken with selective MAO inhibitors, such as selegiline.
- Assess patient for skin changes regularly because risk of melanoma is increased in those with Parkinson's disease. It isn't clear whether increased risk results from the disease or drugs used to treat it.

PATIENT TEACHING

- Instruct patient to always take entacapone with carbidopa and levodopa because it has no antidyskinetic effect of its own.
- Inform patient that dizziness and sleepiness are more common at beginning of treatment, especially in those with hypotension.
- Advise patient not to participate in potentially hazardous activities until drug's CNS effects are known, especially if he's also taking CNS depressants.
- If patient is scheduled for surgery, instruct him to inform surgeon and anesthesiolo-

gist about entacapone use before the procedure because COMT inhibitors such as entacapone may interact with some drugs used in surgical procedures.

- Caution patient that entacapone may increase adverse effects of carbidopa and levodopa, such as nausea and uncontrolled movements. If these adverse effects do increase, advise him to contact prescriber immediately because carbidopa and levodopa dosage may need to be lowered.
- Inform patient that urine may turn brown-orange while he's taking entacapone but that this is a harmless effect.
- Urge patient to have regular skin examinations by a dermatologist or other qualified health professional.
- Advise patient to notify prescriber about intense urges, including those for gambling or sex. Dosage may need to be reduced or drug discontinued.

epinephrine (adrenaline)

Adrenalin, Adrenalin Chloride Solution, Ana-Guard, Bronkaid Mist, Bronkaid Mistometer (CAN), EpiPen (CAN), EpiPen Auto-Injector, EpiPen Jr. (CAN), EpiPen Jr. Auto-Injector, Primatene Mist

epinephrine bitartrate

Asthmahaler Mist, Bronkaid Suspension Mist

racepinephrine

AsthmaNefrin, MicroNefrin, Nephron, Vaponefrin

Class and Category

Chemical class: Catecholamine

Therapeutic class: Antianaphylactic, bronchodilator, cardiac stimulant, vasopressor

Pregnancy category: C

Indications and Dosages

↗ *To treat bronchospasm*

INHALED SOLUTION (EPINEPHRINE)

Adults and children age 4 and over. 1 to 3 inhalations (10 drops) by hand-bulb nebulizer no more than every 3 hr.

ulizer no more than every 3 hr.

INHALED SOLUTION (RACEPINEPHRINE)

Adults and children age 4 and over.

3 inhalations of 0.5 ml (10 drops) by hand-bulb nebulizer, or 0.2 to 0.5 ml (4 to 10 drops) of diluted solution given over 15 min by jet nebulizer; repeated after 3 to 4 hr, if needed.

ORAL INHALED AEROSOL (EPINEPHRINE BITARTRATE)

Adults and children age 4 and over.

1 inhalation (160 mcg) repeated after 1 min, if needed; then repeated after at least 3 hr.

ORAL INHALER (EPINEPHRINE)

Adults and children age 4 and over.

1 inhalation (200 to 275 mcg) repeated after at least 1 min, if needed; then repeated after at least 3 hr.

↗ *To treat croup*

INHALED SOLUTION (RACEPINEPHRINE)

Children. 0.05 ml/kg diluted to 3 ml in normal saline solution and given over 15 min every 2 hr, as needed. *Maximum:* 0.5 ml/dose.

↗ *To treat anaphylaxis*

I.V. INFUSION

Adults and adolescents. 100 to 250 mcg given slowly.

I.M. OR SUBCUTANEOUS INJECTION

Adults and adolescents. 100 to 500 mcg repeated every 10 to 15 min, as needed.

Maximum: 1 mg/dose; three doses.

Children. 10 mcg/kg repeated every 15 min for three doses. *Maximum:* 300 mcg/dose.

↗ *To treat severe anaphylactic shock*

I.V. INFUSION

Adults. 1 mcg/min titrated to 2 to 10 mcg/min for desired hemodynamic response.

↗ *To treat cardiac arrest*

I.V. INJECTION

Adults. 0.5 to 1 mg every 3 to 5 min during resuscitation.

Children. 10 mcg/kg followed by 100 mcg/kg every 3 to 5 min, if needed. If two doses produce no response, subsequent doses are increased to 200 mcg/kg every 5 min.

Neonates. 10 to 30 mcg/kg every 3 to 5 min.

Mechanism of Action

Acts on alpha and beta receptors. This non-selective adrenergic agonist stimulates:

- alpha₁ receptors, which constricts arteries and may decrease bronchial secretions
- presynaptic alpha₂ receptors, which inhibits norepinephrine release by way of

negative feedback

- postsynaptic α_2 receptors, which constricts arteries
- β_1 receptors, which induces positive chronotropic and inotropic responses
- β_2 receptors, which dilates arteries, relaxes bronchial smooth muscles, increases glycogenolysis, and prevents mast cells from secreting histamine and other substances, thus reversing bronchoconstriction and edema.

Route	Onset	Peak	Duration
I.V., I.M.	Rapid	Unknown	1–2 min
SubQ	5–10 min	In 20 min	Short
Oral	1–5 min	In 5–15 min	Up to 3 hr

Incompatibilities

Don't mix epinephrine with alkalis or oxidizing agents, including bromine, chlorine, chromates, iodine, metal salts (as from iron), nitrites, oxygen, and permanganates, because these substances can destroy epinephrine.

Contraindications

Cerebral arteriosclerosis, coronary insufficiency, counteraction of phenothiazine-induced hypotension, dilated cardiomyopathy, general anesthesia with halogenated hydrocarbons or cyclopropane, hypersensitivity to epinephrine or its components, labor, angle-closure glaucoma, organic brain damage, shock (nonanaphylactic)

Interactions

DRUGS

alpha-adrenergic blockers, drugs with alpha-adrenergic action, rapid-acting vasodilators: Blockage of epinephrine's alpha-adrenergic effect, possibly causing severe hypotension and tachycardia

amyl nitrite, nitrates: Decreased antianginal effects

antihypertensives, diuretics used to treat hypertension: Decreased antihypertensive effects

beta blockers: Mutual inhibition of therapeutic effects, possibly severe hypertension and cerebral hemorrhage

chlorpheniramine, diphenhydramine, levothyroxine, MAO inhibitors, tricyclic antidepressants, tripeleminamine: Possibly increased

effects of epinephrine

digoxin, diuretics, quinidine: Increased risk of arrhythmias

dihydroergotamine, ergoloid mesylates, ergonovine, ergotamine, methylergonovine, methysergide, oxytocin: Increased risk of vasoconstriction, causing gangrene, peripheral vascular ischemia, or severe hypertension

ergot alkaloids: Possibly reversed pressor effects of epinephrine

hydrocarbon inhalation anesthetics:

Increased risk of severe atrial and ventricular arrhythmias

insulin, oral antidiabetic drugs: Decreased effects of these drugs

MAO inhibitors: Possibly increased vasopressor effect of epinephrine and hypertensive crisis

maprotiline, tricyclic antidepressants:

Potentiated cardiovascular effects of epinephrine, possibly causing arrhythmias, hyperpyrexia, severe hypertension, or tachycardia

sympathomimetics: Additive CNS stimulation, increased cardiovascular effects of either drug

thyroid hormones: Increased effects of either drug

xanthines: CNS stimulation and toxic effects

Adverse Reactions

CNS: Anxiety, apprehensiveness, chills, fever, dizziness, drowsiness, hallucinations, headache, insomnia, light-headedness, nervousness, restlessness, seizures, stroke, temporary worsening of Parkinson's disease, tremor, weakness

CV: Arrhythmias, including ventricular fibrillation; chest discomfort or pain; fast, irregular, or slow heartbeat; palpitations; severe hypertension; tachycardia

EENT: Blurred vision, dry mouth or throat, miosis

ENDO: Hyperglycemia in diabetics

GI: Anorexia, heartburn, nausea, vomiting

GU: Dysuria

MS: Muscle twitching, severe muscle spasms

RESP: Dyspnea

SKIN: Cold skin, diaphoresis, ecchymosis, flushed or red face or skin, pallor, tissue necrosis

Other: Hyperkalemia; hypokalemia; injec-

tion site coldness, hypoaesthesia, pain, pallor, and stinging

Nursing Considerations

- Use epinephrine with extreme caution in patients with angina, arrhythmias, asthma, degenerative heart disease, or emphysema. Epinephrine's inotropic effect equals that of dopamine and dobutamine; its chronotropic effect exceeds that of both.
- Use drug cautiously in elderly patients and those with cardiovascular disease (other than listed above), diabetes mellitus, hypertension, hyperthyroidism, prostatic hypertrophy, and psychoneurologic disorders.
- Be aware that some preparations contain sulfites, which may cause allergic-type reactions. However, the presence of sulfites in epinephrine should not deter its use in a patient with anaphylaxis, even if patient is sensitive to sulfites. Monitor patient closely for adverse effects.
- Dilute the 1:1,000 (1-mg/ml) solution of parenteral epinephrine before I.V. use.
- Shake suspension thoroughly before withdrawing dose; refrigerate it between uses.
- Inspect epinephrine solution or suspension before use. If it's pink or brown, air has entered a multidose vial. If it's discolored or contains particles, discard it. Also discard unused portions of parenteral epinephrine.
- For injection, rotate sites because repeated injections in the same site may cause vasoconstriction and localized necrosis.
- Be aware that drug shouldn't be given by intra-arterial injection because marked vasoconstriction may cause gangrene.
- Avoid giving injection into buttocks because drug may be less effective when given there, especially for treating anaphylaxis.
- Monitor patient for potassium imbalances. Initially, hyperkalemia occurs when hepatocytes release potassium. Hypokalemia may quickly follow as skeletal muscles take up potassium.
- To minimize insomnia, give last dose a few hours before bedtime.

WARNING To treat cardiac arrest, at least twice the peripheral I.V. dose of epinephrine may be given by endotracheal instillation. Two dilutions are needed for this regimen; use great caution to avoid making medication errors.

PATIENT TEACHING

- Warn patient not to exceed recommended dosage or to shorten interval because of the risk of adverse reactions and tolerance.
- Advise patient to notify prescriber if symptoms don't improve or if they improve but then worsen.
- Instruct patient to take the day's last dose a few hours before bedtime to avoid insomnia.
- Caution patient not to use inhalation solution that is pink or brown or that contains particles.
- Teach patient how to use oral inhaler or inhalation solution, as needed.
- If patient also uses an oral corticosteroid inhaler, instruct him to use epinephrine inhaler first, wait 5 minutes, and then use corticosteroid inhaler to increase effectiveness.
- Teach patient and family how to administer epinephrine subcutaneously in an emergency. Tell them to inject drug into anterolateral aspect of the thigh, through the clothing if necessary. Explain that solution is light sensitive and should be stored in the carrying case and at room temperature. Tell them not to refrigerate drug and to replace solution if it discolors.
- Caution patient to avoid accidental injecting drug into his fingers, hands, toes, or feet because epinephrine is a strong vasoconstrictor and could cause loss of blood flow to the area, resulting in gangrene. If accidental injection occurs in any of these areas, instruct patient to go immediately to nearest emergency room.
- Advise patient to notify prescriber immediately if he has blurred vision, chest pain, trouble breathing, a fast or irregular heartbeat, or increased sweating.
- Inform patient with diabetes that epinephrine may cause hyperglycemia. Inform patient with Parkinson's disease that symptoms may temporarily worsen but this should not deter use of drug.

eplerenone

Inspira

Class and Category

Chemical class: Methyl ester

Therapeutic class: Antihypertensive
Pregnancy category: B

Indications and Dosages

➤ *To improve survival of stable patients with left ventricular systolic dysfunction and congestive heart failure after an acute MI*

TABLETS

Adults. *Initial:* 25 mg daily, increased to 50 mg daily within 4 wk, if needed.

➤ *To treat hypertension alone or with other antihypertensive drugs*

TABLETS

Adults. *Initial:* 50 mg daily, increased to 50 mg b.i.d. after 4 wk, if needed.

DOSAGE ADJUSTMENT For patients taking weak CYP450 3A4 inhibitors, such as erythromycin, saquinavir, verapamil, and fluconazole, initial dosage reduced to 25 mg daily.

Mechanism of Action

Blocks the binding of aldosterone at its mineralocorticoid receptor sites located in the kidneys, heart, blood vessels, and brain. This action decreases blood pressure by preventing aldosterone from inducing sodium reabsorption and possibly other mechanisms that contribute to raising blood pressure.

Contraindications

Hyperkalemia (serum potassium level greater than 5.5 mEq/L); hypersensitivity to eplerenone or its components; renal insufficiency (serum creatinine level greater than 2.0 mg/dl in men or 1.8 mg/dl in women or creatinine clearance less than 50 ml/min/1.73 m²); type 2 diabetes mellitus complicated by microalbuminuria; use of potassium supplements, potassium-sparing diuretics, or strong CYP3A4 inhibitors, such as ketoconazole or itraconazole

Interactions

DRUGS

ACE inhibitors, angiotensin II receptor antagonists: Increased risk of hyperkalemia
CYP450 3A4 inhibitors: Increased blood level and effect of eplerenone
lithium: Possibly lithium toxicity
NSAIDs: Possibly reduced antihypertensive effect of eplerenone

FOODS

grapefruit: Possibly increased blood level

and effect of eplerenone

Adverse Reactions

CNS: Dizziness, fatigue, headache

CV: Angina pectoris, hypercholesterolemia, hypertriglyceridemia, MI

ENDO: Gynecomastia, mastodynia

GI: Abdominal pain, diarrhea, increased liver enzyme levels

GU: Albuminuria, elevated BUN and serum creatinine levels, vaginal bleeding

RESP: Cough

Other: Flulike symptoms, hyperkalemia, hyponatremia, increased uric acid level

Nursing Considerations

- Monitor patient's blood pressure regularly to evaluate eplerenone effectiveness.
- Monitor patient's serum potassium level every 2 weeks for the first month or two of therapy and monthly thereafter, as ordered.
- Be aware that patients who take an ACE inhibitor or an angiotensin II receptor antagonist during eplerenone therapy have an increased risk of hyperkalemia.

PATIENT TEACHING

- Caution patient not to use potassium-containing supplements or salt substitutes because increased potassium levels can lead to serious adverse reactions to eplerenone.
- Urge patient to tell all prescribers about eplerenone use because of possible interactions.

epoetin alfa (EPO, erythropoietin alfa, recombinant erythropoietin, r-HuEPO)

Epogen, Eprex (CAN), Procrit

Class and Category

Chemical class: 165–amino acid glycoprotein identical to human erythropoietin

Therapeutic class: Anianemic

Pregnancy category: C

Indications and Dosages

➤ *To treat anemia from renal failure*

I.V. OR SUBCUTANEOUS INJECTION

Adults and adolescents. *Initial:* 50 to 100 units/kg 3 times/wk, increased by

25 units/kg after 8 wk if hematocrit hasn't risen by 5 or 6 points or is below desired range (30% to 36%). *Maintenance:* Dosage gradually decreased by 25 units/kg at 4-wk intervals or longer to lowest dose that keeps hematocrit at 30% to 36%. *Maximum:* 300 units/kg 3 times/wk.

Children on dialysis. 50 units/kg 3 times/wk; increased after 8 wk if hematocrit hasn't risen by 5 or 6 points and is still below desired range of 30% to 36%. *Maintenance:* Dosage gradually decreased to lowest dose that keeps hematocrit at 30% to 36%.

➤ *To treat anemia in HIV-infected patients who take zidovudine*

I.V. OR SUBCUTANEOUS INJECTION

Adults with serum erythropoietin level of 500 mU/ml or less who receive 4,200 mg or less of zidovudine/wk. *Initial:* 100 units/kg 3 times/wk, increased by 50 to 100 units/kg every 4 to 8 wk after 8 wk of therapy.

Maintenance: Dosage gradually titrated to maintain desired response, based on such factors as variations in zidovudine dosage and occurrence of infection or inflammation. *Maximum:* 300 units/kg 3 times/wk.

➤ *To treat anemia from chemotherapy*

SUBCUTANEOUS INJECTION

Adults. *Initial:* 150 units/kg 3 times/wk. Dosage decreased by 25% if hemoglobin level approaches 12 g/dl or increases more than 1 g/dl in any 2-wk period. Dose withheld if hemoglobin exceeds 13 g/dl and resumed at 25% less than previous dose after hemoglobin has fallen to 12 g/dl. Dosage increased to 300 units/kg 3 times/wk after 8 wk if response is inadequate. *Maximum:* 300 units/kg 3 times/wk. Or, 40,000 units weekly. Dosage decreased by 25% if hemoglobin level approaches 12 g/dl or increases more than 1 g/dl in any 2-wk period. Dose withheld if hemoglobin level exceeds 13 g/dl and resumed at 25% less than previous dose after hemoglobin has fallen to 12 g/dl. Dosage increased to 60,000 units weekly after 8 wk if hemoglobin level has not increased at least 1 g/dl without RBC transfusion.

➤ *To reduce the need for blood transfusion in anemic patients having surgery*

SUBCUTANEOUS INJECTION

Adults. 300 units/kg daily for 10 days before surgery, on day of surgery, and 4 days after surgery; or 600 units/kg/wk starting 3 wk

before surgery for a total of 3 doses. Dose of 300 units/kg repeated on day of surgery. **DOSAGE ADJUSTMENT** For patients with anemia from renal failure, dosage temporarily reduced or drug discontinued if hematocrit reaches or exceeds 36%; drug is resumed at a lower dose when hematocrit returns to desired range. For patients with anemia from zidovudine use, therapy temporarily stopped if hematocrit reaches or exceeds 40% and is resumed at a 25% lower dose when hematocrit returns to desired range.

Route	Onset	Peak	Duration
I.V.,	In 2–6 wk	In 2 mo	About
SubQ			2 wk

Mechanism of Action

Stimulates the release of reticulocytes from the bone marrow into the bloodstream, where they develop into mature RBCs.

Incompatibilities

Don't mix epoetin alfa with any other drug.

Contraindications

Hypersensitivity to human albumin or products made from mammal cells, uncontrolled hypertension

Interactions

DRUGS

antihypertensives: Increased blood pressure (to hypertensive level), especially when hematocrit rises rapidly

heparin: Increased heparin requirement in hemodialysis patients

iron supplements: Increased iron requirement and need for increased dose

Adverse Reactions

CNS: Anxiety, asthenia, dizziness, fatigue, fever, headache, insomnia, paresthesia, seizures, stroke

CV: Chest pain, deep vein thrombosis, edema, hypertension, MI, tachycardia

GI: Constipation, diarrhea, indigestion, nausea, vomiting

GU: UTI

HEME: Polycythemia

MS: Arthralgia, bone pain, muscle weakness

RESP: Cough, dyspnea, pulmonary congestion, upper respiratory tract infection

SKIN: Rash, pruritus, urticaria

Other: Flulike symptoms, hyperkalemia, injection site reaction, trunk pain

Nursing Considerations

- Use epoetin alfa cautiously in patients who have conditions that could decrease or delay response to drug, such as aluminum intoxication, folic acid deficiency, hemolysis, infection, inflammation, iron deficiency, malignant neoplasm, osteitis (fibrosa cystica), or vitamin B₁₂ deficiency.
- Also use drug cautiously in patients with cardiovascular disorders caused by hypertension, a history of porphyria or seizures, vascular disease, or a hematologic disorder, such as hypercoagulation, myelodysplastic syndrome, or sickle cell disease.

WARNING Multidose vial of epoetin contains benzyl alcohol, which can cause a fatal toxic syndrome in neonates and immature infants characterized by CNS, respiratory, circulatory, and renal impairment and metabolic acidosis.

- Use lowest possible dose in cancer patients because drug has shortened survival rate and increased tumor progression in patients with certain types of cancers, such as breast, non-small cell lung, head and neck, and lymphoid cancers. Drug should only be used to treat anemia caused by myelosuppressive chemotherapy in cancer patients.
- Don't shake vial while preparing to avoid denaturing glycoprotein, inactivating drug.
- Discard unused portion of single-dose vial because it contains no preservatives. Discard unused portion of multidose vial after 21 days.
- Baseline hemoglobin level should be above 10 but below 13 g/dl if drug is given to patient scheduled for surgery. Watch closely throughout surgical period for deep vein thrombosis, especially in patients not receiving prophylactic anticoagulation, because risk increases.

WARNING Target hemoglobin shouldn't exceed 12 g/dl when treating anemia in patients with chronic renal failure. Exceeding 12 g/dl increases risk of life-threatening adverse cardiovascular effects.

- Expect to increase heparin dose if patient receives hemodialysis because epoetin alfa can increase the RBC volume, which could cause clots to form in the dialyzer, hemodialysis vascular access, or both.
- Expect to give an iron supplement (I.V. iron dextran, if needed) because iron

requirements rise when erythropoiesis consumes existing iron stores.

- Monitor drug effectiveness by checking hematocrit, typically twice weekly until it stabilizes at 30% to 36%. After that, monitoring can be less frequent.
- Take seizure precautions.
- Check hemoglobin and hematocrit levels, as ordered, with twice-weekly measurements recommended for chronic renal failure patients and weekly measurements recommended for zidovudine-treated HIV-infected and cancer patients.
- Risk of hypertensive or thrombotic complications increases if hematocrit rises more than 4 points in 2 weeks.

PATIENT TEACHING

- Before epoetin alfa therapy starts, explain its serious adverse effects.
- Teach patient how to administer drug and how to dispose of needles properly. Caution him against reusing needles.
- Advise patient that the risk of seizures is highest during the first 90 days of epoetin alfa therapy. Urge him not to engage in hazardous activities during this time.
- Stress the importance of complying with the dosage regimen and keeping follow-up medical appointments and appointments for laboratory tests.
- Encourage patient to eat iron-rich foods.
- Review possible adverse reactions, and urge patient to notify prescriber if he experiences chest pain, headache, hives, rapid heartbeat, rash, seizures, shortness of breath, or swelling.
- Advise women of childbearing age to use effective contraception during therapy if pregnancy isn't desired because menses may resume after epoetin alfa therapy.

epoprostenol sodium (PGI₂, PGX, prostacyclin)

Flolan

Class and Category

Chemical class: Natural prostaglandin

Therapeutic class: Antihypertensive, vasodilator

Pregnancy category: B

Indications and Dosages

↗ *To provide long-term treatment of primary pulmonary hypertension*

I.V. INFUSION

Adults. *Initial:* 2 nanograms/kg/min, increased by 2 nanograms/kg/min every 15 min or longer until dose-limiting effects occur (abdominal, chest, or musculoskeletal pain; anxiety; bradycardia; dizziness; dyspnea; flushing; headache; hypotension; nausea; tachycardia; vomiting; or other adverse reactions). *Maintenance:* Dosage reduced by at least 4 nanograms/kg/min by continuous infusion.

DOSAGE ADJUSTMENT Infusion rate adjusted based on persistence, recurrence, or worsening of primary pulmonary hypertension and dose-related adverse reactions.

Mechanism of Action

Directly relaxes vascular smooth muscles through its action as a natural prostaglandin. This results in arterial dilation and inhibition of platelet aggregation. These actions decrease pulmonary vascular resistance, increase cardiac index and oxygen delivery, and limit thrombus formation.

Incompatibilities

Don't mix epoprostenol with other parenteral solutions or drugs.

Contraindications

Hypersensitivity to epoprostenol or its components; long-term use in patients with heart failure caused by severe left ventricular systolic dysfunction; pulmonary edema that developed while establishing epoprostenol dosage

Interactions**DRUGS**

anticoagulants, antiplatelet drugs, NSAIDs: Increased risk of bleeding
antihypertensives, diuretics, vasodilators: Decreased blood pressure

Adverse Reactions

CNS: Anxiety, chills, confusion, dizziness, fever, headache, nervousness, paresthesia, syncope, weakness

CV: Bradycardia, chest pain, hypotension, tachycardia

GI: Abdominal pain, diarrhea, nausea, vomiting

HEME: Bleeding events, thrombocytopenia

MS: Arthralgia, jaw pain, myalgia

RESP: Dyspnea, hypoxia

SKIN: Flushing

Other: Flulike symptoms, injection site infection and pain, sepsis, weight loss or gain

Nursing Considerations

- Use epoprostenol cautiously in elderly patients because they may have decreased hepatic, renal, or cardiac function, or other diseases or may receive other drugs that can interact with epoprostenol.
- Reconstitute drug only with sterile diluent that comes with package. Don't dilute reconstituted epoprostenol.
- To make 100 ml of reconstituted solution at 3,000 nanograms/ml, dissolve contents of 0.5-mg vial with 5 ml of diluent; withdraw 3 ml and add diluent to make 100 ml. To make 100 ml of solution at 5,000 nanograms/ml, dissolve contents of 0.5-mg vial with 5 ml of diluent; withdraw contents and add diluent to make 100 ml. To make 100 ml of solution at 10,000 nanograms/ml, dissolve contents of two 0.5-mg vials each with 5 ml of diluent; withdraw contents and add diluent to make 100 ml. To make 100 ml of solution at 15,000 nanograms/ml, dissolve contents of 1.5-mg vial with 5 ml of diluent; withdraw contents and add diluent to make 100 ml.
- Give continuous infusion through central venous catheter. Use peripheral I.V. infusion only until central access established.
- Use a small, lightweight, ambulatory infusion pump able to deliver 2 nanograms/kg/min. It should have alarms for occlusion, end of infusion, and low battery. Use a polyvinyl chloride, polypropylene, or glass reservoir. Keep a backup pump and infusion set nearby to minimize disruptions in delivery.
- At room temperature, administer a single container of reconstituted solution over 8 hours. For extended use at temperatures above 77° F (25° C), use a cold pouch with frozen gel packs to keep drug at 36° to 46° F (2° to 8° C) for 12 hours.
- After a new infusion rate has been established, monitor patient closely for adverse reactions. Measure each blood pressure with patient standing and supine. Also, monitor heart rate for several hours after dosage adjustment.

- During prolonged infusion, watch for dose-related adverse reactions. If they develop, expect to decrease infusion by 2 nanograms/kg/min every 15 minutes, as prescribed, until reactions resolve.
- Avoid abrupt withdrawal or a sudden large reduction in infusion rate, which could cause rebound pulmonary hypertension (asthenia, dizziness, dyspnea) or death.
- Protect reconstituted drug from light, and refrigerate for no more than 48 hours. Discard solution that has been frozen or been refrigerated for more than 48 hours.
- Watch for evidence of bleeding, especially if patient has other risk factors for bleeding, because epoprostenol is a potent inhibitor of platelet aggregation.

PATIENT TEACHING

- Explain that epoprostenol is infused continuously through permanent indwelling central venous catheter by infusion pump.
- Stress that patient must commit to long-term therapy, possibly for years.
- Teach patient or caregiver how to reconstitute drug, administer it, and care for the permanent central venous catheter.
- Urge patient to maintain prescribed infusion rate and to consult prescriber before altering it.
- Caution patient that even brief interruptions in drug delivery may cause rapid worsening of symptoms.
- Instruct patient to notify prescriber if adverse reactions occur.
- Make sure patient or caregiver has ready access to emergency phone numbers.

eprosartan mesylate

Teveten

Class and Category

Chemical class: Monomethanesulfonate, nonbiphenyl nontetrazole angiotensin II receptor antagonist

Therapeutic class: Antihypertensive

Pregnancy category: Not rated

Indications and Dosages

↗ *To control blood pressure in patients with essential hypertension*

TABLETS

Adults. *Initial:* 600 mg daily. *Maximum:* 800 mg once daily or in divided doses b.i.d.

Mechanism of Action

Blocks the effects of angiotensin II (a potent vasoconstrictor that's part of the renin-angiotensin-aldosterone system) by blocking its binding to angiotensin I receptors in vascular smooth muscles, adrenal glands, and other tissues. This action halts angiotensin II's negative feedback on renin secretion. Thus, circulating renin and angiotensin II levels rise and vascular resistance declines.

Contraindications

Hypersensitivity to eprosartan or components

Adverse Reactions

CNS: Depression, dizziness, drowsiness, fatigue

CV: Angina pectoris, atrial fibrillation, bradycardia, extrasystole, hypertriglyceridemia, hypotension, palpitations, tachycardia

EENT: Pharyngitis, rhinitis

GI: Abdominal pain

GU: Oliguria, UTI

MS: Myalgia, rhabdomyolysis

RESP: Cough, upper respiratory tract infection

Nursing Considerations

- Watch for excessive hypotension if patient receives other cardiac drugs.
- Expect maximum blood pressure response after about 3 weeks.
- Be aware that, unlike ACE inhibitors, eprosartan doesn't affect bradykinin breakdown and cause the characteristic ACE cough.

PATIENT TEACHING

- Explain that maximum blood pressure response may not occur for 3 to 4 weeks.
- Tell patient that drug may cause dizziness, drowsiness, or very low blood pressure. Urge him to rise slowly to upright position.

eptifibatide

Integrilin

Class and Category

Chemical class: Cyclic heptapeptide

Therapeutic class: Platelet aggregation inhibitor

Pregnancy category: B

E
F

Indications and Dosages

↗ *To treat unstable angina and non-Q-wave MI*

I.V. INFUSION

Adults. *Initial:* 180 mcg/kg over 1 to 2 min as soon as possible after diagnosis.

Maintenance: 2 mcg/kg/min by continuous infusion starting immediately after initial dose and continuing until discharge or coronary artery bypass grafting, up to 72 hr.

DOSAGE ADJUSTMENT For patients with serum creatinine level of 2 to 4 mg/dl, initial dosage reduced to 135 mcg/kg over 1 to 2 min and maintenance dosage to 0.5 mcg/kg/min by continuous infusion. Dosage discontinued before coronary artery bypass graft surgery or if platelet count is less than 100,000/mm³.

↗ *To prevent thrombosis related to percutaneous transluminal coronary angioplasty (PTCA)*

I.V. INFUSION

Adults. *Initial:* 135 mcg/kg over 1 to 2 min immediately before procedure.

Maintenance: 0.5 mcg/kg/min by continuous infusion beginning just after initial dose and continuing for 20 to 24 hr.

Maximum: 96 hr of therapy.

Route	Onset	Peak	Duration
I.V.	Immediate	In 15 min	4–8 hr

Mechanism of Action

Reversibly inhibits platelet aggregation by preventing fibrinogen, von Willebrand factor, and other adhesive ligands from binding to glycoprotein IIb/IIIa receptors on activated platelets. As a result, eptifibatide disrupts final cross-linking stage of platelet aggregation—and thrombus formation.

Incompatibilities

Don't administer eptifibatide through the same I.V. line as furosemide.

Contraindications

Active bleeding or stroke during prior 30 days, bleeding diathesis, dependency on dialysis, history of hemorrhagic stroke, hypersensitivity to eptifibatide, major surgery during previous 4 weeks, serum creatinine level of 2 mg/dl or higher (for 180-mcg/kg dose or 2-mcg/kg/min infusion) or 4 mg/dl or higher (for 135-mcg/kg dose or 0.5-mcg/kg/min infusion), severe uncon-

trolled hypertension (systolic pressure above 200 mm Hg, diastolic pressure above 110 mm Hg), thrombocytopenia (platelet count below 100,000/mm³)

Interactions

DRUGS

anticoagulants, clopidogrel, dipyridamole, NSAIDs, thrombolytics, ticlopidine: Additive pharmacologic effects, increased risk of bleeding

other platelet aggregation inhibitors (especially inhibitors of platelet receptor glycoprotein IIb/IIIa, such as abciximab): Increased risk of additive pharmacologic effects

Adverse Reactions

CNS: Intracranial hemorrhage

CV: Hypotension

GI: Hematemesis

GU: Hematuria

HEME: Bleeding, decreased hemoglobin level, thrombocytopenia

Other: Anaphylaxis

Nursing Considerations

- Expect to obtain APTT and PT as a baseline and hematocrit, platelet count, and hemoglobin and serum creatinine levels before therapy.
- Withdraw bolus dose of eptifibatide from a 10-ml (2 mg/ml) vial into a syringe.
- Using vented I.V. infusion set, give continuous infusion directly from the 100-ml (0.75 mg/ml) vial. Be sure to center the spike in the circle on top of vial stopper.
- Expect to keep APTT between 50 and 70 seconds or per facility protocol during therapy unless patient has PTCA.
- If patient has PTCA, expect to maintain activated clotting time between 200 and 250 seconds during the procedure.
- During therapy, avoid arterial and venous punctures, I.M. injections, urinary catheters, nasotracheal or nasogastric intubation, and use of noncompressible I.V. sites, such as subclavian and jugular veins.
- Expect to discontinue eptifibatide and heparin and monitor patient closely if platelet count falls below 100,000/mm³.
- Plan to stop drug, as prescribed, if patient undergoes coronary artery bypass surgery.

PATIENT TEACHING

- Instruct patient to immediately report bleeding during eptifibatide therapy.
- Reassure patient that he'll be monitored

closely throughout therapy.

- Advise patient to avoid activities that may lead to bruising and bleeding.

ergoloid mesylates (dihydrogenated ergot alkaloids)

Gerimal, Hydergine, Hydergine LC

Class and Category

Chemical class: Dihydrogenated ergot alkaloid derivative

Therapeutic class: Antidementia adjunct, cerebral metabolic enhancer

Pregnancy category: Not rated

Indications and Dosages

➤ *To treat age-related decline in mental capacity*

CAPSULES, ORAL SOLUTION, S.L. TABLETS, TABLETS

Adults. 1 to 2 mg t.i.d.

Route	Onset	Peak	Duration
P.O.	3 wk or more	Unknown	Unknown

Mechanism of Action

May increase cerebral metabolism, blood flow, and oxygen uptake. These actions may increase neurotransmitter levels.

Contraindications

Acute or chronic psychosis, hypersensitivity to ergoloid mesylates or their components

Interactions

DRUGS

delavirdine, efavirenz, indinavir, nelfinavir, saquinavir: Increased risk of ergotism (*blurred vision, dizziness, and headache*)
dopamine: Increased risk of gangrene

Adverse Reactions

CNS: Dizziness, headache, light-headedness, syncope

CV: Bradycardia, orthostatic hypotension

EENT: Blurred vision, nasal congestion, tongue soreness (with S.L. tablets)

GI: Abdominal cramps, anorexia, nausea, vomiting

SKIN: Flushing, rash

Nursing Considerations

- Expect ergoloid mesylates to be prescribed

only after a pathophysiologic cause for mental decline has been ruled out.

- Measure blood pressure and pulse rate and rhythm before therapy begins and monitor them frequently during therapy.
- If bradycardia or hypotension develops, expect to discontinue drug permanently.

PATIENT TEACHING

- Stress the importance of adhering to prescribed dosage and schedule.
- Teach caregiver to place S.L. tablet under patient's tongue and withhold food, fluids, and cigarettes until tablet dissolves.
- Instruct patient not to swallow S.L. tablets.
- Advise caregiver to skip a missed dose and resume the regular dosing schedule. Warn against doubling the dose, and urge caregiver to notify prescriber if patient misses two or more doses in a row.
- Instruct caregiver to store drug in a tightly closed, light-resistant container.
- Inform caregiver and family that drug may take 3 to 4 weeks to produce its effects.
- Stress the importance of follow-up care.

ergotamine tartrate

Ergomar (CAN), Ergostat, Gynergen (CAN), Medihaler Ergotamine (CAN)

Class and Category

Chemical class: Ergot alkaloid

Therapeutic class: Vascular headache suppressant

Pregnancy category: X

Indications and Dosages

➤ *To relieve vascular headaches, such as migraine, migraine variants, and cluster headaches*

S.L. TABLETS

Adults. *Initial:* 2 mg at first sign of attack and repeated every 30 min, p.r.n.

Maximum: 6 mg/day and no more than twice/wk at least 5 days apart.

TABLETS

Adults. *Initial:* 1 to 2 mg at first sign of attack, repeated every 30 min, p.r.n.

Increased to 3 mg for subsequent attacks if needed and if lower dose was well tolerated.

Maximum: 6 mg daily.

ORAL INHALATION AEROSOL

Adults. 1 (360-mcg) inhalation at first sign of attack and repeated every 5 min, p.r.n.

Maximum: 2.16 mg daily and no more than twice/wk at least 5 days apart.

Route	Onset	Peak	Duration
P.O., S.L.	Unknown	1–5 hr	Unknown

Mechanism of Action

Directly stimulates vascular smooth muscles, constricting arteries and veins and depressing vasomotor centers in the brain.

Contraindications

Coronary artery disease, hypersensitivity to ergot alkaloids, hypertension, impaired hepatic or renal function, malnutrition, peripheral vascular disease (Raynaud's disease, severe arteriosclerosis, syphilitic arteritis, thromboangiitis obliterans, thrombophlebitis), pregnancy or risk of pregnancy, sepsis, severe pruritus

Interactions

DRUGS

beta blockers: Increased risk of vasoconstriction and, possibly, peripheral gangrene
erythromycin, troleandomycin: Possibly increased risk of peripheral vasospasm and ischemia

nitrates: Increased ergotamine effects, decreased antianginal effects of nitrates, increased risk of hypertension

sumatriptan: Possibly additive vasoconstriction

vasoconstrictors: Increased risk of dangerous hypertension

ACTIVITIES

smoking: Possibly increased risk of peripheral vasoconstriction and ischemia

Adverse Reactions

CNS: Anxiety, confusion, dizziness, drowsiness, paresthesia, severe headache

CV: Chest pain, fast or slow heart rate, heart valve fibrosis, increased or decreased blood pressure, MI, weak pulse

EENT: Dry mouth, miosis, vision changes

GI: Nausea, vomiting

MS: Arm, back, or leg pain; muscle weakness in legs

SKIN: Cold, cyanotic, or pale feet or hands; pruritus

Other: Edema of face, feet, fingers, or lower legs; physical dependence

Nursing Considerations

- Use ergotamine cautiously in elderly

patients.

- If patient receives long-term therapy, monitor pain control; he may need increasingly higher doses to obtain relief.
- Notify prescriber at the first sign of vasospasm and expect to discontinue drug.

PATIENT TEACHING

- Teach patient to take a tablet at the first sign of headache and to lie down in a quiet, dark room.
- Instruct patient not to swallow S.L. tablet but to let it dissolve under his tongue. Advise him not to drink, eat, or smoke until tablet has dissolved.
- Stress the importance of adhering to prescribed dosage and schedule because of drug's potential for dependence.
- Warn patient not to smoke while taking ergotamine (especially heavy smokers) because combining drug with nicotine, which also constricts vessels, may increase risk of peripheral vascular ischemia.
- Advise patient to notify prescriber if usual doses fail to relieve headaches or if headache frequency or severity increases.
- Urge patient to avoid alcohol because it worsens headaches. Also suggest that patient avoid excessive cold, which may increase peripheral vasoconstriction.
- Instruct patient to notify prescriber if an infection develops because severe infection may increase sensitivity to drug.
- Advise patient to notify prescriber if he experiences chest pain; numbness, pain, or tingling in fingers or toes; pulse rate changes; swelling of face, feet, fingers, or lower legs; or vision changes.

ertapenem sodium

Invanz

Class and Category

Chemical class: Synthetic 1- β methyl-carbapenem

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

- ↗ *To treat moderate to severe infections, such as complicated intra-abdominal infections due to Escherichia coli, Clostridium clostridioforme, Eubacterium lentum, Pepto-strepto-*

coccus species, *Bacteroides fragilis*, *B. distasonis*, *B. ovatus*, *B. thetaiotaomicron*, or *B. uniformis*; *complicated skin and skin-structure infections due to Staphylococcus aureus (methicillin-susceptible strains only)*, *Streptococcus pyogenes*, *E. coli*, or *Peptostreptococcus species*; *community-acquired pneumonia due to Streptococcus pneumoniae (penicillin-susceptible strains only, including cases with concurrent bacteremia)*, *Haemophilus influenzae (beta-lactamase-negative strains only)*, or *Moraxella catarrhalis*; *complicated UTI (including pyelonephritis) due to E. coli (including cases with concurrent bacteremia) or Klebsiella pneumoniae*; and *acute pelvic infections (including postpartum endomyometritis, septic abortion, and postsurgical gynecologic infections) due to Streptococcus agalactiae, E. coli, B. fragilis, Porphyromonas asaccharolytica, Peptostreptococcus species, or Prevotella bivia*

I.V. INFUSION

Adults and adolescents. 1 g daily, infused over 30 min, for up to 14 days.

Children ages 3 months to 13 years. 15 mg/kg b.i.d., infused over 30 min, for up to 14 days. *Maximum:* 1 g daily.

I.M. INJECTION

Adults and adolescents. 1 g daily for up to 7 days.

Children ages 3 months to 13 years. 15 mg/kg b.i.d. for up to 7 days. *Maximum:* 1 g daily.

DOSAGE ADJUSTMENT Dosage decreased to 500 mg daily for patients with advanced renal insufficiency (creatinine clearance less than or equal to 30 ml/min/1.73 m²) or end-stage renal insufficiency (creatinine clearance less than or equal to 10 ml/min/1.73 m²). For patients on hemodialysis who have received 500 mg of ertapenem within 6 hr of hemodialysis, supplemental dose of 150 mg given after hemodialysis.

Mechanism of Action

Inhibits bacterial cell wall synthesis by binding to specific penicillin-binding proteins inside the cell wall. Penicillin-binding proteins are responsible for various steps in bacterial cell wall synthesis. By binding to these proteins, ertapenem leads to bacterial cell wall lysis.

Incompatibilities

Don't mix ertapenem with other drugs. Don't dilute it with solutions containing dextrose.

Contraindications

Hypersensitivity to ertapenem, its components, or other drugs in the same class; hypersensitivity to local anesthetics (I.M. form only, because lidocaine hydrochloride 1% is used as a diluent); patients who have experienced anaphylactic reactions to beta-lactam drugs

Interactions

DRUGS

probenecid: Increased ertapenem half-life, increased and prolonged blood ertapenem level

valproic acid: Possibly decreased serum valproic acid level and increased risk of breakthrough seizures

Adverse Reactions

CNS: Aggression, agitation, anxiety, asthenia, confusion, delirium, disorientation, dizziness, dyskinesia, fatigue, fever, hallucinations, headache, hypothermia, insomnia, mental changes, myoclonus, seizures, somnolence, stupor, tremor

CV: Chest pain, edema, hypertension, hypotension, tachycardia, thrombophlebitis

EENT: Nasopharyngitis, oral candidiasis, viral pharyngitis

ENDO: Hyperglycemia

GI: Abdominal pain, acid regurgitation, *Clostridium difficile* colitis, constipation, diarrhea, elevated liver function test results, indigestion, nausea, small-intestine obstruction, vomiting

GU: Dysuria, elevated serum creatinine level, proteinuria, RBCs and WBCs in urine, UTI, vaginitis

HEME: Anemia, decreased hematocrit, decreased WBC count, eosinophilia, increased WBC count, neutropenia, prolonged PT, thrombocytopenia, thrombocytosis

MS: Leg pain

RESP: Atelectasis, cough, crackles, dyspnea, pneumonia, respiratory distress, upper respiratory tract infection, wheezing

SKIN: Cellulitis, dermatitis, erythema, extravasation, pruritus, rash

Other: Anaphylaxis; death; hyperkalemia; hypokalemia; infusion site induration, pain,

phlebitis, redness, swelling, or warmth

Nursing Considerations

- Obtain sputum, urine, or other specimens for culture and sensitivity testing, as ordered, before giving ertapenem. Expect to start therapy before results are available.
- When preparing drug for I.V. use, reconstitute 1 g with 10 ml of sterile water for injection, 0.9% sodium chloride injection, or bacteriostatic water for injection. Don't use solutions that contain dextrose. Shake well to dissolve. Immediately transfer reconstituted drug to 50 ml normal saline solution. Use within 6 hours if stored at room temperature, 24 hours if refrigerated at 5° C (41° F). Don't freeze. Give I.V. infusion over 30 minutes.
- Inspect drug for particles and discoloration after reconstitution.
- For I.M. injection, reconstitute 1 g of drug with 3.2 ml of 1% lidocaine hydrochloride injection (without epinephrine). Shake thoroughly to form solution. Use within 1 hour after preparation. Withdraw contents of vial and inject deep into a large muscle mass such as the gluteal muscle.

WARNING Don't give reconstituted I.M. solution by I.V. route because of possible adverse reaction to lidocaine hydrochloride injection used to reconstitute drug.

- Monitor patient closely for a life-threatening anaphylactic reaction. Patients with a history of hypersensitivity to penicillin, cephalosporins, other beta-lactams, or other allergens are at increased risk.

WARNING If ertapenem triggers an anaphylactic reaction, stop drug, notify prescriber immediately, and provide appropriate therapy. Anaphylaxis requires immediate treatment with epinephrine as well as airway management and administration of oxygen and I.V. corticosteroids, as needed.

- Be aware that patients with a history of seizures, other CNS disorders that predispose them to seizures (such as brain lesions), or compromised renal function may be at increased risk for seizures. Administer anticonvulsant, as ordered.
- Monitor patient for diarrhea during and for at least 2 months after drug therapy; diarrhea may signal pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and

expect to withhold ertapenem and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

- Be aware that because ertapenem is excreted in breast milk, its use by nursing mothers is carefully evaluated.

PATIENT TEACHING

- Instruct patient receiving ertapenem to immediately report signs of anaphylaxis, such as rash, itching, or shortness of breath; or signs of superinfection, such as severe diarrhea or white patches on tongue or in mouth.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.

erythromycin

(contains 250, 333, or 500 mg of base per delayed-release capsule, delayed-release tablet, or tablet)

Apo-Erythro (CAN), E-Mycin, Erybid (CAN), ERYC, Ery-Tab, Ilotycin, Novo-Rythro Encap (CAN), PCE

erythromycin estolate

(contains 250 mg of base per capsule or tablet, or 125 or 250 mg of base per 5 ml of oral suspension)

Ilosone, Novo-Rythro (CAN)

erythromycin ethylsuccinate

(contains 1 g of base per 1.6 g of oral suspension or tablet)

Apo-Erythro-ES (CAN), E.E.S., EryPed, Erythro, Novo-Rythro (CAN)

erythromycin gluceptate

(contains 500 or 1,000 mg of base per vial)

Ilotycin

erythromycin lactobionate

(contains 500 or 1,000 mg of base per vial)

Erythrocin

erythromycin stearate

(contains 125 or 250 mg of base per 5 ml of oral suspension, or 250 or 500 mg of base per tablet)

Apo-Erythro-S (CAN), Erythrocin, Erythrocin, My-E, Novo-Rythro (CAN), Wintrocin

Class and Category

Chemical class: Macrolide

Therapeutic class: Antiacne agent, antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat mild to moderate upper respiratory tract infections caused by Haemophilus influenzae, Streptococcus pneumoniae, or Streptococcus pyogenes (group A beta-hemolytic streptococcus)*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults. 250 to 500 mg (base) every 6 hr for 10 days.

Children. 250 to 500 mg (base) q.i.d. or 20 to 50 mg (base)/kg daily in divided doses for 10 days. For *H. influenzae* infections, erythromycin ethylsuccinate is administered with 150 mg/kg daily of sulfisoxazole. *Maximum:* Adult dosage, or 6 g daily for erythromycin ethylsuccinate.

➤ *To treat lower respiratory tract infections caused by S. pneumoniae or S. pyogenes (group A beta-hemolytic streptococcus)*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults. 250 to 500 mg (base) every 6 hr for 10 days.

Children. 250 to 500 mg (base) q.i.d. or 20 to 50 mg (base)/kg daily in divided doses

for 10 days. *Maximum:* Adult dosage.

➤ *To treat respiratory tract infections caused by Mycoplasma pneumoniae*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults. 500 mg (base) every 6 hr for 5 to 10 days or up to 3 wk for severe infections.

➤ *To treat mild to moderate skin and soft-tissue infections caused by S. pyogenes or Staphylococcus aureus*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults. 250 mg (base) every 6 hr or 500 mg (base) every 12 hr for 10 days. *Maximum:* 4 g (base) daily.

Children. 250 to 500 mg (base) q.i.d. or 20 to 50 mg (base)/kg daily in divided doses for 10 days. *Maximum:* Adult dosage.

➤ *To treat acne vulgaris*

DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, TABLETS

Adults and adolescents. *Initial:* 250 mg (base) every 6 hr, 333 mg (base) every 8 hr, or 500 mg (base) every 12 hr for 4 wk. *Maintenance:* 333 to 500 mg (base) daily.

➤ *To treat pertussis (whooping cough) caused by Bordetella pertussis*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Children. 500 mg (base) q.i.d. or 40 to 50 mg (base)/kg daily in divided doses for 5 to 14 days.

➤ *To treat diphtheria*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults and children. 500 mg (base) every 6 hr for 10 days.

➤ *To treat erythrasma*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults and children. 250 mg (base) t.i.d. for 21 days.

➤ *To treat intestinal amebiasis*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults. 250 mg (base) every 6 hr for 10 to 14 days.

Children. 30 to 50 mg (base)/kg daily in

divided doses for 10 to 14 days

↗ *To treat pelvic inflammatory disease caused by Neisseria gonorrhoeae*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults. 500 mg (base) I.V. every 6 hr for 3 days and then 250 mg (base) P.O. or I.V. every 6 hr for 7 days.

↗ *To treat conjunctivitis in newborns*

I.V. INFUSION

Neonates. 50 mg (base)/kg daily in 4 divided doses for 14 days.

↗ *To treat pneumonia in neonates*

I.V. INFUSION

Neonates. 50 mg (base)/kg daily in divided doses for 21 days.

↗ *To treat urogenital infections caused by Chlamydia trachomatis during pregnancy*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS

Adults. 500 mg (base) on an empty stomach every 6 hr for 7 days; or 250 mg (base) on an empty stomach every 6 hr for at least 14 days.

↗ *To treat nongonococcal urethritis or uncomplicated urethral, endocervical, or rectal infections caused by C. trachomatis*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS

Adults. 500 mg (base) every 6 hr for 7 days. If patient can't tolerate high doses, 250 mg (base) every 6 hr for 14 days.

↗ *To treat primary syphilis*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS

Adults. 20 to 40 g (base) in divided doses over 10 to 15 days.

↗ *To treat Legionnaire's disease*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults. 1 to 4 g (base) daily in divided doses for 10 to 14 days.

↗ *To treat rheumatic fever*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults. 250 mg (base) every 12 hr.

↗ *To prevent bacterial endocarditis in patients with penicillin allergy who plan dental or upper respiratory tract surgery*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults. 1 g (base) given 1 to 2 hr before procedure and then 500 mg (base) 6 hr after initial dose.

Children. 20 mg (base)/kg given 2 hr before procedure and then 10 mg (base)/kg 6 hr after initial dose.

↗ *To treat listeriosis*

CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION

Adults. 250 mg (base) every 6 hr or 500 mg (base) every 12 hr. *Maximum:* 4 g (base) daily.

Mechanism of Action

Binds with the 50S ribosomal subunit of the 70S ribosome in many types of aerobic, anaerobic, gram-positive, and gram-negative bacteria. This action inhibits RNA-dependent protein synthesis in bacterial cells, causing them to die.

Contraindications

Astemizole, cisapride, pimozide, or terfenadine therapy; hypersensitivity to erythromycin, macrolide antibiotics, or their components; hepatic disease (erythromycin estolate)

Interactions

DRUGS

alfentanil: Decreased alfentanil clearance, prolonged alfentanil action
astemizole, cisapride, terfenadine: Increased risk of cardiotoxicity, torsades de pointes, ventricular tachycardia, and death
atorvastatin, lovastatin, pravastatin, simvastatin: Increased risk of rhabdomyolysis
carbamazepine, valproic acid: Possibly inhibited metabolism of these drugs, increasing their blood levels and risk of toxicity
chloramphenicol, lincomycins: Antagonized effects of these drugs
cyclosporine: Increased risk of nephrotoxicity
digoxin: Increased serum digoxin level and risk of digitalis toxicity
diltiazem, verapamil: Increased risk of life-threatening cardiac events
ergotamine: Decreased ergotamine metabolism, increased risk of vasospasm from

ergotamine use

hepatotoxic drugs: Increased risk of hepatotoxicity

midazolam, triazolam: Increased pharmacologic effects of these drugs

oral contraceptives: Failed contraception, hepatotoxicity

ototoxic drugs: Increased risk of ototoxicity if patient with impaired renal function receives high doses of erythromycin

penicillins: Interference with bactericidal effects of penicillins

sildenafil: Increased effects of sildenafil

warfarin: Prolonged PT and risk of hemorrhage, especially in elderly patients

xanthines (except dyphylline): Increased serum theophylline level and risk of theophylline toxicity

ACTIVITIES

alcohol use: Increased alcohol level (by 40%) with I.V. erythromycin

Adverse Reactions

CNS: Fatigue, fever, malaise, weakness

CV: Prolonged QT interval, torsades de pointes, ventricular arrhythmias

EENT: Hearing loss, oral candidiasis

GI: Abdominal cramps and pain, diarrhea, hepatotoxicity, nausea, pseudomembranous colitis, vomiting

GU: Vaginal candidiasis

MS: New or aggravated myasthenia gravis syndrome

SKIN: Erythema, jaundice, pruritus, rash

Other: Fluid overload (from I.V. infusion), injection site inflammation and phlebitis

Nursing Considerations

- Use erythromycin cautiously in patients with impaired hepatic function because drug is metabolized by the liver.
- Use erythromycin cautiously in elderly patients, especially those with renal or hepatic dysfunction, because these patients are at increased risk of hearing loss and torsades de pointes. They're also at increased risk of bleeding if taking an oral anticoagulant.
- Before giving first erythromycin dose, expect to obtain body fluid or tissue sample for culture and sensitivity testing.
- Reconstitute parenteral form before administration. Add at least 10 ml of preservative-free sterile water for injection to each 500-mg vial or at least 20 ml of diluent to each 1-g vial.
- For prolonged infusion, expect to infuse a buffered solution up to 24 hours after dilution.
- For intermittent infusion, dilute dose in 100 to 250 ml normal saline solution or D₅W if needed; give slowly over 20 to 60 minutes.
- When giving I.V. erythromycin gluceptate, dilute the solution if needed to 1 g/L in normal saline solution or D₅W injection for slow, continuous infusion. Diluted solution remains potent for 7 days if refrigerated.
- When giving I.V. erythromycin lactobionate, dilute the solution if needed to 1 to 5 mg/ml in normal saline solution, lactated Ringer's solution, or other electrolyte solution for slow, continuous infusion. Diluted solution remains potent for 14 days if refrigerated and for 24 hours at room temperature.
- Be aware that infusions prepared in piggyback infusion bottles stay potent for 30 days if frozen, 24 hours if refrigerated, or 8 hours at room temperature. Don't store infusions prepared in the ADD-vantage system.
- Don't use diluent with benzyl alcohol if parenteral erythromycin is for a neonate. It may cause a fatal toxic syndrome of CNS depression, hypotension, metabolic acidosis, renal failure, respiratory problems, and, possibly, seizures and intracranial hemorrhage.
- Periodically monitor liver function test results to detect hepatotoxicity, which is most common with erythromycin estolate. Signs typically appear within 2 weeks after continuous therapy starts and resolve when it stops.
- Assess hearing regularly, especially in elderly patients and those who receive 4 g or more daily or have hepatic or renal disease. Hearing impairment begins 36 hours to 8 days after treatment starts and usually begins to improve 1 to 14 days after it stops.
- During I.V. therapy, watch for evidence of fluid overload, such as acute dyspnea and crackles.
- Monitor infants for vomiting or irritability with feeding because infantile hypertrophic pyloric stenosis has been reported.

- Assess myasthenia gravis patients for weakness because drug may aggravate it. Keep in mind that myasthenic syndrome may arise in patients previously undiagnosed with myasthenia gravis.
- Watch closely for signs and symptoms of superinfection. If they occur, notify prescriber and expect to stop drug and provide appropriate therapy.
- Monitor patient for diarrhea during and for at least 2 months after erythromycin therapy; diarrhea may signal pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold drug and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- If patient receives an order for urine catecholamine analysis, notify prescriber because erythromycin interferes with fluorometric measurement of urine catecholamines.

PATIENT TEACHING

- Urge patient to complete prescribed therapy, even if he feels better before it's finished.
- Tell patient to notify prescriber if symptoms worsen or don't improve after a few days.
- Teach patient how to administer prescribed form of erythromycin. Instruct him to swallow capsules or tablets whole. For an oral suspension, teach him to use the calibrated measuring device provided to ensure accurate doses. Remind him to shake the suspension before measuring a dose.
- Advise patient to take oral form of erythromycin with a full glass of water on an empty stomach (except erythromycin ethylsuccinate, which is better absorbed with food).
- If GI distress occurs, instruct patient to take oral form with food.
- Instruct patient to promptly notify prescriber if he develops allergic reactions, hearing changes, or signs of hepatic dysfunction.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.

escitalopram oxalate

Lexapro

Class and Category

Chemical class: Pure S+ enantiomer of racemic bicyclic phthalane derivative citalopram

Therapeutic class: Antidepressant

Pregnancy category: C

Indications and Dosages

↗ *To treat generalized anxiety disorder or major depression*

ORAL SOLUTION, TABLETS

Adults. *Initial:* 10 mg daily in morning or evening, increased to 20 mg daily after 1 or more wk, as needed.

↗ *To treat major depression*

ORAL SOLUTION, TABLETS

Adults. *Initial:* 10 mg daily, morning or evening, increased to 20 mg daily after 1 wk, as needed.

Adolescents ages 12 to 17. *Initial:* 10 mg daily, morning or evening, increased to 20 mg daily after 3 wk, as needed.

DOSAGE ADJUSTMENT Dosage shouldn't exceed 10 mg daily for elderly patients and those with hepatic impairment.

Mechanism of Action

Inhibits reuptake of the neurotransmitter serotonin by CNS neurons, thereby increasing the amount of serotonin available in nerve synapses. An elevated serotonin level may result in elevated mood and reduced depression.

Contraindications

Hypersensitivity to escitalopram, citalopram or its components; use within 14 days of MAO inhibitor therapy

Interactions

DRUGS

aspirin, NSAIDs, warfarin: Possibly increased risk of bleeding

carbamazepine: Possibly increased clearance of escitalopram

cimetidine: Possibly increased plasma escitalopram level

CNS drugs: Additive CNS effects

lithium: Possible enhancement of the sero-

tonergic effects of escitalopram

MAO inhibitors: Possibly hyperpyretic episodes, hypertensive crisis, serotonin syndrome, and severe seizures

metoprolol: Increased plasma metoprolol levels with decreased cardioselectivity of metoprolol

naratriptan, sumatriptan, zolmitriptan: Possibly weakness, hyperreflexia, and incoordination

St. John's wort: Increased risk of serotonin syndrome

sibutramine: Increased risk of serotonin syndrome

ACTIVITIES

alcohol use: Possibly increased cognitive and motor effects of alcohol

Adverse Reactions

CNS: Abnormal gait, acute psychosis, aggression, akathisia, delirium, dizziness, dyskinesia, dystonia, extrapyramidal effects, fatigue, headache, hypomania, insomnia, lethargy, mania, myoclonus, neuroleptic malignant syndrome, paresthesia, seizures, serotonin syndrome, somnolence, suicidal ideation

CV: Atrial fibrillation, cardiac failure, deep vein or phlebitis thrombosis, hypotension, MI, prolonged QT interval, thrombosis, torsades de pointes, ventricular arrhythmias

EENT: Diplopia, dry mouth, glaucoma, nystagmus, rhinitis, sinusitis, toothache, visual hallucinations

ENDO: Diabetes mellitus, hyperprolactinemia, syndrome of inappropriate ADH secretion

GI: Abdominal pain, constipation, decreased appetite, diarrhea, flatulence, GI bleeding or hemorrhage, hepatic necrosis, hepatitis, indigestion, nausea, pancreatitis, rectal hemorrhage, vomiting

GU: Acute renal failure, anorgasmia, decreased libido, ejaculation disorders, impotence, priapism

HEME: Bleeding, decreased prothrombin time, hemolytic anemia, leukopenia, thrombocytopenia

MS: Neck or shoulder pain, rhabdomyolysis

RESP: Pulmonary embolism

SKIN: Ecchymosis, erythema multiforme, increased sweating, photosensitivity, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, flulike

symptoms, hyponatremia

Nursing Considerations

- Use escitalopram cautiously in patients with history of mania or seizures, patients with severe renal impairment, and those with diseases or conditions that produce altered metabolism or hemodynamic responses.
- Monitor patient—especially elderly patient—for hyposmolarity of serum and urine and for hyponatremia (headache, trouble concentrating, impaired memory, weakness, unsteadiness) because they may indicate escitalopram-induced syndrome of inappropriate ADH secretion.
- Watch for signs of misuse or abuse, such as development of tolerance, increasing dosage without approval, and drug-seeking behavior; drug's potential for physical and psychological dependence is unknown.
- Monitor patient for bleeding, especially if patient is also taking aspirin, an NSAID, or an anticoagulant. Bleeding can range from ecchymoses, hematomas, epistaxis and petechiae to life-threatening hemorrhages.
- Expect prescriber to reassess patient periodically to determine the continued need for therapy and evaluate dosage.
- If patient (particularly a child or an adolescent) takes escitalopram for depression, watch closely for suicidal tendencies, especially when therapy starts or dosage changes, because depression may worsen temporarily.
- If escitalopram will be stopped, expect to taper dosage to avoid serious adverse reactions.

PATIENT TEACHING

- Inform patient that alcohol use isn't recommended during escitalopram therapy because it may decrease his ability to think clearly and perform motor skills.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient that drug shouldn't be taken with citalopram hydrobromide because of potentially additive effects.
- Tell patient that improvement may not be noticed for 1 to 4 weeks after therapy begins. Emphasize the importance of continuing therapy as prescribed.
- If patient (particularly a child or an adolescent) takes drug for depression, urge

caregivers to watch closely for suicidal tendencies, especially when therapy starts or dosage changes.

- Warn patient not to stop taking drug abruptly. Explain that gradual tapering helps to avoid withdrawal symptoms.
- Urge patient to inform prescriber of any OTC drugs he takes because of potential for interactions.
- Review signs and symptoms of hyponatremia, and instruct patient to report them to prescriber.
- Warn patient that escitalopram increases bleeding risk if taken with aspirin, an NSAID, or an anticoagulants and that bleeding events could range from mild to severe. Tell patient to seek emergency care for serious or prolonged bleeding.

esmolol hydrochloride

Brevibloc

Class and Category

Chemical class: Beta blocker

Therapeutic class: Antiarrhythmic, anti-hypertensive

Pregnancy category: C

Indications and Dosages

➤ *To treat supraventricular tachycardia*

I.V. INFUSION

Adults. *Loading:* 500 mcg/kg over 1 min.

Maintenance: If response to loading dose is adequate after 5 min, 50 mcg/kg/min infused for 4 min. If response is inadequate after 5 min, another 500 mcg/kg may be given over 1 min followed by 100 mcg/kg/min for 4 min. Sequence repeated, as needed, until adequate response occurs, increasing maintenance dosage by 50 mcg/kg/min at each step. *Maximum:* 200 mcg/kg/min for 48 hr.

Children. 50 mcg/kg/min titrated every 10 min up to 300 mcg/kg/min.

➤ *To treat intraoperative and postoperative tachycardia and hypertension*

I.V. INFUSION

Adults. *Initial:* 250 to 500 mcg/kg over 1 min. *Maintenance:* 50 mcg/kg/min

infused over 4 min. If response is inadequate after 5 min, another 250 to 500 mcg/kg

may be given over 1 min followed by 100 mcg/kg/min for 4 min. Sequence repeated, as needed, up to 4 times, increasing by 50 mcg/kg/min each time.

Maximum: 200 mcg/kg/min for 48 hr.

DOSAGE ADJUSTMENT Loading doses omitted, increments decreased to 25 mcg/kg/min, and titration intervals increased to 10 min as heart rate approaches desired level or if blood pressure decreases too much.

Route	Onset	Peak	Duration
I.V.	Immediate	Unknown	10–20 min

Mechanism of Action

Inhibits stimulation of beta₁ receptors mainly in the heart, which decreases cardiac excitability, cardiac output, and myocardial oxygen demand. Esmolol also decreases renin release from kidneys, which helps reduce blood pressure.

Incompatibilities

Don't mix esmolol with 5% sodium bicarbonate injection.

Contraindications

Cardiogenic shock, hypersensitivity to beta blockers, overt heart failure, second- or third-degree heart block, sinus bradycardia

Interactions

DRUGS

antihypertensives: Possibly hypotension
insulin, oral antidiabetics: Possibly masking of signs and symptoms of hypoglycemia caused by these drugs

MAO inhibitors: Possibly severe hypertension if esmolol is given within 14 days of discontinuing MAO inhibitor therapy
neuromuscular blockers: Possibly potentiated and prolonged action of these drugs

phenytoin: Possibly increased cardiac depression

reserpine: Possibly bradycardia and hypotension

sympathomimetics, xanthine derivatives: Possibly inhibited therapeutic effects of both drugs

Adverse Reactions

CNS: Anxiety, confusion, depression, dizziness, fatigue, fever, headache, syncope

CV: Bradycardia, chest pain, decreased peripheral circulation, heart block,

hypotension

GI: Nausea, vomiting

RESP: Dyspnea, wheezing

SKIN: Diaphoresis, flushing, pallor

Other: Infusion site pain, redness, and swelling

Nursing Considerations

- Use esmolol cautiously if patient has supraventricular arrhythmias with decreased cardiac output, hypotension, or other hemodynamic compromise or is taking drugs that decrease peripheral resistance or myocardial filling, contractility, or impulse generation.
- Also use drug cautiously in patients with impaired renal function because drug is excreted by the kidneys. Patients with end-stage renal disease have an increased risk of adverse reactions.
- Avoid giving esmolol for intraoperative or postoperative hypertension caused by hypothermia-induced vasoconstriction.
- Expect to give lowest possible dose to patients with allergies, asthma, bronchitis, or emphysema. If patient develops broncho-spasm, expect to discontinue infusion immediately and give a beta₂-stimulating drug, as ordered.
- Don't give 250 mg/ml (2,500 mg/10 ml) dosage strength by direct I.V. push. Dilute it to a 10-mg/ml infusion by first removing 20 ml from 500 ml of a compatible I.V. solution, such as D₅W or dextrose 5% in normal saline solution, and then adding 5 g of esmolol to the solution.
- Use diluted solution within 24 hours if stored at room temperature.
- Use 100-mg vial (prediluted to 10 mg/ml) for loading dose. For 70-kg (154-lb) patient, loading dose for 500 mcg/kg/min is 3.5 ml.
- Monitor blood pressure and heart rate often during therapy. Hypotension can occur at any dose but usually is dose related. It typically reverses within 30 minutes after dose is decreased or infusion stopped.
- Inspect site often for thrombophlebitis (pain, redness, swelling at site). Infusion of 20 mg/ml is more likely to cause serious vein irritation than 10 mg/ml. Extravasation of 20 mg/ml may cause a serious local reaction and skin necrosis. Don't give more than 10 mg/ml into a small vein or using a butterfly catheter.

PATIENT TEACHING

- Urge patient to report adverse reactions immediately.
- Reassure patient that his blood pressure, heart rate, and response to therapy will be monitored throughout esmolol therapy.

esomeprazole magnesium

Nexium, Nexium I.V.

Class and Category

Chemical class: Substituted benzimidazole

Therapeutic class: Antilulcerative

Pregnancy category: B

Indications and Dosages

➤ *To treat gastroesophageal reflux disease (GERD)*

DELAYED-RELEASE CAPSULES

Adults. 20 to 40 mg daily for 4 to 8 wk; may be repeated for another 4 to 8 wk if ulcer hasn't healed. *Maintenance:* 20 mg daily for up to 6 mo.

Adolescents ages 12 to 17. 20 or 40 mg once daily for up to 8 wk.

Children ages 1 to 11. 10 mg once daily for up to 8 wk.

DOSAGE ADJUSTMENT For children weighing 20 kg (44 lb) or more and being treated for healing of erosive esophagitis in GERD, dosage may be increased to 20 mg once daily for 8 wk, if needed.

➤ *To treat GERD in a patient with a history of erosive esophagitis who can't take the drug by mouth*

I.V. INFUSION, I.V. INJECTION

Adults. 20 to 40 mg daily infused for no less than 3 min (I.V. injection) or 10 to 30 min (I.V. infusion).

➤ *As adjunct to treat duodenal or gastric ulcer associated with Helicobacter pylori*

DELAYED-RELEASE CAPSULES

Adults. 40 mg daily with amoxicillin 1,000 mg b.i.d. and clarithromycin 500 mg b.i.d. for 10 days.

➤ *To reduce the risk of gastric ulcer formation in patients who are receiving continuous NSAID therapy and who either are over age 60 or have a history of gastric ulcer*

DELAYED-RELEASE CAPSULES

Adults. 20 to 40 mg daily for up to 6 mo.

↗ *To treat pathological hypersecretory conditions, including Zollinger-Ellison syndrome*

DELAYED-RELEASE CAPSULES

Adults. 40 mg b.i.d.

DOSE ADJUSTMENT For patients with severe hepatic insufficiency, maximum 20 mg daily.

Mechanism of Action

Interferes with gastric acid secretion by inhibiting the hydrogen-potassium-adenosine triphosphatase ($H^+ - K^+ - ATPase$) enzyme system, or proton pump, in gastric parietal cells. Normally, the proton pump uses energy from hydrolysis of ATPase to drive H^+ and chloride (Cl^-) out of parietal cells and into the stomach lumen in exchange for potassium (K^+), which leaves the stomach lumen and enters parietal cells. After this exchange, H^+ and Cl^- combine in the stomach to form hydrochloric acid (HCl). Esomeprazole irreversibly inhibits the final step in gastric acid production by blocking exchange of intracellular H^+ and extracellular K^+ , thus preventing H^+ from entering the stomach and additional HCl from forming.

Incompatibilities

Don't give esomeprazole with any other drug through the same I.V. site or tubing.

Contraindications

Hypersensitivity to esomeprazole or its components

Interactions**DRUGS**

antimicrobials: Increased esomeprazole level
atazanavir, nelfinavir: Decreased blood levels of these drugs

diazepam: Possibly increased diazepam level

digoxin, iron salts, ketoconazole: Possibly decreased absorption of these drugs

saquinavir: Increased plasma saquinavir level with increased toxicity

voriconazole: Increased esomeprazole exposure and risk of adverse effects

warfarin: Possibly increased INR and PT, leading to abnormal bleeding

FOODS

all foods: Decreased bioavailability of esomeprazole

Adverse Reactions

CNS: Agitation, aggression, depression, dizziness, headache, hallucinations, hepatic encephalopathy

EENT: Blurred vision, dry mouth, mucosal discoloration, sinusitis, stomatitis, taste disturbance

ENDO: Gynecomastia

GI: Abdominal pain; Barrett's esophagus; benign polyps or nodules; candidiasis; constipation; diarrhea; duodenitis; dyspepsia; esophagitis; esophageal stricture, ulceration, or varices; flatulence; gastric ulcer; gastritis; hepatic failure; hepatitis; jaundice; nausea; pancreatitis

GU: Interstitial nephritis

HEME: Agranulocytosis, pancytopenia

MS: Muscle weakness, myalgia

RESP: Bronchospasm, respiratory tract infection

SKIN: Alopecia, diaphoresis, erythema multiforme, photosensitivity, pruritus, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, infusion site redness or pruritus

Nursing Considerations

- Give oral esomeprazole at least 1 hour before meals because food decreases bioavailability.

WARNING If patient takes drug with amoxicillin or clarithromycin for *H. pylori*-related ulcer, severe diarrhea may indicate pseudomembranous colitis. Obtain stool cultures, as ordered.

- Always flush I.V. line with normal saline solution injection, lactated Ringer's injection, or 5% dextrose injection before and after giving esomeprazole intravenously.
- For I.V. injection, reconstitute powder with 5 ml of normal saline solution injection and give as a bolus dose over 3 or more minutes. Once reconstituted, drug may be stored at room temperature for up to 12 hours.
- For I.V. infusion, reconstitute powder with 5 ml of normal saline solution injection, lactated Ringer's injection, or 5% dextrose injection. Further dilute reconstituted solution to make a final volume of 50 ml, and infuse over 10 to 30 minutes. Reconstituted drug may be stored at room temperature up to 6 hours if mixed with 5% dextrose injection or up to 12 hours if

mixed with normal saline solution or lactated Ringer's injection.

- Be aware that patient receiving I.V. esomeprazole should be switched to oral form as soon as possible.

PATIENT TEACHING

- If patient has trouble swallowing esomeprazole capsules, tell him to open capsule and sprinkle pellets into a table-spoon of cool applesauce. Tell him not to chew pellets and to discard any unused pellets.
- Urge patient to tell prescriber if he takes antacids.

estazolam

Class, Category, and Schedule

Chemical class: Benzodiazepine

Therapeutic class: Sedative-hypnotic

Pregnancy category: X

Controlled substance schedule: IV

Indications and Dosages

➤ *To treat insomnia*

TABLETS

Adults. 1 to 2 mg at bedtime.

DOSE ADJUSTMENT Starting dose 0.5 mg for small or debilitated elderly patients.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	6–8 hr

Mechanism of Action

May potentiate effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptors in limbic and cortical areas of CNS. By binding to these receptors, estazolam increases GABA's inhibitory effects and blocks cortical and limbic arousal.

Contraindications

Acute angle-closure glaucoma; hypersensitivity to estazolam, other benzodiazepines, or their components; pregnancy; psychosis

Interactions

DRUGS

barbiturates, carbamazepine, phenytoin, rifampin: Possibly decreased estazolam level
carbamazepine: Possibly increased blood

carbamazepine level

cimetidine, diltiazem, disulfiram, erythromycin, fluoxetine, fluvoxamine, isoniazid, itraconazole, ketoconazole, nefazodone, oral contraceptives, propoxyphene, ranitidine, verapamil: Possibly increased blood level and impaired hepatic metabolism of estazolam
clozapine: Possibly cardiac arrest or respiratory depression

CNS depressants: Possibly potentiated CNS depression

levodopa: Possibly decreased therapeutic effects of levodopa

FOODS

grapefruit juice: Possibly increased blood level and impaired hepatic metabolism of drug

ACTIVITIES

alcohol use: Possibly potentiated CNS depression

Adverse Reactions

CNS: Amnesia, anxiety, ataxia, confusion, delusions, depression, dizziness, drowsiness, euphoria, headache, hypokinesia, irritability, malaise, nervousness, slurred speech, tremor

CV: Chest pain, palpitations, tachycardia

EENT: Blurred vision, dry mouth, increased salivation, photophobia

GI: Abdominal pain, constipation, diarrhea, nausea, thirst, vomiting

GU: Libido changes

RESP: Respiratory depression

SKIN: Diaphoresis

Other: Physical or psychological dependence

Nursing Considerations

- Use estazolam with extreme caution in patients with a history of drug or alcohol abuse because of risk of addiction. Expect to give drug for no more than 12 weeks.
- Use cautiously in elderly or debilitated patients and those with depression or impaired hepatic, renal, or respiratory function.
- Expect to stop drug gradually to prevent withdrawal symptoms. Avoid stopping abruptly if patient has history of seizures.
- Monitor respiratory status, especially in patients with respiratory compromise, who are at increased risk for respiratory depression.
- If patient takes estazolam for depression,

watch for suicidal tendencies, especially when therapy starts or dosage changes.

PATIENT TEACHING

- Warn patient not to exceed prescribed time because of risk of addiction.
- Because estazolam can reduce alertness, advise patient to avoid hazardous activities until CNS effects of the drug are known.
- Advise patient not to drink alcohol or take other CNS depressants during therapy because of the risk of additive effects.
- Warn elderly and debilitated patients and those with impaired hepatic or renal function about risk of excessive sedation or mental impairment and need to report them.
- If patient takes 2-mg dosage for a long time, warn against stopping drug abruptly.

estradiol

Estrace, Estrasorb, Estring, Estrogel, Evamist, Vagifem

estradiol acetate

Femring, Femtrace

estradiol cypionate

depGynogen, Depo-Estradiol, Depogen, Dura-Estrin, E-Cypionate, Estragyn LA 5, Estro-Cyp, Estrofem, Estro-L.A.

estradiol

transdermal system

Alora, Climara, Esclim, Estraderm, Estrasorb, Estrogel, FemPatch, Menostar, Vivelle, Vivelle-Dot

estradiol valerate

Clinagen LA 40, Delestrogen, Dioval 40, Dioval XX, Duragen-20, Estra-L 40, Estro-Span, Femogex (CAN), Gynogen L.A. 20, Gynogen L.A. 40, Menaval-20, Valergen 10, Valergen 20, Valergen 40

ethinyl estradiol

Estinyl

Class and Category

Chemical class: Estrogen derivative, steroid

hormone

Therapeutic class: Antineoplastic, anti-osteoporotic agent, ovarian hormone replacement

Pregnancy category: X

Indications and Dosages

↗ *To treat menopausal symptoms*

TABLETS (ESTRADIOL)

Adult menopausal and postmenopausal women. Starting on day 5 of a cycle, 0.5 to 2 mg daily in cycles of 3 wk on, 1 wk off. **Adult postmenopausal women with intact uterus receiving progestin.** 0.5 to 2 mg daily with daily progestin. Or, 0.5 to 2 mg daily on days 1 through 25 of a 28-day cycle, with progestin starting day 12 or 16 and continuing through day 25 of the cycle; then no drugs on days 26 through 28, as prescribed.

VAGINAL RING (ESTRADIOL ACETATE [FEMRING])

Adult women. One ring (0.05 mg or 0.1 mg of estradiol/24 hr) inserted into upper third of vaginal vault and replaced every 3 mo.

TABLETS (ESTRADIOL ACETATE [FEMTRACE])

Adult menopausal and postmenopausal women. *Initial:* 0.45 mg daily. May be increased to 0.9 mg daily and then 1.8 mg daily as needed.

TABLETS (ETHINYL ESTRADIOL)

Adult menopausal and postmenopausal women. 0.02 to 0.05 mg daily in cycles of 3 wk on, 1 wk off.

Adult postmenopausal women with intact uterus receiving progestin. 0.02 to 0.05 mg daily with daily progestin; or 0.02 to 0.05 mg daily on days 1 through 25 of a 28-day cycle, with progestin starting day 12 or 16 and continuing through day 25; then no drugs on days 26 through 28, as prescribed.

DOSAGE ADJUSTMENT Dosage may be reduced to less than 1 mg daily (estradiol) or 0.05 mg daily (ethinyl estradiol) for patients with only vaginal or vulvar symptoms.

I.M. INJECTION (ESTRADIOL CYPIONATE IN OIL)

Adult women. 1 to 5 mg as a single dose every 3 to 4 wk as needed.

I.M. INJECTION (ESTRADIOL VALERATE IN OIL)

Adult women. 10 to 20 mg every 4 wk as needed.

TRANSDERMAL (ALORA, ESTRADERM, VIVELLE, VIVELLE-DOT)

Adult menopausal and postmenopausal

women. *Initial:* 0.025 to 0.05 mg daily in cycles of 3 wk on, 1 wk off. One patch applied to trunk or buttocks and replaced twice/wk (every 3 to 4 days). Adjust dosage to control symptoms, as prescribed.

TRANSDERMAL (CLIMARA)

Adult women. *Initial:* 0.025 mg daily. One patch applied to trunk or buttocks, replaced every wk. Titrate dosage to control symptoms, as prescribed. Schedule will be cyclic unless patient has had a hysterectomy.

TRANSDERMAL (ESCLIM)

Adult women. *Initial:* 0.025 mg daily. One patch applied to upper arm, upper thigh, or buttocks and replaced twice/wk (every 3 to 4 days). Adjust dosage to control symptoms, as prescribed. Use a cyclic schedule, as prescribed, unless patient has had a hysterectomy.

TRANSDERMAL (ESTRASORB)

Adult women. 3.48 g daily in morning. Half of dose (1 pouchful) applied to one thigh and rubbed over entire thigh and calf for 3 min, repeated on other thigh and calf.

TRANSDERMAL (ESTROGEL)

Adult women. 1.25 g daily applied in thin layer from wrist to shoulder on inside and outside of one arm.

TRANSDERMAL (FEMPATCH)

Adult women. *Initial:* 0.025 mg daily. One patch applied to buttocks and replaced every wk. If symptoms aren't relieved after 4 to 6 wk, increased to two patches every wk, as prescribed. Follow a cyclic schedule, as prescribed, unless patient has had a hysterectomy.

TRANSDERMAL MIST (EVAMIST)

Adult women. *Initial:* 1.53 mg (1 spray) once daily in the morning. Dosage may be increased to 3.06 mg (2 sprays) once daily in the morning and then to 4.59 mg (3 sprays) once daily in the morning as needed.

➤ *To treat menopausal symptoms as combination therapy in patients with an intact uterus*

TRANSDERMAL ESTRADIOL (ALORA, ESTRADERM, VIVELLE, VIVELLE-DOT), IN COMBINATION WITH ESTRADIOL AND NORETHINDRONE ACETATE (COMBIPATCH)

Adult women. 0.05 mg daily estradiol-only transdermal system applied for first 14 days of 28-day cycle and replaced twice/wk, according to product directions. Estradiol

and norethindrone acetate transdermal system applied for remaining 14 days of 28-day cycle and replaced twice/wk during this period.

➤ *To treat postmenopausal vaginal and urogenital symptoms*

VAGINAL CREAM (ESTRACE)

Adult women. *Initial:* 2 to 4 g (200 to 400 mcg) daily for 1 to 2 wk. Then, dosage gradually reduced to half of initial dose, as prescribed, for 1 to 2 wk. *Maintenance:* 1 g (100 mcg) daily 1 to 3 times/wk for 3 wk, followed by 1 wk of no drugs. Repeat cyclically as needed.

VAGINAL RING (ESTRING)

Adult women. One ring (7.5 mcg of estradiol/24 hr) inserted into upper third of vaginal vault and replaced every 3 mo.

VAGINAL RING (FEMRING)

Adult women. One ring (0.05 or 0.1 mg of estradiol/24 hr) inserted into upper third of vaginal vault and replaced every 3 mo.

INTRAVAGINAL TABLETS (VAGIFEM)

Adult women. *Initial:* 10-mcg tablet daily for 2 wk, followed by 1 tablet twice weekly. Dosage increased to 25 mcg, as needed.

➤ *To prevent osteoporosis secondary to estrogen deficiency due to either natural or surgical menopause*

TABLETS (ESTRADIOL)

Adult women. At least 0.5 mg daily cyclically or continuously, adjusted as needed to control concurrent menopausal symptoms, as prescribed.

TABLETS (ETHINYL ESTRADIOL)

Adult women. At least 0.02 mg daily cyclically or continuously, as prescribed.

TRANSDERMAL (ALORA, VIVELLE-DOT)

Adult women. *Initial:* 0.025 mg daily continuously. One patch applied to lower abdomen or buttocks and replaced twice/wk. Adjust dosage to control symptoms and maintain bone density, as prescribed.

TRANSDERMAL (CLIMARA)

Adult women. *Initial:* 0.025 mg daily. One patch applied to trunk or buttocks and replaced every wk. Adjust dosage to control symptoms, as prescribed. Follow a cyclic schedule, as prescribed, unless patient has had a hysterectomy.

TRANSDERMAL (ESTRADERM)

Adult women. *Initial:* 0.05 mg daily. One patch applied to trunk or buttocks and replaced twice/wk. Adjust dosage to control

symptoms, as prescribed. Follow a cyclic schedule, as prescribed, unless patient has had a hysterectomy.

TRANSDERMAL (MENOSTAR)

Adult women. *Initial:* 0.014 mg daily. One patch applied to lower abdomen and replaced every wk. Follow a cyclic schedule, as prescribed, unless patient has had a hysterectomy.

↗ *To treat estrogen deficiency due to oophorectomy, primary ovarian failure, or female hypogonadism*

TABLETS (ESTRADIOL)

Adult women. 0.5 to 2 mg daily continuously or in cycles of 3 wk on, 1 wk off.

TABLETS (ETHINYL ESTRADIOL)

Adult women. For primary ovarian failure or oophorectomy, 0.05 mg t.i.d. initially, then 0.05 mg daily after a few weeks, cyclically or continuously. For female hypogonadism, 0.05 mg once daily to t.i.d. for first 2 wk of a theoretical menstrual cycle. A progestin may be added, as prescribed, during last half of cycle to help induce menses.

I.M. INJECTION (ESTRADIOL CYPIONATE IN OIL)

Adult women. 1.5 to 2 mg every mo (for female hypogonadism only).

I.M. INJECTION (ESTRADIOL VALERATE IN OIL)

Adult women. 10 to 20 mg every mo as needed.

TRANSDERMAL (ALORA, ESTRADERM, VIVELLE)

Adult women. *Initial:* 0.05 mg daily. One patch applied to trunk or buttocks and replaced twice/wk. Titrate dosage to control symptoms, as prescribed. Follow a cyclic schedule, as prescribed, unless patient has had a hysterectomy.

TRANSDERMAL (CLIMARA)

Adult women. *Initial:* 0.05 mg daily. One patch applied to trunk or buttocks and replaced every wk. Adjust dosage to control symptoms, as prescribed. Follow a cyclic schedule, as prescribed, unless patient has had a hysterectomy.

TRANSDERMAL (ESCLIM)

Adult women. *Initial:* 0.025 mg daily. One patch applied to upper arm, upper thigh, or buttocks and replaced twice/wk (every 3 to 4 days). Adjust dosage to control symptoms, as prescribed. Follow a cyclic schedule, as prescribed, unless patient has had a hysterectomy.

TRANSDERMAL (FEMPATCH)

Adult women. *Initial:* 0.025 mg. One patch

applied to buttocks and replaced every wk. If symptoms aren't relieved after 4 to 6 wk, increased to two patches every wk, as prescribed. Follow a cyclic schedule unless patient has had a hysterectomy.

↗ *To treat dysfunctional uterine bleeding from hormonal imbalance in patients with hypoplastic or atrophic endometrium and without uterine disease*

TRANSDERMAL (CLIMARA)

Adult women. *Initial:* 0.05 mg daily. One patch applied to trunk or buttocks and replaced every wk. Adjust dosage to control symptoms, as prescribed. Follow a cyclic schedule, as prescribed.

TRANSDERMAL (FEMPATCH)

Adult women. *Initial:* 0.025 mg daily. One patch applied to buttocks and replaced every wk. If symptoms aren't relieved after 4 to 6 wk, increased to two patches every wk, as prescribed. Follow a cyclic schedule, as prescribed.

↗ *To provide palliative treatment for inoperable, progressive breast cancer in selected men and postmenopausal women*

TABLETS (ESTRADIOL)

Adults. 10 mg t.i.d. for at least 3 mo.

TABLETS (ETHINYL ESTRADIOL)

Adults. 1 mg t.i.d. for at least 3 mo.

↗ *To treat advancing, inoperable prostate cancer*

TABLETS (ESTRADIOL)

Adult men. 1 to 2 mg b.i.d. or t.i.d., adjusted or continued, as prescribed, according to patient response.

TABLETS (ETHINYL ESTRADIOL)

Adult men. 0.15 to 3 mg daily, adjusted or continued, as prescribed, according to patient response.

I.M. INJECTION (ESTRADIOL VALERATE)

Adult men. 30 mg every 1 to 2 wk, adjusted or continued, as prescribed, according to patient response.

Mechanism of Action

Increases the rate of DNA and RNA synthesis in cells of female reproductive organs, pituitary gland, hypothalamus, and other target organs. In the hypothalamus, estrogens reduce release of gonadotropin-releasing hormone, which decreases pituitary release of follicle-stimulating hormone and luteinizing hormone. In women, these hor-

mones are required for normal genitourinary and other essential body functions.

At the cellular level, estrogens increase cervical secretions, cause endometrial cell proliferation, and improve uterine tone. Estrogen replacement helps maintain genitourinary function and reduces vasomotor symptoms when estrogen production declines as a result of menopause, surgical removal of ovaries, or other estrogen deficiency states. Estrogen replacement also helps prevent osteoporosis by inhibiting bone resorption.

In men, estrogens inhibit pituitary secretion of luteinizing hormone and decrease testicular secretion of testosterone. These actions may decrease prostate tumor growth and lower the level of prostate-specific antigen (PSA).

Contraindications

Active deep vein thrombosis, pulmonary embolism, or history of these conditions; active or recent (within past year) arterial thromboembolic disease, such as stroke or MI; hepatic dysfunction or disease; hypersensitivity to estradiol, ethinyl estradiol, or their components; hypersensitivity to tartrazine dye (contained in 0.02-mg estradiol and ethinyl estradiol tablets); known or suspected breast cancer or history of breast cancer except in appropriately selected patients being treated for metastatic disease; known or suspected estrogen-dependent cancer; pregnancy; undiagnosed abnormal genital bleeding

Interactions

DRUGS

aminocaproic acid: Possibly increased hypercoagulability caused by aminocaproic acid
barbiturates, carbamazepine, hydantoin, rifabutin, rifampin: Possibly reduced activity of estradiol

bromocriptine: Possibly decreased therapeutic effects of bromocriptine

calcium: Possibly increased calcium absorption

corticosteroids: Increased therapeutic and toxic effects of corticosteroids

cyclosporine: Increased risk of hepatotoxicity and nephrotoxicity

didanosine, lamivudine, zalcitabine: Possibly pancreatitis

hepatotoxic drugs, such as isoniazid: Increased

risk of hepatitis and hepatotoxicity
oral antidiabetic drugs: Decreased therapeutic effects of these drugs

somatrem, somatropin: Possibly accelerated epiphyseal maturation

tamoxifen: Possibly decreased therapeutic effects of tamoxifen

thyroid hormone replacement: Decreased effectiveness

vitamin C: Decreased metabolism and possibly increased adverse effects of estradiol

warfarin: Decreased anticoagulant effect

FOODS

grapefruit juice: Decreased estradiol metabolism and possibly increased adverse effects

ACTIVITIES

smoking: Increased risk of stroke, pulmonary embolism, thrombophlebitis, and transient ischemic attack

Adverse Reactions

CNS: Dementia, depression, dizziness, headache, migraine headache, stroke

CV: Hypertension, MI, peripheral edema, pulmonary embolism, thromboembolism, thrombophlebitis

EENT: Intolerance of contact lenses, retinal vascular thrombosis, vision changes

ENDO: Breast enlargement, pain, tenderness, or tumors; gynecomastia; hyperglycemia

GI: Abdominal cramps or pain, anorexia, bowel obstruction (vaginal ring), constipation, diarrhea, elevated liver function test results, enlargement of hepatic hemangiomas, gallbladder disease or obstruction, hepatitis, increased appetite, nausea, pancreatitis, vomiting

GU: Amenorrhea, breakthrough bleeding, cervical erosion, clear vaginal discharge, decreased libido (males), dysmenorrhea, endometrial cancer, impotence, increased libido (females), ovarian cancer, pelvic pain, prolonged or heavy menstrual bleeding, ring adherence, testicular atrophy, vaginal candidiasis, worsening of endometriosis

MS: Arthralgia

SKIN: Acne, alopecia, hirsutism, jaundice, melasma, oily skin, purpura, rash, seborrhea, urticaria

Other: Angioedema, folic acid deficiency, hypercalcemia (in metastatic bone disease), toxic shock syndrome (vaginal ring), weight gain

Nursing Considerations

WARNING Be aware that estradiol (Estrace) and ethinyl estradiol (Estinyl) are distinct and separate products and that their dosing isn't equivalent.

- Use estradiol cautiously in patients with asthma, chorea, diabetes mellitus, epilepsy, migraine headaches, porphyria, systemic lupus erythematosus, or hepatic hemangiomas because estradiol may worsen these disorders.
- Administer oral preparations with or immediately after food to decrease nausea.
- For I.M. injection of estradiol cypionate or estradiol valerate, roll vial and syringe between palms to evenly disperse drug. Use at least a 21G needle because of viscosity of oil-based solution. Use a dry, sterile syringe. Inject deep into upper outer quadrant of gluteal muscle. Aspirate before injection to avoid injection into a blood vessel.
- Be aware that, in patients who are converting from oral estrogen to transdermal system, oral estrogen should be stopped 1 week before skin patches are applied.
- Expect to begin prophylaxis treatment against osteoporosis at the start of menopause.
- Be aware that estrogen therapy should be given cyclically or combined with a progestin for 10 to 14 days per month in women with an intact uterus to minimize the risk of endometrial hyperplasia.

WARNING Be aware that severe hypercalcemia may occur in patients with bone metastasis due to breast cancer because estrogens influence the metabolism of calcium and phosphorus. Monitor for toxic effects of increased calcium absorption in patients who are predisposed to hypercalcemia or nephrolithiasis.

WARNING Assess patient for possible contact lens intolerance or changes in vision or visual acuity because estrogens can cause keratoconus, leading to increased curvature of the cornea. Be prepared to discontinue drug immediately, as prescribed, if patient experiences sudden partial or complete loss of vision or sudden onset of diplopia, migraine, or proptosis.

- Monitor PT test results of patients receiving warfarin for loss of anticoagulant effect because estrogens increase produc-

tion of clotting factors VII, VIII, IX, and X and promote platelet aggregation.

- Watch for elevated liver function test results because estrogens may worsen such conditions as acute intermittent or variegate hepatic porphyria.
- Closely monitor patient's blood pressure. A few patients may experience a substantial increase in blood pressure as an idiosyncratic reaction to estrogen. Monitor patients who already have hypertension for increases in blood pressure because estrogens may cause fluid retention. Also monitor patients with asthma, heart disease, migraines, renal disease, or seizure disorder for exacerbation of these conditions.
- Watch for peripheral edema or mild weight gain because estrogens can cause sodium and fluid retention.
- Frequently monitor serum glucose level in patients who have diabetes mellitus because estrogens may decrease insulin sensitivity and alter glucose tolerance.

WARNING Expect to stop estrogen therapy in any woman who develops signs or symptoms of cancer; cardiovascular disease, such as stroke, MI, pulmonary embolism, or venous thrombosis; or dementia.

- Be aware that exogenous estradiol and progestins may worsen mood disorders, including depression. Monitor patient for anxiety, depression, dizziness, fatigue, insomnia, or mood changes.
- Assess skin for melasma (tan or brown patches), which may develop on forehead, cheeks, temples, and upper lip. These patches may persist after drug is stopped.
- Check patient's triglyceride level routinely because, in patients with hypertriglyceridemia, estrogen therapy may increase serum triglyceride level enough to cause pancreatitis and other complications.
- Monitor serum PSA level in patients with inoperable prostate cancer to determine if patient is responding to hormone therapy. If patient responds (usually within 3 months), expect therapy to continue until disease is significantly advanced.
- Monitor thyroid function test results in patients with hypothyroidism because long-term use of ethinyl estradiol may decrease effectiveness of thyroid therapy.

- Expect to stop estrogen therapy several weeks before patient undergoes major surgery, as prescribed, because certain procedures are associated with prolonged immobilization and therefore pose a risk of thromboembolism.
- If patient takes thyroid hormone replacement therapy, monitor her for increased signs and symptoms of hypothyroidism because estradiol may increase thyroid binding globulin levels, which may make the patient's current dose of thyroid hormone insufficient.

PATIENT TEACHING

- Before therapy starts, inform patient of risks involved in estrogen therapy, such as increased risk of breast, endometrial, or ovarian cancer; cardiovascular disease; dementia (if age 65 or over); gallbladder disease; and vision abnormalities.
 - Advise patient to remain recumbent for at least 30 minutes after applying estradiol vaginal cream. Inform her that she may use a sanitary napkin (but not a tampon) to protect clothing after application.
 - Teach patient proper application and use of transdermal patch. Instruct her not to apply patch to breasts, waistline, or other areas where it may not adhere properly. Advise her to rotate application sites at least weekly and to remove old patch before applying new one. If patch falls off, instruct her to reapply it to another area or to apply a new patch and continue the original treatment schedule. Caution her not to expose patch to sun for long periods. Explain that she may bathe while wearing the patch.
 - Teach patient to apply Estrogel to clean, dry skin of one arm, using applicator. Stress importance of transferring all of the gel from applicator to arm. Tell patient to spread gel as thinly as possible over entire inside and outside of arm from wrist to shoulder. Advise her to wash her hands with soap and water afterward and to avoid fire and smoking until gel has dried because it's flammable. Tell patient never to apply gel to breasts. Warn that gel is alcohol-based and that patient should avoid fire, flame, or smoking until gel has dried.
 - Inform patient that each pouch of Estrasorb contains half of daily dose.
- Instruct her to apply emulsion to clean, dry skin on top of thigh and to rub it into entire thigh and calf for 3 minutes. Tell her to rub any excess emulsion onto her buttocks. Then, advise her to repeat procedure on her other thigh and calf using the second pouch. Tell her to wash her hands with soap and water after the application and to dress only after affected areas are dry.
- Teach patient proper use of estradiol vaginal ring. Instruct her to insert ring in upper third of vagina, to keep it there for 90 days, and then to remove it and insert a new ring. Or she may remove it during the 90-day dosage period, rinse it with lukewarm (not hot or boiling) water, and reinsert it as needed for personal hygiene. Remind patient that she shouldn't be able to feel the ring when it's in place. If she does, she should use a finger to push the ring farther into her vagina. If vaginal wall ulceration or erosion occurs, suggest that patient leave ring out and not replace it until healing is complete to keep ring from adhering to healing tissue.
 - Instruct patient using estradiol vaginal ring to remove ring immediately and contact prescriber if she develops fever, nausea, vomiting, diarrhea, muscle pain, dizziness, faintness, or a sunburn rash on face or body that may suggest a rare but serious bacterial infection called toxic shock syndrome. Also urge patient to seek prompt medical care if ring becomes attached to vaginal wall (rare), making removal difficult.
 - Instruct patient prescribed transdermal Evamist to prime the pump of a new device before the first dose by holding the container upright with the cover in place and spraying 3 sprays. Then, to deliver a dose, she should spray the mist on the inner aspect of her forearm starting near the elbow. Instruct her to let the mist dry for 2 minutes and to not wash the area for at least 30 minutes.
 - Inform patient receiving estradiol treatment that she should have an annual pelvic examination to screen for cervical dysplasia.
 - Tell patient who has an intact uterus and is prescribed transdermal Menostar that she will need to receive progesterin for 14

days every 6 to 12 months and have an endometrial biopsy yearly.

Class and Category

Chemical class: Estrogen derivative, steroid hormone

Therapeutic class: Antiosteoporotic agent, ovarian hormone replacement

Pregnancy category: X

Indications and Dosages

↗ *To treat moderate to severe vasomotor menopausal symptoms*

TABLETS (CENESTIN, PREMARIN)

Adults. 0.3 to 1.25 mg daily (Cenestin, Premarin) or cyclically 25 days on, 5 days off (Premarin only). Dosage increased as needed to control symptoms.

TABLETS (ENJUVIA)

Adults. 0.625 mg daily. Dosage increased as needed to control symptoms.

TABLETS (PREMPRO)

Adults. 0.3 mg conjugated estrogens and 1.5 mg medroxyprogesterone daily. Increased up to 0.625 mg conjugated estrogens and 5 mg medroxyprogesterone daily as needed.

TABLETS (PREMPHASE)

Adults. 0.625 mg conjugated estrogens daily on days 1 through 14 and combination product (0.625 mg conjugated estrogens and 5 mg medroxyprogesterone) on days 15 through 28.

↗ *To treat vaginal and vulvar atrophy*

TABLETS (CENESTIN, PREMARIN)

Adults. 0.3 to 1.25 mg daily (Cenestin, Premarin) or cyclically 25 days on, 5 days off (Premarin only). Dosage increased as needed to control symptoms.

TABLETS (PREMPRO)

Adults. 0.3 mg conjugated estrogens and 1.5 mg medroxyprogesterone daily. Increased up to 0.625 mg conjugated estrogens and 5 mg medroxyprogesterone daily as needed.

TABLETS (PREMPHASE)

Adults. 0.625 mg conjugated estrogens daily on days 1 through 14 and combination product (0.625 mg conjugated estrogens and 5 mg medroxyprogesterone) on days 15 through 28.

↗ *To treat atrophic vaginitis and vaginal and vulvar atrophy*

VAGINAL CREAM (PREMARIN)

Adults. 0.5 to 2 g daily in cycles of 3 wk on, 1 wk off.

↗ *To treat moderate to severe vaginal dryness and pain with intercourse and symptoms of vulvar and vaginal atrophy in menopause*

TABLETS (ENJUVIA)

Adults. 0.3 mg daily.

VAGINAL CREAM (PREMARIN)

Adults. 0.5 g twice/wk. Or, 0.5 g daily for 21 days followed by 7 days off, with cycle repeated every 28 days.

VAGINAL CREAM (SCE-A)

Adults. 1 g daily for 1 wk, followed by 1 g twice/wk.

↗ *To prevent postmenopausal osteoporosis*

TABLETS (CENESTIN, PREMARIN)

Adults. 0.625 mg daily continuously or in cycles of 25 days on, 5 days off.

TABLETS (PREMPRO)

Adults. 0.3 mg conjugated estrogens and 1.5 mg medroxyprogesterone daily. Increased to 0.625 mg conjugated estrogens and 5 mg medroxyprogesterone daily as needed.

TABLETS (PREMPHASE)

Adults. 0.625 mg conjugated estrogens daily

on days 1 through 14 and combination product (0.625 mg conjugated estrogens and 5 mg medroxyprogesterone) on days 15 through 28.

➤ *To provide palliative treatment for advanced androgen-dependent prostate cancer*

TABLETS (PREMARIN)

Adults. 1.25 to 2.5 mg t.i.d.

➤ *To provide palliative treatment for metastatic breast cancer*

TABLETS (PREMARIN)

Adults. 10 mg t.i.d. for 3 mo or longer.

➤ *To treat dysfunctional uterine bleeding*

I.V. INFUSION, I.M. INJECTION (PREMARIN)

Adults. 25 mg, repeated in 6 to 12 hr if needed.

➤ *To treat estrogen deficiency from oophorectomy or primary ovarian failure*

TABLETS (PREMARIN)

Adults. 1.25 mg daily in cycles of 3 wk on, 1 wk off.

➤ *To treat female hypogonadism*

TABLETS (PREMARIN)

Adults. 0.3 to 0.625 mg daily in cycles of 3 wk on, 1 wk off. Increased as needed every 6 to 12 mo.

Mechanism of Action

Increase the rate of DNA and RNA synthesis in the cells of female reproductive organs, hypothalamus, pituitary glands, and other target organs. In the hypothalamus, estrogens reduce the release of gonadotropin-releasing hormone, which decreases pituitary release of follicle-stimulating hormone and luteinizing hormone. In women, these hormones are required for normal genitourinary and other essential body functions. At the cellular level, estrogens increase cervical secretions, cause endometrial cell proliferation, and increase uterine tone. Estrogen replacement helps maintain genitourinary function and reduce vasomotor symptoms when estrogen production declines from menopause, surgical removal of ovaries, or other estrogen deficiency. Estrogen also helps prevent osteoporosis by keeping bone resorption from exceeding bone formation.

In men, estrogens inhibit pituitary secretion of luteinizing hormone and decrease testicular secretion of testosterone. These actions may decrease prostate tumor growth and lower the level of prostate-spe-

cific antigen.

Contraindications

Active deep vein thrombosis, pulmonary embolism, or history of these conditions; active or recent (within past year) arterial thromboembolic disease such as stroke or MI; hepatic dysfunction or disease; hypersensitivity to estrogens or their components; known or suspected breast cancer or history of breast cancer; known or suspected estrogen-dependent cancer; pregnancy; undiagnosed abnormal genital bleeding

Incompatibilities

Don't combine I.V. estrogens with acid solutions, ascorbic acid, and protein hydrolysate because they're incompatible.

Interactions

DRUGS

aminocaproic acid: Possibly increased level of hypercoagulability caused by aminocaproic acid

barbiturates, carbamazepine, hydantoin, rifabutin, rifampin: Possibly reduced activity of estrogen and medroxyprogesterone

bromocriptine: Possibly interference with bromocriptine's therapeutic effects

calcium: Possibly increased calcium absorption

corticosteroids: Increased therapeutic and toxic effects of corticosteroids

cyclosporine: Increased risk of hepatotoxicity and nephrotoxicity

didanosine, lamivudine, zalcitabine: Possibly pancreatitis

hepatotoxic drugs (such as isoniazid): Increased risk of hepatitis and hepatotoxicity

oral antidiabetic drugs: Decreased therapeutic effects of these drugs

somatrem, somatropin: Possibly accelerated epiphyseal maturation

tamoxifen: Possibly interference with tamoxifen's therapeutic effects

thyroid hormone replacement: Decreased effectiveness

warfarin: Decreased anticoagulant effect

ACTIVITIES

smoking: Increased risk of stroke, pulmonary embolism, thrombophlebitis, and transient ischemic attack

Adverse Reactions

CNS: Asthenia, dementia, depression, dizziness, growth benign meningioma,

headache, insomnia, migraine headache, mood disturbance, nervousness, paresthesia, stroke

CV: Hypertension, MI, peripheral edema, thromboembolism, thrombophlebitis, vasodilation

EENT: Intolerance of contact lenses, pharyngitis, retinal vascular thrombosis, rhinitis, sinusitis

ENDO: Breast enlargement, pain, tenderness, or tumors; gynecomastia (men); hot flashes; hyperglycemia

GI: Abdominal cramps or pain, anorexia, cholestatic jaundice, constipation, diarrhea, flatulence, gallbladder disease or obstruction, hepatic hemangioma enlargement, hepatitis, increased appetite, ischemic colitis, nausea, pancreatitis, vomiting

GU: Amenorrhea, breakthrough bleeding, cervical erosion, clear vaginal discharge, decreased libido (men), dysmenorrhea, endometrial cancer or hyperplasia, impotence, increased libido (women), leukorrhea, ovarian cancer, prolonged or heavy menstrual bleeding, testicular atrophy, uterine leiomyomata enlargement, vaginal candidiasis, vaginitis, vaginal site reactions (vaginal administration only) such as burning, irritation, and genital pruritus

MS: Arthralgias, back pain

RESP: Bronchitis, increased cough, pulmonary embolism

SKIN: Acne, alopecia, chloasma, erythema multiforme, erythema nodosum, hemorrhagic eruption, hirsutism, melasma, oily skin, pruritus, purpura, rash, seborrhea, urticaria

Other: Anaphylaxis, angioedema, flu syndrome, folic acid deficiency, hypercalcemia (in metastatic bone disease), weight gain

Nursing Considerations

- Use conjugated estrogens cautiously in patients with severe hypocalcemia because a sudden increase in serum calcium level may cause adverse reactions.
- Reconstitute conjugated estrogens with normal saline solution, dextrose, or invert sugar solution and use within a few hours. Discard solution that contains precipitate.

WARNING Monitor serum calcium level to detect severe hypercalcemia in patients with bone metastasis from breast cancer.

- Watch for elevated liver function test results because estrogen and progestins

may worsen such conditions as acute intermittent or variegate hepatic porphyria.

- Assess hypertensive patients for increases in blood pressure because estrogens may cause fluid retention.
- Monitor patients with asthma, diabetes mellitus, endometriosis, heart disease, lupus erythematosus, migraine headaches, renal disease, or seizure disorder for worsening of these conditions.
- If patient takes warfarin, assess PT for loss of anticoagulant effects because estrogens increase production of clotting factors and promote platelet aggregation.
- Expect to stop drug during periods of immobilization, 4 weeks before elective surgery, and if jaundice develops.

WARNING Expect to stop estrogen combination therapy in any woman who develops signs or symptoms of cancer; cardiovascular disease, such as MI, pulmonary embolism, venous thrombosis, or stroke; or dementia.

- Check triglyceride level routinely because, in hypertriglyceridemia, estrogen therapy may increase triglycerides enough to cause pancreatitis and other complications.
- If patient takes thyroid hormone replacement therapy, monitor her for increased signs and symptoms of hypothyroidism because estrogen may increase thyroid binding globulin level, which may make the patient's current dose of thyroid hormone insufficient.
- Estrogen may worsen mood disorders, including depression. Monitor patient for depression, fatigue, insomnia, or mood changes.

PATIENT TEACHING

- Explain the risks of estrogen therapy, including increased risk of breast, endometrial, or ovarian cancer; cardiovascular disease; dementia; and gallbladder disease.
- Instruct patient how to use vaginal cream and to cleanse plunger by removing it from barrel and washing it with mild soap and warm water after each use.
- Urge patient to immediately report breakthrough bleeding to prescriber.
- Instruct patient to perform monthly breast self-examination and to comply with all prescribed follow-up examinations.
- Warn female patient that long-term use

may increase risk of dementia, heart disease, stroke, gallbladder disease, and breast or endometrial cancer.

- Inform patient that estrogen vaginal cream may alter effectiveness of condoms, diaphragms, or cervical caps made of latex or rubber.

eszopiclone

Lunesta

Class, Category, and Schedule

Chemical class: Pyrrolopyrazine derivative of cyclopyrrolone class

Therapeutic class: Sedative-hypnotic

Pregnancy category: C

Controlled substance schedule: IV

Indications and Dosages

➤ **To treat insomnia**

TABLETS

Adults. *Initial:* 2 mg immediately at bedtime. May be increased to 3 mg at bedtime, as needed. *Maintenance:* 3 mg at bedtime.

DOSE ADJUSTMENT For elderly patients who have trouble falling asleep or patients with severe hepatic impairment, dosage decreased to 1 mg at bedtime. For elderly patients who have trouble staying asleep, dosage may be increased to 2 mg at bedtime.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	Unknown

Mechanism of Action

May potentiate effects of the inhibitory neurotransmitter gamma-aminobutyric acid (GABA) by binding close to or with benzodiazepine receptors in limbic and cortical areas of the CNS. By binding to these receptor sites and areas, eszopiclone increases GABA's inhibitory effects and blocks cortical and limbic arousal, thereby inducing and maintaining sleep.

Contraindications

Hypersensitivity to eszopiclone or its components

Interactions

DRUGS

clarithromycin, itraconazole, ketoconazole,

nefazodone, nelfinavir, ritonavir, trolean-domycin: Increased eszopiclone level
rifampin: Decreased eszopiclone level

ACTIVITIES

alcohol use: Additive effect on psychomotor performance

Adverse Reactions

CNS: Agitation, anxiety, bizarre behavior such as sleep driving, confusion, depersonalization, depression, dizziness, hallucinations, headache (including migraine), nervousness, neuralgia, somnolence, unusual dreams

CV: Chest pain, peripheral edema

EENT: Dry mouth, taste perversion

ENDO: Gynecomastia

GI: Diarrhea, hepatitis, indigestion, nausea, vomiting

GU: Decreased libido, dysmenorrhea, UTI

RESP: Asthma, respiratory tract infection

SKIN: Pruritus, rash

Other: Generalized pain, heat stroke, viral infection

Nursing Considerations

- Use eszopiclone cautiously in patients with severe mental depression or reduced respiratory function; drug may intensify mental depression and lead to respiratory depression.

PATIENT TEACHING

- Instruct patient not to exceed prescribed eszopiclone dosage and not to stop drug abruptly because withdrawal symptoms may occur.
- Because eszopiclone can reduce alertness, advise patient to take drug immediately before bedtime and to avoid potentially hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcohol and CNS depressants because of additive effects.
- Advise woman of childbearing age to notify prescriber if she becomes or intends to become pregnant during therapy.
- Explain that sleep may be disturbed for the first few nights after therapy.
- Warn patient and caregiver that some patients have performed bizarre activities after taking drug, such as driving the car, preparing and eating food, making phone calls, or having sex while not fully awake and often with no memory of the event. These episodes usually occur in patients

who have taken the drug with alcohol or other CNS depressant or who have exceeded the recommended dose. If such an episode occurs, the prescriber should be notified and eszopiclone therapy discontinued immediately.

etanercept

Enbrel

Class and Category

Chemical class: Dimeric recombinant human p75 tumor necrosis factor receptor
Therapeutic class: Disease-modifying anti-rheumatoid drug
Pregnancy category: B

Indications and Dosages

➤ *To reduce signs and symptoms of rheumatoid or psoriatic arthritis, slow structural damage in active arthritis, and improve physical function in patients with psoriatic arthritis, alone or in combination with methotrexate*

SUBCUTANEOUS INJECTION

Adults. 50 mg once/wk on same day each wk.

➤ *To reduce signs and symptoms of active ankylosing spondylitis*

SUBCUTANEOUS INJECTION

Adults. 50 mg once/wk on same day each wk.

➤ *To reduce signs and symptoms of juvenile rheumatoid arthritis*

SUBCUTANEOUS INJECTION

Children ages 4 to 17. 0.4 mg/kg twice/wk 3 to 4 days apart for 3 to 7 mo. Or, 0.8 mg/kg once/wk on same day each wk for 3 to 7 mo. *Maximum:* 25 mg twice/wk or 50 mg weekly.

➤ *To treat chronic moderate-to-severe plaque psoriasis in candidates for systemic therapy or phototherapy*

SUBCUTANEOUS INJECTION

Adults. *Initial:* 50 mg twice/wk 3 to 4 days apart for 3 mo; then reduced to 50 mg/wk.

➤ *To reduce signs and symptoms of moderately to severely active polyarticular juvenile idiopathic arthritis*

SUBCUTANEOUS INJECTION

Children ages 2 to 17. 0.8 mg/kg/wk. *Maximum:* 50 mg/wk.

Incompatibilities

Don't combine etanercept with other drugs.

Contraindications

Hypersensitivity to etanercept, hamster protein, or their components; sepsis or risk of it

Interactions

DRUGS

cyclophosphamide: Possibly increased risk of malignancy

sulfasalazine: Possibly decreased neutrophil count

Adverse Reactions

CNS: Asthenia, chills, dizziness, fever, headache, multiple sclerosis, seizures

CV: Congestive heart failure, hypertension, hypotension, peripheral edema

EENT: Optic neuritis, pharyngitis, rhinitis, sinusitis

GI: Abdominal abscess, abdominal pain, autoimmune hepatitis, cholecystitis, diarrhea, gastroenteritis, indigestion, nausea, noninfectious hepatitis, vomiting

GU: Pyelonephritis

HEME: Aplastic anemia, neutropenia, pancytopenia

MS: Osteomyelitis, septic arthritis, transverse myelitis

RESP: Bronchitis, cough, pneumonia, upper respiratory tract infection

SKIN: Cellulitis, foot abscess, leg ulceration, pruritus, rash, urticaria

Other: Angioedema; injection site edema, erythema, itching, and pain; malignancy, such as leukemia or lymphoma; sepsis; varicella infection

Nursing Considerations

- Screen patient for latent tuberculosis with a tuberculin skin test before starting etanercept therapy. If test is positive, expect to give treatment, as ordered, before starting etanercept. Also screen patient for hepatitis B. If present, expect etanercept therapy to be withdrawn because antirheumatic therapies like etanercept may reactivate hepatitis B.
- Use cautiously in patients with a history of recurrent infection, underlying conditions that may predispose them to infections, or an existing chronic, latent, or localized infection because etanercept increases their risk of infection.
- Use cautiously in patients with COPD, and

Mechanism of Action

Etanercept reduces joint inflammation from rheumatoid arthritis by binding with tumor necrosis factor (TNF), a cytokine, or protein, that plays an important role in normal inflammatory and immune responses.

In rheumatoid arthritis, the immune and inflammatory process triggers release of TNF, mainly from macrophages. TNF then binds to TNF receptors on cell membranes, as shown below left. This action renders TNF biologically active

and triggers a cascade of inflammatory events that results in increased inflammation of the synovial membrane, release of destructive lysosomal enzymes, and further joint destruction.

Etanercept binds to TNF and prevents it from binding with TNF receptors on the cell membranes, as shown below right. This action renders bound TNF biologically inactive, prevents TNF-mediated cellular responses, and significantly reduces inflammatory activity.

E
F

monitor respiratory status closely because etanercept therapy may increase patient's risk of adverse respiratory reactions.

- Use cautiously in patients with preexisting or recent onset CNS demyelinating disorders because drug may worsen these conditions. Also use cautiously in patients with heart failure because drug may worsen it.
- Tumor necrosis factor antagonists shouldn't be given with etanercept because doing so increases the risk of serious infection.

WARNING Don't use the diluent provided with etanercept (bacteriostatic water for injection, USP, with 0.9% benzyl alcohol) for patients who have benzyl alcohol hypersensitivity. Instead, use sterile water for injection for these patients.

WARNING If you have a latex allergy, don't handle needle cover of diluent syringe because it contains dry natural rubber.

- When giving etanercept to children, don't use the 25-mg prefilled syringe if the child

weighs less than 31 kg (68 lb). The 50-mg prefilled syringe or SureClick autoinjector may be used for children who weigh 63 kg (138 lb) or more.

WARNING Expect to stop etanercept if patient develops sepsis.

- Avoid giving live-virus vaccines to patients who are taking etanercept because drug decreases immune response and increases risk of secondary transmission of vaccine virus.
- Monitor immunosuppressed patients for evidence of acute or chronic infection, including chills, fever, and tachycardia, because etanercept decreases defenses against infection. It also increases the risk of developing malignant tumors.
- Continue giving corticosteroids, NSAIDs, and other analgesics, as prescribed, during etanercept therapy.
- Malignancies, especially lymphomas and leukemias, have been reported rarely in patients taking tumor necrosis factor

blockers such as etanercept. Children, adolescents, and patients with rheumatoid arthritis, especially those with very active disease, are at greatest risk. Monitor closely.

PATIENT TEACHING

- Inform patient that etanercept is given by a small injection under the skin, and teach him proper injection technique if needed.
- If patient will take 50-mg dose, explain that a prefilled syringe is available to eliminate the need to mix or draw up drug.
- If patient will take less than 50-mg dose or prefers not to use prefilled syringe, advise him to use drug as soon as possible after dissolving powder. Dissolved powder may be kept in refrigerator for up to 6 hours after mixing and then should be discarded.
- Instruct patient to rotate injection sites among thigh, stomach, and upper arms and to avoid areas that are tender, red, bruised, or hard. Advise him to keep each site at least 10 away from a previous site.
- Urge patient to use needles and syringes once and discard in puncture-proof container.
- Caution patient that the risk of malignancies such as leukemia and lymphoma may be higher in those who take etanercept, especially children and adolescents. Tell him to seek medical attention promptly for any suspicious signs and symptoms.
- Urge patient to consult prescriber immediately if he develops an infection because drug may decrease the body's infection-fighting ability.
- Caution patient who hasn't had chickenpox to contact prescriber right away if he's exposed because he may develop a more serious infection.
- Urge patient to seek immediate emergency care if he develops a persistent fever, bruising, bleeding, or pallor while taking drug.

ethacrynic acid

Edecrin

ethacrynate sodium

Edecrin

Class and Category

Chemical class: Ketone derivative of anolyoxyacetic acid

Therapeutic class: Diuretic

Pregnancy category: B

Indications and Dosages

➤ *To promote diuresis in heart failure; hepatic cirrhosis; renal disease; ascites of short duration caused by cancer, idiopathic edema, or lymphedema; and edema in children (excluding infants with congenital heart disease or nephrotic syndrome)*

ORAL SOLUTION, TABLETS

Adults. *Initial:* 50 to 100 mg daily as a single dose or in divided doses. Dosage increased by 25 to 50 mg daily, if needed.

Maintenance: 50 to 200 mg daily.

Maximum: 400 mg daily.

Children (except infants). *Initial:* 25 mg daily. Dosage increased in 25-mg increments daily, if needed.

I.V. INFUSION

Adults. *Initial:* 50 mg or 0.5 to 1 mg/kg. Dose repeated in 2 to 4 hr, if needed, then every 4 to 6 hr based on patient response. In an emergency, dose repeated every 1 hr, if needed. *Maximum:* 100 mg as single dose.

Route	Onset	Peak	Duration
P.O.	30 min	2 hr	6–8 hr
I.V.	5 min	15–30 min	2 hr

Mechanism of Action

Probably inhibits the sulfhydryl-catalyzed enzyme systems that cause sodium and chloride resorption in the proximal and distal tubules and the ascending limb of the loop of Henle. These inhibitory effects increase urinary excretion of sodium, chloride, and water, causing profound diuresis. Drug also increases the excretion of potassium, hydrogen, calcium, magnesium, bicarbonate, ammonium, and phosphate.

Contraindications

Anuria; hypersensitivity to ethacrynic acid, ethacrynate sodium, sulfonyleureas, or their components; infancy; severe diarrhea

Interactions

DRUGS

ACE inhibitors, antihypertensives: Possibly hypotension

aminoglycosides: Increased risk of ototoxicity

amiodarone: Increased risk of arrhythmias

amphotericin B: Increased risk of electrolyte imbalances, nephrotoxicity, and ototoxicity
anticoagulants, thrombolytics: Possibly potentiated anticoagulation and risk of hemorrhage

corticosteroids: Increased risk of gastric hemorrhage

digoxin: Increased risk of digitalis toxicity
insulin, oral antidiabetic drugs: Possibly increased serum glucose level and decreased therapeutic effects of these drugs

lithium: Increased risk of lithium toxicity
neuromuscular blockers: Possibly increased neuromuscular blockade

NSAIDs: Possibly decreased effects of ethacrynic acid

sympathomimetics: Possibly interference with hypotensive effects of ethacrynic acid and ethacrynate sodium

ACTIVITIES

alcohol use: Possibly potentiated hypotensive and diuretic effects of ethacrynic acid and ethacrynate sodium

Adverse Reactions

CNS: Confusion, fatigue, headache, malaise, nervousness

CV: Orthostatic hypotension

EENT: Blurred vision, hearing loss, ototoxicity (ringing or buzzing in ears), sensation of fullness in ears, yellow vision

ENDO: Hyperglycemia, hypoglycemia

GI: Abdominal pain, anorexia, diarrhea, dysphagia, GI bleeding (I.V. form), nausea, vomiting

GU: Hematuria (I.V. form), interstitial nephritis, polyuria

HEME: Agranulocytosis, severe neutropenia, thrombocytopenia

SKIN: Rash

Other: Hyperuricemia, hypochloremic alkalosis, hypokalemia, hypomagnesemia, hyponatremia, hypovolemia, infusion site irritation and pain

Nursing Considerations

WARNING Give ethacrynic acid and ethacrynate sodium cautiously in patients with advanced hepatic cirrhosis, especially those with a history of electrolyte imbalance or hepatic encephalopathy; both forms of drug may lead to lethal hepatic coma.

- Dilute ethacrynate sodium with D₅W or normal saline solution for I.V. infusion.

Discard unused portion after 24 hours.

- Don't use diluted ethacrynate sodium that's cloudy or opalescent.
- Infuse I.V. ethacrynate sodium slowly over 30 minutes.
- Weigh patient daily, and assess him for signs and symptoms of electrolyte imbalances and dehydration.
- Monitor blood pressure and fluid intake and output, and check laboratory test results.
- Report significant changes. Prescriber may reduce dosage or temporarily stop drug.
- If hypokalemia develops, administer replacement potassium, as ordered.
- Monitor serum glucose level frequently, especially if patient has diabetes mellitus; both forms of drug may cause hyperglycemia or hypoglycemia.
- Notify prescriber if patient experiences hearing loss, vertigo, or ringing, buzzing, or sense of fullness in his ears. Drug may need to be discontinued.

PATIENT TEACHING

- Instruct patient to take the last dose of ethacrynic acid several hours before bedtime to avoid sleep interruption from diuresis. If patient receives once-daily dosing, advise him to take the dose in the morning to avoid sleep disturbance caused by nocturia.
- Suggest that patient take ethacrynic acid with food or milk to reduce the likelihood of GI distress.
- Advise patient to change position slowly to minimize effects of orthostatic hypotension, especially if he also takes an antihypertensive.
- Unless contraindicated, urge patient to eat more high-potassium foods and to take a potassium supplement, if prescribed, to prevent hypokalemia.
- Caution patient not to drink alcohol, stand for prolonged periods, or exercise during hot weather because these activities may exacerbate orthostatic hypotension.
- Instruct patient to notify prescriber if he has diarrhea; buzzing, fullness, or ringing in his ears; hearing loss; severe nausea; vertigo; or vomiting. Drug may need to be discontinued.
- Remind diabetic patients to check their serum glucose levels often for changes.

ethambutol hydrochloride

Etibi (CAN), Myambutol

Class and Category

Chemical class: Diisopropylethylene diamide derivative

Therapeutic class: Antitubercular

Pregnancy category: C

Indications and Dosages

↗ *As adjunct to treat tuberculosis and atypical mycobacterial infections caused by Mycobacterium tuberculosis*

TABLETS

Adults and adolescents who haven't received previous antituberculous therapy. 15 mg/kg daily.

Adults and adolescents who have received antituberculous therapy. 25 mg/kg daily; after 60 days, decreased to 15 mg/kg daily.

Mechanism of Action

May suppress bacterial multiplication by interfering with RNA synthesis in susceptible bacteria that are actively dividing.

Contraindications

Hypersensitivity to ethambutol or its components, inability to report changes in vision, optic neuritis

Interactions

DRUGS

antacids that contain aluminum hydroxide:

Decreased absorption of ethambutol
other neurotoxic drugs: Increased risk of neurotoxicity, such as optic and peripheral neuritis

Adverse Reactions

CNS: Burning sensation or weakness in arms and legs, confusion, disorientation, dizziness, fever, headache, malaise, paresthesia, peripheral neuritis

EENT: Blurred vision, decreased visual acuity, eye pain, optic neuritis, red-green color blindness

GI: Abdominal pain, anorexia, hepatic dysfunction, nausea, vomiting

HEME: Leukopenia, neutropenia, thrombocytopenia

MS: Arthralgia, gouty arthritis, joint pain

RESP: Pulmonary infiltrates

SKIN: Dermatitis, erythema multiforme, pruritus, rash

Other: Anaphylaxis, hypersensitivity syndrome (rash or exfoliative dermatitis, eosinophilia, and one of the following: hepatitis, pneumonitis, nephritis, myocarditis, pericarditis), lymphadenopathy

Nursing Considerations

- Expect prescriber to refer patient for an ophthalmologic examination that includes tests for visual fields, acuity, and red-green color blindness before taking ethambutol and monthly thereafter. This is especially likely if therapy is prolonged or dosage exceeds 15 mg/kg daily.

WARNING Notify prescriber immediately if patient develops vision changes, and expect ethambutol to be stopped if they occur.

- Expect to give the patient at least one other antituberculous with ethambutol, as prescribed, because bacteria may become resistant quickly to a single drug.
- Monitor laboratory test results for changes in liver function or for increased serum uric acid level if patient has gouty arthritis or impaired renal function. Notify prescriber of any abnormalities.
- Obtain a monthly sputum specimen, as ordered, to check bacteriologic response in sputum-positive patient.
- Know that successful ethambutol therapy typically takes 6 to 12 months but may take years.

PATIENT TEACHING

- Teach patient to recognize possible adverse reactions to ethambutol.
- Advise patient to take drug with food if he experiences adverse GI reactions.
- Instruct patient to take a missed dose as soon as he remembers, unless it's nearly time for the next dose, but not to double-dose.
- Explain that ethambutol therapy may last months or years and that compliance is essential.
- Advise patient to notify prescriber if no improvement occurs within 3 weeks of starting ethambutol therapy; if bothersome or severe adverse reactions occur; if his vision changes; or if a rash, fever, or joint pain (possible hypersensitivity) develops.

ethchlorvynol

Placidyl

Class, Category, and Schedule

Chemical class: Chlorinated tertiary acetylenic carbinol

Therapeutic class: Sedative-hypnotic

Pregnancy category: C

Controlled substance schedule: IV

Indications and Dosages

↗ *To provide short-term relief from insomnia*

CAPSULES

Adults. 0.5 to 1 g at bedtime for no longer than 1 wk.

Route	Onset	Peak	Duration
P.O.	15–60 min	Unknown	5 hr

Mechanism of Action

Exerts sedative-hypnotic, muscle relaxant, and anticonvulsant effects possibly by depressing the reticular activating system.

Contraindications

Hypersensitivity to ethchlorvynol or its components, porphyria

Interactions

DRUGS

CNS depressants, tricyclic antidepressants: Increased CNS depression

oral anticoagulants: Decreased anticoagulant effects

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Ataxia, dizziness, facial numbness, fatigue, light-headedness, syncope, unsteadiness, weakness

CV: Hypotension

EENT: Blurred vision, unpleasant aftertaste

GI: Epigastric pain, indigestion, nausea, vomiting

HEME: Thrombocytopenia

SKIN: Jaundice, rash, urticaria

Other: Physical and psychological dependence

Nursing Considerations

- If patient awakens too early after taking 0.5 or 0.75 g of ethchlorvynol at bedtime,

ask prescriber if he may take a single supplemental dose of 200 mg.

- Assess for signs of addiction if patient has taken drug for 2 weeks or longer.
- Be aware that ethchlorvynol shouldn't be given for longer than 1 week. If patient has received prolonged therapy, expect to discontinue drug gradually to prevent withdrawal symptoms. Notify prescriber if you detect evidence of withdrawal, such as diaphoresis, hallucinations, irritability, muscle twitching, nausea, nervousness, restlessness, seizures, sleep disturbance, tremor, vomiting, and weakness.

PATIENT TEACHING

- Caution patient not to exceed prescribed dosage or dosing frequency because of ethchlorvynol's habit-forming potential. Instruct him not to use drug for more than 1 week.
- Advise patient to take ethchlorvynol with food or milk to minimize adverse GI reactions.
- If patient has taken long-term ethchlorvynol therapy, warn against stopping drug abruptly; advise him to contact prescriber for guidelines to reduce dosage.
- Direct patient to avoid alcohol and other CNS depressants during ethchlorvynol therapy because they increase the risk of adverse reactions.
- Advise patient to avoid potentially hazardous activities until drug's CNS effects are known.

ethionamide

Trecator-SC

Class and Category

Chemical class: Thiamide analogue of isonicotinic acid

Therapeutic class: Antituberculotic

Pregnancy category: Not rated

Indications and Dosages

↗ *As adjunct to treat tuberculosis*

TABLETS

Adults. 0.5 to 1 g daily in divided doses every 8 to 12 hr, together with other antituberculotics. *Maximum:* 1 g daily.

Children. 15 to 20 mg/kg daily in divided doses every 8 to 12 hr, together with other antituberculotics. *Maximum:* 750 mg daily.

Mechanism of Action

May inhibit peptide synthesis, resulting in bacteriostatic action against *Mycobacterium tuberculosis*.

Contraindications

Hypersensitivity to ethionamide or its components, severe hepatic damage

Interactions

DRUGS

cycloserine: Increased risk of adverse CNS effects, especially seizures

other neurotoxic drugs: Increased risk of neurotoxicity, such as optic and peripheral neuritis

Adverse Reactions

CNS: Burning or pain in arms and legs, clumsiness, confusion, depression, mental or mood changes, paresthesia, unsteadiness

CV: Orthostatic hypotension

EENT: Blurred vision, eye pain, increased salivation, metallic taste, optic neuritis, stomatitis, vision loss

ENDO: Goiter, hypoglycemia, hypothyroidism

GI: Anorexia, hepatitis, nausea, vomiting

SKIN: Jaundice, rash

Nursing Considerations

- Use ethionamide cautiously in patients with a history of hypersensitivity to isoniazid, niacin, pyrazinamide, or chemically related drugs; these patients also may be hypersensitive to ethionamide.
- Expect to give another antituberculous with ethionamide to decrease the risk of development of bacterial resistance.
- Also plan to give pyridoxine to prevent or minimize peripheral neuritis (burning, numbness, pain, or tingling in hands and feet), especially if patient has already had isoniazid-induced peripheral neuritis.
- Monitor liver function test results, and assess for signs of impaired function, such as hepatitis and jaundice.
- Question patient regularly about vision changes. Notify prescriber about blurred vision, eye pain, or loss of vision or acuity.
- Monitor compliance; treatment may need to continue for 1 to 2 years or indefinitely.

PATIENT TEACHING

- Advise patient to take ethionamide with food if adverse GI reactions occur.
- Instruct patient to take a missed dose as

soon as he remembers unless it's nearly time for the next dose. Caution him not to double the dose.

- Encourage patient to notify prescriber if no improvement occurs within 3 weeks; if bothersome or severe adverse reactions occur; if his vision changes; or if he has burning, numbness, pain, or tingling in his hands and feet.
- Inform patient that therapy may have to continue for months or years and that compliance is essential.

ethosuximide

Zarontin

Class and Category

Chemical class: Succinimide derivative

Therapeutic class: Anticonvulsant

Pregnancy category: Not rated

Indications and Dosages

↗ *To manage absence seizures in a patient who also has generalized tonic-clonic seizures*

CAPSULES, SYRUP

Adults and children age 6 and over. *Initial*: 500 mg daily. *Maintenance*: Increased by 250 mg every 4 to 7 days until control is achieved with minimal adverse reactions.

Children ages 3 to 6. *Initial*: 250 mg daily. *Maintenance*: Increased by 250 mg every 4 to 7 days until control is achieved with minimal adverse reactions.

Mechanism of Action

Elevates the seizure threshold and reduces the frequency of attacks by depressing the motor cortex and elevating the threshold of CNS response to convulsive stimuli.

Contraindications

Hypersensitivity to ethosuximide, succinimides, or their components

Interactions

DRUGS

carbamazepine, phenobarbital, phenytoin, primidone: Possibly decreased blood ethosuximide level

CNS depressants: Possibly increased CNS depression

haloperidol: Possibly decreased blood haloperidol level

loxapine, MAO inhibitors, maprotiline, molindone, phenothiazines, pimozide, tricyclic antidepressants: Possibly lowered seizure threshold and reduced therapeutic effect of ethosuximide
valproic acid: Increased or decreased blood ethosuximide level

ACTIVITIES

alcohol use: Possibly increased CNS depression

Adverse Reactions

CNS: Aggressiveness, ataxia, decreased concentration, dizziness, drowsiness, euphoria, fatigue, headache, hyperactivity, irritability, lethargy, nightmares, sleep disturbance, suicidal ideation

EENT: Gingival hypertrophy, myopia, tongue swelling

GI: Abdominal and epigastric pain, abdominal cramps, anorexia, diarrhea, hiccups, indigestion, nausea, vomiting

GU: Increased libido, microscopic hematuria, vaginal bleeding

HEME: Agranulocytosis, aplastic anemia, eosinophilia, leukopenia, pancytopenia

SKIN: Erythematous and pruritic rash, hirsutism, Stevens-Johnson syndrome, systemic lupus erythematosus, urticaria

Other: Hypersensitivity reaction, weight loss

Nursing Considerations

- Use ethosuximide with extreme caution in patients with hepatic or renal disease.
- Give other anticonvulsants concurrently, as prescribed, to control generalized tonic-clonic seizures.
- Monitor CBC and platelet count and assess for signs of infection, such as cough, fever, and pharyngitis. Also routinely evaluate liver and renal function test results.
- Take safety precautions because drug may cause adverse CNS reactions, such as dizziness and drowsiness.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

PATIENT TEACHING

- Stress the importance of complying with ethosuximide regimen.
- Advise patient to take a missed dose as soon as he remembers unless it's nearly time for the next dose. Warn him not to double the dose.

- Instruct patient not to engage in potentially hazardous activities until drug's CNS effects are known.
- Caution patient not to stop taking drug abruptly; doing so increases the risk of absence seizures.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report any concerns immediately to prescriber.
- Encourage female patient who becomes pregnant while taking ethosuximide to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that this registry is collecting information about the safety of antiepileptic drugs during pregnancy.

ethotoin

Peganeone

Class and Category

Chemical class: Hydantoin derivative

Therapeutic class: Anticonvulsant

Pregnancy category: D

Indications and Dosages

↗ *To treat tonic-clonic and simple or complex partial seizures as initial or adjunct therapy, or when other drugs are ineffective*

TABLETS

Adults and adolescents. *Initial*: 0.5 to 1 g on the first day in four to six divided doses, increased over several days until desired response is reached. *Maintenance*: 2 to 3 g daily in four to six divided doses.

Maximum: 3 g daily.

Children. *Initial*: Up to 750 mg daily, based on weight and age, in 4 to 6 divided doses, adjusted as needed and tolerated.

Maintenance: 0.5 to 1 g daily in 4 to 6 divided doses. *Maximum*: 3 g daily.

DOSAGE ADJUSTMENT For debilitated patients, initial dosage lowered to reduce the risk of adverse reactions.

Mechanism of Action

Limits the spread of seizure activity and the start of new seizures by:

- regulating voltage-dependent sodium and calcium channels in neurons

- inhibiting calcium movement across neuronal membranes
- enhancing sodium-potassium adenosine triphosphatase activity in neurons and glial cells.

These actions may result from ethotoin's ability to slow the recovery rate of inactivated sodium channels.

Contraindications

Hematologic disorders; hepatic dysfunction; hypersensitivity to ethotoin, phenytoin, other hydantoins, or their components

Interactions

DRUGS

acetaminophen: Increased risk of hepatotoxicity with long-term acetaminophen use

amiodarone: Possibly increased blood ethotoin level and risk of toxicity

antacids: Possibly decreased ethotoin effectiveness

bupropion, clozapine, loxapine, MAO inhibitors, maprotiline, phenothiazines, pimoziide, thioxanthenes: Possibly lowered seizure threshold and decreased therapeutic effects of ethotoin; possibly intensified CNS depressant effects of these drugs

chloramphenicol, cimetidine, disulfiram, flucanazole, isoniazid, methylphenidate, metronidazole, omeprazole, phenylbutazone, ranitidine, salicylates, sulfonamides, trimethoprim: Possibly impaired metabolism of these drugs and increased risk of ethotoin toxicity

corticosteroids, cyclosporine, digoxin, disopyramide, doxycycline, furosemide, levodopa, mexiletine, quinidine: Decreased therapeutic effects of these drugs

diazoxide: Possibly decreased therapeutic effects of both drugs

estrogens, progestins: Decreased effects of these drugs, increased blood ethotoin level

folic acid, leucovorin: Increased ethotoin metabolism, decreased seizure control

haloperidol: Possibly lowered seizure threshold, decreased ethotoin effects, and decreased blood haloperidol level

insulin, oral antidiabetic drugs: Possibly increased blood glucose level and decreased therapeutic effects of these drugs

lidocaine: Increased lidocaine metabolism, leading to reduced concentration

methadone: Possibly increased methadone metabolism and withdrawal symptoms

molindone: Possibly lowered seizure thresh-

old and impaired absorption and decreased therapeutic effects of ethotoin

oral anticoagulants: Possibly impaired metabolism of these drugs and increased risk of ethotoin toxicity; possibly increased anticoagulant effect initially, but decreased effect with prolonged therapy

oral contraceptives that contain estrogen and progestin: Possibly breakthrough bleeding and decreased contraceptive effectiveness

rifampin: Possibly decreased therapeutic effects of ethotoin

streptozocin: Possibly decreased therapeutic effects of streptozocin

sucralfate: Possibly decreased ethotoin absorption

tricyclic antidepressants: Possibly lowered seizure threshold and decreased therapeutic effects of ethotoin; possibly decreased blood level of tricyclic antidepressants

valproic acid: Possibly decreased ethotoin level, increased valproic acid level

vitamin D analogues: Decreased vitamin D analogue activity; risk of anticonvulsant-induced rickets and osteomalacia

xanthines: Possibly inhibited ethotoin absorption and increased clearance of xanthines

ACTIVITIES

alcohol use: Possibly decreased ethotoin effectiveness, increased CNS depression

Adverse Reactions

CNS: Clumsiness, confusion, drowsiness, excitement, peripheral neuropathy, sedation, slurred speech, stuttering, suicidal ideation, tremor

EENT: Nystagmus

GI: Constipation, diarrhea, nausea, vomiting

HEME: Agranulocytosis, leukopenia, thrombocytopenia

SKIN: Rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Lymphadenopathy, systemic lupus erythematosus

Nursing Considerations

- Obtain CBC and differential before treatment and monthly for first few months of ethotoin therapy, as ordered.

WARNING Ethotoin shouldn't be stopped abruptly because of risk of status epilepticus. Plan to reduce dosage gradually or substitute another drug, as prescribed.

- Monitor patient for signs and symptoms of infection or unusual bleeding because ethotoin may cause hematologic toxicity.
- Because of ethotoin's potential for hepatotoxicity, monitor liver function test results and expect drug to be discontinued if test results are abnormal.
- Notify prescriber immediately and expect ethotoin to be stopped and replaced with another drug if patient has decreased blood counts, enlarged lymph nodes, or rash.
- Be aware that ethotoin may be substituted for phenytoin without loss of seizure control if patient develops severe gingival hyperplasia or other adverse reactions. Expect ethotoin dosage to be 4 to 6 times greater than phenytoin dosage.
- Institute and maintain seizure precautions according to facility protocol.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

PATIENT TEACHING

- Instruct patient to take ethotoin exactly as prescribed and not to stop it abruptly.
- Advise patient to take drug with food to enhance absorption and reduce adverse GI effects.
- Advise patient to report easy bruising, epistaxis, fever, malaise, petechiae, or sore throat to prescriber immediately.
- Instruct patient to keep medical appointments to monitor drug effectiveness and check for adverse reactions. Explain the need for periodic laboratory tests.
- Urge patient to avoid alcohol during ethotoin therapy.
- Caution patient to avoid hazardous activities until drug's adverse effects are known.
- Encourage patient to wear or carry medical identification indicating his diagnosis and drug therapy.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report any concerns immediately to prescriber.
- Encourage female patient who becomes pregnant while taking ethotoin to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that this registry is collecting information about the safety of antiepileptic drugs during pregnancy.

etidronate disodium

Didronel

Class and Category

Chemical class: Bisphosphonate

Therapeutic class: Antihypercalcemic agent, bone resorption inhibitor

Pregnancy category: B (oral), C (parenteral)

Indications and Dosages

➤ *To treat Paget's disease of bone (osteitis deformans)*

TABLETS

Adults. 5 to 10 mg/kg daily for up to 6 mo, or 11 to 20 mg/kg daily for up to 3 mo.

➤ *To prevent and treat heterotopic ossification after total hip replacement*

TABLETS

Adults. 20 mg/kg daily for 1 mo before surgery and then 20 mg/kg daily for 3 mo after surgery for a total of 4 mo of treatment.

➤ *To prevent and treat heterotopic ossification after spinal cord injury*

TABLETS

Adults. 20 mg/kg daily for 2 wk and then 10 mg/kg daily for 10 wk for a total of 12 wk of treatment.

➤ *To treat moderate to severe hypercalcemia caused by cancer*

I.V. INFUSION

Adults. *Initial:* 7.5 mg/kg daily infused over at least 2 hr for 3 to 7 successive days. Oral etidronate may begin at 20 mg/kg/day for 30 days on the day after last infusion.

DOSAGE ADJUSTMENT Dosage reduced in renal impairment. Drug not given if serum creatinine level exceeds 5 mg/dl.

Mechanism of Action

Inhibits normal and abnormal bone resorption by reducing bone turnover and slowing the remodeling of pagetic or heterotopic bone. Etidronate also decreases the elevated cardiac output seen in Paget's disease of bone and reduces local increases in skin temperature. It also inhibits the abnormal bone resorption that may occur with cancer and reduces the amount of calcium that enters the blood from resorbed bone.

Contraindications

Esophageal abnormalities that delay gastric emptying, such as achalasia and stricture; hypersensitivity to etidronate, bisphospho-

nates, or their components; severe renal impairment

Interactions

DRUGS

antacids that contain aluminum, calcium, or magnesium; vitamin and mineral supplements that contain aluminum, calcium, iron, or magnesium: Decreased etidronate absorption

FOODS

high-calcium food (such as milk and other dairy products): Decreased etidronate absorption

Adverse Reactions

EENT: Altered taste, metallic taste

GI: Diarrhea, elevated liver function test results, nausea

GU: Nephrotoxicity

MS: Bone fractures, bone pain, osteonecrosis of jaw

Other: Hypocalcemia

Nursing Considerations

- Use etidronate cautiously in patients with upper GI problems such as Barrett's esophagus, dysphagia, other esophageal diseases, gastritis, duodenitis, or ulcers because drug may cause local irritation of the upper GI mucosa.
- Anticipate starting etidronate as soon as possible after spinal cord injury, preferably before signs of heterotopic ossification.
- Expect etidronate not to inhibit healing of spinal fractures, affect prosthesis, or disrupt trochanter attachment when used after total hip replacement.
- Give oral form 2 hours before meals to prevent decreased absorption.
- Dilute parenteral form in at least 250 ml of normal saline solution.
- Give parenteral form slowly over at least 2 hours.
- Store diluted parenteral solution at room temperature for up to 48 hours.

WARNING Watch for hypocalcemia if patient receives parenteral form for more than 3 days.

- When treating hypercalcemia, expect to continue giving drug for up to 90 days if serum calcium level remains within acceptable range.
- Monitor patient for adverse esophageal effects such as esophagitis, esophageal ulcers, and esophageal erosions that may

occur with bleeding, as well as gastric and duodenal ulcers, because these adverse effects have occurred with other oral biphosphonates.

- Risk of severe adverse esophageal reactions increases in patients who lie down after taking drug, who fail to swallow it with a full glass of water, or who continue to take drug after developing symptoms of esophageal irritation.
- Make sure patient has had a dental check-up before having an invasive dental procedure during etidronate therapy, especially if he has cancer; is receiving chemotherapy, head or neck radiation, or a corticosteroid; or has poor oral hygiene because the risk of osteonecrosis is increased in these patients.

PATIENT TEACHING

- Instruct patient to take etidronate tablets on an empty stomach—2 hours before meals, antacids, or calcium supplements. Urge him to drink a full glass of water with tablets and to avoid taking drug with milk or other high-calcium foods.
- Tell patient to take a missed dose as soon as he remembers as long as 2 hours have elapsed since his last meal. Instruct him not to eat for another 2 hours. Warn against doubling the dose.
- Inform patient with Paget's disease that his response to etidronate may be slow and may continue for months after treatment.

etodolac

Lodine, Lodine XL

Class and Category

Chemical class: Pyranoindoleacetic acid derivative

Therapeutic class: Analgesic, anti-inflammatory

Pregnancy category: C

Indications and Dosages

↗ *To manage osteoarthritis*

CAPSULES, TABLETS

Adults. *Initial:* 800 to 1,200 mg daily in divided doses. *Maintenance:* 600 to 1,200 mg daily in divided doses. *Maximum:* 1,200 mg daily for patients weighing 60 kg (132 lb) or more; 20 mg/kg daily for those less than 60 kg.

E.R. TABLETS

Adults. 400 to 1,000 mg daily.

↗ *To relieve mild to moderate pain*

CAPSULES, TABLETS

Adults. *Initial:* 400 mg and then 200 to 400 mg every 6 to 8 hr. *Maximum:* 1,200 mg daily for patients weighing 60 kg or more; 20 mg/kg/day for patients weighing less than 60 kg.

Route	Onset	Peak	Duration
P.O.	30 min	1–2 hr	4–12 hr

Mechanism of Action

Blocks the activity of cyclooxygenase, the enzyme needed for prostaglandin synthesis. Prostaglandins, important mediators of the inflammatory response, cause local vasodilation with swelling and pain. By inhibiting cyclooxygenase and prostaglandins, this NSAID causes inflammatory symptoms and pain to subside.

Contraindications

Angioedema, asthma, bronchospasm, nasal polyps, rhinitis, or urticaria induced by aspirin, iodides, or NSAIDs; coronary artery bypass graft surgery; hypersensitivity to etodolac or its components

Interactions**DRUGS**

ACE inhibitors: Possibly decreased hypotensive effects of these drugs

acetaminophen (long-term use): Increased risk of adverse renal effects

antacids: Decreased blood etodolac level

antiplatelets, oral anticoagulants, thrombolytics: Prolonged PT (with warfarin), increased risk of bleeding

cidofovir: Possibly nephrotoxicity

corticosteroids: Increased risk of adverse GI effects

cyclosporine: Increased nephrotoxic effects, increased blood cyclosporine level

digoxin: Increased blood digoxin level and risk of digitalis toxicity

insulin, oral antidiabetic drugs: Increased risk of hypoglycemia

lithium: Increased blood lithium level and, possibly, toxicity

loop diuretics: Possibly decreased effects of loop diuretics

methotrexate: Increased risk of methotrexate toxicity

phenylbutazone: Possibly altered etodolac clearance

salicylates: Decreased blood etodolac level, increased risk of adverse GI effects

warfarin: Synergistic bleeding effects

ACTIVITIES

alcohol use, smoking: Increased risk of adverse GI effects

Adverse Reactions

CNS: Asthenia, chills, depression, dizziness, drowsiness, fatigue, fever, insomnia, irritability, malaise, nervousness, seizures, somnolence, syncope, stroke

CV: Edema, heart failure, hypertension, MI, palpitations, tachycardia, vasculitis

EENT: Blurred vision, deafness, loss of taste, photophobia, tinnitus

ENDO: Hyperglycemia in diabetics

GI: Abdominal pain or distention, anorexia, constipation, diarrhea, diverticulitis, dyspepsia, dysphagia, elevated liver function test results, esophagitis, flatulence, gastritis, gastroenteritis, gastroesophageal reflux disease, GI bleeding and ulceration, GI perforation, hemorrhoids, hepatic failure, hepatitis, hiatal hernia, indigestion, melena, nausea, pancreatitis, peptic ulcer, perforation of stomach or intestines, stomatitis, vomiting

GU: Dysuria, elevated serum creatinine level, hematuria, renal failure or insufficiency, renal papillary necrosis, urinary frequency

HEME: Agranulocytosis, aplastic anemia, easy bruising, hemolytic anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia

MS: Arthralgia, muscle pain

RESP: Asthma, bronchospasm, pulmonary infiltrate with eosinophilia, respiratory depression

SKIN: Erythema multiforme, exfoliative dermatitis, flushing, leukocytoclastic vasculitis, pruritus, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria, vesiculobullous or other rash

Other: Anaphylaxis, angioedema, lymphadenopathy, sepsis

Other: Anaphylaxis, angioedema, lymphadenopathy, sepsis

MS: Arthralgia, muscle pain

RESP: Asthma, bronchospasm, pulmonary infiltrate with eosinophilia, respiratory depression

SKIN: Erythema multiforme, exfoliative dermatitis, flushing, leukocytoclastic vasculitis, pruritus, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria, vesiculobullous or other rash

Other: Anaphylaxis, angioedema, lymphadenopathy, sepsis

Other: Anaphylaxis, angioedema, lymphadenopathy, sepsis

Other: Anaphylaxis, angioedema, lymphadenopathy, sepsis

Other: Anaphylaxis, angioedema, lymphadenopathy, sepsis

Nursing Considerations

- Assess patient's hydration status and rehydrate, if needed and as ordered, before starting etodolac therapy.
- Use etodolac with extreme caution in patients with a history of ulcer disease or GI bleeding because NSAIDs increase the

risk of GI bleeding and ulceration. Expect to use etodolac for the shortest time possible in these patients. Also use with extreme caution in patients with advanced renal disease because etodolac is eliminated mainly by the kidneys.

- Be aware that serious GI tract ulceration, bleeding, and perforation may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, withhold drug and notify prescriber immediately.
- Use etodolac cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

WARNING Monitor patient closely for thrombotic events, including stroke and MI, because NSAIDs increase the risk.

- Especially if patient is elderly or taking etodolac long-term, watch for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver function test results. Rarely, elevated levels may progress to severe hepatic reactions, including fatal hepatitis, hepatic necrosis, and hepatic failure.
- Monitor BUN and serum creatinine levels in patients with heart failure, hepatic dysfunction, or impaired renal function; those taking diuretics or ACE inhibitors; and elderly patients because drug may cause renal failure.
- Monitor CBC for decreased hemoglobin level and hematocrit because drug may worsen anemia.

WARNING If patient has bone marrow suppression or is receiving antineoplastic drug therapy, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of etodolac may mask it, such as fever and pain.

- Assess patient's skin routinely for rash or other signs of hypersensitivity reaction because etodolac and other NSAIDs may cause serious skin reactions without warning, even in patients with no history of NSAID hypersensitivity. Stop drug at first sign of reaction and notify prescriber.

- If patient also takes acetaminophen, monitor fluid intake and output and BUN and serum creatinine levels for signs of adverse renal reactions.

PATIENT TEACHING

- Tell patient to take etodolac with food or after meals if adverse GI reactions occur.
- Caution him to avoid aspirin or aspirin-containing products while taking drug.
- Advise patient not to smoke or drink alcohol during therapy because these activities increase the risk of adverse GI reactions.
- Inform patient that he may experience dizziness or drowsiness.
- Instruct him to notify prescriber immediately about blood in urine, easy bruising, itching, rash, swelling, or yellow eyes or skin.
- Caution pregnant patient not to take etodolac or other NSAIDs during the third trimester because drug may cause premature closure of the ductus arteriosus.
- Explain that etodolac may increase the risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention for possible reactions, chest pain, shortness of breath, weakness, and slurring of speech.
- Tell patient that etodolac therapy also may increase the risk of serious adverse GI reactions; stress the importance of seeking immediate medical attention for such signs and symptoms as epigastric or abdominal pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.
- Explain the possibility of rare but serious skin reactions. Urge patient to seek immediate medical attention for rash, blisters, itching, fever, or other indications of hypersensitivity.

exenatide

Byetta

Class and Category

Chemical class: Amino acid peptide amide

Therapeutic class: Antidiabetic drug

Pregnancy category: C

Indications and Dosages

↗ *Adjunct treatment to improve blood glu-*

lose levels in patients with type 2 diabetes mellitus who are taking metformin, a sulfonylurea, a thiazolidinedione, or a combination of metformin and a sulfonylurea or metformin and a thiazolidinedione but have not achieved adequate glucose control

SUBCUTANEOUS INJECTION

Adults. *Initial:* 5 mcg b.i.d., given within 60 min before morning and evening meals. After 1 mo, increased as needed to 10 mcg b.i.d., given within 60 min before morning and evening meals.

↗ *Adjunct treatment to diet and exercise to improve blood glucose levels in patients with type 2 diabetes mellitus*

SUBCUTANEOUS INJECTION

Adults. *Initial:* 5 mcg b.i.d., given within 60 min before morning and evening meals. After 1 mo, increased as needed to 10 mcg b.i.d., given within 60 min before morning and evening meals.

Route	Onset	Peak	Duration
SubQ	Immediate	2.1 hr	Unknown

Contraindications

Hypersensitivity to exenatide or its components, ketoacidosis, type 1 diabetes mellitus

Interactions

DRUGS

oral antidiabetics: Increased risk of hypoglycemia
oral drugs: May decrease rate and extent of absorption of these drugs
warfarin: Possibly increased INR with increased risk of bleeding

Adverse Reactions

CNS: Asthenia, dizziness, headache, jitteriness, somnolence
CV: Chest pain
EENT: Decreased taste
ENDO: Hypoglycemia
GI: Abdominal distention or pain, anorexia, constipation, diarrhea, dyspepsia, flatulence, gastroesophageal reflux, indigestion, nausea, pancreatitis (including life-threatening hemorrhagic or necrotizing), vomiting
GU: Decreased renal function
RESP: Chronic hypersensitivity pneumonitis
SKIN: Diaphoresis, pruritus, rash, urticaria
Other: Anaphylaxis, angioedema, anti-exenatide antibodies, dehydration, elevated anti-exenatide antibody level, injection site reactions, weight loss

Nursing Considerations

- Exenatide isn't recommended for patients

Mechanism of Action

Normally, when serum glucose level rises, insulin is secreted within 10 minutes. This first-phase insulin response is absent in patients with type 2 diabetes. Exenatide, an incretin mimetic, restores the first-phase insulin response and improves the second-phase response that immediately follows. It does so by promoting incretins that spur insulin synthesis and release from beta cells by binding and activating human GLP-1 receptors to reduce fasting and postprandial serum glucose levels.

The drug also suppresses inappropriately elevated glucagon secretion. Lower serum glucagon level leads to decreased hepatic glucose output and decreased insulin demand. It also slows gastric emptying and thus the rise of serum glucose level.

- with severe GI disease, patients with creatinine clearance less than 30 ml/ min/ 1.73 m², or patients having dialysis because of adverse GI or renal effects.
- Use exenatide cautiously in a renal transplant patient or patient with moderate renal disease when dosage is increased from 5 mcg to 10 mcg. Monitor renal function throughout therapy, and notify prescriber of abnormalities.
- If patient also takes a sulfonylurea, the sulfonylurea dosage may need to be decreased to reduce the risk of hypoglycemia. Usually, no dosage adjustment is needed for a patient taking metformin.
- Administer drug into patient's thigh, abdomen, or upper arm.
- Monitor patient's blood glucose level. If control decreases despite the patient's best efforts, drug may need to be discontinued because of the possibility that anti-exenatide antibodies have formed.
- Monitor patient for evidence of acute pancreatitis, such as persistent, severe abdominal pain accompanied by vomiting, especially when drug is started or dosage increased. Notify prescriber, and expect to stop exenatide and give supportive care.

PATIENT TEACHING

- Teach patient how to give a subcutaneous injection and how to use pen injector.
- Inform patient that exenatide may be administered in the thigh, abdomen, or upper arm. Stress the need to rotate injection sites.
- Stress the need to use drug within 60 minutes before morning and evening meals or the two main meals of the day, about 6 hours or more apart, never after a meal.
- If patient misses a dose, tell him to resume treatment with the next scheduled dose.
- Advise patient that drug should look clear and colorless. Caution against using pre-filled pen device in which solution looks cloudy or colored or contains particles.
- Instruct patient to check expiration date on the vial and not to use drug if date has passed.
- Advise patient to refrigerate drug before first use and protect it from light. After first use, drug may be stored at room temperature of 77° F (25° C) or less.
- Tell patient to discard pen injector 30 days after initial use, even if some drug is left.

- Alert patient that pen doesn't come with needles and that he'll need to buy them.
- Warn patient that nausea may occur at the beginning of therapy.
- Inform patient taking a sulfonylurea to be alert for hypoglycemic reactions because risk increases with both drugs. Review ways to treat such reactions, and tell patient to alert prescriber if they occur often or are severe.
- Instruct female patient of childbearing potential to tell her prescriber if she is, could be, or is planning to become pregnant.
- Tell patient to seek emergency care for persistent, severe abdominal pain and vomiting.
- Caution patient that exenatide doesn't replace diet and exercise measures.

ezetimibe

Zetia

Class and Category

Chemical class: Azetidinone

Therapeutic class: Antihypercholesterolemic

Pregnancy category: C

Indications and Dosages

↗ *To treat heterozygous familial and non-familial hypercholesterolemia or homozygous sitosterolemia; as adjunct with HMG-CoA reductase inhibitors to treat heterozygous familial and nonfamilial hypercholesterolemia; with fenofibrate to treat mixed hyperlipidemia and with atorvastatin or simvastatin to treat patients with homozygous familial hypercholesterolemia*

TABLETS

Adults. 10 mg daily.

Contraindications

Active hepatic dysfunction, hypersensitivity to ezetimibe or its components

Interactions

DRUGS

cholestyramine: Reduced effects of ezetimibe

cyclosporine: Increased blood cyclosporine and ezetimibe levels

fenofibrate, gemfibrozil: Increased blood ezetimibe level

Mechanism of Action

Reduces blood cholesterol by inhibiting its absorption through the small intestine. Normally, in the intestinal lumen, lipids break down to cholesterol and other substances that create smaller droplets called micelles, as shown below left. The micelles enter intestinal epithelial cells called enterocytes, where they combine with triglycerides, cholesterol, and other substances to form chylomi-

cons. Chylomicrons then pass through to the lymphatic system to be carried to the blood.

Ezetimibe blocks cholesterol absorption into enterocytes and keeps cholesterol from moving through the intestinal wall, as shown below right. Reduced cholesterol absorption from the intestine decreases chylomicron and LDL cholesterol content.

Adverse Reactions

CNS: Depression, dizziness, fatigue, headache, paresthesia

CV: Chest pain

EENT: Pharyngitis, sinusitis

GI: Abdominal pain, cholelithiasis, cholecystitis, diarrhea, elevated liver function test results, hepatitis, nausea, pancreatitis

HEME: Thrombocytopenia

MS: Arthralgia, back or limb pain, elevated CK level, myalgia, myopathy, rhabdomyolysis

RESP: Cough, upper respiratory tract infection

SKIN: Erythema multiforme, rash, urticaria

Other: Anaphylaxis, angioedema, influenza, viral infection

Nursing Considerations

- Monitor liver function test results before and during ezetimibe therapy, as ordered.
- Know that you should give ezetimibe 2 hours before or 4 hours after giving bile acid sequestrant, cholestyramine, or colestipol.

PATIENT TEACHING

- Direct patient to follow a low-cholesterol

diet as an adjunct to ezetimibe therapy. Recommend weight loss and exercise programs, as appropriate.

- If patient also takes a bile acid sequestrant, tell him to take ezetimibe either 2 hours before or at least 4 hours after it to prevent drug interactions.
- Advise patient to report unexplained muscle pain, tenderness, or weakness.

famotidine

Act (CAN), Apo-Famotidine (CAN), Dyspep HB (CAN), Gen-Famotidine (CAN), Mylanta-AR, Novo-Famotidine (CAN), Nu-Famotidine (CAN), Pepcid, Pepcid AC, Pepcid RPD

Class and Category

Chemical class: Thiazole derivative

Therapeutic class: Antilucer agent, gastric acid secretion inhibitor

Pregnancy category: B

Indications and Dosages

➤ To provide short-term treatment of

*active duodenal ulcer***ORAL SUSPENSION, TABLETS (CHEWABLE, ORAL DISINTEGRATING, AND REGULAR)**

Adults and adolescents. 40 mg daily at bedtime or 20 mg b.i.d.

Children. 0.5 mg/kg daily as a single dose at bedtime or in divided doses b.i.d.

I.V. INFUSION OR INJECTION

Adults and adolescents over age 16. 20 mg every 12 hr, infused over 15 to 30 min or injected over at least 2 min.

Children ages 1 to 16. *Initial:* 0.25 mg/kg every 12 hr, infused over 15 to 30 min or injected over at least 2 min. *Maximum:* 40 mg daily.

↗ *To prevent recurrence of duodenal ulcer*

ORAL SUSPENSION, TABLETS (CHEWABLE, ORAL DISINTEGRATING, AND REGULAR)

Adults and adolescents. 20 mg daily at bedtime.

↗ *To provide short-term treatment for active, benign gastric ulcer*

ORAL SUSPENSION, TABLETS (CHEWABLE, ORAL DISINTEGRATING, AND REGULAR)

Adults and adolescents. 40 mg daily at bedtime.

Children. 0.5 mg/kg daily as a single dose at bedtime or in divided doses b.i.d.

I.V. INFUSION OR INJECTION

Adults and adolescents over age 16. 20 mg every 12 hr.

Children ages 1 to 16. *Initial:* 0.25 mg/kg every 12 hr. *Maximum:* 40 mg daily.

↗ *To treat gastroesophageal reflux disease (GERD)*

ORAL SUSPENSION, TABLETS (CHEWABLE, ORAL DISINTEGRATING, AND REGULAR)

Adults and adolescents. 20 mg b.i.d. for up to 6 wk.

Children weighing more than 10 kg (22 lb). 1 to 2 mg/kg daily in divided doses b.i.d.

Children weighing less than 10 kg. 1 to 2 mg/kg daily in divided doses t.i.d.

ORAL SUSPENSION

Infants age 4 months to 1 year. 0.5 mg/kg daily in divided doses b.i.d. for up to 8 wk.

Infants age 3 months or less. 0.5 mg/kg daily for up to 8 wk.

I.V. INFUSION OR INJECTION

Children ages 1 to 16. *Initial:* 0.25 mg/kg every 12 hr. *Maximum:* 40 mg daily.

↗ *To treat esophagitis caused by gastroesophageal reflux*

ORAL SUSPENSION, TABLETS (CHEWABLE, ORAL**DISINTEGRATING, AND REGULAR)**

Adults and adolescents. 20 to 40 mg b.i.d. for up to 12 wk.

↗ *To treat gastric hypersecretory conditions, such as Zollinger-Ellison syndrome*

ORAL SUSPENSION, TABLETS (CHEWABLE, ORAL DISINTEGRATING, AND REGULAR)

Adults and adolescents. *Initial:* 20 mg every 6 hr. Dosage adjusted, if needed, based on patient response.

I.V. INFUSION OR INJECTION

Adults and adolescents. 20 mg every 12 hr.

↗ *To prevent heartburn and indigestion*

TABLETS (CHEWABLE, ORAL DISINTEGRATING, AND REGULAR)

Adults and adolescents. 10 mg 1 hr before eating. *Maximum:* 20 mg every 24 hr.

↗ *To treat heartburn and indigestion*

TABLETS (CHEWABLE, ORAL DISINTEGRATING, AND REGULAR)

Adults and adolescents. 10 mg at onset of symptoms. *Maximum:* 20 mg every 24 hr for up to 2 wk unless prescribed otherwise.

DOSAGE ADJUSTMENT Oral or parenteral dosage reduced or dosing interval increased (to 36 to 48 hr), if needed, in patients with renal insufficiency and creatinine clearance of 49 ml/min/1.73 m² or less.

Route	Onset	Peak	Duration
P.O.	1 hr	1–4 hr	10–12 hr
I.V.	In 30 min	0.5–3 hr	10–12 hr

Contraindications

Hypersensitivity to famotidine, other H₂-receptor antagonists, or their components

Interactions**DRUGS**

antacids, sucralfate: Possibly decreased absorption of famotidine

bone marrow depressants: Increased risk of blood dyscrasias

itraconazole, ketoconazole: Possibly decreased absorption of these drugs

ACTIVITIES

alcohol use: Possibly increased blood alcohol level

Adverse Reactions

CNS: Agitation (infants), anxiety, asthenia, confusion, depression, dizziness, fatigue, fever, hallucinations, headache, insomnia,

Mechanism of Action

In normal digestion, parietal cells in the gastric epithelium secrete hydrogen (H^+) ions, which combine with chloride ions (Cl^-) to form hydrochloric acid (HCl), as shown below left. However, HCl can inflame, ulcerate, and perforate gastric and intestinal mucosa normally protected

by mucus. Famotidine, an H_2 -receptor antagonist, reduces HCl formation by preventing histamine from binding with H_2 receptors on the surface of parietal cells, as shown below right. By doing so, drug helps prevent peptic ulcers from forming and helps heal existing ones.

mental or mood changes, paresthesia, seizures, somnolence

CV: Arrhythmias, AV block, palpitations

EENT: Dry mouth, laryngeal edema, taste alteration, tinnitus

GI: Abdominal pain, anorexia, cholestatic jaundice, constipation, diarrhea, elevated liver enzymes, hepatitis, nausea, vomiting

GU: Decreased libido

HEME: Agranulocytosis, aplastic anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia

MS: Arthralgia, muscle cramps

RESP: Bronchospasm, dyspnea, interstitial pneumonia, wheezing

SKIN: Acne, alopecia, dry skin, erythema multiforme, exfoliative dermatitis, flushing, jaundice, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, facial edema, hyperuricemia

Nursing Considerations

- Shake famotidine oral suspension vigorously for 5 to 10 seconds before administration.
- Dilute injection form (2 ml) with normal saline solution or other solution to 5 to 10 ml; give I.V. injection over at least 2 minutes. Or dilute in 100 ml of D₅W and infuse over 15 to 30 minutes. Or

infuse premixed injection (20 mg/50 ml normal saline solution) over 15 to 30 minutes.

WARNING Be aware that Pepcid AC chewable tablets contain aspartame, which can be dangerous for patients who have phenylketonuria.

PATIENT TEACHING

- Instruct patient to store famotidine oral suspension at room temperature (below 86° F [30° C]) and to protect it from freezing. Tell her to shake the bottle vigorously for 5 to 10 seconds after adding water and right before use.
- Advise patient who uses Pepcid RPD to store drug in unopened package. For each dose, instruct her to open blister pack with dry hands, place a tablet on her tongue, let it dissolve, and swallow it with saliva.
- If patient uses chewable tablets, instruct her to chew them thoroughly before swallowing.
- If patient also takes antacids, instruct her to wait 30 to 60 minutes after taking famotidine, if possible, before taking antacid.
- Caution patient to avoid alcohol and smoking during famotidine therapy because they irritate the stomach and can delay ulcer healing.
- Advise patient to notify prescriber if she

develops pain or has trouble swallowing or if she has bloody vomit or black stools.

- Caution patient not to take famotidine with other acid-reducing products.

febuxostat

Uloric

Class and Category

Chemical class: Non-purine xanthine oxidase inhibitor

Therapeutic class: Antigout

Pregnancy category: C

Indications and Dosages

➤ *To treat chronic hyperuricemia in patients with gout*

TABLETS

Adults. *Initial:* 40 mg once daily, increased after 2 wk to 80 mg once daily, if needed.

Route	Onset	Peak	Duration
P.O.	2–3 days	1–1.5 hr	Unknown

Mechanism of Action

Inhibits the action of xanthine oxidase, the key enzyme responsible for purine breakdown. Xanthine oxidase catalyzes conversion of xanthine to uric acid, thereby increasing uric acid levels. High uric acid levels cause gout attacks. Inhibiting xanthine oxidase causes uric acid levels to drop, decreasing the risk of gout attack.

Contraindications

Concurrent use of azathioprine, mercaptopurine, or theophylline; hypersensitivity to febuxostat or its components

Interactions

DRUGS

azathioprine, mercaptopurine, theophylline: Possibly increased serum levels of these drugs, leading to toxicity

Adverse Reactions

CNS: Dizziness, hemiparesis, lacunar infarction, stroke, transient ischemic attack

CV: Angina, chest pain or discomfort, ECG abnormalities, MI

EENT: Blurred vision, deafness, epistaxis, nasal dryness, paranasal sinus hypersecretion, pharyngeal edema, sneezing, taste disturbance, throat irritation, tinnitus

ENDO: Breast pain, gynecomastia, hot flashes, hypoglycemia

GI: Diarrhea, dyspepsia, GI discomfort, hepatomegaly, liver function abnormalities, nausea, vomiting

GU: Decreased libido, erectile dysfunction, hematuria, nephrolithiasis, pollakiuria, proteinuria, renal failure or insufficiency, urgency

HEME: Anemia, idiopathic thrombocytopenic purpura, leukocytosis, leukopenia, neutropenia, pancytopenia, splenomegaly, thrombocytopenia

MS: Arthralgia, joint stiffness or swelling

RESP: Upper respiratory tract infection

SKIN: Dermatitis, ecchymosis, eczema, flushing, hair color or growth changes, hyperhidrosis, peeling skin, petechiae, photosensitivity, rash

Other: Gout flares, hypersensitivity

Nursing Considerations

- Febuxostat therapy isn't recommended for patients in whom rate of urate formation is greatly increased, as in malignancy and its treatment or Lesch-Nyhan syndrome.
 - Monitor patient's serum uric acid level, as prescribed, to determine drug effectiveness. Expect it to take about 2 weeks for uric acid level to be therapeutically altered. Dose may be increased from 40 mg to 80 mg daily if target serum uric acid level fails to fall below 6 mg/dl.
 - Monitor patient for gout flares, which may occur after therapy is started because of changing serum uric acid levels that result in mobilization of urate from tissue deposits. Expect prescriber to order an NSAID or colchicine when febuxostat therapy starts. If patient has a gout flare-up during treatment, notify prescriber, and expect symptoms to be managed. Know that febuxostat therapy usually isn't discontinued during this time.
 - Monitor patient for evidence of cardiovascular thrombosis, such as acute MI or stroke, because drug may increase patient's risk of developing these disorders.
 - Monitor patient's liver enzyme levels, as ordered, especially 2 and 4 months after therapy starts and periodically thereafter.
- PATIENT TEACHING**
- Inform patient that a gout attack may occur when febuxostat therapy starts and

that NSAIDs or colchicine may be prescribed, usually along with febuxostat, to prevent it.

- Instruct patient to seek emergency care immediately for signs or symptoms of a heart attack or stroke.
- Tell patient that periodic blood tests will be needed to determine drug's effectiveness and to detect adverse effects.

felbamate

Felbatol

Class and Category

Chemical class: Dicarbamate

Therapeutic class: Anticonvulsant

Pregnancy category: C

Indications and Dosages

↗ *To treat partial seizures in patients who don't respond to other drugs*

ORAL SUSPENSION, TABLETS

Adults and adolescents over age 14. *Initial:* 1,200 mg daily in divided doses t.i.d. or q.i.d. Dosage increased over several weeks based on patient response. *Maximum:* 3,600 mg daily.

Children ages 2 to 14. *Initial:* 15 mg/kg daily in divided doses t.i.d. or q.i.d. Dosage increased over several weeks based on patient response. *Maximum:* 3,600 mg daily or 45 mg/kg daily.

↗ *As adjunct to treat generalized or partial seizures associated with Lennox-Gastaut syndrome in children*

ORAL SUSPENSION, TABLETS

Children ages 2 to 14. *Initial:* 15 mg/kg daily in divided doses t.i.d. or q.i.d. while decreasing other anticonvulsant drugs by 20% to control their blood levels. Felbamate dosage increased by 15 mg/kg daily every wk. *Maximum:* 3,600 mg daily or 45 mg/kg daily.

DOSE ADJUSTMENT Dosage reduced by 50% in patients with renal impairment.

Mechanism of Action

May exert anticonvulsant effects by antagonizing the amino acid glycine. When glycine binds to N-methyl-D-aspartate (NMDA) receptors in the CNS, the frequency at which receptor-gated calcium ion channels open is increased—an important

factor in initiating seizures. Felbamate may raise the seizure threshold by blocking NMDA receptors so glycine can't bind to them.

Contraindications

Hepatic dysfunction; history of blood dyscrasias; hypersensitivity to felbamate, other carbamates, or their components

Interactions

DRUGS

carbamazepine: Decreased blood carbamazepine level and increased felbamate clearance, resulting in decreased blood felbamate level

fosphenytoin, phenytoin: Increased blood phenytoin level and increased felbamate clearance, resulting in decreased blood felbamate level

methsuximide: Increased adverse effects of methsuximide

oral contraceptives: Possibly decreased effectiveness of oral contraceptives

phenobarbital: Decreased blood felbamate level, increased blood phenobarbital level and risk of adverse effects

valproic acid: Increased blood valproic acid level and increased risk of adverse effects

Adverse Reactions

CNS: Abnormal gait, aggressiveness, agitation, anxiety, dizziness, drowsiness, fever, headache, insomnia, mood changes, suicidal ideation, tremor

EENT: Altered taste, diplopia, rhinitis

GI: Abdominal pain, anorexia, constipation, diarrhea, elevated liver function test results, hepatic failure, indigestion, nausea, vomiting

HEME: Aplastic anemia, leukopenia, pancytopenia, thrombocytopenia

RESP: Upper respiratory tract infection

SKIN: Photosensitivity, purpura, rash

Other: Anaphylaxis, lymphadenopathy, weight loss

Nursing Considerations

- Check liver function test results before starting felbamate, and expect to check results every 1 to 2 weeks during treatment. Notify prescriber immediately and expect to stop drug if results are abnormal.
- Plan to taper dosage by one-third every 4 to 5 days as prescribed. If patient receives adequate amounts of other anticonvulsant drugs, felbamate may be

stopped without tapering, if needed.

WARNING Assess for signs of aplastic anemia and bone marrow depression. Signs may not appear until several months after therapy begins. Expect to stop felbamate if bone marrow depression develops.

- If patient receives adjunctive therapy, expect adverse reactions to resolve as other anticonvulsant dosages decrease.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

PATIENT TEACHING

- Direct patient to shake suspension before using and to use a calibrated spoon or container to measure each dose.
- Instruct patient to store oral suspension and tablets at room temperature.
- Because drug may cause photosensitivity, urge patient to protect skin from sun and to avoid sunlamps and tanning booths.
- Explain that dizziness and drowsiness may occur. Advise her to avoid hazardous activities until drug's CNS effects are known.
- Warn patient not to stop drug abruptly.
- Advise patient to return for ordered liver function tests and to report yellow skin or eyes and dark urine to prescriber.
- Instruct patient to tell prescriber if she experiences bleeding, infection, or fatigue.
- Advise patient to carry medical identification that indicates condition and therapy.
- Because felbamate decreases oral contraceptive effectiveness, discuss alternate contraceptive methods.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report any concerns immediately.
- Encourage female patient who becomes pregnant while taking felbamate to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that this registry is collecting information about the safety of antiepileptic drugs during pregnancy.

felodipine

Plendil, Renedil (CAN)

Class and Category

Chemical class: Dihydropyridine derivative

Therapeutic class: Antihypertensive
Pregnancy category: C

Indications and Dosages

↗ *To manage essential hypertension alone or with other antihypertensives*

E.R. TABLETS

Adults. *Initial:* 5 mg daily. Dosage adjusted every 2 wk to 2.5 to 10 mg daily based on patient response.

DOSAGE ADJUSTMENT Initial or maintenance dosage reduced, if needed, in patients who are over age 65 or have impaired hepatic function.

Route	Onset	Peak	Duration
P.O.	2–5 hr	Unknown	16–24 hr

Mechanism of Action

May slow the movement of extracellular calcium into myocardial and vascular smooth-muscle cells by deforming calcium channels in cell membranes, inhibiting ion-controlled gating mechanisms, and interfering with calcium release from the sarcoplasmic reticulum. The effect of these actions is a decrease in intracellular calcium ions, which inhibits contraction of smooth-muscle cells and dilates coronary and systemic arteries. As with other calcium channel blockers, felodipine's actions result in increased oxygen to the myocardium and reduced peripheral resistance, blood pressure, and afterload.

Contraindications

Hypersensitivity to felodipine or its components

Interactions

DRUGS

anesthetics (hydrocarbon inhalation):

Possibly hypotension

antihypertensives, prazosin: Increased risk of hypotension

beta blockers: Increased adverse effects of beta blockers

cimetidine: Increased felodipine bioavailability

digoxin: Transiently increased blood digoxin level and risk of digitalis toxicity

estrogens: Possibly increased fluid retention and decreased felodipine effects

lithium: Increased risk of neurotoxicity

NSAIDs, sympathomimetics: Possibly

decreased therapeutic effect of felodipine
procainamide, quinidine: Increased risk of prolonged Q-T interval
tacrolimus: Possibly increased blood tacrolimus level and risk of adverse effects

FOODS

grapefruit juice: Doubled felodipine bioavailability

Adverse Reactions

CNS: Asthenia, dizziness, drowsiness, fatigue, headache, paresthesia, syncope, weakness

CV: Chest pain, hypotension, palpitations, peripheral edema, tachycardia

EENT: Gingival hyperplasia, pharyngitis, rhinitis

GI: Abdominal cramps, constipation, diarrhea, indigestion, nausea

HEME: Agranulocytosis

MS: Back pain

RESP: Cough

SKIN: Flushing, rash

Nursing Considerations

- Use felodipine cautiously in patients with heart failure or reduced ventricular function.
 - Monitor blood pressure during dosage titration and throughout felodipine therapy, especially in elderly patients.
 - Felodipine bioavailability increases up to twofold when taken with grapefruit juice.
- WARNING** Felodipine may cause severe hypotension with syncope, which may lead to reflex tachycardia. This can precipitate angina in patients with coronary artery disease or a history of angina.
- Watch for signs of overdose, such as excessive peripheral vasodilation, marked hypotension and, possibly, bradycardia. If they appear, place patient in supine position with legs elevated and give I.V. fluids, as ordered. Expect to give I.V. atropine for bradycardia.

PATIENT TEACHING

- Instruct patient to swallow tablets whole and not to crush or chew them.
- Caution patient not to alter her intake of grapefruit juice during therapy.
- Advise patient to store felodipine at room temperature and to protect it from light.
- Instruct patient to monitor her pulse rate and blood pressure.
- Teach patient how to minimize gingival

hyperplasia.

- Advise patient to notify prescriber immediately if she has palpitations, pronounced dizziness, or swelling of hands or feet.

fenofibrate

Lipofen, Tricor

fenofibric acid

Trilipix

Class and Category

Chemical class: Aryloxisobutyric acid derivative

Therapeutic class: Antihyperlipidemic

Pregnancy category: C

Indications and Dosages

↗ To treat primary hypercholesterolemia or mixed hyperlipidemia

CAPSULES

Adults. 200 mg daily.

TABLETS

Adults. 145 mg daily.

↗ To treat hypertriglyceridemia (Fredrickson types IV and V hyperlipidemia)

CAPSULES

Adults. *Initial*: 67 mg daily with food, increased as needed every 4 to 8 wk.

Maximum: 201 mg daily with meals.

TABLETS

Adults. 48 to 145 mg daily, increased as needed at 4- to 8-wk intervals. *Maximum*: 145 mg daily.

DOSAGE ADJUSTMENT For patients with mild to moderate renal impairment, initial dosage limited to 48 mg daily (tablets) or 67 mg daily (capsules), with dosage increase only after drug's therapeutic and renal effects are known. For elderly patients, dosage limited to 48 mg daily (tablets) or 67 mg daily (capsules).

↗ As adjunct to diet to treat severe hypertriglyceridemia

DELAYED-RELEASE CAPSULES

Adults. *Initial*: 45 mg once daily, increased, as needed every 4- to 8-wk intervals.

Maximum: 135 mg daily.

↗ As adjunct to diet to treat primary hyperlipidemia or mixed dyslipidemia; as adjunct to diet and a HMG-CoA

reductase inhibitor to treat mixed dyslipidemia

DELAYED-RELEASE CAPSULES

Adults. 135 mg daily.

DOSAGE ADJUSTMENT For patients with mild to moderate renal impairment or elderly patients, initial dosage limited to 45 mg once daily, with increase only after drug's therapeutic and renal effects are known.

Route	Onset	Peak	Duration
P.O.	6–8 wk	Unknown	Unknown

Mechanism of Action

May increase the lipolysis of triglyceride-rich lipoproteins and decrease the synthesis of fatty acids and triglycerides by enhancing the activation of lipoprotein lipase and acyl-coenzyme A synthetase. Fenofibrate also may:

- increase hepatic elimination of cholesterol as bile salts
- promote the catabolism of larger, less dense LDLs with a high-binding affinity for cellular LDL receptors.

Contraindications

Breast-feeding; gallbladder disease; hypersensitivity to fenofibrate, fenofibric acid, choline fenofibrate, or their components; hepatic or severe renal impairment

Interactions

DRUGS

bile acid sequestrants: Decreased fenofibrate absorption

cyclosporine: Increased risk of nephrotoxicity
HMG-CoA reductase inhibitors (atorvastatin, cerivastatin, fluvastatin, lovastatin, pravastatin, simvastatin): Increased risk of myopathy, rhabdomyolysis, and acute renal failure

oral anticoagulants: Risk of bleeding

FOODS

all foods: Increased fenofibrate bioavailability when given in capsule form

Adverse Reactions

CNS: Asthenia, fatigue, headache

CV: Deep vein thrombosis

EENT: Rhinitis

GI: Abdominal pain, cholelithiasis, cirrhosis, constipation, diarrhea, elevated liver function test results, hepatitis, nausea, pancreatitis

GU: Increased serum creatinine level, renal failure

HEME: Agranulocytosis, anemia, decreased hematocrit and hemoglobin levels, thrombocytopenia

MS: Arthralgia, back pain, muscle spasms, myopathy, myositis, rhabdomyolysis

RESP: Pulmonary embolus

SKIN: Rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Flulike symptoms

Nursing Considerations

- As ordered, stop drugs that increase serum triglycerides, such as beta blockers, estrogens, and thiazides, and obtain baseline lipid levels before starting fenofibrate.
- Give capsule form with a full glass of water with meals.
- Administer drug 1 hour before or 4 hours after bile acid sequestrants.
- Monitor results of liver and renal function tests. If liver enzyme levels rise to more than three times the upper limit of normal and persist, or if the patient develops gallstones, expect to stop drug.
- Monitor serum triglyceride and cholesterol levels at 4- to 8-week intervals. If levels don't decrease after 2 months at maximum dosage, expect to stop therapy.

WARNING Monitor patient closely for acute hypersensitivity reactions, including severe rash, and notify prescriber if they occur. Patient may need inpatient corticosteroids.

- Assess blood counts periodically, as ordered, during first 12 months of therapy to detect adverse hematologic effects.
- Watch closely for evidence of deep vein thrombosis (pain, swelling, redness in extremity) or pulmonary embolus (sudden onset of anxiety, shortness of breath, restlessness) because risk is higher in patients taking fenofibrate. Notify prescriber immediately, and start emergency treatment, as prescribed.

PATIENT TEACHING

- Stress that drug will be effective only if patient carefully follows prescriber's instructions about diet and exercise.
- Instruct patient to take capsule form with a full glass of water and with food.
- Instruct patient prescribed tablet form to store the tablets in their original, desiccant-containing bottle and to avoid taking any chipped or broken tablets.

- Advise patient to have laboratory tests, as directed, to determine drug's effectiveness. They typically include liver function tests after 3 to 6 months, hematocrit and hemoglobin levels, and WBC counts periodically during first year.
- Urge patient to notify prescriber immediately about chills, fever, or sore throat. Also urge her to tell prescriber about unexplained muscle pain, tenderness, or weakness, especially if accompanied by fatigue or fever.
- Tell patient to seek emergency treatment if he develops pain, swelling, and redness in his limb or sudden shortness of breath, anxiety, and restlessness.

fenoldopam mesylate

Corlopam

Class and Category

Chemical class: Dopamine agonist

Therapeutic class: Antihypertensive

Pregnancy category: B

Indications and Dosages

↗ *To treat severe hypertension when rapid, but quickly reversible, emergency reduction of blood pressure is clinically indicated, including malignant hypertension with deteriorating end-organ function*

I.V. INFUSION

Adults. *Initial:* 0.025 to 0.3 mcg/kg/min, individualized according to patient weight and desired effect. *Usual:* 0.01 to 1.6 mcg/kg/min. *Maximum:* 1.6 mcg/kg/min for up to 48 hr.

Route	Onset	Peak	Duration
I.V.	Rapid	Unknown	Unknown

Mechanism of Action

Stimulates dopamine-1 postsynaptic receptors, which mediate renal and mesenteric vasodilation. Vasodilation lowers blood pressure and total peripheral resistance while increasing renal blood flow.

Contraindications

Hypersensitivity to fenoldopam or its components

Interactions

DRUGS

antihypertensives: Additive hypotensive effect

beta blockers: Increased risk of hypotension
dopamine antagonists, metoclopramide: Possibly decreased effects of fenoldopam

Adverse Reactions

CNS: Anxiety, headache, light-headedness
CV: Hypotension, ST- and T-wave changes, tachycardia

EENT: Increased intraocular pressure

GI: Abdominal pain, nausea

SKIN: Diaphoresis, flushing

Other: Hypokalemia, injection site pain

Nursing Considerations

- Reconstitute by adding 40 mg fenoldopam (4 ml of concentrate) to 1,000 ml normal saline solution or D₅W, or 20 mg fenoldopam (2 ml of concentrate) to 500 ml normal saline solution or D₅W, or 10 mg fenoldopam (1 ml of concentrate) to 250 ml normal saline solution or D₅W to produce a final fenoldopam concentration of 40 mcg/ml.
- Infuse through a mechanical infusion pump for proper control of infusion rate.
- Expect to titrate fenoldopam dosage in increments of 0.05 to 0.1 mcg/kg/min, as prescribed.
- Expect to monitor heart rate and blood pressure every 15 minutes during therapy because most effect on blood pressure occurs within 15 minutes of any dosage change.
- Be aware that patient may be started on oral antihypertensive therapy, as prescribed, any time after blood pressure is stable during fenoldopam infusion.
- Discard any reconstituted solution not used within 24 hours.

WARNING Assess patient for signs of increased myocardial oxygen demand, especially if patient has heart failure or a history of angina, because fenoldopam may produce a rapid decline in blood pressure, resulting in symptomatic hypotension and a dose-dependent increase in heart rate.

- Monitor serum potassium level because fenoldopam decreases serum potassium concentrations, which may result in hypokalemia, exacerbate arrhythmias, or

precipitate conduction abnormalities, especially in patients with cardiac disease.

- Monitor patients with glaucoma or increased intraocular pressure for changes in vision because drug may cause a dose-dependent increase in intraocular pressure.
- Be alert for possible allergic- or anaphylactic-type reaction to sodium metabisulfite, a component of fenoldopam injection, especially in patients with asthma.

PATIENT TEACHING

- Inform patient that she'll be switched to an oral antihypertensive once her blood pressure is controlled.
- Instruct patient to expect frequent monitoring of vital signs.

fenoprofen calcium

Nalfon

Class and Category

Chemical class: Propionic acid derivative

Therapeutic class: Analgesic, anti-inflammatory, antirheumatic

Pregnancy category: Not rated

Indications and Dosages

↗ *To manage mild to moderate pain*

CAPSULES, TABLETS

Adults. 200 mg every 4 to 6 hr, as needed.

↗ *To relieve pain, stiffness, and swelling from rheumatoid arthritis or osteoarthritis*

CAPSULES, TABLETS

Adults. 300 mg or 400 mg to 600 mg t.i.d. or q.i.d. *Maximum:* 3,200 mg daily.

Route	Onset	Peak	Duration
P.O.	15–30 min*	Unknown†	4–6 hr‡

Mechanism of Action

Blocks the activity of cyclooxygenase, the enzyme needed for prostaglandin synthesis.

* For analgesia; 2 days for antirheumatic effects.

† For analgesia; 2 to 3 wk for antirheumatic effects.

‡ For analgesia; unknown for antirheumatic effects.

Prostaglandins, important mediators of the inflammatory response, cause local vasodilation with swelling and pain. When cyclooxygenase is blocked and prostaglandins inhibited, inflammatory symptoms subside. Prostaglandin inhibition also relieves pain because prostaglandins play a role in pain transmission from the periphery to the spinal cord.

Contraindications

Angioedema, asthma, bronchospasm, nasal polyps, rhinitis, or urticaria induced by aspirin, iodides, or NSAIDs; hypersensitivity to fenoprofen or its components; renal impairment; severe hepatic impairment

Interactions

DRUGS

acetaminophen: Increased risk of renal impairment with concurrent long-term use
antacids: Decreased fenoprofen effectiveness
anticoagulants, cefamandole, cefoperazone, cefotetan, heparin, plicamycin, thrombolytics, valproic acid: Increased risk of bleeding
antineoplastics: Increased adverse hematologic effects

glucocorticoids, NSAIDs, potassium supplements: Increased adverse GI effects

insulin, oral antidiabetic drugs: Increased risk of hypoglycemia

lithium: Increased risk of lithium toxicity

methotrexate: Increased risk of methotrexate toxicity

phenobarbital: Possibly decreased elimination half-life of fenoprofen

salicylates: Increased risk of GI bleeding

ACTIVITIES

alcohol use, smoking: Increased risk of GI bleeding

Adverse Reactions

CNS: Agitation, confusion, dizziness, drowsiness, headache, seizures, sleep disturbance, stroke, tremor, weakness

CV: Hypertension, MI, palpitations, peripheral edema, tachycardia, vasodilation

EENT: Blurred vision, dry or sore mouth, hearing loss, tinnitus

GI: Abdominal cramps, distention, and pain; anorexia; constipation; diarrhea; diverticulitis; dysphagia; esophagitis; flatulence; gastritis; gastroenteritis; gastroe-

sophageal reflux disease; GI bleeding or ulceration; hemorrhoids; hepatitis; hiatal hernia; indigestion; jaundice; liver failure; melena; nausea; perforation of stomach or intestines; vomiting

GU: Acute renal failure, dysuria, interstitial nephritis

HEME: Agranulocytosis, anemia, hemolytic anemia, leukopenia, neutropenia, pancytopenia

MS: Muscle spasms and twitching, myalgia

RESP: Dyspnea

SKIN: Diaphoresis, erythema, erythema multiforme, exfoliative dermatitis, pruritus, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema

Nursing Considerations

- Use fenopfen with extreme caution in patients with a history of ulcer disease or GI bleeding because NSAIDs such as fenopfen increase risk of GI bleeding and ulceration. Expect to use fenopfen for the shortest time possible in these patients.
- Serious GI tract ulceration, bleeding, and perforation may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, withhold drug and notify prescriber immediately.
- Use fenopfen cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.
- Give drug with food, milk, or antacids to decrease adverse GI reactions.
- Patients with rheumatoid arthritis may need higher doses than those with osteoarthritis to control their symptoms.

WARNING If patient receives long-term therapy, watch for signs of toxicity, such as agitation; blurred vision; coma; confusion; drowsiness; elevated BUN and serum creatinine levels; indigestion; nausea; rash; seizures; severe headache; slow, labored breathing; tinnitus; and vomiting.

WARNING Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

WARNING If patient has bone marrow suppression or is receiving antineoplastic drug therapy, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflam-

matory and antipyretic actions of fenopfen may mask signs and symptoms of infection, such as fever and pain.

- Monitor patient—especially if she's elderly or receiving long-term fenopfen therapy—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor patient's liver function test results because, in rare cases, elevations may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure.
- Monitor BUN and serum creatinine levels in elderly patients, patients taking diuretics or ACE inhibitors, and patients with heart failure, impaired renal function, or hepatic dysfunction because drug may cause renal failure.
- Monitor CBC for decreased hemoglobin and hematocrit because drug may worsen anemia.
- Assess patient's skin regularly for signs of rash or other hypersensitivity reaction because fenopfen is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID sensitivity. At first sign of reaction, stop drug and notify prescriber.

PATIENT TEACHING

- Advise patient to take fenopfen with food, milk, or antacids to minimize GI distress. Also instruct her to take drug with a full glass of water and to stay upright for 30 minutes afterward to decrease the risk of drug lodging in the esophagus and causing irritation.
- Instruct patient to swallow drug whole and not to crush, break, chew, or open capsules.
 - Caution patient to avoid alcohol, aspirin, and other NSAIDs, unless prescribed, while taking fenopfen.
- If patient takes an anticoagulant, urge her to immediately report bleeding, including bloody or tarry stools and bloody vomitus.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Explain that NSAIDs may increase the risk of serious adverse cardiovascular reactions; urge patient to seek immediate

medical attention if signs or symptoms arise, such as chest pain, shortness of breath, weakness, and slurring of speech.

- Explain that fenoprofen also may increase the risk of serious adverse GI reactions; stress the need to seek immediate medical attention for such signs and symptoms as epigastric or abdominal pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.
- Alert patient to the possibility of rare but serious skin reactions. Urge her to seek immediate medical attention for rash, blisters, itching, fever, or other indications of hypersensitivity.

fentanyl citrate

Actiq, Onsolis, Sublimaze

fentanyl transdermal system

Duragesic

fentanyl iontophoretic transdermal

Ionsys

Class, Category, and Schedule

Chemical class: Opioid, phenylpiperidine derivative

Therapeutic class: Analgesic, anesthesia adjunct

Pregnancy category: C

Controlled substance schedule: II

Indications and Dosages

↗ *To provide surgical premedication*

I.M. INJECTION

Adults. 0.05 to 0.1 mg 30 to 60 min before surgery.

↗ *As adjunct to regional anesthesia*

I.V. OR I.M. INJECTION

Adults. 0.05 to 0.1 mg I.M. or slow I.V. over 1 to 2 min.

↗ *To manage postoperative pain in post-anesthesia care unit*

I.M. INJECTION

Adults. 0.05 to 0.1 mg. Repeated in 1 to 2 hr, if needed.

↗ *To manage acute postoperative pain in hospitalized patients requiring opioid analgesia*

IONTOPHORETIC TRANSDERMAL

Adults. 40 mcg on-demand, released over 10 min. *Maximum:* Six 40-mcg doses/hour and eighty 40-mcg doses/24 hours for maximum of 72 hours.

↗ *To treat breakthrough pain in cancer patients who are receiving opioid therapy and have developed tolerance to it*

TRANSMUCOSAL LOZENGE (ACTIQ)

Adults. *Initial:* 200 mcg placed between cheek and gum for up to 15 min followed by second dose 15 min after first dose ends, if needed. Dosage increased according to patient's needs.

TRANSMUCOSAL SOLUBLE FILM (ONSOLIS)

Adults. *Initial:* 200-mcg film sheet placed against inside of cheek per episode. Increased, as needed, by 200 mcg in each subsequent episode, with doses at least 2 hours apart. *Maximum:* Four 200-mcg film sheets or one 1,200-mcg film sheet four times daily.

↗ *To relieve persistent moderate to severe chronic pain that doesn't respond to less potent drugs and requires around-the-clock opioid administration for an extended time*

TRANSDERMAL SYSTEM

Adults and children age 2 and over. *Initial:* One 25-mcg/hr patch, replaced every 72 hr (or 48 hr, if needed). Dosage increased by 12.5 mcg/hr, as needed, after first 72 hr and then every 6 days. For more than 100 mcg/hr, more than one patch is used.

DOSAGE ADJUSTMENT For elderly, cachectic, or debilitated patients, initial dosage should not exceed 25 mcg/hr unless patient is already receiving more than 135 mg of oral morphine daily or an equivalent dose of another opioid. For patients receiving long-term opioid therapy, dosage adjusted based on previous day's drug requirement. For cancer patients who need more than 800 mcg/day for breakthrough pain, dosage altered or another long-acting opioid given, as prescribed.

Mechanism of Action

Binds to opioid receptor sites in the CNS, altering perception of and emotional response to pain by inhibiting ascending pain pathways. Fentanyl may alter neuro-

transmitter release from afferent nerves responsive to painful stimuli, and it causes respiratory depression by acting directly on respiratory centers in the brain stem.

Route	Onset	Peak	Duration
I.V.	1–2 min	3–5 min	30–60 min
I.M.	7–15 min	20–30 min	1–2 hr
Trans-dermal	12–24 hr	Unknown	Over 72 hr

Contraindications

I.V. or I.M. form: Under age 2, asthma, myasthenia gravis, opioid hypersensitivity or intolerance

Transmucosal form: Acute or chronic pain, including postoperative pain

Transdermal form: Acute or postoperative pain, under age 12 (under age 18 if weight is less than 50 kg [110 lb]), dosage that exceeds 25 mcg/hr at the start of therapy, hypersensitivity to fentanyl (or alfentanil, sufentanil, or adhesives), intermittent pain, treatment of mild to moderate pain responsive to nonopioid drugs

All forms: Hypersensitivity to fentanyl (or alfentanil, sufentanil, or adhesives) or its components, intermittent pain, opioid non-tolerance, significant respiratory depression, treatment of mild to moderate pain responsive to nonopioid drugs, upper airway obstruction

Interactions

DRUGS

amiodarone, amprenavir, aprepitant, clarithromycin, diltiazem, erythromycin, fluconazole, fosamprenavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, troleandomycin, verapamil: Possibly increased opioid effect, leading to increased or prolonged adverse effects, including severe respiratory depression

anticholinergics, antidiarrheals (such as loperamide and paregoric): Increased risk of severe constipation

antihypertensives, diuretics: Possibly potentiated hypotension

benzodiazepines: Possibly reduced fentanyl dose required for anesthesia induction

buprenorphine: Possibly decreased therapeutic effects of buprenorphine

CNS depressants: Possibly increased CNS and respiratory depression and hypotension

cytochrome P-450 inducers (such as rifampin, carbamazepine, and phenytoin):

Possibly induced metabolism and increased clearance of fentanyl

hydroxyzine: Possibly increased analgesic effect of fentanyl and increased CNS depression and hypotension

MAO inhibitors: Possibly unpredictable or fatal effects if taken within 14 days

metoclopramide: Possibly antagonized effect of metoclopramide on gastric motility

nalbuphine, pentazocine: Possibly antagonized analgesic, respiratory depressant, and CNS depressant effects of fentanyl; possibly additive hypotensive and CNS and respiratory depressant effects of both drugs

naloxone: Antagonized analgesic, hypotensive, CNS, and respiratory depressant effects of fentanyl

naltrexone: Possibly blocked therapeutic effects of fentanyl

neuromuscular blockers: Possibly prevention or reversal of muscle rigidity by fentanyl

FOODS

grapefruit juice: Increased blood fentanyl level

ACTIVITIES

alcohol use: Increased CNS and respiratory depression and hypotension

Adverse Reactions

CNS: Agitation, amnesia, anxiety, asthenia, ataxia, confusion, delusions, depression, dizziness, drowsiness, euphoria, fever, hallucinations, headache, lack of coordination, light-headedness, nervousness, paranoia, sedation, seizures, sleep disturbance, slurred speech, syncope, tremor, weakness, yawning

CV: Asystole, bradycardia, chest pain, edema, hypotension, orthostatic hypotension, tachycardia

EENT: Blurred vision, dental caries, dry mouth, gum line erosion, laryngospasm, rhinitis, sneezing, tooth loss

GI: Anorexia, constipation, ileus, indigestion, nausea, vomiting

GU: Anorgasmia, decreased libido, ejaculatory difficulty, urinary hesitancy, urine retention

RESP: Apnea, depressed cough reflex, dyspnea, hypoventilation, respiratory depression

SKIN: Diaphoresis, exfoliative dermatitis, localized skin redness and swelling (with transdermal form), pruritus, rash

Other: Anaphylaxis, drug tolerance, physi-

cal or psychological dependence with long-term use, weight loss

Nursing Considerations

WARNING Fentanyl transdermal system should be used only in patients already receiving opioid therapy and with demonstrated opioid tolerance (taking for a week or longer at least 60 mg of morphine daily, 30 mg of oral oxycodone daily, 8 mg of oral hydromorphone daily, or an equianalgesic dose of another opioid), and require at least a fentanyl dosage of 25 mcg per hour to manage their pain.

- Use caution when titrating fentanyl dosage in elderly patients, especially using intravenous route, because these patients are more sensitive to the drug's effects.
- Use cautiously in patients at risk for opioid abuse, such as those with mental illness or personal or family history of substance abuse. Monitor patient throughout therapy for fentanyl abuse or addiction.
- To reduce skin irritation, spray the allergy inhaler triamcinolone on the patient's skin, as prescribed, before applying a fentanyl patch.
- Expect the blood fentanyl level to be prolonged if patient chews or swallows the transmucosal form because drug is absorbed slowly from GI tract.

WARNING Never apply a transdermal patch if seal has been broken or patch has been cut, damaged, or changed because excessive exposure could occur, resulting in possibly fatal fentanyl overdose.

- Be aware that 100 mcg of fentanyl is equivalent in potency to 10 mg of morphine.
- To achieve optimum pain control with the lowest possible fentanyl dose, also plan to give a nonopioid analgesic, such as acetaminophen, as prescribed.

WARNING Monitor patient's respiratory status closely, especially during the first 24 to 72 hours after therapy starts or dosage increases, because severe hypoventilation may occur without warning at any time during therapy.

- To prevent withdrawal symptoms after long-term use, expect to taper drug dosage gradually, as prescribed.
- Assess patient for withdrawal symptoms after dosage reduction or conversion to another opioid analgesic.

- For patient with bradycardia, implement cardiac monitoring, as ordered, and assess heart rate and rhythm frequently during fentanyl therapy because drug may further slow heart rate.

WARNING Expect respiratory depressant effects to last longer than analgesic effects. Also be prepared for residual drug to potentiate effects of subsequent doses. Residual drug can be detected for at least 6 hours after I.V. dose and 17 hours after other forms. Monitor patient closely for at least 24 hours after therapy ends.

WARNING Assess patient for evidence of overdose, such as cardiopulmonary arrest, hypoventilation, pupil constriction, respiratory and CNS depression, seizures, and shock. Give naloxone (possibly in repeated doses), as prescribed. Be prepared to assist with endotracheal intubation and mechanical ventilation and to provide fluids.

- Monitor blood glucose level of diabetic patient receiving transdermal fentanyl because each unit contains about 2 g of sugar.

WARNING Do not substitute Actiq or Onsolis for any other fentanyl product and do not substitute for each other. Do not convert dosage to or from other products on a mcg-per-mcg basis because doing so may result in a fatal overdose.

PATIENT TEACHING

- Instruct patient to avoid alcohol and other CNS depressants during fentanyl therapy unless prescribed.
- Advise patient not to stop taking drug unless directed by prescriber because withdrawal symptoms may occur. Warn against increasing dose or frequency without consulting prescriber because drug can cause dependency.
- For transdermal form, instruct patient to choose a site with intact (not irritated or irradiated) skin on a flat surface, such as the chest, back, flank, or upper arm, and, if appropriate, to clip, not shave, hair from the site and clean it with water (no soaps, lotions, oils, or alcohol). After site preparation, instruct patient to press patch firmly in place with palm for 30 seconds, making sure edges are sealed. If patch loosens, tell her to tape edges down but not cover the entire patch. If more than one patch is needed, the edges shouldn't

touch or overlap. Instruct patient to remove patch after 72 hours, fold it in half with adhesive sides together, and flush it down the toilet. Remind her not to reuse a site for at least 3 days.

- Warn patient never to apply transdermal patch if seal has been broken or the patch has been cut, damaged, or changed in any way because drug may be released too rapidly. Also warn patient not to expose the application site and surrounding area to direct external heat sources, such as heating pads or electric blankets, heat or tanning lamps, saunas, hot tubs, and heated water beds, while wearing the patch. She should also avoid hot baths or sunbathing because increased body temperature may increase fentanyl release, resulting in a possible overdose. If she develops a fever or becomes overheated from strenuous exercise while wearing a patch, she should contact the prescriber immediately.
- For iontophoretic transdermal form, instruct patient to press button twice firmly within 3 seconds to release a dose. An audible tone will sound when a dose is activated, and a red light will stay on throughout the 10-minute administration. Explain that no more than six doses can be given per hour and no more than 80 doses per 24 hours. Tell the patient that the patch may be replaced once 80 doses are released or 24 hours pass, but that 72 hours is the maximum time the drug can be delivered in this way.
- For Actiq transmucosal form, instruct patient to open the package just before use and to save plastic cap for discarding the unused part of the lozenge. Tell her to place lozenge between her cheek and gum and to suck, not chew, it for 15 minutes. Show her how to move lozenge from one side of her mouth to the other using the handle provided separately.
- For Onsolis transmucosal form, instruct patient to wet inside of cheek with tongue or rinse his mouth with water. Tell him to open package just before use and place entire film sheet on the tip of a dry finger, pink side facing up. Then he should carefully place pink side of film against inside of cheek and press side and hold it in place for 5 seconds. Tell him not to drink anything for 5 minutes or eat for 30 minutes. Warn

patient not to cut or tear film before use. If he uses multiple film sheets, tell him to place them in separately along sheek wall, not on top of each other.

- Onsolis dosage increases must occur only in 200-mcg increments, must be done only in later pain episodes, and must be separated by at least 2 hours from previous dose. If pain isn't relieved within 30 minutes, tell him not to use another dose but to use a rescue drug instead. If dosage increase is needed and continues to be needed, tell patient to contact prescriber for new dosage strength because each episode should be treated with one film sheet of appropriate strength.
- For transmucosal form, urge patient to see a dentist regularly, to brush teeth and floss after each meal, and to avoid frequent consumption of products high in sugar because of increased risk of dental caries.
- For transmucosal form, inform diabetic patient that each unit contains 2 g of sugar. Instruct her to monitor her blood glucose levels closely.
- Remind patient to keep used and unused dosage units out of reach of children and to dispose of drug properly. For buccal tablets, patient should flush leftover drug down the toilet when no longer needed.
- Caution patient that accidentally exposing others to transdermal fentanyl could cause serious adverse reactions. If accidental exposure occurs, the person should remove the patch, wash the area well with water, and seek medical attention.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Tell patient to increase fiber and fluid intake, unless contraindicated, because drug may cause severe constipation. If it persists or becomes severe, urge patient to notify prescriber.

ferrous salts

ferrous fumarate

(contains 100 mg of elemental iron per capsule or per 5 ml of oral suspension, 33 mg of elemental iron per chewable tablet or per 5 ml of oral suspension, 106 mg of elemental iron per E.R. capsule, 15 mg of

elemental iron per 0.6 ml of oral solution, and 20 to 115 mg of elemental iron per tablet)

Femiron, Feostat, Feostat Drops, Ferretts, Fumasorb, Fumerin, Hemocyte, Iron, Neo-Fer (CAN), Nephro-Fer, Novofumar (CAN), Palafer (CAN), Span-FF

ferrous gluconate

(contains 10 mg of elemental iron per capsule, 34 mg of elemental iron per 5 ml of elixir, 37 mg of elemental iron per E.R. tablet, 35 mg of elemental iron per 5 ml of syrup, and 34 to 38 mg of elemental iron per tablet)

Apo-Ferrous Gluconate (CAN), Fergon, Ferralet, Ferralet Slow Release, Fertinic (CAN), Novoferroglyc (CAN), Simron

ferrous sulfate

(contains 50 mg of elemental iron per capsule, 60 mg of elemental iron per dried capsule, 30 to 50 mg of elemental iron per dried E.R. capsule, 50 mg of elemental iron per dried E.R. tablet, 65 mg of elemental iron per dried tablet, 44 mg of elemental iron per 5 ml of elixir, 60 to 65 mg of elemental iron per enteric-coated tablet, 65 to 105 mg of elemental iron per E.R. tablet, 15 mg of elemental iron per 0.6 ml of oral solution, 18 mg of elemental iron per 0.5 ml of oral solution, 25 mg of elemental iron per ml of oral solution, 30 or 60 mg of elemental iron per 5 ml of oral solution, and 39 to 65 mg of elemental iron per tablet)

Apo-Ferrous Sulfate (CAN), Feosol, Feratab, Fer-gen-sol, Fer-In-Sol Capsules, Fer-In-Sol Drops, Fer-In-Sol Syrup, Fer-Iron Drops, Fero-Grad (CAN), Fero-Gradumet, Ferospace, Ferralyn Lanacaps, Ferra-TD, Mol-Iron, Novoferrosulfa (CAN), PMS-Ferrous Sulfate (CAN), Slow-Fe

iron, carbonyl

(contains 50 mg of elemental iron per caplet)

Feosol

Class and Category

Chemical class: Trace element, mineral
Therapeutic class: Antianemic, nutritional supplement

Pregnancy category: Not rated

Indications and Dosages

↗ *To prevent iron deficiency based on U.S. and Canadian recommended daily allowances*

CAPLETS, CAPSULES, CHEWABLE TABLETS, DRIED CAPSULES, DRIED E.R. CAPSULES, DRIED E.R. TABLETS, DRIED TABLETS, ELIXIR, ENTERIC-COATED TABLETS, E.R. CAPSULES, E.R. TABLETS, ORAL SOLUTION, ORAL SUSPENSION, SYRUP, TABLETS
Adult men and children age 11 and over. 10 mg (8 to 10 mg Canadian) elemental iron daily.

Adult women and children age 11 and over. 10 to 15 mg (8 to 13 mg Canadian) elemental iron daily.

Pregnant women. 30 mg (17 to 22 mg Canadian) elemental iron daily.

Breast-feeding women. 15 mg (8 to 13 mg Canadian) elemental iron daily.

Children ages 7 to 10. 10 mg (8 to 10 mg Canadian) elemental iron daily.

Children ages 4 to 6. 10 mg (8 mg Canadian) elemental iron daily.

Children from birth to age 3. 6 to 10 mg (0.3 to 6 mg Canadian) elemental iron daily.

↗ *To replace iron in deficiency states*

CAPLETS, CAPSULES, CHEWABLE TABLETS, DRIED CAPSULES, DRIED E.R. CAPSULES, DRIED E.R. TABLETS, DRIED TABLETS, ELIXIR, ENTERIC-COATED TABLETS, E.R. CAPSULES, E.R. TABLETS, ORAL SOLUTION, ORAL SUSPENSION, SYRUP, TABLETS
Adults and adolescents. 100 to 200 mg elemental iron t.i.d. for 4 to 6 mo.

Children ages 2 to 12 weighing 30 to 50 kg (66 to 110 lb). 50 to 100 mg elemental iron daily in divided doses t.i.d. or q.i.d. for 4 to 6 mo.

Children ages 6 months to 2 years. Up to 6 mg/kg elemental iron daily in divided doses t.i.d. or q.i.d. for 4 to 6 mo.

Infants under age 6 months. 10 to 25 mg elemental iron daily in divided doses t.i.d. or q.i.d. for 4 to 6 mo.

↗ *To provide iron supplementation during pregnancy*

CAPLETS, CAPSULES, CHEWABLE TABLETS, DRIED CAPSULES, DRIED E.R. CAPSULES, DRIED E.R. TABLETS, DRIED TABLETS, ELIXIR, ENTERIC-COATED

TABLETS, E.R. CAPSULES, E.R. TABLETS, ORAL SOLUTION, ORAL SUSPENSION, SYRUP, TABLETS

Pregnant women. 15 to 30 mg elemental iron daily during second and third trimesters.

DOSE ADJUSTMENT Dosage increased if needed for elderly patients, who may not absorb iron as easily as younger adults do.

Mechanism of Action

Acts to normalize RBC production by binding with hemoglobin or by being oxidized and stored as hemosiderin or aggregated ferritin in reticuloendothelial cells of the liver, spleen, and bone marrow. Iron is an essential component of hemoglobin, myoglobin, and several enzymes, including cytochromes, catalase, and peroxidase. Iron is needed for catecholamine metabolism and normal neutrophil function.

Contraindications

Hemochromatosis, hemolytic anemias, hemosiderosis, hypersensitivity to iron salts or their components, other anemic conditions unless accompanied by iron deficiency

Interactions**DRUGS**

acetohydroxamic acid: Reduced absorption of both drugs

antacids, calcium supplements: Decreased iron absorption and effectiveness

ascorbic acid (with doses of 200 mg or more): Increased iron absorption

cholestyramine, cimetidine: Decreased iron absorption

ciprofloxacin, enoxacin, etidronate, lomefloxacin, norfloxacin, ofloxacin, oral tetracyclines: Decreased effectiveness of these drugs

dimercaprol: Possibly combination with iron in body to form a harmful chemical

levodopa: Possibly chelation with iron, decreasing levodopa absorption and blood level

levothyroxine: Decreased levothyroxine effectiveness and, possibly, hypothyroidism

methyl dopa: Decreased methyl dopa absorption and efficacy

penicillamine: Decreased penicillamine absorption because penicillamine chelates heavy metals

vitamin E: Decreased vitamin E absorption

FOODS

coffee; eggs; foods that contain bicarbonates,

carbonates, oxalates, or phosphates; milk and milk products; tea that contains tannic acid; whole-grain breads and cereals and other high-fiber foods: Decreased iron absorption and effectiveness

ACTIVITIES

alcohol abuse (acute or chronic): Increased serum iron level

Adverse Reactions

CNS: Dizziness, fever, headache, paresthesia, syncope

CV: Chest pain, tachycardia

EENT: Metallic taste, tooth discoloration

GI: Abdominal cramps, constipation, epigastric pain, nausea, stool discoloration, vomiting

HEME: Hemochromatosis, hemolysis, hemosiderosis

RESP: Dyspnea

SKIN: Diaphoresis, flushing, rash, urticaria

Nursing Considerations

- Give iron tablets and capsules with a full glass of water or juice. Don't crush enteric-coated tablets or open capsules.
- Because iron solutions may stain teeth, dilute and administer with a straw or place drops in back of patient's throat. Mix the elixir form in water. Fer-In-Sol Drops or Syrup may be mixed with water or juice.
- To maximize absorption, give iron salts 1 hour before or 2 hours after meals. If GI irritation occurs, give with or just after meals.
- Protect liquid form from freezing.
- Be aware that at usual dosages, serum hemoglobin level usually normalizes in about 2 months unless blood loss continues. Treatment lasts for 3 to 6 months to help replenish iron stores.

WARNING Monitor patient for signs of iron overdose, which may include abdominal pain, diarrhea (possibly bloody), nausea, severe vomiting, and sharp abdominal cramps. In case of iron toxicity or accidental iron overdose (a leading cause of fatal poisoning in children under age 6), give deferoxamine, as prescribed. As few as 3 adult iron tablets can cause serious poisoning in young children.

- Don't give antacids, coffee, tea, dairy products, eggs, or whole-grain cereals or breads within 1 hour before or 2 hours after iron.
- Remember that unabsorbed iron turns

stool green or black and can mask blood in stool. Check stool for occult blood, as ordered.

PATIENT TEACHING

- Instruct patient not to chew any solid form of iron except for chewable tablets.
- Inform patient that iron deficiency may cause decreased stamina, learning problems, shortness of breath, and tiredness.
- To improve iron absorption, urge patient to eat lean red meat, chicken, turkey, and fish as well as foods rich in vitamin C (such as citrus fruits and fresh vegetables).
- Urge patient to avoid foods that impair iron absorption, including dairy products, eggs, spinach, and high-fiber foods, such as whole-grain breads and cereals and bran. Also advise her to avoid drinking coffee or tea within 1 hour of iron intake.
- Caution patient not to take antacids or calcium supplements within 1 hour before and 2 hours after taking iron supplement.
- Inform patient that stool should become dark green or black during therapy. Advise her to notify prescriber if it doesn't.
- To minimize tooth stains from liquid iron, instruct patient to mix dose with water, fruit juice, or tomato juice and to drink it with a straw. If patient must take liquid iron by dropper, direct her to place drops well back on the tongue and to follow with water or juice. Tell her that iron stains can be removed by brushing with baking soda (sodium bicarbonate) or medicinal peroxide (hydrogen peroxide 3%).
- Advise patient to consult prescriber before taking large amounts of iron for longer than 6 months.
- Warn patient about high risk of accidental poisoning, and urge her to keep iron preparations out of the reach of children.

fesoterodine fumarate

Toviaz

Class and Category

Chemical class: Muscarinic receptor antagonist

Therapeutic class: Antispasmodic

Pregnancy category: C

Indications and Dosages

↗ *To treat overactive bladder with symptoms of urinary incontinence, urgency, and frequency*

E.R. TABLETS

Adults. *Initial:* 4 mg daily, increased to 8 mg, as needed. *Maximum:* 8 mg daily.

DOSE ADJUSTMENT For patients with severe renal insufficiency or who are taking potent CYP3A4 inhibitors (such as clarithromycin, itraconazole, and ketoconazole), dosage shouldn't exceed 4 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	5 hr	Unknown

Mechanism of Action

Exerts antimuscarinic (atropine-like) and potent direct antispasmodic (papaverine-like) actions on smooth muscle in the bladder. The result is increased bladder capacity and a decreased urge to void. Fesoterodine has an active metabolite that inhibits bladder contraction and decreases detrusor pressure.

Contraindications

Gastric retention, GI obstruction, hypersensitivity to fesoterodine or its components, ileus, pyloric stenosis, uncontrolled narrow-angle glaucoma, urine retention

Interactions

DRUGS

antimuscarinic agents: Possibly increased anticholinergic effects; possibly altered absorption of oral drugs taken concurrently
potent CYP3A4 inhibitors, such as clarithromycin, itraconazole, ketoconazole: Possibly increased serum fesoterodine level and increased risk of adverse effects

FOODS

caffeine: May aggravate bladder symptoms

ACTIVITIES

alcohol use: Increased drowsiness

Adverse Reactions

CNS: Drowsiness, insomnia

CV: Angina, chest pain, peripheral edema, QT-interval prolongation

EENT: Blurred vision; dry eyes, mouth, or throat

GI: Constipation, diverticulitis, dyspepsia, elevated liver enzymes, gastroenteritis, irritable bowel syndrome, nausea, upper

abdominal pain

GU: Dysuria, urine retention, UTI

MS: Back pain

RESP: Cough, upper respiratory tract infection

SKIN: Decreased sweating, rash

Nursing Considerations

- Use cautiously in patients with significant bladder outlet obstruction because fesoterodine can cause urine retention.
- Use cautiously in patients with myasthenia gravis, decreased GI motility, and controlled narrow-angle glaucoma because drug can make these conditions worse.
- Use cautiously in patients taking other drugs with anticholinergic effects, such as antihistamines.

PATIENT TEACHING

- Instruct patient to take drug exactly as prescribed.
- Tell patient to take drug with a full glass of water and not to cut, crush, or chew tablets.
- Explain that drug can cause adverse effects such as constipation and urine retention. If they occur and are severe or prolonged, patient should notify prescriber.
- Advise patient to avoid alcohol consumption during fesoterodine therapy.
- Tell patient to avoid hazardous activities until drug's CNS effects are known.
- Caution patient to avoid strenuous exercise and excessive sun exposure because of increased risk of heatstroke.
- Advise patient to limit caffeine consumption during drug therapy.
- Explain that full benefits of fesoterodine therapy may take 2 to 3 months.
- Inform patient that chewing sugarless gum or sucking hard candy (especially lemon drops) may help ease dry mouth.

filgrastim (granulocyte colony-stimulating factor, rG-CSF)

Neupogen

Class and Category

Chemical class: Granulocyte colony-stimulating factor

Therapeutic class: Antineutropenic,

hematopoietic stimulator

Pregnancy category: C

Indications and Dosages

➤ *To prevent infection after myelosuppressive chemotherapy*

I.V. INFUSION

Adults. 5 mcg/kg daily over 15 to 30 min. Increased, if needed, by 5 mcg/kg with each chemotherapy cycle.

SUBCUTANEOUS INJECTION

Adults. 5 mcg/kg daily for up to 2 wk. Increased, if needed, by 5 mcg/kg with each chemotherapy cycle.

➤ *To reduce duration of neutropenia after bone marrow transplantation*

I.V. INFUSION

Adults. 10 mcg/kg daily over 4 hr or as a continuous infusion over 24 hr.

SUBCUTANEOUS INFUSION

Adults. 10 mcg/kg as a continuous infusion over 24 hr.

➤ *To enhance peripheral blood progenitor cell collection in autologous hematopoietic stem cell transplantation*

SUBCUTANEOUS INFUSION OR INJECTION

Adults. 10 mcg/kg as continuous infusion over 24 hr or a single injection, starting 4 days before first leukapheresis and continuing until last day of leukapheresis.

➤ *To reduce occurrence and duration of neutropenia in congenital neutropenia*

SUBCUTANEOUS INJECTION

Adults. 6 mcg/kg b.i.d.

➤ *To reduce the occurrence and duration of neutropenia in idiopathic or cyclic neutropenia*

SUBCUTANEOUS INJECTION

Adults. 5 mcg/kg daily.

DOSAGE ADJUSTMENT Dosage reduced for patients whose absolute neutrophil count remains above 10,000/mm³.

Route	Onset	Peak	Duration
I.V.	In 5 min	Unknown	Unknown

Mechanism of Action

Is pharmacologically identical to human granulocyte colony-stimulating factor, an endogenous hormone synthesized by monocytes, endothelial cells, and fibroblasts. Filgrastim induces formation of neutrophil progenitor cells by binding directly to receptors on the surface of granulocytes,

which then divide and differentiate. It also potentiates the effects of mature neutrophils, which reduces fever and the risk of infection raised by severe neutropenia.

Incompatibilities

Don't mix filgrastim in vial or syringe with normal saline solution because precipitate will form.

Contraindications

Hypersensitivity to filgrastim, its components, or proteins from *Escherichia coli*

Interactions

DRUGS

growth hormone: Increased bone marrow hematopoietic activity

lithium: Increased neutrophil production

Adverse Reactions

CNS: Fever, headache

CV: Transient supraventricular tachycardia

GI: Splenic rupture, splenomegaly

HEME: Leukocytosis

MS: Arthralgia; myalgia; pain in arms, legs, lower back, or pelvis

SKIN: Pruritus, rash, Sweet's syndrome (acute febrile neutrophilic dermatosis)

Other: Anaphylaxis, injection site pain and redness

Nursing Considerations

- Warm filgrastim to room temperature before injection. Discard drug if stored longer than 6 hours at room temperature or 24 hours in refrigerator.
- Withdraw only one dose from a vial; don't repuncture the vial.
- Don't shake the solution.
- For continuous infusion, dilute in D₅W (not normal saline solution) to produce less than 15 mcg/ml.
- For subcutaneous dose larger than 1 ml, divide and give in more than one site.
- After chemotherapy, give drug over 15 to 30 minutes. Don't give within 24 hours before or after cytotoxic chemotherapy.
- Be aware that needle cover on single-use prefilled syringe contains dry natural rubber and may cause sensitivity reaction. It shouldn't be handled by allergic people.
- Expect to monitor CBC, hematocrit, and platelet count two or three times weekly.
- Inform prescriber and expect to stop drug if leukocytosis develops or absolute neutrophil count consistently exceeds

10,000/mm³.

- Anticipate decreased response to drug if patient has received extensive radiation therapy or long-term chemotherapy.

PATIENT TEACHING

- Teach patient how to prepare, administer, and store filgrastim. Caution her not to reuse needle, syringe, or vial.
- Advise patient prescribed single-use prefilled syringe to notify prescriber if she has an allergy to latex because needle cover may cause sensitivity reaction.
- Provide patient with puncture-resistant container for needle and syringe disposal.
- Advise patient to promptly report pain in left upper quadrant of abdomen or shoulder-tip pain.
- Stress the importance of returning for follow-up laboratory tests.

finasteride

Propecia, Proscar

Class and Category

Chemical class: 4-Azasteroid compound

Therapeutic class: Benign prostatic hyperplasia agent, hair growth stimulant

Pregnancy category: X

Indications and Dosages

↗ *To treat symptomatic benign prostatic hyperplasia; to reduce the risk of symptomatic progression of benign prostatic hyperplasia when given with doxazocin*

TABLETS

Adults. 5 mg daily.

↗ *To treat male-pattern baldness*

TABLETS

Adults. 1 mg daily.

Route	Onset	Peak	Duration
P.O.*	Unknown	8 hr	24 hr†
P.O.‡	In 3 mo	Unknown	Unknown

Mechanism of Action

Inhibits 5-alpha reductase, an intracellular enzyme that converts testosterone to its

* For benign prostatic hyperplasia.

† With single-dose therapy; 2 wk with multiple-dose therapy.

‡ For male-pattern baldness.

metabolite (5- α dihydrotestosterone) in liver, prostate, and skin. The metabolite is a potent androgen partially responsible for benign prostatic hyperplasia and hair loss.

Contraindications

Age (childhood), hypersensitivity to finasteride, sex (female)

Interactions

DRUGS

theophylline: Decreased theophylline level

Adverse Reactions

CNS: Asthenia, dizziness, headache

CV: Hypotension, peripheral edema

EENT: Lip swelling, rhinitis

ENDO: Gynecomastia

GI: Abdominal pain, diarrhea

GU: Decreased ejaculatory volume, decreased libido, impotence, testicular pain

MS: Back pain

RESP: Dyspnea

SKIN: Pruritus, rash, urticaria

Other: Angioedema

Nursing Considerations

- Expect patient to have a digital rectal examination of the prostate before and periodically during finasteride therapy.

PATIENT TEACHING

- **WARNING** Urge patient and female partners to use reliable contraception during therapy because semen of men who take drug can harm male fetuses. Caution women and children not to handle broken tablets.
- Explain how to take drug, and urge patient to follow instructions that accompany it.
- Inform patient that drug may cause decreased ejaculatory volume, decreased libido, and impotence.
- Urge patient to have periodic follow-up to determine drug effectiveness.

flavoxate hydrochloride

Urispas

Class and Category

Chemical class: Flavone derivative

Therapeutic class: Urinary tract antispasmodic

Pregnancy category: B

Indications and Dosages

➤ To relieve dysuria, nocturia, suprapubic pain, urinary frequency and urgency, and urinary incontinence caused by cystitis, prostatitis, urethrocystitis, or urethrorrhinitis

TABLETS

Adults and adolescents. 100 to 200 mg t.i.d. or q.i.d.

Route	Onset	Peak	Duration
P.O.	55 min	112 min	Unknown

Mechanism of Action

Relaxes muscles by cholinergic blockade and counteracts smooth-muscle spasms in the urinary tract.

Contraindications

Achalasia; GI hemorrhage; hypersensitivity to flavoxate or its components; obstruction of the duodenum, ileum, or pylorus; obstructive uropathies of the lower urinary tract

Interactions

DRUGS

bethanechol, metoclopramide: Possibly antagonized GI motility effects of these drugs

Adverse Reactions

CNS: Confusion, decreased concentration, dizziness, drowsiness, fever, headache, nervousness, vertigo

CV: Palpitations, tachycardia

EENT: Accommodation disturbances, blurred vision, dry mouth, eye pain, photophobia, worsening of glaucoma

GI: Constipation, nausea, vomiting

GU: Dysuria

HEME: Eosinophilia, leukopenia

SKIN: Decreased sweating, dermatoses, urticaria

Nursing Considerations

- Monitor for eye pain if patient has glaucoma because flavoxate's anticholinergic effects may worsen glaucoma.

PATIENT TEACHING

- Caution patient about possible dry mouth and photophobia. Advise her to wear sunglasses outdoors, and suggest sugarless candy or gum, ice chips, sips of water, or saliva substitute for dry mouth.
- Advise patient to avoid hazardous activi-

ties until CNS effects of flavoxate are known.

- Caution patient not to become overheated or to take hot baths or saunas during therapy because drug reduces sweating, which can lead to dizziness, fainting, or heat-stroke.
- Instruct patient to notify prescriber immediately if she experiences confusion, drowsiness, dysuria, headache, high fever, hives, nausea, nervousness, palpitations, rash, tachycardia, vertigo, vision problems, vomiting, or worsening dry mouth.

flecainide acetate

Tambocor

Class and Category

Chemical class: Benzamide derivative

Therapeutic class: Class IC antiarrhythmic

Pregnancy category: C

Indications and Dosages

➤ *To prevent and suppress recurrent life-threatening ventricular tachycardia*

TABLETS

Adults. *Initial:* 100 mg every 12 hr (every 8 hr for some patients). Increased by 50 mg b.i.d. every 4 days, if needed, until response occurs. *Maintenance:* Up to 150 mg every 12 hr. *Maximum:* 400 mg daily.

DOSE ADJUSTMENT Initial dose reduced to 100 mg daily or 50 mg every 12 hr for patients with creatinine clearance less than 35 ml/min/1.73 m².

➤ *To prevent paroxysmal atrial fibrillation or flutter or paroxysmal supraventricular tachycardia*

TABLETS

Adults. *Initial:* 50 mg every 12 hr (every 8 hr for some patients). Increased by 50 mg b.i.d. every 4 days, if needed, until response occurs. *Maintenance:* Up to 150 mg every 12 hr. *Maximum:* 300 mg daily.

Mechanism of Action

Achieves antiarrhythmic effect by inhibiting fast sodium channels of myocardial cell membranes, which increase myocardial recovery after repolarization, and by depressing the upstroke of the action potential. Flecainide also produces its antiarrhythmic effect by:

- slowing intracardiac conduction, which slightly increases the duration of the action potential in atrial and ventricular muscle, thus prolonging the PR interval, QRS complex, and QT interval
- shortening the action potential of Purkinje fibers without affecting surrounding myocardial tissue
- inhibiting extracellular calcium influx (at high doses)
- stopping paroxysmal reentrant supraventricular tachycardias by acting on antegrade pathways of dysfunctional AV conduction
- decreasing conduction in accessory pathways in those with Wolff-Parkinson-White syndrome.

Contraindications

Cardiogenic shock, hypersensitivity to flecainide or its components, recent MI, right bundle-branch block associated with left hemiblock or second- or third-degree AV block unless pacemaker is present

Interactions

DRUGS

amiodarone: Increased blood flecainide level

beta blockers, disopyramide, verapamil:

Possibly myocardial depression and increased blood levels of both drugs

calcium channel blockers: Increased risk of arrhythmias

digoxin: Possibly increased blood digoxin level

urinary acidifiers: Possibly increased flecainide elimination and decreased therapeutic effects

urinary alkalizers: Possibly decreased flecainide elimination and increased therapeutic effects

FOODS

acidic juices, foods that decrease urine pH

below 5.0: Increased flecainide elimination and decreased therapeutic effects

foods that increase urine pH above 7.0, strict

vegetarian diet: Decreased flecainide elimination and increased therapeutic effects

ACTIVITIES

smoking: Increased flecainide clearance

Adverse Reactions

CNS: Anxiety, depression, dizziness, drowsiness, fatigue, headache, light-headedness, tremor, weakness

CV: Arrhythmias, chest pain, heart failure, hypotension
EENT: Blurred vision
GI: Abdominal pain, anorexia, constipation, hepatic dysfunction, nausea, vomiting
RESP: Dyspnea
SKIN: Rash

Nursing Considerations

- Monitor urine pH at the start of flecainide therapy.
- Check blood pressure, fluid intake and output, and weight regularly during therapy.
- Monitor trough flecainide level, as needed; therapeutic level is 0.2 to 1 mcg/ml.
- Expect drug to cause mild to moderate negative inotropic effects, minimal cardiovascular effects, and no effect on blood pressure, heart rate, and left ventricular function.

WARNING Because hypokalemia or hyperkalemia may interfere with flecainide's therapeutic effects, monitor serum potassium level before and during therapy and notify prescriber immediately if potassium imbalance develops. Also monitor for and notify prescriber about prolonged PR interval, QRS complex, or QT interval; chest pain; hypotension; and signs of heart failure. Keep in mind that drug can cause fatal proarrhythmias, which is why it isn't considered a first-line antiarrhythmic.

- Expect prolonged flecainide therapy to raise blood alkaline phosphatase level.

PATIENT TEACHING

- Instruct patient to take flecainide at regular intervals to keep a constant blood level.
- Advise patient to take a missed dose as soon as she remembers if it's within 6 hours of the scheduled time.
- Teach patient how to take her pulse, and instruct her to record it daily, along with her weight. Advise her to bring record to follow-up visits.
- Encourage family members to obtain instruction in basic cardiac life support.
- Advise patient to notify prescriber immediately about chest pain, difficulty breathing, and dizziness.
- Caution patient not to stop taking flecainide suddenly but to taper dosage gradually according to prescriber's instructions.

fluconazole

Diflucan

Class and Category

Chemical class: Triazole derivative

Therapeutic class: Antifungal

Pregnancy category: C

Indications and Dosages

↗ *To treat oral and esophageal candidiasis*

ORAL SUSPENSION, TABLETS, I.V. INJECTION

Adults and adolescents. 200 mg on day 1 followed by 100 mg daily for at least 1 (oral) or 3 (esophageal) wk after symptoms resolve.

Children. 3 mg/kg daily for at least 2 (oral) or 3 (esophageal) wk and then for 2 wk after esophageal symptoms resolve.

↗ *To treat systemic candidiasis*

ORAL SUSPENSION, TABLETS, I.V. INJECTION

Adults and adolescents. 400 mg on day 1, followed by 200 mg daily for at least 4 wk and then for additional 2 wk after symptoms resolve.

↗ *To treat cryptococcal meningitis*

ORAL SUSPENSION, TABLETS, I.V. INJECTION

Adults and adolescents. 400 mg daily until patient responds to treatment, then 200 to 400 mg daily for 10 to 12 wk after CSF culture is negative. *Maintenance:* 200 mg daily to suppress relapse.

Children. 6 to 12 mg/kg daily for 10 to 12 wk after CSF culture is negative.

↗ *To prevent candidiasis after bone marrow transplantation*

ORAL SUSPENSION, TABLETS, I.V. INJECTION

Adults and adolescents. 400 mg daily starting several days before procedure if severe neutropenia is expected and continued for 7 days after absolute neutrophil count exceeds 1,000/mm³.

↗ *To treat vaginal candidiasis*

CAPSULES, ORAL SUSPENSION, TABLETS

Adults. 150 mg as a single dose.

DOSAGE ADJUSTMENT Dosage reduced for patients with hepatic or renal impairment. Dosage reduced by 50% for patients with creatinine clearance of 11 to 50 ml/min/1.73 m².

Mechanism of Action

Damages fungal cells by interfering with a cytochrome P-450 enzyme needed to con-

vert lanosterol to ergosterol, an essential part of the fungal cell membrane. Decreased ergosterol synthesis causes increased cell permeability, which allows cell contents to leak. Fluconazole also may inhibit endogenous respiration, interact with membrane phospholipids, inhibit transformation of yeasts to mycelial forms, inhibit purine uptake, and impair biosynthesis of triglycerides and phospholipids.

Incompatibilities

Don't add fluconazole to I.V. bag that contains any other drug.

Contraindications

Hypersensitivity to fluconazole or its components

Interactions

DRUGS

astemizole, terfenadine: Increased blood levels of these drugs

benzodiazepines (short-acting): Possibly increased benzodiazepine level and psychomotor effects

cimetidine: Decreased fluconazole level

cisapride: Possibly increased QT interval, leading to torsades de pointes

cyclosporine: Increased cyclosporine level
glipizide, glyburide, tolbutamide: Increased risk of hypoglycemia

hydrochlorothiazide: Increased fluconazole level from decreased excretion

isoniazid, rifampin: Decreased fluconazole effects

nonседating antihistamines: Increased blood antihistamine level, increased risk of cardiotoxicity

oral anticoagulants: Increased anticoagulant effects

phenytoin: Increased phenytoin level

rifabutin: Increased rifabutin level

theophylline: Increased theophylline level

zidovudine: Increased zidovudine level

Adverse Reactions

CNS: Chills, dizziness, drowsiness, fever, headache, seizures

CV: Prolonged QT interval, torsades de pointes

GI: Abdominal pain, anorexia, constipation, diarrhea, hepatic failure, nausea, vomiting

HEME: Agranulocytosis, leukopenia, thrombocytopenia

SKIN: Exfoliative dermatitis, photosensitiv-

ity, pruritus, rash

Other: Anaphylaxis, angioedema

Nursing Considerations

- Use fluconazole cautiously in patients with potentially proarrhythmic conditions because drug may prolong the QT interval, which can lead to life-threatening torsades de pointes.
- Expect to obtain BUN and serum creatinine levels and culture and sensitivity and liver function test results before therapy starts.
- Refrigerate, but don't freeze, fluconazole oral suspension. Shake well before administering.
- Discard I.V. solution that's cloudy or contains precipitate. Don't infuse more than 200 mg/hr or add supplemental drugs to infusion.
- Monitor hepatic and renal function periodically during therapy, and notify prescriber if you detect signs of dysfunction.
- Assess for rash every 8 hours during therapy, and notify prescriber if rash occurs.
- If patient receives an oral anticoagulant, monitor coagulation test results and assess patient for bleeding.
- Monitor patient for symptoms of overdose, such as hallucinations and paranoia. If they occur, provide supportive treatment, gastric lavage, and, possibly, hemodialysis, which can reduce blood fluconazole level by half after about 3 hours.

PATIENT TEACHING

- Instruct patient to take fluconazole tablets or oral suspension 30 minutes before or 2 hours after meals. Inform her that tablets may be crushed for easier swallowing if needed.
- Advise patient to complete entire course of therapy, even if she feels better.
- If patient takes an oral antidiabetic, urge her to monitor blood glucose level often because of increased risk of hypoglycemia.
- Alert patient that fluconazole may change the taste of food.
- Encourage patient to notify prescriber immediately about diarrhea, headache, nausea, rash, right-upper-quadrant abdominal pain, yellow skin or whites of eyes, or vomiting.
- Suggest that breast-feeding patient consult prescriber because breast-feeding may need to be stopped during therapy.

fludrocortisone acetate

Florinef

Class and Category

Chemical class: Glucocorticoid

Therapeutic class: Mineralocorticoid replacement

Pregnancy category: C

Indications and Dosages

↗ *To treat primary and secondary chronic adrenocortical insufficiency*

TABLETS

Adults and adolescents. *Usual:* 100 mcg daily. Dosage may range from 100 mcg three times/wk to 200 mcg daily.

Children. 50 to 100 mcg daily.

↗ *To treat salt-losing adrenogenital syndrome*

TABLETS

Adults. 100 to 200 mcg daily.

Children. 50 to 100 mcg daily.

DOSAGE ADJUSTMENT Dosage reduced to 50 mcg daily if transient hypertension develops during therapy.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	1–2 days

Mechanism of Action

Enhances sodium reabsorption, hydrogen and potassium excretion, and water retention by the distal renal tubules, much like aldosterone, an endogenous mineralocorticoid. In large doses, fludrocortisone can inhibit endogenous adrenocortical secretion, thymic activity, and pituitary corticotropin excretion. It also can promote glycogen deposits in the liver and induce a negative nitrogen balance when protein intake is deficient.

Contraindications

Hypersensitivity to fludrocortisone, adrenocorticoids, or their components; systemic fungal infections

Interactions

DRUGS

digoxin: Increased risk of digitalis toxicity and arrhythmias from hypokalemia
phenytoin, rifampin: Decreased fludrocorti-

sone effects

potassium-wasting drugs, such as loop diuretics and amphotericin B: Increased risk of severe hypokalemia

Adverse Reactions

CNS: Dizziness, headache, mental changes, seizures

CV: Arrhythmias, heart failure, hypertension, peripheral edema

EENT: Cataracts (with long-term use), increased intraocular pressure

ENDO: Adrenal insufficiency, growth suppression in children, hyperglycemia

GI: Anorexia, nausea, vomiting

GU: Menstrual irregularities

HEME: Easy bruising

MS: Arthralgia, muscle weakness, myalgia, osteoporosis (with long-term use), tendon contractures

SKIN: Acne, diaphoresis, rash, urticaria

Other: Hypokalemia, hypokalemic alkalosis, impaired wound healing, weight gain

Nursing Considerations

- Monitor blood pressure, fluid status, and serum electrolyte levels periodically during fludrocortisone therapy. Watch for signs of heart failure, including adventitious breath sounds, peripheral edema, and weight gain.
- Monitor for signs and symptoms of overdose, such as cardiomegaly, edema, excessive weight gain, hypertension, and hypokalemia. These effects usually subside a few days after therapy stops. Potassium supplementation may be needed.
- Notify prescriber if patient has dizziness, headache, hypertension, hypokalemia, signs of infection, or weight gain.

PATIENT TEACHING

- Instruct patient to take a missed dose of fludrocortisone as soon as she remembers if it's within 12 hours of scheduled time. Warn against double-dosing. Advise her to notify prescriber if she misses more than one dose or if nausea or vomiting prevents her from taking drug.
- Instruct patient to reduce dietary sodium and to eat more potassium-rich foods during therapy.
- Direct patient to weigh herself each morning before breakfast in clothes of similar weight and to notify prescriber if she gains more than 2 lb (0.9 kg) per day or 5 lb

- (2.3 kg) per week. Instruct her to monitor how tightly her rings and shoes fit.
- Advise patient to notify prescriber about stressful events, such as dental extractions, emotional upset, illness, surgery, and trauma; dosage increase may be required.
 - Instruct patient to notify prescriber about dizziness, fever, fluid retention, headache, joint pain, irregular heart rate, muscle weakness, or palpitations.
 - Inform patient that drug may delay wound healing.
 - Caution patient not to stop taking drug abruptly but to taper dosage gradually, as prescribed.
 - Urge patient to wear or carry medical identification that documents corticosteroid use.

flumazenil

Anexate (CAN), Romazicon

Class and Category

Chemical class: Imidazobenzodiazepine derivative

Therapeutic class: Benzodiazepine antidote
Pregnancy category: C

Indications and Dosages

↗ *To reverse sedation from benzodiazepine therapy*

I.V. INJECTION

Adults. 0.2 mg, repeated after 45 to 60 sec if response is inadequate and then repeated every 1 min, if needed. If sedation recurs, regimen is repeated every 20 min or more. *Maximum:* 1 mg over 5 min or 3 mg over 1 hr.

↗ *To reverse benzodiazepine toxicity or suspected overdose*

I.V. INJECTION

Adults. 0.2 mg followed by 0.3 mg 30 to 60 sec later if response is inadequate and then 0.5 mg repeated every 1 min. If sedation recurs, regimen is repeated every 20 min. *Maximum:* 3 mg in 1-hr period.

Mechanism of Action

Antagonizes CNS effects of benzodiazepines by competing for their binding sites.

Contraindications

Evidence of tricyclic antidepressant over-

dose; hypersensitivity to flumazenil, benzodiazepines, or their components; use of benzodiazepine to control intracranial pressure, status epilepticus, or a potentially life-threatening condition

Route	Onset	Peak	Duration
I.V.	1–2 min	6–10 min	Variable

Interactions

DRUGS

benzodiazepines: Benzodiazepine withdrawal symptoms, including seizures

nonbenzodiazepine agonists: Loss of effectiveness of these drugs

tetracyclic or tricyclic antidepressant overdose: High risk of seizures

FOODS

all foods: Increased flumazenil clearance (by half) with food ingestion during I.V. injection

Adverse Reactions

CNS: Agitation, anxiety, ataxia, confusion, dizziness, drowsiness, emotional lability, fatigue, headache, hypoesthesia, insomnia, paresthesia, re sedation, seizures, tremor, vertigo

CV: Hot flashes, hypertension, palpitations

EENT: Blurred vision, diplopia, dry mouth

GI: Nausea, vomiting

RESP: Dyspnea, hyperventilation, hypoventilation

SKIN: Diaphoresis, flushing, rash

Other: Injection site pain and thrombophlebitis

Nursing Considerations

- Use flumazenil cautiously in patients with cardiac disease. Assess for increased stress or anxiety from benzodiazepine withdrawal because patient's blood pressure may rise.

- Give flumazenil undiluted or diluted in a syringe with D₅W, normal saline solution, or lactated Ringer's solution. Administer over 15 to 30 seconds directly into tubing of a free-flowing compatible I.V. solution. Use a large vein, if possible, to minimize pain at site. Avoid extravasation because drug may irritate tissue.

- Be aware that drug may cause signs of benzodiazepine withdrawal in drug-dependent patient. Also, abrupt awakening from benzodiazepine overdose can cause

agitation, dysphoria, and increased adverse reactions.

- Be aware that benzodiazepine reversal may cause an anxiety or a panic attack for patient with a history of these episodes. Expect to adjust dosage carefully.
- Monitor patient for signs of re sedation and hypoventilation for at least 2 hours after giving flumazenil because drug has a short half-life. Be aware that patient shouldn't be discharged until the risk of re sedation has resolved.

PATIENT TEACHING

- Caution patient to avoid alcohol and OTC drugs for 10 to 24 hours after taking drug.
- Advise patient to avoid hazardous activities for 18 to 24 hours after discharge.
- Inform patient and family that agitation, emotional lability, fear, and panic attack (if patient has a history of them) may occur. Tell them to seek medical care if patient has depression, trouble breathing, flushing, hyperventilation, insomnia, palpitations, or tremor.
- Because drug doesn't always reverse post-procedure amnesia, provide written instructions or instructions to caregiver even if patient is alert.

flunisolide

AeroBid, AeroBid-M, Bronalide (CAN), Nasalide, Nasarel, Rhinalar (CAN)

Class and Category

Chemical class: Corticosteroid

Therapeutic class: Antiasthmatic, anti-inflammatory

Pregnancy category: C

Indications and Dosages

↗ *To provide maintenance treatment of asthma, alone or with oral corticosteroids*

INHALATION AEROSOL

Adults and adolescents age 15 and over.

500 mcg (2 inhalations) b.i.d. morning and evening. *Maximum:* 2,000 mcg daily (4 inhalations b.i.d.).

Children ages 6 to 15. 500 mcg (2 inhalations) b.i.d. *Maximum:* 1,000 mcg daily.

↗ *To relieve symptoms of seasonal or perennial rhinitis*

NASAL SOLUTION

Adults. 50 mcg (2 sprays) b.i.d. in each nos-

tril. *Maximum:* 400 mcg daily (16 sprays).

Children. 25 mcg (1 spray) t.i.d. in each nostril. *Maximum:* 200 mcg daily (8 sprays).

Route	Onset	Peak	Duration
Inhalation	In 4 wk	Unknown	Unknown
Nasal	3–7 days	Unknown	4–6 hr

Mechanism of Action

Inhibits cells involved in inflammatory response, such as mast cells, eosinophils, basophils, lymphocytes, macrophages, and neutrophils. Also inhibits production of chemical mediators, such as histamine, eicosanoids, leukotrienes, and cytokines.

Contraindications

Hypersensitivity to flunisolide or its components, primary treatment of status asthmaticus or other asthma episodes that require emergency care, recent nasal surgery (nasal form), untreated localized infection of nasal mucosa (nasal form)

Adverse Reactions

CNS: Anxiety, chills, depression, dizziness, headache, hyperactivity, insomnia, irritability, lethargy, mood changes, nervousness, tremor, vertigo

CV: Hypertension

EENT: Candidiasis (oral and throat), dry mouth and throat, earache, eye infection, hoarseness, loss of smell or taste, mouth irritation, pharyngitis, rhinitis, sinusitis, sneezing

GI: Abdominal pain, anorexia, constipation, diarrhea, flatulence, heartburn, increased appetite, indigestion, nausea, vomiting

GU: Menstrual irregularities

HEME: Eosinophilia

RESP: Bronchitis, dyspnea, pleurisy, pneumonia

SKIN: Acne, eczema, pruritus, rash, urticaria

Other: Growth suppression (children), lymphadenopathy

Nursing Considerations

- Use flunisolide cautiously in patients with ocular herpes simplex, pulmonary tuberculosis, or untreated systemic bacterial, fungal, parasitic, or viral infection.
- If patient receives an oral corticosteroid, expect to taper it slowly 1 week after changing to flunisolide. For patient who

receives prednisone, expect to reduce it by no more than 2.5 mg daily at weekly intervals, beginning at least 1 week after flunisolide therapy starts.

WARNING Assess patient switched from systemic corticosteroid to flunisolide for adrenal insufficiency (fatigue, hypotension, lassitude, nausea, vomiting, weakness) during initial treatment and during stress, trauma, surgery, infection, or other electrolyte-depleting conditions. Notify prescriber immediately if signs or symptoms arise.

- Monitor growth in children; corticosteroids may increase risk of growth suppression.

PATIENT TEACHING

- Teach patient how to use inhaler. When starting a new canister, advise spraying once into the air (avoiding her eyes) to check for mist.
 - Instruct patient to gargle or rinse after each use of flunisolide to help prevent mouth and throat dryness, relieve throat irritation, and prevent oropharyngeal infection.
 - Urge patient to contact prescriber if symptoms haven't improved after 3 weeks.
- WARNING** Caution patient not to use flunisolide to relieve acute bronchospasm.
- If patient switches from an oral corticosteroid to flunisolide, advise her to carry medical identification indicating the need for supplemental systemic corticosteroids during stress or severe asthma attack. Advise her to ask prescriber how to respond to these problems.
 - Caution patient to avoid exposure to chickenpox and measles and to contact prescriber immediately if exposure occurs.

fluoxetine hydrochloride

Prozac, Prozac Weekly, Sarafem

Class and Category

Chemical class: Phenylpropylamine derivative

Therapeutic class: Antibulimic, antidepressant, antiobsessive-compulsive

Pregnancy category: C

Indications and Dosages

↗ *To treat depression*

CAPSULES, ORAL SOLUTION, TABLETS (PROZAC)

Adults. *Initial:* 20 mg daily in the morning. Dosage increased every 4 to 8 wk as needed. Dosage greater than 20 mg daily given b.i.d. morning and noon. *Maximum:* 80 mg daily.

Children and adolescents. *Initial:* 10 mg daily. Increased after 1 wk to 20 mg daily.

DOSAGE ADJUSTMENT For lower-weight children, dosage increased to 20 mg daily only if improvement insufficient after several wk.

DELAYED-RELEASE CAPSULES (PROZAC WEEKLY)

Adults. 90 mg/wk, beginning 7 days after last 20-mg daily dose.

↗ *To treat obsessive-compulsive disorder*

CAPSULES, ORAL SOLUTION, TABLETS (PROZAC)

Adults. *Initial:* 20 mg daily in the morning. Dosage increased every 4 to 8 wk as needed. Dosage greater than 20 mg daily given b.i.d. morning and noon. *Maximum:* 80 mg daily.

Children and adolescents. *Initial:* 10 mg daily. Dosage increased after 2 wk to 20 mg daily. Subsequent dosage increased, as needed, at intervals of at least several wk.

Maintenance: 20 to 60 mg daily.

DOSAGE ADJUSTMENT For lower-weight children, dosage should be increased above 10 mg daily only if clinical improvement remains insufficient after several wk. Maintenance dosage for such patients should not exceed 30 mg daily.

↗ *To treat moderate to severe bulimia nervosa*

CAPSULES, ORAL SOLUTION, TABLETS (PROZAC)

Adults. 60 mg daily in the morning. Some patients may be prescribed a lower dose, which is titrated to 60 mg daily as tolerated.

↗ *To treat panic disorder with or without agoraphobia*

CAPSULES, ORAL SOLUTION, TABLETS (PROZAC)

Adults. *Initial:* 10 mg daily. Dosage increased in 1 wk to 20 mg daily, as needed. *Maximum:* 60 mg daily.

↗ *To treat premenstrual dysmorphic disorder*

CAPSULES (SARAFEM)

Adults. 20 mg daily. Dosage increased as needed. *Maximum:* 80 mg daily.

DOSAGE ADJUSTMENT Dose or frequency reduced for patients with hepatic impair-

ment or concurrent illness, those who take multiple medications, and for elderly patients.

Route	Onset	Peak	Duration
P.O.*	1–6 wk†	Unknown	Unknown

Mechanism of Action

Selectively inhibits reuptake of the neurotransmitter serotonin by CNS neurons and increases the amount of serotonin available in nerve synapses. An elevated serotonin level may result in elevated mood and, consequently, reduced depression.

Contraindications

Hypersensitivity to selective serotonin reuptake inhibitors or their components, use within 14 days of MAO inhibitor therapy

Interactions

DRUGS

alprazolam, diazepam: Possibly prolonged half-life of these drugs
aspirin, NSAIDs, warfarin: Increased anti-coagulant activity and risk of bleeding
astemizole: Increased risk of serious arrhythmias
bupirone: Decreased bupirone effects
clozapine, fluphenazine, haloperidol, maprotiline, trazodone: Increased risk of adverse effects
CYP2D6-metabolized drugs, such as antiarrhythmics (especially flecainide, propafenone), selected antidepressants (tricyclics), antipsychotics (phenothiazines and most atypicals), thioridazine, and vinblastine: Increased plasma levels of these drugs and increased risk of serious adverse reactions
linezolid, lithium, serotonergics (such as amphetamines and other psychostimulants, antidepressants, and dopamine agonists), St. John’s wort, tramadol, triptans: Increased risk of serotonin syndrome
MAO inhibitors: Possibly severe and life-threatening adverse effects
phenytoin: Increased blood phenytoin level and risk of toxicity
pimozide: Possibly bradycardia
sumatriptan: Increased risk of weakness, hyperreflexia, and difficulty with coordina-

tion

tryptophan: Increased risk of central and peripheral toxicity

Adverse Reactions

CNS: Anxiety, chills, dream disturbances, drowsiness, fatigue, fever, headache, hypomania, insomnia, mania, nervousness, neuroleptic malignant syndrome, restlessness, seizures, serotonin syndrome, somnolence, suicidal ideation, tremor, vertigo, weakness, yawning
CV: Hypotension, palpitations
EENT: Abnormal vision, dry mouth, pharyngitis, sinusitis
ENDO: Galactorrhea, gynecomastia, hypoglycemia, syndrome of inappropriate antidiuretic hormone secretion (SIADH)
GI: Anorexia, diarrhea, indigestion, nausea
GU: Decreased libido, ejaculation disorders, impotence
HEME: Altered platelet function, unusual bleeding
MS: Arthralgia, myalgia
RESP: Dyspnea
SKIN: Diaphoresis, pruritus, rash, urticaria
Other: Flulike symptoms, hyponatremia, weight loss

Nursing Considerations

- Use fluoxetine cautiously in patients with a history of seizures.
- **WARNING** Avoid giving fluoxetine within 14 days of an MAO inhibitor or starting MAO inhibitor therapy within 5 weeks of discontinuing fluoxetine.
- In patients taking fluoxetine for depression (especially children, adolescents, and young adults), watch closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during those times.
- Monitor patient closely for evidence of GI bleeding, especially if patient takes another drug known to increase the risk, such as aspirin, an NSAID, or warfarin.
- Monitor patient—especially an elderly patient—for hyposmolarity of serum and urine and for hyponatremia (headache, difficulty concentrating, memory impairment, weakness, unsteadiness), which may indicate fluoxetine-induced SIADH.
- To discontinue, expect to taper drug, as ordered, to minimize adverse reactions.

* Capsules, oral solution, and tablets.
 † For depression and bulimia; 5 wk for obsessive-compulsive disorder.

WARNING Monitor patient for possible serotonin syndrome, characterized by agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching, especially if patient is receiving another drug that raises serotonin level (such as dopamine agonist, MAO inhibitor, tryptophan, amphetamine, and other antidepressant or psychostimulant). In its most severe form, serotonin syndrome can resemble neuroleptic malignant syndrome, which includes a high fever, muscle rigidity, autonomic instability, and possible fluctuations in vital signs and mental status.

- Monitor patient with diabetes mellitus for altered blood glucose level because drug may cause hypoglycemia during therapy and hyperglycemia when it stops. Expect to adjust dosage of antidiabetic drug, as prescribed.
- Expect patient to be reevaluated periodically to determine continued need for therapy.
- When stopping fluoxetine therapy, expect to taper drug to minimize adverse reactions.

PATIENT TEACHING

WARNING Tell patient that drug increases risk of serotonin syndrome, a rare but serious complication, especially when taken with certain other drugs. Teach patient to recognize its signs and symptoms, and advise her to notify prescriber immediately if they occur.

- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.
- Caution patient to avoid hazardous activities until CNS effects of drug are known.
- Caution against stopping fluoxetine abruptly because serious adverse effects may result.
- Advise patient to consult prescriber before taking OTC or prescription drugs, if a rash or hives develop, or if she becomes or intends to become pregnant during therapy.
- Inform patient that drug may take several weeks to achieve full effects.

fluphenazine decanoate

Modecate (CAN), Modecate Concentrate (CAN), Prolixin Decanoate

fluphenazine enanthate

Moditen Enanthate (CAN), Prolixin Enanthate

fluphenazine hydrochloride

Apo-Fluphenazine (CAN), Moditen HCl (CAN), Permitil, Permitil Concentrate, PMS Fluphenazine (CAN), Prolixin, Prolixin Concentrate

Class and Category

Chemical class: Phenothiazine, propylpiperazine derivative
Therapeutic class: Antipsychotic
Pregnancy category: Not rated

Indications and Dosages

↗ *To control psychotic disorders*

ELIXIR, ORAL SOLUTION, TABLETS (FLUPHENAZINE HYDROCHLORIDE)

Adults and adolescents. *Initial:* 2.5 to 10 mg/day in divided doses every 6 to 8 hr. When symptoms are controlled, dosage reduced to 1 to 5 mg daily. *Maximum:* 20 mg/dose with caution.

Children. 250 to 750 mcg once daily to q.i.d.

I.M. INJECTION (FLUPHENAZINE HYDROCHLORIDE)

Adults and adolescents. *Initial:* 1.25 mg, increased as clinical condition tolerates up to 2.5 to 10 mg daily in divided doses every 6 to 8 hr. *Maximum:* 10 mg daily.

DOSAGE ADJUSTMENT For elderly or debilitated patients, dosage reduced to 1 to 2.5 mg daily in divided doses every 6 to 8 hr.

I.M. OR SUBCUTANEOUS INJECTION (FLUPHENAZINE DECANOATE OR ENANTHATE)

Adults. *Initial:* 12.5 to 25 mg every 1 to 4 wk, as needed (decanoate). For doses over 50 mg, next dose increased cautiously by 12.5 mg. Or 25 mg every 2 wk, with dose and dosing interval adjusted based on patient response (enanthate). *Maximum:* 100 mg/dose.

Adolescents and children age 12. *Initial:* 6.25 to 18.75 mg/wk (decanoate), increased to 12.5 to 25 mg every 1 to 3 wk, according to condition.

Children ages 5 to 12. 3.125 to 12.5 mg every 1 to 3 wk (decanoate), according to condition.

Route	Onset	Peak	Duration
P.O.	In 1 hr	Variable	6–8 hr
I.M.*	In 1 hr	Variable	6–8 hr
I.M., SubQ†	In 24– 72 hr	Variable	1–6 wk‡

Mechanism of Action

May block postsynaptic dopamine receptor sites in the CNS. This action may depress areas of the brain that control activity and aggression, including the cerebral cortex, hypothalamus, and limbic system.

Incompatibilities

Don't mix fluphenazine hydrochloride oral solution with beverages that contain caffeine, such as coffee and cola; tannins, such as tea; or pectins, such as apple juice. They're physically incompatible.

Contraindications

Blood dyscrasias, bone marrow depression, cerebral arteriosclerosis, coma, concomitant use of large amounts of another CNS depressant, coronary artery disease, hepatic dysfunction, hypersensitivity to phenothiazines, myeloproliferative disorders, severe CNS depression, severe hypertension or hypotension, subcortical brain damage

Interactions

DRUGS

adsorbent antidiarrheals, aluminum- or magnesium-containing antacids: Possibly inhibited absorption of fluphenazine
amantadine, anticholinergics: Possibly intensified adverse effects of both drugs
amphetamines: Possibly decreased therapeutic effects of both drugs
antihypertensives: Possibly severe hypotension
antithyroid drugs: Increased risk of agranulocytosis

* For hydrochloride.

† For decanoate and enanthate.

‡ For decanoate; 2 wk for enanthate.

beta blockers: Possibly increased blood levels and risk of adverse effects of both drugs
bromocriptine: Decreased bromocriptine effects

CNS depressants: Possibly prolonged and intensified CNS depression

erythromycin: Possibly inhibited fluphenazine metabolism

guanethidine: Decreased hypotensive effect of guanethidine

levodopa: Possibly decreased antidyskinetic effect of levodopa

lithium: Possibly neurotoxicity (disorientation, extrapyramidal reactions, unconsciousness)

mepiridine: Excessive sedation and hypotension

metrizamide: Increased risk of seizures when injected in subarachnoid area during fluphenazine therapy

oral anticoagulants: Possibly decreased anticoagulant effects

pimozide, other drugs that prolong QT interval: Prolonged QT interval and risk of arrhythmias

thiazide diuretics: Increased risk of hyponatremia, hypotension, and water intoxication

tricyclic antidepressants: Possibly prolonged and intensified sedation

ACTIVITIES

alcohol use: Possibly increased CNS depression and increased risk of heatstroke

Adverse Reactions

CNS: Ataxia, cerebral edema, dizziness, drowsiness, headache, insomnia, light-headedness, nervousness, seizures, slurred speech, syncope, worsening psychotic symptoms

CV: AV conduction disorders, bradycardia, cardiac arrest, hypercholesterolemia, hypertension, orthostatic hypotension, QT-interval prolongation, shock, ST-segment depression, tachycardia

EENT: Blurred vision, dry mouth, glaucoma, increased salivation, laryngeal edema, laryngospasm, miosis, mydriasis, nasal congestion, papillary hypertrophy of the tongue, parotid gland enlargement, photophobia, pigmentary retinopathy, ptosis

ENDO: Breast engorgement (females), galactorrhea, hyperglycemia, hypoglycemia, mastalgia, syndrome of inappropriate ADH secretion

GI: Anorexia, constipation, diarrhea, fecal impaction, ileus, increased appetite, nausea, vomiting

GU: Amenorrhea, bladder paralysis, decreased libido, enuresis, menstrual irregularities, polyuria, urinary frequency, urinary incontinence, urine retention

HEME: Anemia, aplastic anemia, eosinophilia, leukopenia, thrombocytopenia, thrombocytopenic or nonthrombocytopenic purpura

RESP: Bronchospasm, dyspnea, increased respiratory depth

SKIN: Contact dermatitis, dry skin, eczema, erythema, jaundice, photosensitivity, pruritus, seborrhea

Other: Heatstroke, hyponatremia, lupuslike symptoms, weight gain

Nursing Considerations

- Fluphenazine shouldn't be used to treat dementia-related psychosis in elderly patients because of an increased mortality risk.
- Use fluphenazine cautiously in patients with a history of glaucoma or renal impairment.
- For I.M. and subcutaneous injection, use at least a 21G needle.
- Monitor temperature; a significant, unexplained rise can indicate intolerance and a need to discontinue drug. Notify prescriber immediately if this occurs.
- Watch for signs of hepatic failure, such as jaundice.
- Notify prescriber about worsening psychotic symptoms: agitation, catatonic state, confusion, depression, hallucinations, lethargy, paranoid reactions.

PATIENT TEACHING

- If patient takes elixir form of fluphenazine, instruct her to keep it in an amber or opaque bottle because drug is sensitive to light.
- Advise patient not to mix oral solution with beverages that contain caffeine (coffee, cola), tannins (tea), or pectins (apple juice).
- Caution patient about possible dizziness or light-headedness.
- Teach patient how to prevent heatstroke, orthostatic hypotension, and photosensitivity reactions.
- Warn against stopping drug abruptly.

flurazepam hydrochloride

Apo-Flurazepam (CAN), Dalmane, Novo-Flupam (CAN), Somnol (CAN)

Class, Category, and Schedule

Chemical class: Benzodiazepine

Therapeutic class: Sedative-hypnotic

Pregnancy category: Not rated

Controlled substance schedule: IV

Indications and Dosages

↗ *To treat insomnia characterized by difficulty falling asleep, frequent nocturnal awakenings, or early-morning awakening*

CAPSULES

Adults. 15 to 30 mg at bedtime.

DOSSAGE ADJUSTMENT Initial dose reduced to 15 mg for elderly or debilitated patients until individual response is known.

Route	Onset	Peak	Duration
P.O.	15–45 min	Unknown	7–8 hr

Mechanism of Action

May potentiate the effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptor sites in the limbic and cortical areas of the CNS. As a result, flurazepam increases GABA's inhibitory effects and blocks cortical and limbic arousal.

Contraindications

Acute angle-closure glaucoma, breast-feeding, hypersensitivity to other benzodiazepines, itraconazole or ketoconazole therapy, psychosis

Interactions

DRUGS

cimetidine, diltiazem, disulfiram, erythromycin, fluoxetine, fluvoxamine, itraconazole, nefazodone, estrogen-containing oral contraceptives, propoxyphene, ranitidine, verapamil: Possibly increased blood level and impaired hepatic metabolism of flurazepam
clozapine: Possibly cardiac arrest or respiratory depression
CNS depressants: Possibly potentiated CNS

depression

levodopa: Possibly decreased therapeutic effects of levodopa

FOODS

grapefruit juice: Possibly increased blood level and impaired hepatic metabolism of flurazepam

ACTIVITIES

alcohol use: Possibly potentiated CNS and respiratory depression

Adverse Reactions

CNS: Amnesia, anxiety, ataxia, bizarre behavior (such as sleep driving), confusion, delusions, depression, dizziness, drowsiness, euphoria, headache, hypokinesia, irritability, malaise, nervousness, slurred speech, tremor

CV: Chest pain, palpitations, tachycardia

EENT: Blurred vision, dry mouth, increased salivation, photophobia

GI: Abdominal pain, constipation, diarrhea, nausea, thirst, vomiting

GU: Libido changes

SKIN: Diaphoresis

Other: Anaphylaxis, angioedema, physical or psychological dependence

Nursing Considerations

- Use flurazepam cautiously in patients with severe mental depression or reduced respiratory function; drug may intensify mental depression and lead to respiratory depression.
- Expect to use lowest effective dose in elderly or debilitated patients to minimize the risk of ataxia, confusion, dizziness, and oversedation.
- Monitor liver function test results, as appropriate.

PATIENT TEACHING

• Instruct patient not to exceed prescribed dosage and not to stop drug abruptly.

WARNING Warn patient that, although rare, drug may cause swelling of the oral cavity or throat, which could cause airway obstruction. If swelling occurs, patient should seek emergency care immediately and never take flurazepam again.

- Caution patient about possible morning dizziness or drowsiness.
- Because flurazepam can reduce alertness, advise patient to avoid hazardous activities until drug's CNS effects are known.
- Caution patient to avoid alcohol and CNS

depressants during therapy.

- Advise patient to notify prescriber if she becomes or intends to become pregnant during therapy.
- Inform patient that sleep may be disturbed for the first few nights after stopping drug.
- Warn patient and caregiver that some patients have performed bizarre activities after taking drug, such as driving their car, preparing and eating food, making phone calls, or having sex while not fully awake and often with no memory of the event. These episodes usually occur in patients who have taken the drug with alcohol or other CNS depressant or who have exceeded the recommended dose. If such an episode occurs, the prescriber should be notified and flurazepam therapy discontinued immediately.

flurbiprofen

Ansaid, Froben (CAN), Froben SR (CAN), Novo-Flurprofen (CAN)

Class and Category

Chemical class: Propionic acid derivative

Therapeutic class: Antiarthritis, anti-inflammatory

Pregnancy category: B (first trimester), Not rated (later trimesters)

Indications and Dosages

↗ *To treat acute or chronic rheumatoid arthritis and osteoarthritis*

E.R. CAPSULES

Adults. 200 mg daily in the evening.

TABLETS

Adults. *Initial*: 200 to 300 mg daily in divided doses b.i.d. to q.i.d. *Maximum*: 300 mg daily (100 mg/dose).

Mechanism of Action

Blocks the activity of cyclooxygenase, the enzyme necessary for prostaglandin synthesis. Prostaglandins, important mediators in the inflammatory response, cause local vasodilation with swelling and pain. They also play a role in pain transmission from the periphery to the spinal cord. By blocking cyclooxygenase and inhibiting prostaglandins, this NSAID causes inflammatory symptoms and pain to subside.

Contraindications

Angioedema, asthma, bronchospasm, nasal polyps, rhinitis, or urticaria induced by aspirin, iodides, or NSAIDs; hypersensitivity to NSAIDs

Interactions

DRUGS

acetaminophen: Increased risk of renal impairment with long-term use of both drugs

antacids: Decreased flurbiprofen effectiveness
anticoagulants, cefamandole, cefoperazone, cefotetan, heparin, plicamycin, thrombolytics, valproic acid: Increased risk of bleeding

antineoplastics: Increased adverse hematologic effects

cyclosporine: Increased risk of nephrotoxicity
diuretics, triamterene: Decreased effectiveness of these drugs

glucocorticoids, other NSAIDs, potassium supplements: Increased adverse GI effects

insulin, oral antidiabetic drugs: Increased risk of hypoglycemia

lithium: Increased risk of lithium toxicity

methotrexate: Increased risk of methotrexate toxicity

salicylates: Increased risk of GI bleeding

ACTIVITIES

alcohol use, smoking: Increased risk of GI bleeding

Adverse Reactions

CNS: Anxiety, cerebral hemorrhage, depression, dizziness, drowsiness, forgetfulness, headache, insomnia, malaise, nervousness, stroke, tremor, weakness

CV: Arrhythmias, heart failure, hypertension, hypotension, palpitations, peripheral edema, tachycardia

EENT: Amblyopia, blurred vision, rhinitis, stomatitis, tinnitus, vision changes

GI: Abdominal cramps or distress, anorexia, constipation, diarrhea, diverticulitis, dysphagia, esophagitis, flatulence, gastritis, gastroenteritis, gastroesophageal reflux disease, GI bleeding or ulceration, hemorrhoids, hiatal hernia, hepatitis, increased appetite, indigestion, jaundice, liver failure, melena, nausea, perforation of stomach or intestines, stomatitis, vomiting

GU: Hematuria, interstitial nephritis, renal failure, UTI

HEME: Agranulocytosis, aplastic anemia, eosinophilia, leukopenia, neutropenia, pan-

cytopenia, thrombocytopenia

SKIN: Erythema multiforme, exfoliative dermatitis, flushing, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Other: Anaphylaxis, angioedema, hyponatremia

Nursing Considerations

- Use flurbiprofen with extreme caution in patients who have a history of ulcer disease or GI bleeding because NSAIDs such as flurbiprofen increase the risk of GI bleeding and ulceration. Expect to use flurbiprofen for the shortest time possible in these patients.
- Be aware that serious GI tract ulceration, bleeding, and perforation may occur without warning signs or symptoms. Elderly patients are at greater risk. To minimize the risk, give flurbiprofen with food. If GI distress occurs, withhold drug and notify prescriber immediately.
- Use flurbiprofen cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

WARNING Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

- Monitor patient—especially if she's elderly or receiving long-term flurbiprofen therapy—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver function test results because, rarely, elevations may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure.
- Monitor BUN and serum creatinine levels in elderly patients, patients taking diuretics or ACE inhibitors, and patients with heart failure, impaired renal function, or hepatic dysfunction; flurbiprofen may cause renal failure.
- Monitor CBC for decreased hemoglobin and hematocrit because drug may worsen anemia.

WARNING If patient has bone marrow suppression or is receiving an antineoplastic drug, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory

and antipyretic actions of flurbiprofen may mask signs and symptoms, such as fever and pain.

- Assess patient's skin regularly for signs of rash or other hypersensitivity reaction because flurbiprofen is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID sensitivity. At first sign of reaction, stop drug and notify prescriber.

PATIENT TEACHING

- Encourage patient to take flurbiprofen with food or milk to avoid GI distress.
- Caution patient about possible blurred vision, dizziness, and drowsiness.
- Advise patient to avoid aspirin, alcohol, and smoking during flurbiprofen therapy.
- Urge patient to notify prescriber immediately if she has blood in urine, easy bruising, itching, rash, swelling, or yellow eyes or skin.
- Caution pregnant patient not to take NSAIDs such as flurbiprofen during the last trimester because they may cause premature closure of the ductus arteriosus.
- Explain that flurbiprofen may increase the risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, weakness, and slurring of speech.
- Explain that flurbiprofen may increase the risk of serious adverse GI reactions; stress the importance of seeking immediate medical attention for such signs and symptoms as epigastric or abdominal pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions. Urge her to seek immediate medical attention for rash, blisters, itching, fever, or other indications of hypersensitivity.

fluticasone propionate

Flonase, Flovent

fluticasone furoate

Veramyst

Class and Category

Chemical class: Trifluorinated corticosteroid

Therapeutic class: Antiasthmatic, anti-inflammatory

Pregnancy category: C

Indications and Dosages

➤ *To prevent asthma attacks, alone or with oral corticosteroids*

INHALATION AEROSOL

Adults and children age 12 and over using bronchodilator therapy. *Initial:* 88 mcg inhaled b.i.d. *Maximum:* 440 mcg inhaled b.i.d.

Adults and children age 12 and over switching from another inhaled corticosteroid. *Initial:* 88 to 220 mcg inhaled b.i.d. *Maximum:* 440 mcg inhaled b.i.d.

Adults and children age 12 and over using oral corticosteroid therapy. *Initial and maximum:* 880 mcg inhaled b.i.d.

Children ages 4 to 11 regardless of previous therapy. 88 mcg b.i.d. *Maximum:* 88 mcg b.i.d.

➤ *To prevent seasonal or perennial allergic rhinitis*

NASAL SUSPENSION (FLONASE)

Adults and children age 12 and over.

Initial: 100 mcg (2 sprays) in each nostril daily or 50 mcg (1 spray) in each nostril b.i.d, as needed. *Maintenance:* 50 mcg (1 spray) in each nostril daily, as tolerated and needed. *Maximum:* 200 mcg daily (4 sprays).

Children ages 4 to 11. 50 or 100 mcg (1 or 2 sprays) in each nostril daily in the morning, as needed. *Maximum:* 200 mcg daily (4 sprays).

➤ *To treat seasonal or perennial allergic rhinitis*

NASAL SUSPENSION (FLONASE)

Adults and children age 12 and over.

Initial: 100 mcg (2 sprays) in each nostril daily or 50 mcg (1 spray) in each nostril b.i.d, as needed. *Maintenance:* 50 mcg (1 spray) in each nostril daily, as tolerated and needed. *Maximum:* 200 mcg daily (4 sprays).

Children ages 4 to 11. 50 or 100 mcg (1 or 2 sprays) in each nostril daily in the morning, as needed. *Maximum:* 200 mcg daily (4 sprays).

NASAL SUSPENSION (VERAMYST)

Adults and children age 12 and over.

Initial: 110 mcg (2 sprays) in each nostril once daily, decreased to 55 mcg (1 spray) in each nostril once daily when symptoms are controlled. **Maintenance:** 55 mcg (1 spray) in each nostril once daily.

Children ages 2 to 11. **Initial:** 55 mcg (1 spray) in each nostril once daily, increased to 110 mcg (2 sprays) in each nostril once daily, as needed. **Maintenance:** 55 mcg (1 spray) in each nostril once daily.

Route	Onset	Peak	Duration
Inhalation	In 24 hr	1–2 wk	Several days
Nasal	12 hr–3 days	4–7 days	1–2 wk

Mechanism of Action

Inhibits cells involved in the inflammatory response of asthma, such as mast cells, eosinophils, basophils, lymphocytes, macrophages, and neutrophils. Fluticasone also inhibits production or secretion of chemical mediators, such as histamine, eicosanoids, leukotrienes, and cytokines.

Contraindications

Hypersensitivity to fluticasone or its components, primary treatment of status asthmaticus or other acute asthma episodes that require intensive measures, untreated nasal mucosal infection (nasal suspension)

Interactions

DRUGS

ketconazole, ritonavir and other strong cytochrome P-450 3A4 inhibitors (long-term use): Possibly increased fluticasone level and decreased serum cortisol level

Adverse Reactions

CNS: Aggressiveness, agitation, depression, difficulty speaking, dizziness, fatigue, fever, headache, insomnia, malaise, restlessness
EENT: Allergic rhinitis, cataracts, conjunctivitis, dry mouth and throat, eye irritation, glaucoma, hoarseness, laryngitis, loss of voice, nasal congestion or discharge, nasal sinus pain, oropharyngeal candidiasis, otitis media, pharyngitis, sinusitis, throat irritation, tonsillitis

ENDO: Adrenal insufficiency, cushingoid symptoms, hyperglycemia, slower growth in children

GI: Abdominal pain, diarrhea, indigestion,

nausea, vomiting

GU: Dysmenorrhea

HEME: Churg-Strauss syndrome, easy bruising, eosinophilia

MS: Arthralgia, myalgia, osteoporosis

RESP: Asthma exacerbation, bronchitis, bronchospasm, chest congestion and tightness, cough, dyspnea, pneumonia, upper respiratory tract infection, wheezing

SKIN: Dermatitis, ecchymosis, pruritus, rash, urticaria

Other: Anaphylaxis, angioedema, flulike symptoms, weight gain

Nursing Considerations

- Use fluticasone cautiously in patients with ocular herpes simplex, pulmonary tuberculosis, or untreated systemic bacterial, fungal, parasitic, or viral infection.
- Although anaphylaxis is rare, monitor patient closely at start of therapy, especially if patient has severe allergy to milk. If hypersensitivity reaction occurs, notify prescriber, expect drug to be discontinued, and provide supportive care, as prescribed.
- If patient takes a systemic corticosteroid, expect to taper dosage by no more than 2.5 mg daily at weekly intervals, starting 1 week after fluticasone therapy begins.

WARNING If patient is switched from systemic corticosteroid to fluticasone, assess for adrenal insufficiency (fatigue, hypotension, lassitude, nausea, vomiting, weakness) early in therapy and when patient has infection, stress, trauma, surgery, or other electrolyte-depleting conditions or procedures. Notify prescriber immediately if signs or symptoms develop.

- As prescribed, administer a fast-acting inhaled bronchodilator if bronchospasm occurs immediately after fluticasone use. Expect to stop fluticasone and start another drug therapy.
- Expect to titrate fluticasone to lowest effective dosage after asthma has stabilized.

PATIENT TEACHING

- Urge patient to use fluticasone regularly, as prescribed, not for acute bronchospasm.
- Teach patient how to administer drug according to the form prescribed (nasal spray or oral inhaler).
- Instruct patient to shake canister and use inhaler according to package instructions. On first use, advise her to spray 4 times

into the air (away from her eyes and shaking inhaler between each test spray) and look for a fine mist. If inhaler hasn't been used for more than 7 days or it's dropped, it will need to be primed again by shaking well and then releasing 1 test spray into the air (away from her face).

- If 2 inhalations are prescribed, tell patient to wait at least 1 minute between them.
- Instruct patient to gargle and rinse her mouth after each dose to help prevent dry mouth and throat, relieve throat irritation, and prevent oropharyngeal yeast infection.
- If patient uses more than 1 inhaler, instruct her to use fluticasone last, at least 5 minutes after previous inhaler.
- Instruct patient to clean inhaler according to manufacturer guidelines at least once a week after her evening dose.
- Inform patient that, when counter reads 020, she should obtain a refill, if needed. When counter reaches 000, she should discard the inhaler.
- Instruct patient using nasal spray to shake container well before each use.
- Explain that symptoms may improve within 2 days but that full improvement may not occur for 1 to 2 weeks or longer.
- Caution patient not to increase dosage but to contact prescriber after 1 week if symptoms continue or worsen.
- Urge patient to tell prescriber immediately if asthma attacks don't respond to bronchodilators during fluticasone therapy.
- If patient is switching from an oral corticosteroid to fluticasone, urge her to carry medical identification indicating the need for supplemental systemic corticosteroids during stress or severe asthma attack.
- Caution patient to avoid people who have infections because fluticasone suppresses the immune system, increasing the risk of infection. Instruct patient to notify prescriber about exposure to chickenpox, measles, or other infections because additional treatment may be needed.

fluvastatin sodium

Lescol, Lescol XL

Class and Category

Chemical class: Heptenoic acid derivative

Therapeutic class: Antihyperlipidemic
Pregnancy category: X

Indications and Dosages

➤ *As adjunct to lower cholesterol level in primary hypercholesterolemia, to decrease progression of coronary atherosclerosis, to reduce risk in patients with coronary artery disease undergoing coronary revascularization*

CAPSULES

Adults. 20 to 40 mg daily in the evening or 40 mg b.i.d. *Maximum:* 40 mg b.i.d.

E.R. TABLETS

Adults. 80 mg in the evening. *Maximum:* 80 mg daily.

➤ *As adjunct to lower cholesterol level in children with heterozygous familial hypercholesterolemia*

CAPSULES

Girls ages 10 to 16 who are at least 1 year past menarche. *Initial:* 20 mg once daily, increased every 6 wk, as needed. *Maximum:* 40 mg b.i.d.

DOSAGE ADJUSTMENT For pediatric patients, if maximum dose of 40 mg b.i.d. is reached with immediate-release capsules, child may be switched to extended-release tablets, 80 mg once daily.

Route	Onset	Peak	Duration
P.O.	In 1–2 wk	In 4–6 wk	Unknown
P.O. (E.R.)	In 2 wk	In 4 wk	Unknown

Mechanism of Action

Interferes with the hepatic enzyme hydroxymethylglutaryl-coenzyme A reductase, reducing formation of mevalonic acid (a cholesterol precursor) and interrupting the pathway by which cholesterol is synthesized. When cholesterol level declines in hepatic cells, LDLs are consumed, which reduces circulating total cholesterol and serum triglycerides.

Contraindications

Acute hepatic disease, breast-feeding, hypersensitivity to fluvastatin or its components, pregnancy, unexplained persistently elevated liver enzyme levels

Interactions

DRUGS

bile acid sequestrants: Possibly decreased

fluvastatin bioavailability
cimetidine, omeprazole, ranitidine: Significantly increased blood fluvastatin level
colchicine, cyclosporine, erythromycin, gemfibrozil, niacin: Increased risk of severe myopathy and rhabdomyolysis
cyclosporine, erythromycin, gemfibrozil, niacin: Increased risk of acute renal failure
fluconazole: Increased fluconazole level
itraconazole, ketoconazole: Increased risk of myopathy
oral contraceptives: Risk of bleeding
rifampin: Significantly decreased blood fluvastatin level, increased plasma clearance

ACTIVITIES

alcohol use: Increased bioavailability and blood level of fluvastatin

Adverse Reactions

CNS: Dizziness, fatigue, headache, insomnia, weakness

EENT: Pharyngitis, rhinitis, sinusitis

GI: Abdominal cramps and pain, constipation, diarrhea, flatulence, indigestion, nausea, vomiting

GU: UTI

MS: Arthritis, back pain, myalgia, myositis, rhabdomyolysis

RESP: Bronchitis, cough, upper respiratory tract infection

SKIN: Pruritus, rash

Nursing Considerations

WARNING Expect to stop drug if CK level rises sharply or myopathy is suspected.

PATIENT TEACHING

- Urge patient to comply with monthly laboratory tests early in treatment.
- Tell patient to follow prescribed low-fat diet.
- Encourage patient to notify prescriber promptly about muscle pain or unexplained weakness.

fluvoxamine maleate

Luvox, Luvox CR

Class and Category

Chemical class: Aralkylketone derivative

Therapeutic class: Antiobsessional

Pregnancy category: C

Indications and Dosages

➤ *To treat obsessive-compulsive disorder*

TABLETS

Adults. *Initial*: 50 mg at bedtime, increased by 50 mg every 4 to 7 days, if needed.

Maximum: 300 mg daily.

Children ages 8 to 17. *Initial*: 25 mg at bedtime, increased by 25 mg every 4 to 7 days, if needed. *Maximum*: 200 mg daily.

DOSAGE ADJUSTMENT Doses divided for adults taking more than 100 mg daily and for children taking more than 50 mg daily; given in 2 equal doses b.i.d. or in 2 unequal doses with the larger dose at bedtime.

CAPSULES

Adults. *Initial*: 100 mg at bedtime, increased by 50 mg weekly, if needed.

Maximum: 300 mg daily.

DOSAGE ADJUSTMENT For elderly patients or those with hepatic impairment, dosage increases with extended-release form are made more slowly.

➤ *To treat social anxiety disorder*

CAPSULES

Adults. *Initial*: 100 mg at bedtime, increased by 50 mg weekly, if needed.

Maximum: 300 mg daily.

DOSAGE ADJUSTMENT For elderly patients or those with hepatic impairment, dosage increases with extended-release form are made more slowly.

Route	Onset	Peak	Duration
P.O.	3–10 wk	Unknown	Unknown

Mechanism of Action

May potentiate serotonin's action by blocking its reuptake at neuronal membranes. An elevated serotonin level may elevate mood and decrease depression and anxiety, which often accompany obsessive-compulsive disorder.

Contraindications

Alosetron, astemizole, cisapride, pimozide, terfenadine, thioridazine, or tizanidine therapy, hypersensitivity to fluvoxamine maleate or its components, use within 14 days of MAO inhibitor

Interactions**DRUGS**

alosepron: Increased plasma alosepron level

alprazolam: Increased plasma alprazolam level

antihistamines: Increased risk of impaired mental and motor skills

aspirin, NSAIDs, warfarin: Risk of bleeding
astemizole, cisapride, pimozide, terfenadine: Possibly fatal QT prolongation

benzodiazepines: Decreased benzodiazepine clearance, possibly impaired memory and motor skills

bupirone: Decreased bupirone effects, increased blood fluvoxamine level, and paradoxical worsening of obsessive-compulsive disorder

carbamazepine: Increased risk of carbamazepine toxicity

clozapine: Increased blood clozapine level

diltiazem: Increased risk of bradycardia

haloperidol: Increased blood haloperidol level, possibly delayed recall and reduced memory and attention span

lithium: Possibly increased serotonin reuptake action of fluvoxamine

MAO inhibitors: Possibly serious or fatal reactions (such as agitation, autonomic instability, coma, delirium, fluctuating vital signs, hyperthermia, myoclonus, and rigidity)

methadone: Possibly significantly increased blood methadone level, increased risk of methadone toxicity

metoprolol, propranolol: Increased blood levels of these drugs, possibly reduced diastolic blood pressure and heart rate induced by these drugs

serotonergics (such as amphetamines and other psychostimulants, antidepressants, and dopamine agonists): Increased risk of serotonin syndrome

sympathomimetics: Possibly increased effects of sympathomimetics and increased risk of serotonin syndrome

tacrine: Increased blood level and therapeutic and adverse effects of tacrine

theophylline: Decreased theophylline clearance, increased risk of theophylline toxicity
tizanidine: Increased risk of serious adverse effects, such as hypotension and profound sedation

tricyclic antidepressants: Increased blood levels of antidepressants

warfarin: Increased blood warfarin level, prolonged PT

FOODS

caffeine: Possibly decreased hepatic clearance of caffeine

ACTIVITIES

smoking: Increased fluvoxamine metabolism

Adverse Reactions

CNS: Agitation, anxiety, apathy, chills, confusion, depression, dizziness, drowsiness, fatigue, headache, hypomania, insomnia, malaise, mania, nervousness, neuroleptic malignant syndrome, sedation, serotonin syndrome, suicidal ideation, tremor, vertigo, yawning

CV: Palpitations, tachycardia

EENT: Altered taste, blurred vision, dry mouth

GI: Anorexia, constipation, diarrhea, flatulence, indigestion, nausea, upper GI bleeding, vomiting

GU: Decreased libido, ejaculation disorders, impotence, urinary frequency, urine retention

HEME: Bleeding events

MS: Muscle twitching

RESP: Dyspnea, upper respiratory tract infection

SKIN: Diaphoresis, rash

Other: Flulike symptoms, weight gain

Nursing Considerations

- Use fluvoxamine cautiously in patients with cardiovascular disease, impaired hepatic or renal function, mania, seizures, or suicidal tendencies.

WARNING Fluvoxamine shouldn't be given within 14 days of an MAO inhibitor.

WARNING Monitor patient for possible serotonin syndrome, characterized by agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching, especially if patient is receiving another drug that raises serotonin level (such as dopamine agonist, MAO inhibitor, tryptophan, amphetamine, or other antidepressant or psychostimulant). In its most severe form, serotonin syndrome can resemble neuroleptic malignant syndrome, which includes a high fever, muscle rigidity, autonomic instability, and possible fluctuations in vital signs and mental status.

- Watch patient closely (especially children, adolescents, and young adults), for suicidal tendencies, particularly when therapy starts and dosage changes, because depres-

sion may worsen temporarily during these times and lead to suicidal ideation.

- Monitor patient for bleeding, especially if patient also takes aspirin, an NSAID, or an anticoagulant. Bleeding can range from ecchymoses, hematomas, epistaxis, and petechiae to life-threatening hemorrhage.
- Discontinue fluvoxamine therapy gradually, as ordered, to prevent unpleasant adverse reactions.

PATIENT TEACHING

- Caution patient not to drink alcohol during fluvoxamine therapy.
- Urge patient to avoid potentially hazardous activities until drug's CNS effects are known.

WARNING Inform patient that fluvoxamine increases the risk of a rare but serious problem: serotonin syndrome. Encourage her to notify prescriber immediately if symptoms develop.

- Caution patient not to stop taking drug abruptly. Explain that gradual tapering helps avoid withdrawal symptoms.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.
- Warn patient that fluvoxamine increases bleeding risk if taken with aspirin, an NSAID, or an anticoagulant and that bleeding events could range from mild to severe. Tell patient to seek emergency care for serious or prolonged bleeding.
- Advise pregnant patient to consult with prescriber before her third trimester about ongoing fluvoxamine therapy because of an increased risk to her unborn child during the third trimester.

folic acid (vitamin B₉)

Apo-Folic (CAN), Folvite,
Novo-Folacid (CAN)

Class and Category

Chemical class: Water-soluble B-complex vitamin

Therapeutic class: Nutritional supplement

Pregnancy category: A

Indications and Dosages

↗ *To prevent deficiency based on U.S. and Canadian recommended daily allowances*

TABLETS

Adult men and boys age 11 and over.

150 to 400 mcg (150 to 220 mcg Canadian) daily.

Adult women and girls age 11 and over.

150 to 400 mcg (145 to 190 mcg Canadian) daily.

Pregnant women. 400 to 800 mcg (445 to 475 mcg Canadian) daily.

Breast-feeding women. 260 to 800 mcg (245 to 275 mcg Canadian) daily.

Children ages 7 to 10. 100 to 400 mcg (125 to 180 mcg Canadian) daily.

Children ages 4 to 6. 75 to 400 mcg (90 mcg Canadian) daily.

Children from birth to age 3. 25 mcg (50 to 80 mcg Canadian) daily.

I.V. INFUSION

Adults and children age 11 and over.

Dosage individualized based on patient need and given as part of total parenteral nutrition solution.

↗ *To treat folic acid deficiency*

TABLETS

Adults and children age 11 and over.

Dosage individualized based on severity of deficiency, as prescribed.

I.V. INFUSION, I.M. OR SUBCUTANEOUS INJECTION

Adults and children age 11 and over.

0.25 to 1 mg daily until hematologic response occurs.

Mechanism of Action

Acts as a catalyst for normal production of red blood cells, helping to prevent megaloblastic anemia, and helps maintain normal homocysteine levels. After being converted to tetrahydrofolic acid in the intestines, folic acid promotes synthesis of several enzymes, including purine and thymidylates; metabolism of amino acids, including glycine and methionine; and metabolism of histidine, all of which are essential for normal cell structure and growth.

Contraindications

Hypersensitivity to folic acid or its components

Interactions

DRUGS

analgesics, carbamazepine, estrogens (including oral contraceptives), phenobarbital, prim-

idone: Possibly increased folic acid requirements

antacids (aluminum- or magnesium-containing), cholestyramine, sulfasalazine:

Possibly decreased folic acid absorption
hydantoin anticonvulsants: Possibly decreased effectiveness of these drugs, possibly increased folic acid requirements
methotrexate, pyrimethamine, triamterene, trimethoprim: Possibly decreased effectiveness of folic acid

Adverse Reactions

Other: Allergic reaction (bronchospasm, erythema, fever, malaise, rash, pruritus)

Nursing Considerations

WARNING Don't give injection form containing benzyl alcohol to neonates or immature infants because a fatal toxic syndrome may occur with CNS, respiratory, circulatory, and renal impairment and metabolic acidosis.

- To prevent decreased absorption, give folic acid supplements at least 1 hour before or 4 hours after cholestyramine or sulfasalazine and don't give antacids within 1 hour before or 2 hours after giving folic acid.
- Know that folic acid will correct hematologic disorders in pernicious anemia, but neurologic problems will progressively worsen.

PATIENT TEACHING

- Advise against taking folic acid supplements as a substitute for proper dietary intake. Explain that good sources of folic acid include green vegetables, potatoes, cereals, and organ meats. Recommend eating raw green vegetables because heat used during cooking destroys up to 90% of folic acid found in food.
- Explain to patients with pernicious anemia that folic acid won't affect the neurologic symptoms associated with the disease.

fondaparinux sodium

Arixtra

Class and Category

Chemical class: Synthetic pentasaccharide

factor Xa inhibitor

Therapeutic class: Antithrombolytic

Pregnancy category: B

Indications and Dosages

➤ *To provide prophylaxis against deep vein thrombosis, which may lead to pulmonary embolism in patients undergoing hip fracture surgery, hip replacement surgery, knee replacement surgery, or abdominal surgery in patients at risk for thromboembolic complications*

SUBCUTANEOUS INJECTION

Adults. *Initial:* After hemostasis has been established, 2.5 mg subcutaneously 6 to 8 hr after surgery, followed by 2.5 mg subcutaneously daily for 5 to 9 days.

Maximum: 2.5 mg subcutaneously daily for 11 days for hip or knee replacement and abdominal surgery and 24 days for hip fracture surgery.

➤ *To treat acute deep vein thrombosis (with warfarin); to treat acute pulmonary embolism (with warfarin) in a hospital setting*

SUBCUTANEOUS INJECTION

Adults. *Initial:* 5 mg if body weight is less than 50 kg (110 lb), 7.5 mg if body weight is 50 to 100 kg (110 to 220 lb), and 10 mg if body weight exceeds 100 kg daily for at least 5 days and until INR is between 2.0 and 3.0 (usually in 5 to 9 days)

Mechanism of Action

Selectively binds to antithrombin III, which enhances the inactivation of clotting factor Xa by antithrombin III. Inactivation of factor Xa interrupts the blood coagulation pathway, which then inhibits thrombin formation. Without thrombin, fibrinogen can't convert to fibrin and clots can't form.

Incompatibilities

Don't mix fondaparinux sodium with other injections or infusions.

Contraindications

Active major bleeding; bacterial endocarditis; body weight less than 50 kg (110 lb) if patient is having hip repair or replacement or knee replacement surgery; fondaparinux-induced thrombocytopenia associated with a positive in vitro test for antiplatelet antibodies; hypersensitivity to fondaparinux; prophylactic fondaparinux therapy in patients weighing less than 50 kg (110 lb)

undergoing hip repair or replacement, knee replacement, or abdominal surgery; severe renal impairment (creatinine clearance less than 30 ml/min/1.73 m²)

Interactions

DRUGS

abciximab, thrombolytics, other drugs that enhance risk of bleeding: Increased risk of hemorrhage and spinal or epidural hematoma

Adverse Reactions

CNS: Confusion, dizziness, fever, headache, insomnia

CV: Edema, elevated serum aminotransferase level, hypotension

GI: Constipation, diarrhea, elevated liver function test results, indigestion, nausea, vomiting

GU: Urine retention, UTI

HEME: Anemia, bleeding, elevated APTT, hematoma, postoperative hemorrhage, thrombocytopenia, thrombocytopenia with thrombosis

SKIN: Bullous eruption, increased wound drainage, rash, purpura

Other: Generalized pain; hypokalemia; injection site bleeding, pruritus, and rash

Nursing Considerations

- Fondaparinux shouldn't be given as prophylaxis for patients who have had a hip fracture, who are having hip or knee replacement or abdominal surgery, or who weigh less than 50 kg (110 lb) because of increased risk of bleeding.
- Use fondaparinux cautiously in elderly patients, especially those weighing less than 50 kg (110 lb) and are receiving the drug for pulmonary embolism or deep vein thrombosis, because the risk of drug-induced bleeding increases with age.
- Don't give initial dose of fondaparinux less than 6 hours after surgery.
- Inspect fondaparinux for particles or discoloration before administration. Be aware that needle guard on prefilled syringe contains dry natural latex rubber and shouldn't be handled by those sensitive to latex.
- Alternate injection sites using left and right anterolateral or left and right posterolateral abdominal wall. Don't expel air bubble from prefilled syringe before injection to prevent expelling drug from syringe. Don't give drug by I.M. injection.

WARNING If patient is receiving fondaparinux with epidural or spinal anesthesia or spinal puncture, watch closely for development of spinal hematoma, which may cause long-term or permanent paralysis. If you see evidence of neurologic impairment, such as changes in sensory or motor function, notify prescriber immediately because urgent care is needed to minimize hematoma's effect. Risk of spinal or epidural hematoma during fondaparinux therapy is increased by indwelling epidural catheters, concurrent use of other drugs that affect hemostasis, a history of traumatic or repeated epidural or spinal punctures, or a history of spinal deformity or spinal surgery.

- Closely monitor patient for bleeding (such as ecchymosis, epistaxis, hematemesis, hematuria, and melena), especially those at risk for decreased drug elimination (such as elderly patients and patients with mild to moderate renal impairment) and those at increased risk for bleeding (such as patients with congenital or acquired bleeding disorders; active ulcerative and angiodysplastic GI disease; hemorrhagic stroke; uncontrolled arterial hypertension; recent brain, spinal, or ophthalmologic surgery; diabetic retinopathy; or a history of heparin-induced thrombocytopenia; and those being treated concomitantly with platelet inhibitors).
- Perform periodic CBC, including platelet count, as ordered. Expect prescriber to discontinue drug if platelet count falls below 100,000/mm³. Be aware that routine coagulation tests, such as PT and INR, are not used to monitor fondaparinux therapy; an anti-Xa assay may be used instead. Also, test stools for occult blood, as ordered.
- Monitor patient with thrombocytopenia for evidence of thrombosis that may appear similar to heparin-induced thrombocytopenia even when no exposure to heparin has taken place. If patient's platelet count falls below 100,000/mm³, fondaparinux should be discontinued.
- Monitor renal function test results, as ordered. Expect to discontinue drug if severe renal impairment or labile renal function occurs during fondaparinux therapy because the risk of hemorrhage increases as renal function decreases.

- Store drug at a controlled room temperature.

PATIENT TEACHING

- Inform patient that fondaparinux can't be taken orally.
- Instruct patient to seek immediate help if she experiences signs of thromboembolism, such as neurologic changes and severe shortness of breath.
- Inform patient about the increased risk of bleeding. Instruct her or family member to watch for and report abdominal or lower back pain, black stools, bleeding gums, bloody urine, or severe headaches.
- Teach patient or family member how to administer fondaparinux by subcutaneous injection at home, if needed. Instruct her not to expel air bubble from a prefilled syringe to avoid expelling some of the drug. Tell her to insert the entire needle into a skinfold held between thumb and forefinger, and remind her to alternate administration sites.
- To minimize bruising, caution the patient not to rub the injection site after giving the drug.
- Review safe handling and disposal of syringes and needles.
- Advise patient to have follow-up appointments and prescribed laboratory tests.

formoterol fumarate dihydrate

Foradil Aerolizer, Oxeze Turbuhaler (CAN), Perforomist

Class and Category

Chemical class: Racemic acid salt
Therapeutic class: Bronchodilator
Pregnancy category: C

Indications and Dosages

➤ *To prevent asthma-induced bronchospasm*

POWDER FOR ORAL INHALATION

Adults and children age 5 and over. 12 mcg every 12 hr through inhaler device.

Maximum: 24 mcg daily.

➤ *To prevent exercise-induced bronchospasm*

POWDER FOR ORAL INHALATION

Adults and adolescents age 12 and over.

12 mcg at least 15 min before exercise every 12 hr p.r.n. *Maximum:* 24 mcg daily.

➤ *To provide long-term treatment of bronchospasm in patients with chronic bronchitis and emphysema*

POWDER FOR ORAL INHALATION

Adults. 12 mcg every 12 hr through inhaler device. *Maximum:* 24 mcg daily.

SOLUTION FOR ORAL INHALATION

Adults. 20 mcg b.i.d. by nebulization. *Maximum:* 40 mcg daily.

Route	Onset	Peak	Duration
Oral inhalation	1–3 min	Unknown	12 hr

Mechanism of Action

Selectively attaches to beta₂ receptors on bronchial membranes, stimulating the intracellular enzyme adenyl cyclase to convert adenosine triphosphate to cAMP. The resulting increase in the intracellular cAMP level relaxes bronchial smooth-muscle cells, stabilizes mast cells, and inhibits histamine release.

Contraindications

Acute asthma, hypersensitivity to formoterol fumarate or its components

Interactions

DRUGS

adrenergics: Possibly increased sympathetic effects of formoterol

beta blockers: Decreased effects of formoterol, possibly severe bronchospasm

corticosteroids, non-potassium-sparing diuretics, xanthine derivatives: Possibly

increased hypokalemic effect of formoterol

disopyramide, MAO inhibitors, phenothiazines, procainamide, quinidine, tricyclic antidepressants: Possibly prolonged QTc interval, increasing risk of ventricular arrhythmias

mias

Adverse Reactions

CNS: Anxiety, dizziness, fatigue, fever, headache, insomnia, malaise, tremor

CV: Angina, arrhythmias, chest pain, hypertension, hypotension, palpitations, tachycardia

EENT: Dry mouth; laryngeal spasm, irritation, or swelling; hoarseness; pharyngitis; rhinitis and tonsillitis (in children); sinusitis

ENDO: Hyperglycemia

GI: Abdominal pain, gastroenteritis, indigestion (in children); nausea

MS: Back pain, leg cramps, muscle spasms

RESP: Asthma exacerbation, bronchitis, bronchospasm (paradoxical or hypersensitivity-induced), cough, dyspnea, increased sputum production, upper respiratory tract infection

SKIN: Dermatitis, pruritus, rash

Other: Anaphylaxis, angioedema, hypokalemia, metabolic acidosis, viral infection (in children)

Nursing Considerations

- Administer formoterol capsules or solution only by oral inhalation.
- Store capsules and solution in their original packaging, and open immediately before use.
- To use delivery system for powder form, place capsule in well of inhaler device. Press and release buttons on side of device to pierce capsule. Have patient inhale rapidly and deeply through mouthpiece; drug is dispersed into airways as patient inhales.
- Give inhalation solution only by standard jet nebulizer and air compressor.

WARNING Monitor patient for worsening or deteriorating asthma because drug isn't rapid-acting and shouldn't be used as a substitute for corticosteroid therapy.

- Watch closely for paradoxical bronchospasm; if this occurs, discontinue formoterol immediately and notify prescriber.
- Monitor patients with a history of cardiovascular disorders, especially coronary insufficiency, arrhythmias, or hypertension. Notify prescriber of any significant increases in pulse rate or blood pressure or worsening of chronic conditions because formoterol may produce cardiovascular reactions, including angina, arrhythmias, hypertension or hypotension, palpitations, and tachycardia. Drug may need to be discontinued if such reactions occur.

PATIENT TEACHING

- Advise patient, especially if she has significant cardiac history, to inform prescriber of any other drugs she takes before beginning formoterol therapy to prevent harmful drug interactions.
- Instruct patient to use manufacturer's plastic device for inhaling powder form of

formoterol, to always use new inhaler that comes with each refill, and not to use a spacer. Tell her never to swallow capsules.

- Teach patient how to properly store powdered drug and inhaler. Instruct her to avoid exposing capsules to moisture and to always handle them with dry hands because powder inside capsules must be dry to be inhaled. Also advise her to keep inhaler in a dry place and not to wash it.
- Teach patient proper use of powdered formoterol delivery system. Instruct her to remove capsule from blister pack just before use, to place capsule in well of inhaler device, to press and release buttons on side of device to pierce capsule, and then to inhale rapidly and deeply through mouthpiece. Emphasize that she should only inhale, not exhale, into device.
- For solution form, teach patient how to use, clean, and store nebulizer equipment. Tell her to leave the vial in its original foil pack until just before use.
- Instruct patient who currently uses oral or inhaled corticosteroids to continue using them, as prescribed, even if she feels better after starting formoterol.
- Caution patient not to increase formoterol dosage or frequency without consulting prescriber because she may need a rapid-acting bronchodilator.
- Urge patient to notify prescriber if her symptoms worsen, if formoterol becomes less effective, or if she needs more inhalations of short-acting beta₂-agonist than usual. This may indicate that her asthma is worsening.
- Instruct patient to notify prescriber immediately if she experiences palpitations, chest pain, rapid heart rate, tremor, or nervousness while taking formoterol because dosage may need to be adjusted.

fosfomycin tromethamine

Monurol

Class and Category

Chemical class: Phosphonic acid derivative

Therapeutic class: Antibiotic

Pregnancy category: B

Indications and Dosages

➤ *To treat uncomplicated UTI (acute cystitis) caused by Enterococcus faecalis or Escherichia coli*

GRANULES FOR ORAL SOLUTION

Women age 18 and over. 3 g as a single dose mixed with water.

Route	Onset	Peak	Duration
P.O.	2–3 days	48 hr	Unknown

Mechanism of Action

Disrupts the formation of bacterial cell walls by blocking cell wall precursors. Specifically, fosfomycin inactivates enolpyruvyl transferase, which irreversibly blocks the condensation of uridine diphosphate-*N*-acetylglucosamine with phosphoenolpyruvate, a preliminary step in bacterial cell wall synthesis. Fosfomycin also decreases adherence of bacteria to epithelial cells of the urinary tract.

Contraindications

Hypersensitivity to fosfomycin or its components

Interactions

DRUGS

metoclopramide: Decreased blood level and urinary excretion of fosfomycin

Adverse Reactions

CNS: Asthenia, dizziness, fever, headache, insomnia, nervousness, paresthesia, somnolence

EENT: Dry mouth, pharyngitis, rhinitis

GI: Abdominal pain, anorexia, constipation, diarrhea, flatulence, indigestion, nausea, pseudomembranous colitis, vomiting

GU: Dysmenorrhea, dysuria, hematuria, menstrual irregularities, vaginitis

MS: Back pain

SKIN: Pruritus, rash

Other: Flu-like symptoms, lymphadenopathy

Nursing Considerations

- Use fosfomycin cautiously in patients with impaired renal function because drug clearance may be decreased.
- Expect to obtain urine specimens for culture and sensitivity tests before and after fosfomycin therapy.
- To reconstitute granules, pour contents of single-dose packet into 90 to 120 ml (3 to

4 oz) of water (not hot water) and stir. Administer immediately after dissolving.

WARNING Expect adverse reactions to increase if more than one dose is used to treat a single episode of acute cystitis.

- Monitor patient for diarrhea during and for at least 2 months after drug therapy; diarrhea may signal pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold fosfomycin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

PATIENT TEACHING

- Explain how to reconstitute fosfomycin, and instruct patient to take drug immediately after it dissolves. Tell her not to take dry granules or mix them with hot water.
- To treat each episode of acute cystitis, advise patient to use only a single dose, as prescribed, to avoid increasing the risk of adverse reactions.
- Urge patient to notify prescriber if symptoms don't improve in 2 to 3 days.
- Instruct patient to return to prescriber for further urine testing after taking fosfomycin.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Explain that watery or bloody stools can occur 2 or more months after therapy and can be serious, requiring prompt treatment.

fosinopril sodium

Monopril

Class and Category

Chemical class: Phosphinic acid derivative

Therapeutic class: Antihypertensive, vasodilator

Pregnancy category: C (first trimester), D (later trimesters)

Indications and Dosages

➤ *To manage blood pressure, alone or with other antihypertensives*

TABLETS

Adults. *Initial:* 10 mg daily. *Maintenance:* 20 to 40 mg daily. *Maximum:* 80 mg daily.

➤ *To treat heart failure*

TABLETS

Adults. 10 mg daily.

DOSAGE ADJUSTMENT Initial dosage reduced to 5 mg daily, if needed, for patients with acute heart failure, moderate to severe renal failure, or recent aggressive diuresis. Dosage may be increased over several weeks to maximum of 40 mg daily.

Route	Onset	Peak	Duration
P.O.	1 hr	2–6 hr	24 hr

Mechanism of Action

May reduce blood pressure by affecting renin-angiotensin-aldosterone system. By inhibiting angiotensin-converting enzyme, foscinopril:

- prevents conversion of angiotensin I to angiotensin II, a potent vasoconstrictor that also stimulates the adrenal cortex to secrete aldosterone
- may inhibit renal and vascular production of angiotensin II
- decreases serum angiotensin II level and increases serum renin activity, which decreases aldosterone secretion, slightly increasing the serum potassium level and fluid loss
- decreases vascular tone and blood pressure
- inhibits aldosterone release, which reduces sodium and water reabsorption and increases their excretion, further reducing blood pressure.

Contraindications

Hypersensitivity to foscinopril, other ACE inhibitors, or their components

Interactions

DRUGS

allopurinol, bone marrow depressants, procainamide, systemic corticosteroids:

Increased risk of potentially fatal neutropenia or agranulocytosis

antacids: Impaired foscinopril absorption
cyclosporine, potassium-sparing diuretics, potassium supplements: Increased risk of hyperkalemia

diuretics, other antihypertensives: Possibly additive hypotension

lithium: Increased blood lithium level and risk of lithium toxicity

NSAIDs: Possibly decreased antihypertensive effect of foscinopril

sodium aurothiomalate: Nitritoid reactions, including facial flushing, nausea, vomiting, and hypotension

FOODS

salt substitutes: Increased risk of hyperkalemia

ACTIVITIES

alcohol use: Possibly additive hypotension

Adverse Reactions

CNS: Confusion, depression, dizziness, drowsiness, fatigue, fever, headache, insomnia, mood changes, sleep disturbance, syncope, tremor, vertigo, weakness

CV: Angina, arrhythmias (including AV conduction disorders, bradycardia, and tachycardia), claudication, hypotension, MI, orthostatic hypotension, palpitations

EENT: Dry mouth, epistaxis, eye irritation, hoarseness, rhinitis, sinus problems, taste perversion, tinnitus, vision changes

GI: Abdominal distention and pain, anorexia, constipation, diarrhea, flatulence, hepatic failure, hepatitis, hepatomegaly, nausea, pancreatitis, vomiting

GU: Decreased libido, flank pain, renal insufficiency, sexual dysfunction, urinary frequency

MS: Arthralgia, gout, myalgia

RESP: Asthma; bronchitis; bronchospasm; dry, persistent, tickling cough; dyspnea; tracheobronchitis; upper respiratory tract infection

SKIN: Diaphoresis, jaundice, photosensitivity, pruritus, rash, urticaria

Other: Anaphylaxis, angioedema, hyperkalemia, weight gain

Nursing Considerations

- Monitor serum potassium level before and during foscinopril therapy, as appropriate.
- Observe patient being treated for heart failure for at least 2 hours after giving drug to detect hypotension or orthostatic hypotension. If either develops, notify prescriber and monitor patient until blood pressure stabilizes. Keep in mind that orthostatic hypotension is unlikely to develop in patients with a systolic blood pressure over 100 mm Hg who receive a 10-mg dose.
- If patient also receives an antacid, separate administration times by at least 2 hours.
- If patient also receives a diuretic or another antihypertensive, expect to reduce its dosage over 2 to 3 days before starting foscinopril. If blood pressure isn't controlled with foscinopril alone, other antihyperten-

sive therapy may resume, as prescribed. If so, observe for excessive hypotension.

WARNING If angioedema affects the face, glottis, larynx, limbs, lips, mucous membranes, or tongue, notify prescriber immediately. Expect to discontinue fosinopril and start appropriate therapy at once. If airway obstruction threatens, promptly give 0.3 to 0.5 ml of epinephrine solution 1:1,000 subcutaneously, as prescribed.

PATIENT TEACHING

- Instruct patient to take fosinopril at same time each day to improve compliance and maintain drug's therapeutic effect.
- Emphasize the importance of taking fosinopril as prescribed, even if patient feels well. Caution her not to stop taking drug without consulting prescriber.
- Explain that drug helps control—but doesn't cure—hypertension and that patient may need lifelong therapy.

WARNING Urge patient to seek immediate medical attention for difficulty breathing or swallowing, hoarseness, or swelling of the face, lips, tongue, or throat.

- Instruct patient to notify prescriber about persistent, severe nausea, vomiting, and diarrhea; resulting dehydration may lead to hypotension.
- Advise patient not to take other drugs or use salt substitutes without consulting prescriber.
- Encourage patient to keep scheduled appointments with prescriber to monitor blood pressure, blood test results, and effects of therapy.
- Caution patient about possible dizziness.
- To minimize effects of orthostatic hypotension, advise patient to rise slowly from a lying or sitting position and to dangle legs over bed for several minutes before standing.
- Reinforce prescriber's recommendations for lifestyle changes, such as smoking cessation, stress reduction, dietary improvements, alcohol avoidance, and regular exercise.
- If patient is a woman of childbearing age, urge her to use contraception during therapy because drug may harm fetus.
- Advise patient to use caution during exercise and hot weather because of the increased risk of dehydration from excessive sweating.

fosphenytoin sodium

Cerebryx

Class and Category

Chemical class: Hydantoin derivative
Therapeutic class: Anticonvulsant
Pregnancy category: D

Indications and Dosages

↗ *To treat status epilepticus*

I.V. INFUSION, I.M. INJECTION

Adults and adolescents. *Initial:* 15 to 20 mg of phenytoin equivalent (PE)/kg I.V. at 100 to 150 PE/min. *Maintenance:* 4 to 6 mg PE/kg daily I.V. or I.M. in divided doses b.i.d. to q.i.d. *Maximum:* 30 mg PE/kg as total loading dose.

Children. *Initial:* 15 to 20 mg PE/kg I.V. given at up to 3 mg PE/kg/min.

Maintenance: 4 to 6 mg PE/kg daily I.V. or I.M. in divided doses b.i.d. to q.i.d.

↗ *To prevent or treat seizures during and after neurosurgery*

I.V. INFUSION, I.M. INJECTION

Adults and adolescents. *Initial:* 10 to 20 mg PE/kg I.V., not to exceed 150 mg PE/min. *Maintenance:* 4 to 6 mg PE/kg daily I.V. or I.M. in divided doses b.i.d. to q.i.d. *Maximum:* 30 mg PE/kg as total loading dose.

Mechanism of Action

Is converted from fosphenytoin (a prodrug) to phenytoin, which limits the spread of seizure activity and the start of new seizures. Phenytoin does so by regulating voltage-dependent sodium and calcium channels in neurons, inhibiting calcium movement across neuronal membranes, and enhancing the sodium-potassium-adenosine triphosphatase activity in neurons and glial cells. These actions may stem from phenytoin's ability to slow the recovery rate of inactivated sodium channels.

Contraindications

Hypersensitivity to fosphenytoin, phenytoin, other hydantoins, or their components

Interactions

DRUGS

acetaminophen (long-term use): Increased

risk of hepatotoxicity

acyclovir: Decreased blood phenytoin level, loss of seizure control

alfentanil: Increased clearance and

decreased effectiveness of alfentanil

amiodarone, fluoxetine: Possibly increased

blood phenytoin level and risk of toxicity

antacids: Possibly decreased phenytoin effectiveness

antineoplastics: Increased phenytoin metabolism

beta blockers: Increased myocardial depression

bupropion, clozapine, loxapine, MAO inhibitors,

maprotiline, phenothiazines, pimozide,

thioxanthenes: Possibly lowered seizure

threshold and decreased therapeutic effects

of phenytoin, possibly intensified CNS

depressant effects of these drugs

calcium: Possibly impaired phenytoin

absorption

calcium channel blockers: Possibly increased blood phenytoin level

carbamazepine: Decreased blood carba-

mazepine level, possibly increased blood

phenytoin level and risk of toxicity

chloramphenicol, cimetidine, disulfiram, iso-

niazid, methylphenidate, metronidazole,

phenylbutazone, ranitidine, salicylates, sul-

fonomides, trimethoprim: Possibly impaired

metabolism of these drugs, increased risk of

phenytoin toxicity

CNS depressants: Possibly increased CNS

depression

corticosteroids, cyclosporine, digoxin, disopyr-

amide, doxycycline, furosemide, levodopa,

mexiletine, quinidine: Decreased therapeutic

effects of these drugs

diazoxide: Possibly decreased therapeutic

effects of both drugs

dopamine: Possibly sudden hypotension or

cardiac arrest after I.V. fosphenytoin

administration

estrogen- and progestin-containing contra-

ceptives: Possibly breakthrough bleeding

and decreased contraceptive effectiveness

estrogens, progestins: Decreased therapeutic

effects, increased blood phenytoin level

felbamate: Possibly impaired metabolism

and increased blood level of phenytoin

fluconazole, itraconazole, ketoconazole,

miconazole: Increased blood phenytoin level

folic acid: Increased phenytoin metabolism,

decreased seizure control

haloperidol: Possibly lowered seizure thresh-

old and decreased therapeutic effects of

phenytoin; possibly decreased blood halo-

peridol level

insulin, oral antidiabetic drugs: Possibly

increased blood glucose level and decreased

therapeutic effects of these drugs

lamotrigine: Possibly decreased therapeutic

effects of lamotrigine

lidocaine: Possibly decreased blood lido-

caine level, increased myocardial depression

lithium: Increased risk of lithium toxicity

methadone: Possibly increased methadone

metabolism, leading to withdrawal symp-

toms

molindone: Possibly lowered seizure thresh-

old, impaired absorption, and decreased

therapeutic effects of phenytoin

omeprazole: Possibly increased blood

phenytoin level

oral anticoagulants: Possibly impaired

metabolism of these drugs and increased

risk of phenytoin toxicity; possibly

increased anticoagulant effects initially and

then decreased effects with prolonged ther-

apy

rifampin: Possibly decreased therapeutic

effects of phenytoin

streptozocin: Possibly decreased therapeutic

effects of streptozocin

sucralfate: Possibly decreased phenytoin

absorption

tricyclic antidepressants: Possibly lowered

seizure threshold and decreased therapeutic

effects of phenytoin; possibly decreased

blood antidepressant level

valproic acid: Decreased blood phenytoin

level, increased blood valproic acid level

vitamin D analogues: Decreased vitamin D

analogue activity

xanthines: Possibly inhibited phenytoin

absorption and increased clearance of xan-

thines

zaleplon: Increased clearance and decreased

effectiveness of zaleplon

ACTIVITIES

alcohol use: Possibly decreased phenytoin

effectiveness

Adverse Reactions

CNS: Agitation, amnesia, asthenia, ataxia,

cerebral edema, chills, coma, confusion,

delusions, depression, dizziness, emotional

lability, encephalitis, encephalopathy,

extrapyramidal reactions, fever, headache,

hemiplegia, hostility, hypoesthesia, lack of coordination, malaise, meningitis, nervousness, neurosis, paralysis, personality disorder, positive Babinski's sign, seizures, somnolence, speech disorders, stroke, stupor, subdural hematoma, syncope, transient paresthesia, tremor, vertigo

CV: Atrial flutter, bradycardia, bundle-branch block, cardiac arrest, cardiomegaly, edema, heart failure, hypertension, hypotension, orthostatic hypotension, palpitations, PVCs, shock, tachycardia, thrombophlebitis

EENT: Amblyopia, conjunctivitis, diplopia, dry mouth, earache, epistaxis, eye pain, gingival hyperplasia, hearing loss, hyperacusis, increased salivation, loss of taste, mydriasis, nystagmus, pharyngitis, photophobia, rhinitis, sinusitis, taste perversion, tinnitus, tongue swelling, visual field defects

ENDO: Diabetes insipidus, hyperglycemia, ketosis

GI: Anorexia, constipation, diarrhea, dysphagia, elevated liver function test results, flatulence, gastritis, GI bleeding, hepatic necrosis, hepatitis, ileus, indigestion, nausea, vomiting

GU: Albuminuria, dysuria, incontinence, oliguria, polyuria, renal failure, urine retention, vaginal candidiasis

HEME: Anemia, easy bruising, leukopenia, thrombocytopenia

MS: Arthralgia, back pain, leg cramps, muscle twitching, myalgia, myasthenia, myoclonus, myopathy

RESP: Apnea, asthma, atelectasis, bronchitis, dyspnea, hemoptysis, hyperventilation, hypoxia, increased cough, increased sputum production, pneumonia, pneumothorax

SKIN: Contact dermatitis, diaphoresis, maculopapular or pustular rash, photosensitivity, skin discoloration, skin nodule, Stevens-Johnson syndrome, transient pruritus, urticaria

Other: Cachexia, cryptococcosis, dehydration, facial edema, flulike symptoms, hyperkalemia, hypokalemia, hypophosphatemia, infection, injection site reaction, lymphadenopathy, sepsis

Nursing Considerations

- Express the dosage, concentration, and infusion rate of fosphenytoin in PE units. Misreading an order or a label could result in massive overdose.

- Refrigerate unopened fosphenytoin at 2° to 8° C (36° to 46° F), but don't freeze.
- Dilute drug in D₅W or normal saline solution to 1.5 to 25 mg PE/ml.
- Inspect parenteral solution before administration. Discard solution that contains particles or is discolored.
- Be aware that drug shouldn't be given I.M. for status epilepticus because I.V. route allows faster onset and peak.
- Keep in mind that I.V. fosphenytoin administration doesn't require use of a filter, as with phenytoin administration.
- Don't give fosphenytoin solution faster than 150 mg PE/minute because of the risk of hypotension. For a 50-kg (110-lb) patient, infusion typically takes 5 to 7 minutes. Fosphenytoin can be given more rapidly than I.V. phenytoin.
- Follow loading dose with maintenance dosage of oral or parenteral phenytoin or parenteral fosphenytoin, as prescribed.
- As prescribed, give I.V. benzodiazepine (such as lorazepam or diazepam) with fosphenytoin; otherwise, drug's full antiepileptic effect won't be immediate.
- Monitor ECG, blood pressure, and respiratory function for 10 to 20 minutes after infusion ends.
- Expect to obtain blood fosphenytoin (phenytoin) level 2 hours after I.V. infusion or 4 hours after I.M. injection. Therapeutic level generally ranges from 10 to 20 mcg/ml; steady-state may take several days to several weeks to reach.
- Be aware that I.V. or I.M. fosphenytoin may be substituted for oral phenytoin sodium at same total daily dose and frequency. If prescribed, give daily amount in two or more divided doses to maintain seizure control.
- When switching between phenytoin and fosphenytoin, remember that small differences in phenytoin bioavailability can lead to significant changes in blood phenytoin level and an increased risk of toxicity.
- If drug causes transient, infusion-related paresthesia and pruritus, decrease or discontinue infusion, as ordered.
- Monitor CBC for thrombocytopenia or leukopenia—signs of hematologic toxicity. Also monitor serum albumin level and results of renal and liver function tests.
- Anticipate increased frequency and severi-

ty of adverse reactions after I.V. administration in patients with hepatic or renal impairment or hypoalbuminemia.

- Discontinue drug, as ordered, if signs of hypersensitivity develop: acute hepatotoxicity (hepatic necrosis and hepatitis), fever, lymphadenopathy, and skin reactions during first 2 months of therapy.
- Monitor phenytoin level to detect early signs of toxicity, such as diplopia, nausea, severe confusion, slurred speech, and vomiting. Expect to reduce or stop drug.

WARNING Monitor patient for seizures; at toxic levels, phenytoin is excitatory.

WARNING If patient has bradycardia or heart block rhythm, notify prescriber and expect to withhold drug; severe cardiovascular reactions and death have occurred.

- Expect to provide vitamin D supplement if patient has inadequate dietary intake and is receiving long-term anticonvulsant treatment.
- Document type, onset, and characteristics of seizures and response to treatment.

PATIENT TEACHING

- Inform patient that fosphenytoin typically is used for short-term treatment.
- Instruct patient to notify prescriber immediately about bothersome symptoms, especially rash and swollen glands.
- Because gingival hyperplasia may develop during long-term therapy, emphasize need for good oral hygiene and gum massage.
- Urge patient to consume adequate amounts of vitamin D.

frovatriptan succinate

Frova

Class and Category

Chemical class: Selective 5-hydroxytryptamine₁ (5-HT₁) receptor agonist, triptan

Therapeutic class: Antimigraine agent

Pregnancy category: C

Indications and Dosages

↗ *To treat acute migraine with or without aura*

TABLETS

Adults. 2.5 mg, repeated in 2 hr if needed.

Maximum: 7.5 mg daily.

Mechanism of Action

Binds to 5-HT_{1B} and 5-HT_{1D} receptors on extracerebral and intracranial arteries to inhibit excessive dilation of these vessels. This action may decrease carotid arterial blood flow, thus relieving acute migraines. Frovatriptan may also relieve pain by inhibiting the release of proinflammatory neuropeptides and reducing transmission of trigeminal nerve impulses from sensory nerve endings during a migraine attack.

Contraindications

Hypersensitivity to frovatriptan or its components, basilar or hemiplegic migraines, cerebrovascular or peripheral vascular disease, ischemic or vasospastic coronary artery disease (CAD), uncontrolled hypertension, use within 24 hours of other serotonin-receptor agonists or ergotamine-containing or ergot-type drugs

Interactions

DRUGS

dihydroergotamine mesylate, other ergotamine-containing drugs: Possibly prolonged vasospastic reaction

oral contraceptives, propranolol: Possibly increased blood frovatriptan level
selective serotonin reuptake inhibitors, such as citalopram, escitalopram, fluoxetine, fluvoxamine, paroxetine, sertraline; serotonin norepinephrine reuptake inhibitors, such as duloxetine, venlafaxine: Increased risk of life-threatening serotonin syndrome

Adverse Reactions

CNS: Anxiety, dizziness, dysesthesia, fatigue, headache, hypoesthesia, insomnia, paresthesia, seizures, serotonin syndrome

CV: Arrhythmias (such as bradycardia and tachycardia), chest pain, coronary artery vasospasm, ECG changes, MI, myocardial ischemia (transient), palpitations, ventricular fibrillation, ventricular tachycardia

EENT: Abnormal vision, dry mouth, indigestion, rhinitis, sinusitis, tinnitus

GI: Abdominal pain, diarrhea, indigestion, vomiting

MS: Skeletal pain

SKIN: Diaphoresis, flushing

Other: Generalized pain

Nursing Considerations

- Use frovatriptan cautiously in patients

- with peripheral vascular disease because drug may cause vasospastic reactions, leading to vascular and colonic ischemia with abdominal pain and bloody diarrhea. Assess patient's peripheral circulation and bowel sounds during frovatriptan therapy.
- Don't give frovatriptan within 24 hours of another 5-HT₁ receptor agonist, such as sumatriptan or rizatriptan, or of an ergot-amine-containing or ergot-type drug, such as dihydroergotamine or methysergide.
 - Administer tablet with fluids.
 - Assess patient for headache before administering second dose. Don't administer more than three 2.5-mg tablets a day.

WARNING Be aware that some patients have had serious adverse cardiac reactions—including fatal ones—after using 5-HT₁ receptor agonists. However, these reactions are extremely rare; most were reported in patients with risk factors for CAD.

- Assess patient's cardiovascular status and institute continuous ECG monitoring, as ordered, immediately after drug administration in patients with cardiovascular risk factors because they're at risk for asymptomatic cardiac ischemia.
- Assess patient for arrhythmias, chest pain, and other signs of heart disease in patients with risk factors for CAD. Expect to periodically assess cardiovascular status of patients on long-term therapy.
- Be aware that the safety of treating more than four migraine attacks in 30 days (on average) has not been established.
- Regularly monitor blood pressure of hypertensive patients during therapy because frovatriptan may produce a transient increase in blood pressure.

WARNING Monitor patient for possible serotonin syndrome, characterized by agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching, especially if patient is receiving another drug that raises serotonin level (such as selective serotonin reuptake inhibitors or serotonin norepinephrine reuptake inhibitors). In its most severe form, serotonin syndrome can resemble neuroleptic malignant syndrome, which includes a high fever, muscle rigidity, and autonomic instability with possible

fluctuations in vital signs and mental status changes.

PATIENT TEACHING

- Instruct patient to read and follow manufacturer's instructions for using frovatriptan to ensure maximum therapeutic results.
- Remind patient not to exceed prescribed daily dosage.
- Encourage patient to lie down in a dark, quiet room after taking drug to help relieve migraine.
- Instruct patient to seek emergency care for chest, jaw, or neck tightness after drug use because drug may cause coronary artery vasospasm.
- Urge patient to report palpitations.
- Caution patient about possible adverse CNS effects, and advise her to avoid hazardous activities until drug's CNS effects are known.
- Stress need to report any unusual or severe symptoms immediately.

furazolidone

Furoxone

Class and Category

Chemical class: MAO inhibitor, nitrofurantoin derivative

Therapeutic class: Antibiotic, antiprotozoal

Pregnancy category: C

Indications and Dosages

➤ To treat bacterial diarrhea and cholera

ORAL SUSPENSION, TABLETS

Adults and adolescents. 100 mg every 6 hr for 5 to 7 days.

Infants and children age 1 month and over. 1.25 mg/kg every 6 hr for 5 to 7 days.

Maximum: 8.8 mg/kg daily.

➤ To treat giardiasis

ORAL SUSPENSION, TABLETS

Adults and adolescents. 100 mg every 6 hr for 7 to 10 days.

Infants and children age 1 month and over. 1.25 to 2 mg/kg every 6 hr for 7 to 10 days.

Maximum: 8.8 mg/kg daily.

Mechanism of Action

May interfere with several bacterial enzyme systems through DNA strand damage. Furazolidone also prevents the inactivation

of tyramine by GI and hepatic MAO because it is similar in structure and actions to MAO inhibitors.

Contraindications

Age less than 1 month; hypersensitivity to furazolidone, other nitrofurans, or their components

Interactions

DRUGS

levodopa: Increased therapeutic and adverse effects (particularly hypertension) of levodopa

mepredine: Possibly agitation, apnea, coma, diaphoresis, fever, and seizures

other MAO inhibitors, sedatives, sympathomimetics, tranquilizers, tricyclic antidepressants: Possibly sudden and severe hypertensive crisis

selective serotonin reuptake inhibitors: Increased risk of serotonin syndrome

FOODS

foods and beverages with high content of tyramine or other vasopressor amines:

Possibly sudden and severe hypertensive crisis

ACTIVITIES

alcohol use: Possibly disulfiram-like reaction

Adverse Reactions

CNS: Headache, malaise

ENDO: Hypoglycemia

GI: Abdominal pain, diarrhea, nausea, vomiting

GU: Darkened urine

HEME: Hemolytic anemia, leukopenia

Other: Allergic reaction (arthralgia, dyspnea, fever, hypotension, urticaria, vesicular morbilliform rash)

Nursing Considerations

- Ask patient if she has a history of blood disorders—especially glucose-6-phosphate dehydrogenase (G6PD) deficiency—before giving furazolidone.
- As ordered, check G6PD level before giving furazolidone to whites of Mediterranean and Near Eastern origin, Asians, or blacks; G6PD deficiency may worsen drug's hemolytic effect.
- If no response occurs within 7 days, expect to discontinue drug because organism is resistant. Provide therapy with other antibiotics, as prescribed.
- If giardiasis symptoms persist, expect to

obtain three stool specimens for analysis several days apart, starting 3 to 4 weeks after treatment ends.

PATIENT TEACHING

- Instruct patient to take drug at evenly spaced intervals around the clock.
- Advise patient to take drug with food if GI distress occurs.
- Direct patient to take a missed dose as soon as she remembers, unless it's nearly time for the next scheduled dose. Caution against double-dosing.
- Instruct patient to take furazolidone for the full time prescribed, even if she feels better before finishing the prescription, because stopping too soon could result in reinfection.
- Advise patient to store furazolidone between 59° and 86° F (15° and 30° C), protected from moisture and light.
- Inform patient that drug may cause dizziness and usually turns urine brown.
- Instruct patient to avoid alcohol during therapy and for 4 days afterward.
- Give patient a list of products to avoid during furazolidone therapy and for at least 2 weeks afterward, such as foods and beverages that contain tyramine and other vasopressor amines (for example, ripe cheese, beer, red and white wine, and smoked or pickled meat, poultry, or fish), OTC appetite suppressants, cough and cold medicines, and other drugs, unless prescribed.
- Instruct patient to notify prescriber if she experiences difficult breathing, fever, flushing, itching, muscle aches, or rash.

furosemide

Apo-Furosemide (CAN), Furoside (CAN), Lasix, Lasix Special (CAN), Myrosemide, Novosemide (CAN), Uritol (CAN)

Class and Category

Chemical class: Sulfonamide

Therapeutic class: Antihypertensive, diuretic

Pregnancy category: C

Indications and Dosages

↗ *To reduce edema caused by cirrhosis, heart failure, and renal disease, including nephrotic syndrome*

ORAL SOLUTION, TABLETS

Adults. 20 to 80 mg as a single dose, increased by 20 to 40 mg every 6 to 8 hr until desired response occurs. *Maximum:* 600 mg daily.

Children. 2 mg/kg as a single dose, increased by 1 to 2 mg/kg every 6 to 8 hr until desired response occurs. *Maximum:* 6 mg/kg/dose.

I.V. INFUSION, I.V. OR I.M. INJECTION

Adults. 20 to 40 mg as a single dose, increased by 20 mg every 2 hr until desired response occurs.

Children. 1 mg/kg as a single dose, increased by 1 mg/kg every 2 hr until desired response occurs. *Maximum:* 6 mg/kg/dose.

DOSE ADJUSTMENT Initial single dose limited to 20 mg for elderly patients.

➤ *To manage mild to moderate hypertension, as adjunct to treat acute pulmonary edema and hypertensive crisis*

ORAL SOLUTION, TABLETS

Adults. *Initial:* 40 mg b.i.d., adjusted until desired response occurs. *Maximum:* 600 mg daily.

I.V. INFUSION OR INJECTION

Adults with normal renal function. 40 to 80 mg as a single dose over several minutes.

Adults with acute renal failure or pulmonary edema. 100 to 200 mg as a single dose over several minutes.

DOSE ADJUSTMENT For patients with acute pulmonary edema without hypertensive crisis, dosage reduced to 40 mg followed by 80 mg 1 hr later if therapeutic response doesn't occur.

Route	Onset	Peak	Duration
P.O.	20–60 min	1–2 hr	6–8 hr
I.V.	5 min	In 30 min	2 hr
I.M.	30 min	Unknown	2 hr

Mechanism of Action

Inhibits sodium and water reabsorption in the loop of Henle and increases urine formation. As the body's plasma volume decreases, aldosterone production increases, which promotes sodium reabsorption and the loss of potassium and hydrogen ions. Furosemide also increases the excretion of calcium, magnesium, bicarbonate, ammonium, and phosphate. By reducing intracellular and extracellular fluid volume, the

drug reduces blood pressure and decreases cardiac output. Over time, cardiac output returns to normal.

Incompatibilities

Don't mix furosemide (a milky, buffered alkaline solution) with highly acidic solutions.

Contraindications

Anuria unresponsive to furosemide; hypersensitivity to furosemide, sulfonamides, or their components

Interactions**DRUGS**

ACE inhibitors: Possibly first-dose hypotension

aminoglycosides, cisplatin: Increased risk of ototoxicity

amiodarone: Increased risk of arrhythmias from hypokalemia

chloral hydrate: Possibly diaphoresis, hot flashes, and hypertension

digoxin: Increased risk of digitalis toxicity related to hypokalemia

insulin, oral antidiabetic drugs: Increased blood glucose level

lithium: Increased risk of lithium toxicity

NSAIDs: Possibly decreased diuresis

phenytoin, probenecid: Possibly decreased therapeutic effects of furosemide

propranolol: Possibly increased blood propranolol level

thiazide diuretics: Possibly profound diuresis and electrolyte imbalances

ACTIVITIES

alcohol use: Possibly increased hypotensive and diuretic effects of furosemide

Adverse Reactions

CNS: Dizziness, fever, headache, paresthesia, restlessness, vertigo, weakness

CV: Orthostatic hypotension, shock, thromboembolism, thrombophlebitis

EENT: Blurred vision, oral irritation, ototoxicity, stomatitis, tinnitus, transient hearing loss (rapid I.V. injection), yellow vision

ENDO: Hyperglycemia

GI: Abdominal cramps, anorexia, constipation, diarrhea, gastric irritation, hepatocellular insufficiency, indigestion, jaundice, nausea, pancreatitis, vomiting

GU: Bladder spasms, glycosuria

HEME: Agranulocytosis (rare), anemia, aplastic anemia (rare), azotemia, hemolytic

anemia, leukopenia, thrombocytopenia
MS: Muscle spasms

SKIN: Bullous pemphigoid, erythema multiforme, exfoliative dermatitis, photosensitivity, pruritus, purpura, rash, urticaria

Other: Allergic reaction (interstitial nephritis, necrotizing vasculitis, systemic vasculitis), dehydration, hyperuricemia, hypochloremia, hypokalemia, hyponatremia, hypovolemia

Nursing Considerations

WARNING Use furosemide cautiously in patients with advanced hepatic cirrhosis, especially those who also have a history of electrolyte imbalance or hepatic encephalopathy; drug may lead to lethal hepatic coma.

- Obtain patient's weight before and periodically during furosemide therapy to monitor fluid loss.
- For once-a-day dosing, give drug in the morning so patient's sleep won't be interrupted by increased need to urinate.
- Prepare drug for infusion with normal saline solution, lactated Ringer's solution, or D₅W.
- Administer drug slowly I.V. over 1 to 2 minutes to prevent ototoxicity.
- Expect patient to have periodic hearing tests during prolonged or high-dose I.V. therapy.
- Monitor blood pressure and hepatic and renal function as well as BUN, blood glucose, and serum creatinine, electrolyte, and uric acid levels, as appropriate.
- Be aware that elderly patients are more susceptible to hypotensive and electrolyte-altering effects and thus are at greater risk for shock and thromboembolism.
- If patient is at high risk for hypokalemia, give potassium supplements along with furosemide, as prescribed.
- Expect to discontinue furosemide at maximum dosage if oliguria persists for more than 24 hours.
- Be aware that furosemide may worsen left ventricular hypertrophy and adversely affect glucose tolerance and lipid metabolism.
- Notify prescriber if patient experiences hearing loss, vertigo, or ringing, buzzing, or sense of fullness in her ears. Drug may need to be discontinued.

PATIENT TEACHING

- Instruct patient to take furosemide at the same time each day to maintain therapeutic effects. Urge her to take it as prescribed, even if she feels well.
- Instruct patient to take the last dose of furosemide several hours before bedtime to avoid sleep interruption from diuresis. If patient receives once-daily dosing, advise her to take the dose in the morning to avoid sleep disturbance caused by nocturia.
- Advise patient to change position slowly to minimize effects of orthostatic hypotension and to take furosemide with food or milk to reduce GI distress.
- Caution patient about drinking alcoholic beverages, standing for prolonged periods, and exercising in hot weather because these actions increase the hypotensive effect of furosemide.
- Emphasize the importance of weight and diet control, especially limiting sodium intake.
- Unless contraindicated, urge patient to eat more high-potassium foods and to take a potassium supplement, if prescribed, to prevent hypokalemia.
- Instruct patient to keep follow-up appointments with prescriber to monitor progress. Urge her to notify prescriber about persistent, severe nausea, vomiting, and diarrhea because they may cause dehydration.
- Inform diabetic patient that furosemide may increase blood glucose level, and advise her to check her blood glucose level frequently.

G H I

gabapentin

Neurontin

Class and Category

Chemical class: Cyclohexane-acetic acid derivative

Therapeutic class: Anticonvulsant

Pregnancy category: C

Indications and Dosages

↗ *To manage postherpetic neuralgia*

CAPSULES, ORAL SOLUTION, TABLETS

Adults. *Initial:* 300 mg on day 1, increased to 300 mg b.i.d. on day 2, increased to 300 mg t.i.d. on day 3, and increased gradually thereafter according to pain response, up to 600 mg t.i.d. *Maximum:* 1,800 mg daily.

↗ *As adjunct to treat partial seizures*

CAPSULES, ORAL SOLUTION, TABLETS

Adults and adolescents. *Initial:* 300 mg t.i.d., increased gradually according to clinical response. *Maintenance:* 900 to 1,800 mg daily. *Maximum:* 3,600 mg daily.

DOSE ADJUSTMENT If creatinine clearance is 30 to 60 ml/min/1.73 m², dosage reduced to 300 mg b.i.d.; if it's 15 to 29 ml/min/1.73 m², to 300 mg daily; and if it's less than 15 ml/min/1.73 m², to 300 mg every other day.

Mechanism of Action

Is structurally like gamma-aminobutyric acid (GABA), the main inhibitory neurotransmitter in the brain. Although gabapentin's exact mechanism of action is unknown, GABA inhibits the rapid firing of neurons associated with seizures.

Contraindications

Hypersensitivity to gabapentin or its components

Interactions

DRUGS

aluminum- and magnesium-containing antacids: Decreased gabapentin bioavailability

CNS depressants: Increased CNS depression

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Agitation, altered proprioception, amnesia, anxiety, apathy, aphasia, asthenia, ataxia, cerebellar dysfunction, chills, CNS tumors, decreased or absent reflexes, delusions, depersonalization, depression, disappearance of aura, dizziness, dream disturbances, dysesthesia, dystonia, emotional lability, euphoria, facial paralysis, fatigue, fever, hallucinations, headache, hemiplegia, hostility, hyperkinesia, hyperreflexia, hypoesthesia, hypotonia, intracranial hemorrhage, lack of coordination, malaise, migraine headache, nervousness, occipital neuralgia, paranoia, paresis, paresthesia, positive Babinski's sign, psychosis, sedation, seizures, somnolence, stupor, subdural hematoma, suicidal ideation, syncope, tremor, vertigo

CV: Angina, hypertension, hypotension, murmur, palpitations, peripheral edema, peripheral vascular insufficiency, tachycardia, vasodilation

EENT: Abnormal vision, amblyopia, blepharospasm, cataracts, conjunctivitis, diplopia, dry eyes and mouth, earache, epistaxis, eye hemorrhage, eye pain, gingival bleeding, gingivitis, glossitis, hearing loss, hoarseness, increased salivation, inner ear infection, loss of taste, nystagmus, pharyngitis, photophobia, ptosis (bilateral or unilateral), rhinitis, sensation of fullness in ears, stomatitis, taste perversion, tinnitus, tooth discoloration, visual field defects

GI: Abdominal pain, anorexia, constipation, diarrhea, fecal incontinence, flatulence, gastroenteritis, hemorrhoids, hepatitis, hepatomegaly, increased appetite, indigestion, melena, nausea, thirst, vomiting

GU: Acute renal failure, decreased libido, impotence

HEME: Anemia, coagulation defect, decreased WBC count, leukopenia, thrombocytopenia

MS: Arthralgia, arthritis, back pain, bone fractures, dysarthria, joint stiffness or swelling, muscle twitching, myalgia, positive Romberg test, tendinitis

RESP: Apnea, cough, dyspnea, pneumonia, pseudocroup

SKIN: Abrasion, acne, alopecia, cyst, dia-

phoresis, dry skin, eczema, hirsutism, pruritus, purpura, rash, seborrhea, urticaria

Other: Dehydration, facial edema, lymphadenopathy, viral infection, weight gain or loss

Nursing Considerations

- As needed, open gabapentin capsules and mix contents with water, fruit juice, apple sauce, or pudding before administration.
- Administer initial dose at bedtime to minimize adverse reactions, especially ataxia, dizziness, fatigue, and somnolence.
- Give drug at least 2 hours after an antacid.
- Don't exceed 12 hours between doses on a 3-times-a-day schedule.
- Be aware that routine monitoring of blood gabapentin level isn't needed.

WARNING To discontinue drug or switch to an a different anticonvulsant, expect to change gradually over at least 1 week, as prescribed, to avoid loss of seizure control.

- Monitor renal function test results, and expect to adjust dosage, if needed.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

PATIENT TEACHING

- If patient has trouble swallowing gabapentin capsules, advise him to open them and sprinkle contents in juice or on soft food immediately before use.
- Instruct patient not to take drug within 2 hours after taking an antacid.
- Urge patient to take a missed dose as soon as he remembers. If the next dose is in less than 2 hours, tell him to wait 1 to 2 hours before taking it and then resume his regular schedule. Caution against doubling the dose.
- Caution patient not to stop drug abruptly.
- Inform patient about possible ataxia, dizziness, drowsiness, and nystagmus. Advise him to avoid hazardous activities until drug's CNS effects are known.
- To prevent complications from adverse oral reactions (such as gingivitis), encourage patient to use good oral hygiene and to seek routine dental care.
- Explain that adverse effects usually are mild to moderate and decline with time.
- Urge patient to keep follow-up appointments with prescriber to check progress.
- Urge caregivers to watch closely for evidence of suicidal tendencies, especially

when therapy starts or dosage changes, and to report concerns immediately.

- Urge woman who becomes pregnant while taking gabapentin to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that this registry is collecting information about the safety of antiepileptic drugs during pregnancy.

galantamine hydrobromide

Razadyne, Razadyne ER

Class and Category

Chemical class: Tertiary alkaloid

Therapeutic class: Antidementia agent

Pregnancy category: B

Indications and Dosages

↗ *To treat mild to moderate Alzheimer's-type dementia*

ORAL SOLUTION, TABLETS

Adults. *Initial:* 4 mg b.i.d. Dosage increased by 8 mg daily every 4 wk, if tolerated.

Maximum: 12 mg b.i.d.

DOSE ADJUSTMENT For patients with moderately impaired hepatic or renal function, maximum dosage shouldn't exceed 16 mg daily.

E.R. CAPSULES

Adults. *Initial:* 8 mg daily. Dosage increased by 8 mg daily every 4 wk if tolerated.

Maximum: 24 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	Unknown

Mechanism of Action

Reduces acetylcholine metabolism by competitively and reversibly inhibiting the brain enzyme acetylcholinesterase. Acetylcholine-producing neurons degenerate in the brains of patients with Alzheimer's disease. Inhibition of acetylcholinesterase increases the amount of acetylcholine, which is needed for nerve impulse transmission.

Contraindications

Hypersensitivity to galantamine hydrobromide or its components, severe hepatic or renal impairment (creatinine clearance less

than 9 ml/min/1.73 m²)

Interactions

DRUGS

amitriptyline, fluoxetine, fluvoxamine, quini-dine: Possibly decreased galantamine clearance

anticholinergics: Possibly interference with cholinesterase activity

cholinergic agonists, cholinesterase inhibitors, neuromuscular blockers: Possibly exaggerated effects of these drugs and galantamine

cimetidine: Possibly increased galantamine bioavailability

ketoconazole, paroxetine: Increased galantamine bioavailability

Adverse Reactions

CNS: Aggression, asthenia, depression, dizziness, fatigue, fever, headache, insomnia, malaise, somnolence, stroke, suicidal ideation, syncope, tremor

CV: AV block, bradycardia, chest pain, MI, myocardial ischemia

EENT: Rhinitis

GI: Abdominal pain, anorexia, diarrhea, flatulence, GI bleeding, indigestion, nausea, vomiting

GU: Hematuria, incontinence, renal failure or insufficiency, UTI

HEME: Anemia

Other: Dehydration, hypokalemia, weight loss

Nursing Considerations

- Give galantamine twice daily with morning and evening meals, and ensure adequate fluid intake to prevent GI symptoms.
- If therapy is interrupted for several days, expect to restart drug at lowest dose because benefits are lost when it is discontinued.
- Monitor patient's CV status closely because cholinesterase inhibitors like galantamine may have a depressive effect on sinoatrial and AV nodes and may lead to bradycardia and AV block.
- Monitor patient for progressive deterioration of mental status because drug is less effective as Alzheimer's disease progresses and intact cholinergic neurons decrease.

PATIENT TEACHING

- Instruct patient to take or caregiver to give regular-strength drug with morning and evening meals. Extended-release capsules should be given once in the morning,

preferably with food.

- Tell patient or caregiver to notify prescriber immediately if therapy stops for several days. Prescriber may restart at lowest dose.
- Instruct patient to maintain adequate fluid intake throughout galantamine therapy.
- Advise patient not to drive or perform activities requiring alertness, especially during first weeks of treatment, because drug may cause dizziness and drowsiness.
- Inform patient and family members that drug isn't a cure for Alzheimer's disease.

gemfibrozil

Apo-Gemfibrozil (CAN), Gen-Fibro (CAN), Lopid, Novo-Gemfibrozil (CAN), Nu-Gemfibrozil (CAN)

Class and Category

Chemical class: Fibric acid derivative, phenoxybutanoic acid

Therapeutic class: Antihyperlipidemic

Pregnancy category: C

Indications and Dosages

↗ *As adjunct (with diet) to treat hyperlipidemia types IIb, IV, and V*

CAPSULES, TABLETS

Adults. 600 mg before meals b.i.d.

Route	Onset	Peak	Duration
P.O.	2–5 days	4 wk	Unknown

Mechanism of Action

May decrease hepatic triglyceride production by reducing VLDL synthesis, inhibiting peripheral lipolysis, and decreasing hepatic extraction of free fatty acids. Gemfibrozil also may inhibit synthesis and increase clearance of apolipoprotein B, a carrier molecule for VLDL. In addition, it may accelerate turnover and removal of total cholesterol from the liver while increasing cholesterol excretion in the feces. As a result, triglyceride, total cholesterol, and VLDL levels decrease; the HDL level increases; and the LDL level is unaffected.

Contraindications

Concurrent therapy with repaglinide, gallbladder disease, hepatic or severe renal dys-

function, hypersensitivity to gemfibrozil or its components

Interactions

DRUGS

chenodiol, ursodiol: Decreased effectiveness of gemfibrozil

HMG-CoA reductase inhibitors: Increased risk of rhabdomyolysis and acute renal failure

oral anticoagulants: Increased anticoagulation

repaglinide: Increased serum repaglinide level and risk of severe hypoglycemia

Adverse Reactions

CNS: Chills, fatigue, headache, hypoesthesia, paresthesia, seizures, somnolence, syncope, vertigo

CV: Vasculitis

EENT: Blurred vision, cataracts, hoarseness, retinal edema, taste perversion

GI: Abdominal or epigastric pain, cholelithiasis, colitis, diarrhea, flatulence, heartburn, hepatoma, nausea, pancreatitis, vomiting

GU: Decreased male fertility, dysuria, impotence

HEME: Anemia, bone marrow hypoplasia, eosinophilia, leukopenia, thrombocytopenia

MS: Arthralgia, back pain, myalgia, myasthenia, myopathy, myositis, rhabdomyolysis, synovitis

RESP: Cough

SKIN: Eczema, jaundice, pruritus, rash

Other: Anaphylaxis, angioedema, increased risk of bacterial and viral infections, lupus-like symptoms, weight loss

Nursing Considerations

- Monitor serum triglyceride and cholesterol levels, as appropriate.
- Periodically review CBC and liver function test results during therapy, as ordered.
- If serum triglyceride and cholesterol levels don't improve within 3 months, expect to switch to a different drug, as prescribed.

PATIENT TEACHING

- Instruct patient to take gemfibrozil 30 minutes before breakfast and 30 minutes before dinner.
- Advise patient to take a missed dose as soon as he remembers, unless it's nearly time for the next dose. Caution against doubling the dose.
- Stress importance of a low-fat diet, regular

exercise, alcohol avoidance, and smoking cessation, as appropriate.

- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to notify prescriber if he experiences chills; cough; fever; hoarseness; lower back, side, or muscle pain; painful or difficult urination; severe abdominal pain with nausea and vomiting; tiredness; or weakness.
- If patient also takes an oral anticoagulant, urge him to report unusual bleeding or bruising; anticoagulant dosage may need to be reduced.
- Advise patient to keep scheduled appointments with prescriber to check progress.

gemifloxacin mesylate

Active

Class and Category

Chemical class: Fluoroquinolone

Therapeutic class: Antibiotic

Pregnancy category: C

Indications and Dosages

↗ *To treat acute bacterial exacerbation of chronic bronchitis caused by Streptococcus pneumoniae, Haemophilus influenzae, H. parainfluenzae, or Moraxella catarrhalis*

TABLETS

Adults. 320 mg daily for 5 days.

↗ *To treat mild to moderate community-acquired pneumonia caused by S. pneumoniae, H. influenzae, M. catarrhalis, Mycoplasma pneumoniae, Chlamydia pneumoniae, or Klebsiella pneumoniae*

TABLETS

Adults. 320 mg daily for 7 days.

DOSE ADJUSTMENT Dosage should be decreased to 160 mg daily in patients with creatinine clearance of 40 ml/min/1.73 m² or less.

Route	Onset	Peak	Duration
P.O.	0.5–2 hr	Unknown	Unknown

Mechanism of Action

Inhibits actions of the enzymes DNA gyrase and topoisomerase IV, which are required

for bacterial growth, thereby causing bacterial cells to die.

Contraindications

Hypersensitivity to gemifloxacin, its components, or other fluroquinolones

Interactions

DRUGS

aluminum and magnesium antacids, didanosine as chewable or buffered tablets or pediatric powder for oral solution, ferrous sulfate, sucralfate, zinc or other metal cations:

Reduced blood gemifloxacin level
antipsychotics; class IA antiarrhythmics, such as procainamide and quinidine; class III antiarrhythmics, such as amiodarone and sotalol; erythromycin; tricyclic antidepressants: Possibly prolonged QT interval
probenecid: Increased blood gemifloxacin level

warfarin: Possibly enhanced warfarin anticoagulant effects

Adverse Reactions

CNS: Dizziness, fever, headache, syncope, transient ischemic attack

CV: Peripheral edema, prolonged QT interval, supraventricular tachycardia, vasculitis

EENT: Taste perversion

GI: Abdominal pain, acute hepatic necrosis or failure, diarrhea, elevated liver function test results, hepatitis, jaundice, nausea, pseudomembranous colitis, vomiting

GU: Acute renal insufficiency or failure, interstitial nephritis

HEME: Agranulocytosis, aplastic or hemolytic anemia, elevated platelet count, elevated INR, hemorrhage, leukopenia, pancytopenia, thrombocytopenia

MS: Arthralgia, myalgia, tendinitis, tendon rupture

RESP: Allergic pneumonitis

SKIN: Erythema multiforme, exfoliation, facial swelling, photosensitivity, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, serum sickness

Nursing Considerations

- Review patient's medical history before giving gemifloxacin, which shouldn't be used in patient with a history of prolonged QT interval, patient with uncorrected electrolyte disorders, or patient

receiving class IA or III antiarrhythmics because of increased risk of prolonged QT interval. Monitor elderly patients closely because they may be more susceptible to prolonged QT interval.

- Use cautiously in patients with CNS disorders, such as epilepsy, or in those prone to seizures because other fluroquinolones have caused seizures, increased intracranial pressure, and toxic psychosis. Monitor patient closely; if CNS alterations occur, notify prescriber immediately and expect drug to be discontinued.
- Monitor patient closely for hypersensitivity reaction, which may occur as soon as first dose. If patient has such evidence as angioedema, bronchospasm, dyspnea, itching, rash, jaundice, shortness of breath, and urticaria, notify prescriber immediately and expect drug to be discontinued.
- Monitor patients prone to tendinitis, such as the elderly, athletes, and those taking corticosteroids, for reports of tendon pain, inflammation, or rupture. If present, notify prescriber. Expect gemifloxacin to be discontinued, patient placed on bedrest with no exercise of affected limb, and diagnostic tests ordered to confirm rupture.
- Notify prescriber about severe or prolonged diarrhea; it may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold gemifloxacin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- Monitor patients, especially women under age 40 and postmenopausal women receiving hormone replacement therapy, for rash. It may appear days after therapy starts and resolve in 7 days. Notify prescriber immediately if rash occurs because it can be severe in about 10% of patients.
- If patient takes warfarin, monitor coagulation status, as ordered, because adding gemifloxacin may increase risk of bleeding.

PATIENT TEACHING

- Tell patient to swallow tablet whole and take with a full glass of liquid.
- Warn patient not to increase dose because doing so may cause life-threatening cardiac arrhythmias.
- Instruct patient to complete entire course of therapy, even if symptoms decrease

before prescription is finished.

- Caution patient to avoid sun exposure as much as possible while taking gemifloxacin. Patient who can't avoid sun exposure should apply sunscreen and wear a hat, sunglasses, and long sleeves to cover as much skin as possible.
- Instruct patient to maintain adequate hydration throughout therapy to keep urine from becoming too concentrated. Tell patient to increase fluid intake if urine darkens or amount voided decreases.
- Caution patient to avoid hazardous activities until CNS effects of drug are known.
- Instruct patient to seek medical attention and notify prescriber immediately if he has tendon pain, tenderness, or rupture; evidence of hypersensitivity reaction, such as rash, urticaria, difficulty breathing, or facial swelling; or palpitations or fainting spells. The drug may need to be stopped.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Explain that watery or bloody stools can occur 2 or more months after therapy and can be serious, requiring prompt treatment.
- Tell patient to consult prescriber before starting any new medications, including OTC products, because gemifloxacin may interact adversely.
- Inform patient that magnesium and/or aluminum antacids; products containing iron; multivitamins containing zinc or other metal cations; and didanosine (Videx) chewable or buffered tablets and pediatric powder for oral solution (if prescribed) shouldn't be taken within 3 hours before or 2 hours after gemifloxacin and that gemifloxacin should be taken at least 2 hours before sucralfate (if prescribed).
- Instruct patient to alert prescriber about severe diarrhea, even up to 2 months after gemifloxacin therapy has ended.

gentamicin sulfate

Cidomycin (CAN), Garamycin, G-Mycin, Jenamicin

Class and Category

Chemical class: Aminoglycoside derived from *Micromonospora purpurea*

Therapeutic class: Antibiotic

Pregnancy category: D

Indications and Dosages

➤ *To treat serious bacterial infections caused by aerobic gram-negative organisms and some gram-positive organisms, including Citrobacter species, Enterobacter species, Escherichia coli, Klebsiella species, Proteus species, Pseudomonas aeruginosa, Serratia species, Staphylococcus aureus, and many strains of Streptococcus species*

I.V. INFUSION, I.M. INJECTION

Adults and adolescents. 1 to 1.7 mg/kg every 8 hr for 7 to 10 days.

Children. 2 to 2.5 mg/kg every 8 hr for 7 to 10 days.

Infants. 2.5 mg/kg every 8 to 16 hr for 7 to 10 days.

Premature or full-term neonates up to age 1 week. 2.5 mg/kg every 12 to 24 hr for 7 to 10 days.

INTRATHECAL (INTRALUMBAR OR INTRAVENTRICULAR) INJECTION

Adults and adolescents. 4 to 8 mg daily.

Infants and children age 3 months and over. 1 to 2 mg daily.

➤ *To treat uncomplicated UTI*

I.V. INFUSION, I.M. INJECTION

Adults and adolescents weighing more than 60 kg (132 lb). 160 mg once daily or 80 mg every 12 hr.

Adults and adolescents weighing less than 60 kg. 3 mg/kg once daily or 1.5 mg/kg every 12 hr.

DOSAGE ADJUSTMENT Supplemental dose of 1 to 1.7 mg/kg (2 to 2.5 mg/kg for children) given by I.M. injection or I.V. infusion after hemodialysis, based on infection severity.

Mechanism of Action

Binds to negatively charged sites on the outer cell membrane of bacteria, thereby disrupting the membrane's integrity. Gentamicin also binds to bacterial ribosomal subunits and inhibits protein synthesis. Both actions lead to cell death.

Incompatibilities

Don't administer gentamicin through same I.V. line as other drugs, especially beta-lactam antibiotics (penicillins and cephalosporins), because substantial mutual inactivation may occur. Give drugs through sepa-

rate sites.

Contraindications

Hypersensitivity or serious toxic reaction to other aminoglycosides, hypersensitivity to gentamicin or its components

Interactions

DRUGS

aminoglycosides (concurrent use of two or more): Decreased bacterial uptake of each drug, increased risk of ototoxicity and nephrotoxicity
cephalosporins, enflurane, methoxyflurane, vancomycin: Increased risk of nephrotoxicity
loop diuretics: Increased risk of ototoxicity and nephrotoxicity
neuromuscular blockers: Prolonged respiratory depression, increased neuromuscular blockade
penicillins: Inactivation of gentamicin by certain penicillins, increased risk of nephrotoxicity

Adverse Reactions

CNS: Acute organic mental syndrome, confusion, depression, fever, headache, increased protein in cerebrospinal fluid, lethargy, myasthenia gravis-like syndrome, neurotoxicity (dizziness, hearing loss, tinnitus, vertigo), peripheral neuropathy or encephalopathy (muscle twitching, numbness, seizures, skin tingling), pseudotumor cerebri

CV: Hypertension, hypotension, palpitations

EENT: Blurred vision, increased salivation, laryngeal edema, ototoxicity, stomatitis, vision changes

GI: Anorexia, nausea, splenomegaly, transient hepatomegaly, vomiting

GU: Nephrotoxicity

HEME: Anemia, eosinophilia, granulocytopenia, increased or decreased reticulocyte count, leukopenia, thrombocytopenia

MS: Arthralgia, leg cramps

RESP: Pulmonary fibrosis, respiratory depression

SKIN: Alopecia, generalized burning sensation, pruritus, purpura, rash, urticaria

Other: Anaphylaxis, injection site pain, superinfection, weight loss

Nursing Considerations

- Before gentamicin therapy begins, expect to obtain a body fluid or tissue specimen for culture and sensitivity testing, as

ordered, or check test results, if available.

- Drug is best absorbed when given by I.V. route. Blood level is unpredictable after I.M. administration.
- For I.V. use, dilute each dose with 50 to 200 ml normal saline solution or D₅W to yield no more than 1 mg/ml. Administer slowly over 30 to 60 minutes.
- Don't give gentamicin through same I.V. line as other drugs without first consulting pharmacist.
- Expect to adjust dosage based on peak and trough blood drug levels drawn after third maintenance dose, as prescribed.
- Don't give gentamicin by subcutaneous route because it may be painful.
- When assisting with intrathecal injection, use only 2 mg/ml of preservative-free preparation. Drug may be injected directly or delivered by implanted reservoir.
- Don't give drug to pregnant patient because it can cause hearing loss in fetus.

WARNING When giving pediatric injectable form of drug, be alert for allergic reactions—including anaphylaxis and possibly life-threatening asthmatic episodes—because drug contains sodium bisulfite.

- Assess patient for evidence of other infections because gentamicin may cause overgrowth of nonsusceptible organisms.
- Be aware that premature infants, neonates, and elderly patients have an increased risk of nephrotoxicity.

PATIENT TEACHING

- Stress importance of completing full course of gentamicin therapy.
- Instruct patient to immediately report adverse reactions, such as hearing loss, to avoid permanent effects.

glimepiride

Amaryl

Class and Category

Chemical class: Sulfonylurea

Therapeutic class: Antidiabetic

Pregnancy category: C

Indications and Dosages

↗ To control blood glucose level in type 2 diabetes mellitus

TABLETS

Adults. 1 to 2 mg daily with first meal of

the day. *Maintenance:* 1 to 4 mg daily, increased by 1 to 2 mg every 1 to 2 wk as needed for blood glucose control.

Maximum: 8 mg daily.

DOSAGE ADJUSTMENT Initial dosage reduced to 1 mg daily if needed for patients with renal impairment.

↗ *As adjunct (with insulin) to control blood glucose level*

TABLETS

Adults. 8 mg daily with low-dose insulin.

Route	Onset	Peak	Duration
P.O.	2–3 hr	Unknown	Over 24 hr

Mechanism of Action

Stimulates insulin release from beta cells in pancreas. Glimepiride also increases peripheral tissue sensitivity to insulin, either by enhancing insulin binding to cellular receptors or by increasing the number of insulin receptors.

Contraindications

Diabetes complicated by pregnancy; diabetic coma; hypersensitivity to glimepiride, sulfonyleureas, or their components; ketoacidosis; sole therapy for type 1 diabetes mellitus

Interactions

DRUGS

ACE inhibitors, anabolic steroids, androgens, azole antifungals, bromocriptine, chloramphenicol, clarithromycin, disopyramide, fibric acid derivatives, fluoxetine, guanethidine, H₂-receptor antagonists, insulin, magnesium salts, MAO inhibitors, methyl dopa, NSAIDs, octreotide, oral anticoagulants, oxyphenbutazone, phenylbutazone, probenecid, quinidine, quinolones, salicylates, sulfonamides, tetracycline, theophylline, tricyclic antidepressants, urinary acidifiers: Increased risk of hypoglycemia

asparaginase, calcium channel blockers, cholestyramine, clonidine, corticosteroids, danazol, diazoxide, estrogen, glucagon, hydantoins, isoniazid, lithium, morphine, nicotinic acid, oral contraceptives, phenothiazines, rifabutin, rifampin, sympathomimetics, thiazide diuretics, thyroid drugs, urinary alkalinizers: Increased risk of hyperglycemia
beta blockers: Possibly hyperglycemia or masking of hypoglycemia signs
digoxin: Increased risk of digitalis toxicity
pentamidine: Initially hypoglycemia and

then hyperglycemia if beta cell damage occurs

ACTIVITIES

alcohol use: Altered blood glucose control (usually hypoglycemia)

Adverse Reactions

CNS: Abnormal gait, anxiety, asthenia, chills, depression, dizziness, fatigue, headache, hypertonia, hypoesthesia, insomnia, malaise, migraine headache, nervousness, paresthesia, somnolence, syncope, tremor, vertigo

CV: Arrhythmias, edema, hypertension, vasculitis

EENT: Blurred vision, conjunctivitis, eye pain, pharyngitis, retinal hemorrhage, rhinitis, taste perversion, tinnitus

ENDO: Hypoglycemia

GI: Anorexia, constipation, diarrhea, elevated liver function test results, epigastric discomfort or fullness, flatulence, heartburn, hunger, nausea, proctocolitis, trace blood in stool, vomiting

GU: Darkened urine, decreased libido, dysuria, polyuria

HEME: Agranulocytosis, aplastic anemia, eosinophilia, hemolytic anemia, hepatic porphyria, leukopenia, pancytopenia

MS: Arthralgia, leg cramps, myalgia

RESP: Dyspnea

SKIN: Allergic skin reactions, diaphoresis, eczema, erythema multiforme, exfoliative dermatitis, flushing, jaundice, lichenoid reactions, maculopapular or morbilliform rash, photosensitivity, pruritus, urticaria

Other: Disulfiram-like reaction

Nursing Considerations

- Monitor fasting blood glucose level to determine response to glimepiride. Expect to check glycosylated hemoglobin level every 3 to 6 months to evaluate long-term blood glucose control.
- Arrange for dietary consultation and diabetic teaching, if appropriate. Ask dietitian to discuss amount of alcohol patient can consume without risking hypoglycemia.
- Expect to switch patient to insulin therapy, as prescribed, during physical stress, such as infection, surgery, and trauma.

WARNING Expect a higher risk of hypoglycemia when giving glimepiride to a malnourished or debilitated patient or one with renal, hepatic, pituitary, or adrenal

insufficiency. Also be aware that hypoglycemia may be more difficult to recognize in patients with autonomic neuropathy, the elderly, and patients taking beta blockers or other sympatholytic agents. Monitor blood glucose level closely.

- Monitor patient with a history of allergies to other sulfonamide derivatives closely because he may be allergic to glimepiride. If allergic reactions persist or worsen (dyspnea, drop in blood pressure, or shock), expect drug to be discontinued.

PATIENT TEACHING

- Instruct patient to take glimepiride just before first meal of the day. Caution him not to skip the meal after taking drug.
- Urge patient not to skip doses or increase dosage without consulting prescriber.
- Urge patient to report signs of hypoglycemia, such as anxiety, confusion, dizziness, excessive sweating, headache, and nausea.
- Encourage patient to carry candy or other simple sugars to treat mild hypoglycemia.
- Advise patient to consult prescriber before taking any OTC drug.
- Urge patient to carry identification indicating that he has diabetes.
- Teach patient how to monitor his blood glucose level.
- Teach patient about exercise, diet, signs of hyperglycemia and hypoglycemia, hygiene, foot care, and ways to avoid infection.
- Instruct patient to notify prescriber about darkened urine, difficulty controlling his blood glucose level, easy bruising, fever, rash, sore throat, or unusual bleeding.
- If photosensitivity is a problem, instruct patient to avoid direct sunlight and to wear sunscreen.

glipizide

Glucotrol, Glucotrol XL

Class and Category

Chemical class: Sulfonylurea

Therapeutic class: Antidiabetic

Pregnancy category: C

Indications and Dosages

↗ *To control blood glucose level in type 2 diabetes mellitus*

E.R. TABLETS

Adults. *Initial:* 5 mg daily with breakfast.

Dosage increased by 5 mg daily every 3 mo, if needed. *Maintenance:* 5 to 10 mg daily. *Maximum:* 20 mg daily.

TABLETS

Adults. *Initial:* 5 mg 30 min before first meal of day. Dosage adjusted by 2.5 to 5 mg every 2 to 3 days. For daily dose of 15 mg or less, give as a single dose. For dose above 15 mg daily, give in 2 divided doses. *Maximum:* 40 mg daily.

↗ *As adjunct to or replacement for insulin therapy in type 2 diabetes mellitus*

CAPSULES, TABLETS

Adults who need more than 20 units insulin daily. 5 mg daily, while decreasing insulin dosage by one-half. Further insulin reductions are based on clinical response.

DOSE ADJUSTMENT Initial dosage reduced to 2.5 mg daily if needed for patients over age 65 and those with hepatic disease.

Route	Onset	Peak	Duration
P.O.	10–30 min	30 min–2 hr	12–24 hr
P.O. (E.R.)	Unknown	Unknown	18–24 hr

Mechanism of Action

Stimulates insulin release from beta cells in pancreas. Glipizide also increases peripheral tissue sensitivity to insulin, either by increasing insulin binding to cellular receptors or by increasing number of insulin receptors.

Contraindications

Diabetes complicated by pregnancy; diabetic coma; hypersensitivity to glipizide, sulfonylureas, or their components; ketoacidosis; sole therapy for type 1 diabetes mellitus

Interactions

DRUGS

ACE inhibitors, anabolic steroids, androgens, azole antifungals, bromocriptine, chloramphenicol, disopyramide, fibric acid derivatives, guanethidine, H₂-receptor antagonists, insulin, magnesium salts, MAO inhibitors, methyl dopa, octreotide, oral anticoagulants, oxyphenbutazone, phenylbutazone, probenecid, quinidine, salicylates, sulfonamides, tetracycline, theophylline, tricyclic antidepressants, urinary acidifiers: Increased risk of hypoglycemia
asparaginase, calcium channel blockers, cholestyramine, clonidine, corticosteroids,

danazol, diazoxide, estrogen, glucagon, hydantoin, isoniazid, lithium, morphine, nicotinic acid, oral contraceptives, phenothiazines, rifabutin, rifampin, sympathomimetics, thiazide diuretics, thyroid drugs, urinary alkalinizers: Increased risk of hyperglycemia
beta blockers: Possibly hyperglycemia or masking of hypoglycemia signs
digitalis glycosides: Increased risk of digitalis toxicity
pentamidine: Initially hypoglycemia and then hyperglycemia if beta cell damage occurs

FOODS

all foods: Possibly delayed absorption of tablets if taken within 30 minutes of meal

ACTIVITIES

alcohol use: Altered blood glucose control (usually hypoglycemia)

Adverse Reactions

CNS: Abnormal gait, anxiety, asthenia, chills, depression, dizziness, fatigue, headache, hypertonia, hypoesthesia, insomnia, malaise, migraine headache, nervousness, paresthesia, somnolence, syncope, tremor, vertigo

CV: Arrhythmias, edema, hypertension, vasculitis

EENT: Blurred vision, conjunctivitis, eye pain, pharyngitis, retinal hemorrhage, rhinitis, taste perversion, tinnitus

ENDO: Hypoglycemia

GI: Abdominal pain, anorexia, constipation, diarrhea, elevated liver function test results, epigastric discomfort or fullness, flatulence, heartburn, hunger, nausea, proctocolitis, trace blood in stool, vomiting

GU: Darkened urine, decreased libido, dysuria, polyuria

HEME: Agranulocytosis, aplastic anemia, eosinophilia, hemolytic anemia, hepatic porphyria, leukopenia, pancytopenia

MS: Arthralgia, leg cramps, myalgia

RESP: Dyspnea

SKIN: Allergic skin reactions, diaphoresis, eczema, erythema multiforme, exfoliative dermatitis, flushing, jaundice, lichenoid reactions, maculopapular or morbilliform rash, photosensitivity, urticaria

Other: Disulfiram-like reaction

Nursing Considerations

- Use cautiously in patients with glucose 6-phosphate dehydrogenase deficiency

because hemolytic anemia may develop. Monitor patient's CBC closely.

- To improve blood glucose control, give drug in divided doses instead of once daily.
- Check blood glucose level at least three times daily for a patient switching from insulin to glipizide. Patients who take more than 40 units of insulin daily may need hospitalization during transition.
- If patient gradually loses responsiveness to glipizide, expect to give a second antidiabetic to maintain blood glucose control.
- Monitor fasting blood glucose level to determine response to drug. Expect to check glycosylated hemoglobin every 3 to 6 months or as ordered to evaluate long-term blood glucose control.
- Expect to switch patient to insulin therapy, as prescribed, during physical stress, such as infection, surgery, or trauma.

WARNING Risk of hypoglycemia is higher when giving glipizide to a malnourished or debilitated patient or one with renal, hepatic, pituitary, or adrenal insufficiency.

PATIENT TEACHING

- Tell patient to take glipizide 30 minutes before the first meal of the day. Caution him not to skip the meal after taking the drug.
- Advise patient not to skip doses or increase the dosage without consulting prescriber.
- Urge patient to report evidence of hypoglycemia, such as anxiety, confusion, dizziness, excessive sweating, headache, and nausea.
- Encourage patient to carry candy or other simple sugars to treat mild hypoglycemia.
- Caution patient to consult prescriber before taking any OTC drugs.
- Urge patient to carry identification indicating that he has diabetes.
- Teach patient how to monitor his blood glucose level.
- Teach patient about exercise, diet, signs of hyperglycemia and hypoglycemia, hygiene, foot care, and ways to avoid infection.
- Instruct patient to notify prescriber if he experiences darkened urine, easy bruising, fever, hypoglycemia or hyperglycemia, rash, sore throat, and unusual bleeding.
- If photosensitivity is a problem, instruct patient to avoid direct sunlight and to wear sunscreen.

glucagon

GlucaGen, Glucagon Diagnostic Kit, Glucagon Emergency Kit

Class and Category

Chemical class: Synthetic hormone
Therapeutic class: Antihypoglycemic, diagnostic aid adjunct
Pregnancy category: B

Indications and Dosages

↗ *To provide emergency treatment of severe hypoglycemia*

I.V., I.M., OR SUBCUTANEOUS INJECTION
Adults and children weighing more than 20 kg (44 lb) or, with GlucaGen, more than 25 kg (55 lb). 1 mg, repeated in 15 min if needed.

Children weighing 20 kg or less or, with GlucaGen, 25 kg or less. 0.5 mg, or 0.02 to 0.03 mg/kg, repeated in 15 min, if needed.

↗ *To provide diagnostic assistance by inhibiting bowel peristalsis in radiologic examination of GI tract*

I.V. INJECTION

Adults. 0.25 to 2 mg before procedure. Dose, route, and timing vary with segment of GI tract examined and length of procedure.

Route	Onset	Peak	Duration
I.V.	5–20 min*†	Unknown	90 min*‡
I.M.	15–26 min*§	Unknown	90 min*
SubQ	30–45 min*	Unknown	90 min*

Mechanism of Action

Increases production of adenylate cyclase, which catalyzes conversion of adenosine triphosphate to cAMP, a process that in turn activates phosphorylase. Phosphory-

* For antihypoglycemic action.

† 45 sec to 1 min for smooth-muscle relaxation.

‡ 9 to 25 min for smooth-muscle relaxation.

§ 4 to 10 min for smooth-muscle relaxation.

|| 12 to 32 min for smooth-muscle relaxation.

lase promotes breakdown of glycogen to glucose (glycogenolysis) in the liver. As a result, blood glucose level increases and GI smooth muscles relax.

Incompatibilities

Don't mix glucagon with sodium chloride or solutions that have a pH of 3.0 to 9.5; use with dextrose solutions instead.

Contraindications

Hypersensitivity to glucagon or its components, pheochromocytoma

Interactions

DRUGS

oral anticoagulants: Possibly increased anticoagulant effects

Adverse Reactions

CV: Hypertension, hypotension (with hypersensitivity reaction), tachycardia

GI: Nausea, vomiting

RESP: Bronchospasm, respiratory distress

SKIN: Urticaria

Nursing Considerations

- Rouse patient as quickly as possible because prolonged hypoglycemia can cause cerebral damage.
- For I.V. use, reconstitute 1-mg vial of glucagon with 1 ml of diluent or 10-mg vial with 10 ml of diluent. Don't give more than 1 mg/ml. For large doses, dilute with sterile water for injection.
- Before injecting glucagon, place unconscious patient on his side to prevent aspiration of vomitus when he regains consciousness.
- Administer by slow I.V. injection to decrease risk of adverse reactions, such as tachycardia and vomiting.
- If patient doesn't respond to glucagon, expect to give I.V. dextrose.
- When patient is conscious or diagnostic procedure is completed, give oral carbohydrates to restore hepatic glycogen stores and prevent secondary hypoglycemia.
- Keep in mind that glucagon isn't effective in patients with depleted hepatic glycogen stores caused by such conditions as adrenal insufficiency, chronic hypoglycemia, and starvation.

PATIENT TEACHING

- Instruct patient to monitor blood glucose level, especially with signs of hypoglycemia.

- Teach patient and family members how to recognize signs of hypoglycemia and when to notify prescriber.
- Advise patient to carry candy or other simple sugars to treat early hypoglycemia.
- Emphasize importance of a consistent diet, regular exercise, and proper use of insulin or oral antidiabetic drug.
- Make sure unstable diabetic patients and family members know how to give glucagon subcutaneously in case of hypoglycemia. Instruct family members to keep patient on his side and give him a carbohydrate when he awakens. Advise against giving fluids by mouth until patient is fully conscious.
- Instruct patient and family members to call for emergency medical assistance after glucagon treatment, especially if patient can't ingest oral glucose or if he's taking the sulfonyleurea chlorpropamide, in case secondary hypoglycemia occurs.

glyburide (glibenclamide)

Albert Glyburide (CAN), Apo-Glyburide (CAN), DiaBeta, Euglucon (CAN), Gen-Glybe (CAN), Glynase PresTab, Medi-Glybe (CAN), Micronase, Novo-Glyburide (CAN), Nu-Glyburide (CAN)

Class and Category

Chemical class: Sulfonyleurea

Therapeutic class: Antidiabetic

Pregnancy category: C (B for Glynase PresTab and Micronase)

Indications and Dosages

↗ *To control blood glucose level in type 2 diabetes mellitus*

MICRONIZED TABLETS

Adults. *Initial:* 1.5 to 3 mg daily with first meal of day, increased by up to 1.5 mg at weekly intervals, if needed. *Maintenance:* 0.75 to 12 mg as a single dose or in divided doses with meals.

NONMICRONIZED TABLETS

Adults. *Initial:* 2.5 to 5 mg daily with first meal of the day, increased by up to 2.5 mg at weekly intervals, if needed. *Maintenance:* 1.25 to 20 mg daily as a single dose or in divided doses with meals.

DOSAGE ADJUSTMENT For conversion from insulin to glyburide for adults who use more than 40 units of insulin daily, initial dosage adjusted to 5 mg nonmicronized or 3 mg micronized glyburide as a single dose with 50% of usual insulin dose; glyburide dosage increased gradually, as needed. For adults who use less than 40 units insulin daily, usual glyburide dosage is used when insulin is discontinued.

For elderly patients, initial dosage possibly reduced to 1.25 mg nonmicronized glyburide daily, gradually increased by 2.5 mg/wk, as needed; or 0.75 to 3 mg micronized daily, gradually increased by 1.5 mg/wk, as needed.

Route	Onset	Peak	Duration
P.O.*	1 hr	2.3–3.5 hr	12–24 hr
P.O.†	15–60 min	1–3 hr	24 hr

Mechanism of Action

Stimulates insulin release from beta cells in the pancreas. Glyburide also increases peripheral tissue sensitivity to insulin either by enhancing insulin binding to cellular receptors or by increasing the number of insulin receptors.

Contraindications

Concurrent therapy with bosentan, diabetes complicated by pregnancy; diabetic ketoacidosis; hypersensitivity to glyburide, sulfonyleureas, or their components; ketoacidosis; type 1 diabetes mellitus

Interactions

DRUGS

ACE inhibitors, anabolic steroids, androgens, azole antifungals, bromocriptine, chloramphenicol, clarithromycin, disopyramide, fibric acid derivatives, fluoxetine, guanethidine, H₂-receptor antagonists, insulin, magnesium salts, MAO inhibitors, methyl dopa, NSAIDs, octreotide, oral anticoagulants, oxyphenbutazone, phenylbutazone, probenecid, quimidine, quinolones, salicylates, sulfonamides, tetracycline, theophylline, tricyclic antidepressants, urinary acidifiers: Increased risk of hypoglycemia
asparaginase, calcium channel blockers, cholestyramine, clonidine, corticosteroids,

* Micronized.

† Nonmicronized.

danazol, diazoxide, estrogen, glucagon, hydantoin, isoniazid, lithium, morphine, nicotinic acid, oral contraceptives, phenothiazines, rifabutin, rifampin, sympathomimetics, thiazide diuretics, thyroid drugs, urinary alkalinizers: Increased risk of hyperglycemia
beta blockers: Possibly hyperglycemia or masking of hypoglycemia signs
bosentan: Increased risk of elevated liver enzymes

cyclosporine: Increased cyclosporine plasma level and toxicity

digitalis glycosides: Increased risk of digitalis toxicity

miconazole (oral): Possibly severe hypoglycemia

oral anticoagulants: Possibly potentiated or weakened anticoagulant effects

pentamidine: Initial hypoglycemia and then hyperglycemia if beta cell damage occurs

rifampin: Decreased glyburide effectiveness

FOODS

high-fat foods: Reduced bioavailability of nonmicronized glyburide

ACTIVITIES

alcohol use: Altered blood glucose control (usually hypoglycemia)

Adverse Reactions

CNS: Abnormal gait, anxiety, asthenia, chills, depression, dizziness, fatigue, headache, hypertonia, hypoesthesia, insomnia, malaise, migraine headache, nervousness, paresthesia, somnolence, syncope, tremor, vertigo

CV: Arrhythmias, edema, hypertension, vasculitis

EENT: Blurred vision, conjunctivitis, eye pain, pharyngitis, retinal hemorrhage, rhinitis, taste perversion, tinnitus

ENDO: Hypoglycemia

GI: Anorexia, constipation, cholestatic jaundice, diarrhea, elevated liver function test results, epigastric discomfort or fullness, flatulence, heartburn, hepatic failure, hepatitis, hunger, nausea, proctocolitis, trace blood in stool, vomiting

GU: Decreased libido, dysuria, polyuria

HEME: Agranulocytosis, aplastic anemia, eosinophilia, hemolytic anemia, hepatic porphyria, leukopenia, pancytopenia

MS: Arthralgia, leg cramps, myalgia

RESP: Dyspnea

SKIN: Allergic skin reactions, diaphoresis, eczema, erythema multiforme, exfoliative

dermatitis, flushing, jaundice, lichenoid reactions, maculopapular or morbilliform rash, photosensitivity, urticaria

Other: Disulfiram-like reaction

Nursing Considerations

- Use cautiously in patients with glucose 6-phosphate dehydrogenase deficiency because hemolytic anemia may develop. Monitor patient's CBC closely.
- Give glyburide as single dose before first meal of the day. If patient takes more than 10 mg daily or if severe GI distress occurs, give in 2 divided doses before meals.
- Monitor fasting blood glucose level to determine patient's response to glyburide. Expect to check glycosylated hemoglobin every 3 to 6 months or as ordered to evaluate long-term blood glucose control.
- When patient switches from insulin to glyburide, check blood glucose level three times daily before meals.
- Be aware that micronized tablets aren't equal to nonmicronized tablets; they contain smaller particles, which affects drug bioavailability.

WARNING Expect a higher risk of hypoglycemia when giving drug to a malnourished or debilitated patient or one with renal, hepatic, pituitary, or adrenal insufficiency. Also be aware that hypoglycemia may be more difficult to recognize in patients with autonomic neuropathy, the elderly, and patients who are taking beta blockers or other sympatholytic agents. Monitor blood glucose level closely.

- Monitor patient with history of allergies to other sulfonamide derivatives closely because he may be allergic to glyburide. If allergic reactions persist or worsen (dyspnea, drop in blood pressure, or shock), expect drug to be discontinued.
- Administer insulin as needed and prescribed during periods of increased stress, such as infection, surgery, and trauma.
- Arrange for diabetic teaching and consultation between patient and dietitian, if appropriate.

PATIENT TEACHING

- Instruct patient to take glyburide just before first meal of the day. Caution him not to skip the meal after taking drug.
- Advise patient not to take nonmicronized glyburide with a high-fat meal because it may reduce glyburide bioavailability.

- Caution patient to avoid skipping doses, discontinuing glyburide, or taking OTC drugs without first consulting prescriber.
- Teach patient how to monitor his blood glucose level and when to notify prescriber about changes.
- Urge patient to report signs of hypoglycemia: anxiety, confusion, dizziness, excessive sweating, headache, and nausea.
- Suggest that patient carry candy or other simple sugars to treat mild hypoglycemia.
- Urge patient to avoid alcohol because it increases the risk of hypoglycemia.
- Advise patient to carry identification indicating that he has diabetes.
- Teach patient about exercise, diet, signs of hyperglycemia and hypoglycemia, hygiene, foot care, and ways to avoid infection.
- Instruct patient to notify prescriber if he experiences easy bruising, fever, hypoglycemia or hyperglycemia, rash, sore throat, and unusual bleeding.
- If photosensitivity is a problem, instruct patient to avoid direct sunlight and to wear sunscreen.

glycopyrrolate

Robinul, Robinul Forte

Class and Category

Chemical class: Quaternary ammonium compound

Therapeutic class: Antiarrhythmic, anticholinergic, cholinergic adjunct

Pregnancy category: B

Indications and Dosages

↗ *To treat peptic ulcer disease*

TABLETS

Adults and adolescents. 1 to 2 mg b.i.d. or t.i.d. *Maximum:* 8 mg daily.

I.V. OR I.M. INJECTION

Adults and adolescents. 0.1 to 0.2 mg every 4 hr, p.r.n. *Maximum:* 4 doses daily.

↗ *To reduce gastric acid and respiratory secretions before anesthesia*

I.M. INJECTION

Adults and adolescents. 0.0044 mg/kg 30 to 60 min before anesthesia or when preanesthesia sedative or opioid is given.

Children over age 2. 0.0044 to 0.0088 mg/kg 30 to 60 min before anesthesia or when preanesthesia sedative or opioid is given.

↗ *To counteract intraoperative and anesthesia-induced arrhythmias*

I.V. INJECTION

Adults and adolescents. 0.1 mg, repeated every 2 to 3 min, if needed.

Children over age 2. 0.0044 mg/kg. Dose repeated every 2 to 3 min, if needed.

Maximum: 0.1 mg as a single dose.

↗ *As cholinergic adjunct in curariform block*

I.V. INJECTION

Adults and children over age 2. 0.2 mg glycopyrrolate for each 1 mg neostigmine or 5 mg pyridostigmine when given together.

Route	Onset	Peak	Duration
P.O.	60 min	Unknown	8–12 hr
I.V.	1 min	Unknown	2–3 hr*
I.M.,	15–30	30–45	2–3 hr*
SubQ	min	min	

Mechanism of Action

Inhibits acetylcholine's action on postganglionic muscarinic receptors throughout the body. Depending on the receptors' location, glycopyrrolate produces various effects, such as:

- reducing the volume and acidity of gastric secretions
- controlling excessive bronchial, pharyngeal, and tracheal secretions and dilating the bronchi
- inhibiting vagal stimulation of the heart
- relaxing smooth muscle in the GI and GU tracts.

Incompatibilities

Don't mix glycopyrrolate with alkaline drugs or solutions that have a pH over 6.0 because drug stability may be affected. A pH over 6.0 may occur if glycopyrrolate is mixed with dexamethasone sodium phosphate or LR solution. Gas or precipitate may form if glycopyrrolate is mixed in same syringe as chloramphenicol, diazepam, dimenhydrinate, methohexital sodium, pentobarbital sodium, secobarbital sodium, sodium bicarbonate, or thiopental sodium.

Contraindications

Angle-closure glaucoma, asthma, hemor-

* For vagal blocking effect; up to 7 hr for reduction of saliva.

rhage with unstable cardiovascular status, hepatic disease, hypersensitivity to anticholinergics, ileus, intestinal atony, myasthenia gravis, obstructive GI or urinary disorders, severe ulcerative colitis, toxic megacolon

Interactions

DRUGS

anticholinergics, antiparkinsonian drugs, phenothiazines, tricyclic antidepressants:

Possibly increased anticholinergic effects
antidiarrheals (adsorbent): Decreased glycopyrrolate absorption, leading to decreased therapeutic effectiveness

antimyasthenics: Possibly reduced intestinal motility

atenolol: Possibly potentiated atenolol effects

calcium- or magnesium-containing antacids, carbonic anhydrase inhibitors, citrates, sodium bicarbonate: Possibly reduced excretion of glycopyrrolate and increased therapeutic and adverse effects

cyclopropane: Possibly ventricular arrhythmias

digoxin: Possibly potentiated digoxin effects

haloperidol, phenothiazines: Possibly decreased effectiveness of these drugs

ketoconazole: Possibly decreased ketoconazole absorption

metoclopramide: Possibly antagonized effects of metoclopramide

opioids: Possibly severe constipation and urine retention, risk of ileus

potassium chloride: Possibly increased severity of potassium chloride–induced gastric lesions

Adverse Reactions

CNS: Confusion, dizziness, drowsiness, headache, insomnia, nervousness, weakness

CV: Bradycardia (low doses), heart block, palpitations, prolonged QT interval, tachycardia (high doses)

EENT: Blurred vision, cycloplegia, dilated pupils, dry mouth, increased intraocular pressure, loss of taste, mydriasis, nasal congestion, photophobia, taste perversion

GI: Abdominal distention, constipation, dysphagia, nausea, vomiting

GU: Impotence, urinary hesitancy, urine retention

RESP: Dyspnea

SKIN: Decreased sweating (heat exhaus-

tion), dry skin, flushing, pruritus, urticaria

Other: Anaphylaxis

Nursing Considerations

- Use glycopyrrolate cautiously in patients with autonomic neuropathy, hepatic disease, mild to moderate ulcerative colitis, prostatic hypertrophy, or hiatal hernia because drug's anticholinergic effect can worsen these conditions; gastric ulcer because drug may delay gastric emptying; and renal disease because drug excretion may be altered.
- Give tablets 30 to 60 minutes before meals.
- As needed and prescribed, give 2-mg dose at bedtime to ensure overnight control of symptoms.
- For I.V. use, administer by direct injection without diluting. Or inject into tubing of flowing I.V. solution unless it contains an alkaline drug or sodium bicarbonate.
- Closure system contains dry natural rubber that may cause hypersensitivity reaction if handled by or used to inject someone with latex sensitivity.
- Use continuous cardiac monitoring, as ordered, to assess patient for arrhythmias during drug administration.

WARNING Check all doses carefully because even a slight overdose can lead to toxicity.

- To prevent overheating caused by decreased sweating, adjust the room temperature and make sure patient is well hydrated.

PATIENT TEACHING

- Advise patient to take glycopyrrolate tablets 30 to 60 minutes before meals.
- Instruct patient to consult prescriber before taking any OTC drugs.
- Caution patient about possible drowsiness and dizziness and need to avoid hazardous activities until drug's effects are known.
- Suggest that patient use sugarless hard candy, ice, or saliva substitute to relieve dry mouth.
- Instruct patient to avoid exertion and hot environments because he's prone to heat exhaustion while taking glycopyrrolate.
- Urge patient to drink at least 8 glasses of water daily, unless contraindicated.
- Tell patient to notify prescriber about abdominal distention, trouble breathing or urinating, eye pain, irregular heartbeat, sensitivity to light, or severe constipation.

- Advise patient to wear sunglasses in bright light.
- Inform male patient that reversible impotence may occur during therapy.
- If urinary hesitancy occurs, advise patient to void before taking each dose.

golimumab

Simponi

Class and Category

Chemical class: Human IgG₁ monoclonal antibody

Therapeutic class: Biologic disease-modifying anti-rheumatic drug (DMARD)

Pregnancy category: B

Indications and Dosages

↗ *To treat moderate to severe active rheumatoid arthritis in combination with methotrexate; to treat active psoriatic arthritis or ankylosing spondylitis with or without methotrexate or other nonbiologic DMARDs*

SUBCUTANEOUS INJECTION

Adults. 50 mg monthly.

Route	Onset	Peak	Duration
SubQ	Unknown	2–6 days	Unknown

Mechanism of Action

Binds to a cytokine protein, tumor necrosis factor alpha (TNFα), to block interaction with its receptors, which prevents biological activity of TNFα. Elevated TNFα levels in the blood, synovium, and joints may play an important role in pathophysiology of such inflammatory diseases as rheumatoid arthritis, psoriatic arthritis, and ankylosing spondylitis. Reduced TNFα activity in these disorders improves signs and symptoms.

Contraindications

Hypersensitivity to golimumab or its components

Interactions

DRUGS

abatacept, anakinra, rituximab: Possibly increased risk of serious infection
cytochrome P-450 substrates such as cyclosporine, theophylline, warfarin: Effects or blood levels of these drugs may change

when golimumab therapy starts or stops *live vaccines:* Increased risk of adverse vaccine effects

Adverse Reactions

CNS: Dizziness, fever, paresthesia

CV: Hypertension

EENT: Nasopharyngitis, oral herpes, pharyngitis, rhinitis, sinusitis

GI: Elevated liver enzyme levels

RESP: Bronchitis, pneumonia, tuberculosis, upper respiratory tract infection

SKIN: Cellulitis, new or worsening psoriasis

Other: Abscess, antibody formation, infections (including invasive fungal infections and reactivation of hepatitis B infection in chronic carriers), influenza, injection site erythema, lupus-like syndrome, malignancies such as lymphoma or leukemia, sepsis

Nursing Considerations

- Make sure patient has a tuberculin skin test before therapy starts. If skin test is positive, treatment of latent tuberculosis must start before golimumab therapy starts, as prescribed. Also expect anti-tuberculosis therapy to be started if patient has a history of latent or active tuberculosis, if adequate therapy can't be confirmed, or if patient has a negative test for latent tuberculosis but also has risk factors for tuberculosis.

WARNING If patient has evidence of an active infection when drug is prescribed, golimumab therapy shouldn't start until infection has been treated. Monitor all patients for infection during therapy, especially those receiving immunosuppressants. If a serious infection, an opportunistic infection, or sepsis develops, expect prescriber to stop drug and start appropriate antimicrobial therapy.

- Patients with a history of cancer, except those successfully treated for non-melanoma skin cancer, should be thoroughly evaluated before golimumab therapy starts because treatment may pose more risks than benefits. Patients with rheumatoid arthritis may have a higher risk than the general population for developing leukemia while taking a TNF blocker such as golimumab.
- Use golimumab cautiously in patients with recurrent infection or increased risk of infection, patients who live in regions

where tuberculosis and histoplasmosis are endemic, and patients with a history of hepatitis B infection because drug increases risk of infection.

- Use golimumab cautiously in patients with congestive heart failure, demyelinating disorders such as multiple sclerosis, and hematologic cytopenias because these disorders have occurred with use of other TNF blockers.
- Be aware that needle cover of syringe contains dry rubber. Don't handle if you're allergic to latex.
- Take golimumab out of the refrigerator 30 minutes before giving injection to allow time for drug to warm up to room temperature. Never warm drug in any other way. Rotate injection sites.

PATIENT TEACHING

- Explain that first injection of golimumab must be administered with a health care professional present.
- Teach patient or caregiver how to give golimumab as a subcutaneous injection at home, if applicable. Tell him to let prefilled syringe or autoinjector sit at room temperature outside carton for 30 minutes before injecting. Tell him not to warm drug in any other way and not to remove needle cover or cap while letting golimumab warm up.
- Teach patient using autoinjector not to pull the device away from his skin until he hears a first "click" and then a second "click" indicating the injection is finished. It may take up to 15 seconds before second click is heard and, if device is pulled away from the skin before the second click, a full dose may not have been given.
- Emphasize need to inject full amount in prefilled syringe to obtain correct 50-mg dose. Instruct patient to discard any drug left in prefilled syringe or autoinjector.
- If patient is allergic to latex, explain that needle cover contains natural dry rubber.
- Instruct patient or caregiver to use a puncture resistant container to dispose of needles and syringes at home.
- Inform patient that drug must be refrigerated (not frozen).
- Urge patient to check expiration dates and not to use outdated drug.
- Teach patient to rotate injection sites and never to give injection into an area where

skin is tender, bruised, red, or hard.

- Explain that tuberculosis may occur during golimumab therapy. Instruct him to report persistent cough, wasting or weight loss, and low-grade fever to prescriber.
- Teach patient to recognize evidence of infection and bleeding disorders and to tell prescriber if they occur; drug may need to be stopped. Advise patient to avoid people with infections and to have all prescribed laboratory tests performed.
- Inform patient that golimumab therapy increases the risk of certain kinds of cancer, especially lymphomas and leukemias. Emphasize the importance of having follow-up visits and reporting unusual or sudden onset of signs or symptoms.
- Caution against receiving live-virus vaccines while taking golimumab; doing so may adversely affect the immune system.
- Tell patient to report lupus-like signs and symptoms that, although rare, may occur during therapy, such as chest pain that doesn't go away, shortness of breath, joint pain, or a rash on cheeks or arms that's sensitive to the sun. Explain that drug may need to be discontinued if these occur.
- Advise patient to tell all health care providers about golimumab therapy and to tell prescriber about any OTC drugs, herbal remedies, and vitamin and mineral supplements being taken.

granisetron hydrochloride

Kytril, Sancuso

Class and Category

Chemical class: Carbazone

Therapeutic class: Antiemetic

Pregnancy category: B

Indications and Dosages

➤ *To prevent nausea and vomiting caused by chemotherapy*

ORAL SOLUTION, TABLETS

Adults and adolescents. 1 mg up to 1 hr before chemotherapy, repeated 12 hr later. Or, 2 mg up to 1 hr before chemotherapy.

I.V. INFUSION

Adults and adolescents. 10 mcg/kg diluted and infused over 5 min, starting 30 min

before chemotherapy; or 10 mcg/kg undiluted and infused over 30 sec, starting 30 min before chemotherapy.

TRANSDERMAL

Adults. 3.1 mg/24 hr patch applied to upper outer arm 24 to 48 hr before chemotherapy and worn up to 7 days. Patch removed no sooner than 24 hr after chemotherapy is completed.

↗ *To prevent nausea and vomiting caused by radiation therapy*

ORAL SOLUTION, TABLETS

Adults and adolescents. 2 mg daily given 1 hr before radiation therapy.

↗ *To prevent or treat postoperative nausea and vomiting*

I.V. INJECTION

Adults and adolescents. 1 mg given over 30 sec before induction of anesthesia or immediately before reversal anesthesia for prevention. 1 mg administered over 30 sec after surgery for treatment.

Mechanism of Action

Has a high affinity for serotonin receptors along vagal nerve endings in intestines. Because of this affinity, granisetron prevents nausea and vomiting that usually result when serotonin is released by damaged enterochromaffin cells.

Incompatibilities

Don't mix granisetron in same solution as other drugs.

Contraindications

Hypersensitivity to granisetron or its components

Interactions

DRUGS

drugs that prolong the QT interval: Increased risk of QT-interval prolongation

Adverse Reactions

CNS: Asthenia, chills, CNS stimulation, drowsiness, fever, headache, insomnia, somnolence

CV: Hypertension, prolonged QT interval

EENT: Taste perversion

GI: Abdominal pain, anorexia, constipation, diarrhea, elevated liver function test results, nausea, vomiting

HEME: Anemia, leukopenia, thrombocytopenia

SKIN: Alopecia, reactions at patch applica-

tion site (pruritus, rash, redness)

Nursing Considerations

- Use cautiously in patients with arrhythmias or cardiac conduction disorders because granisetron may prolong QT interval. Patients especially at risk include those with cardiac disease or electrolyte abnormalities and those receiving cardiotoxic chemotherapy or therapy with another drug that prolongs QT interval.
- For use with chemotherapy, dilute I.V. preparation of granisetron with normal saline solution or D₅W to total volume of 20 to 50 ml. Mixture may be stored up to 24 hours. Use only on days when chemotherapy is given.
- Apply transdermal patch to patient's upper outer arm 24 to 48 hours before chemotherapy, and don't remove it until at least 24 hours after chemotherapy is completed.

PATIENT TEACHING

- Inform patient that granisetron is given orally or I.V. before chemotherapy to help prevent nausea.
- Instruct patient to take granisetron tablet without food to avoid reducing drug bioavailability.
- Advise patient to report constipation, fever, severe diarrhea, or severe headache. Also caution about possible drowsiness.
- Advise patient wearing granisetron patch to cover it with clothing if there's a risk of exposure to sunlight. Tell patient to continue covering application site with clothing for 10 days after removal of patch.

guaifenesin

Anti-Tuss, Balmiril Expectorant (CAN), Benylin-E (CAN), Breonesin, Calmylin Expectorant (CAN), Gee-Gee, Genatuss, GG-CEN, Glycotuss, Glytuss, Guaituss, Halotussin, Hytuss, Hytuss 2X, Mucinex, Organidin NR, Resyl (CAN), Robitussin, Scot-tussin Expectorant, Uni-tussin

Class and Category

Chemical class: Glyceryl guaiacolate

Therapeutic class: Expectorant

Pregnancy category: C

Indications and Dosages

➤ *To relieve cough, especially when secretions are thick*

CAPSULES, ORAL SOLUTION, SYRUP, TABLETS

Adults and adolescents. 200 to 400 mg every 4 hr. *Maximum:* 2,400 mg daily.

CAPSULES, ORAL SOLUTION, SYRUP

Children ages 6 to 12. 100 to 200 mg every 4 hr. *Maximum:* 1,200 mg daily.

➤ *To promote productive cough*

E.R. TABLETS (MUCINEX)

Adults and adolescents. 600 to 1,200 mg every 12 hr. *Maximum:* 2,400 mg daily.

Route	Onset	Peak	Duration
P.O.	30 min	Unknown	4–6 hr

Mechanism of Action

Increases fluid and mucus removal from the upper respiratory tract by increasing the volume of secretions and reducing their adhesiveness and surface tension.

Contraindications

Hypersensitivity to guaifenesin

Adverse Reactions

CNS: Dizziness, headache

GI: Nausea and vomiting (with large doses)

SKIN: Rash, urticaria

Nursing Considerations

- As prescribed and as appropriate, give liquid forms of guaifenesin to children.
- Watch for evidence of more serious condition, such as cough that lasts longer than 1 week, fever, persistent headache, and rash.

PATIENT TEACHING

- Instruct patient to take each dose with a full glass of water.
- Advise patient not to break, crush, or chew E.R. tablets but to swallow them whole.
- Tell patient to increase fluid intake (unless contraindicated) to help thin secretions.
- Advise patient not to take drug longer than 1 week and to notify prescriber about fever, persistent headache, or rash.

guanadrel sulfate

Hylorel

Class and Category

Chemical class: Guanidine derivative

Therapeutic class: Antihypertensive

Pregnancy category: B

Indications and Dosages

➤ *To manage hypertension*

TABLETS

Adults. 5 mg b.i.d., increased to 20 to 75 mg daily in divided doses t.i.d. or q.i.d., if needed.

DOSE ADJUSTMENT Initial dosage reduced to 5 mg daily if needed for patients with renal impairment or creatinine clearance of 30 to 60 ml/min/1.73 m². Then adjusted after at least 7 days. Initial dosage reduced to 5 mg every other day if needed for patients with creatinine clearance less than 30 ml/min/1.73 m². Then dosage adjusted after at least 2 wk.

Route	Onset	Peak	Duration
P.O.	30 min–2 hr	4–6 hr	4–14 hr

Mechanism of Action

Exerts antihypertensive effect at peripheral sympathetic nerve endings. Through an uptake mechanism, guanadrel is stored in adrenergic neurons, where it displaces norepinephrine from its storage sites. This action blocks normal release of norepinephrine in response to nerve impulses, which depletes norepinephrine stores in synapses and relaxes vessel walls, thus reducing peripheral resistance and blood pressure.

Contraindications

Heart failure not caused by hypertension, hypersensitivity to guanadrel or its components, MAO inhibitor use within 1 week of guanadrel use, pheochromocytoma

Interactions

DRUGS

alpha blockers, beta blockers, rauwolfia alkaloids: Possibly orthostatic hypotension or bradycardia

amphetamines, appetite suppressants, cyclobenzaprine, haloperidol, loxapine, maprotiline, methylphenidate, phenothiazines, thioxanthenes, tricyclic antidepressants: Decreased antihypertensive effect of guanadrel

anticholinergics: Possibly decreased inhibition of gastric acid secretion

barbiturates, opioids: Possibly increased

hypotensive effect

MAO inhibitors: Possibly severe blood pressure increase

NSAIDs: Possibly sodium and water retention and decreased antihypertensive effect of guanadrel

sympathomimetics: Possibly reduced antihypertensive effect of guanadrel, leading to hypertension; possibly potentiated effects of sympathomimetics

vasodilators: Increased orthostatic hypotension

ACTIVITIES

alcohol use: Increased hypotensive effect

Adverse Reactions

CNS: Confusion, drowsiness, fatigue, headache, light-headedness, paresthesia, sleep disturbance

CV: Chest pain, orthostatic hypotension, palpitations, peripheral edema

EENT: Blurred vision, dry mouth and throat, glossitis

GI: Abdominal cramps or pain, anorexia, constipation, diarrhea, indigestion, nausea, vomiting

GU: Difficult ejaculation, hematuria, impotence, nocturia, urinary frequency or urgency

MS: Arthralgia, back or neck pain, joint inflammation, leg cramps, muscle weakness, myalgia

RESP: Cough, dyspnea

Other: Excessive weight gain or loss

Nursing Considerations

- Use guanadrel cautiously in patients with asthma because drug may aggravate this condition. Monitor patient for acute dyspnea, wheezing, and other evidence of asthma attack. Notify prescriber immediately if they develop.

WARNING Assess patient for evidence of overdose, such as blurred vision, dizziness, and syncope.

- Be aware that elderly patients have a greater risk of dizziness and syncope.
- Assess for signs of fluid retention and heart failure, including crackles, a new S₃ heart sound, and sudden weight gain.

PATIENT TEACHING

- Explain that guanadrel won't cure high blood pressure but will help control it.
- Instruct patient to take drug at the same time each day to improve compliance and

blood pressure control.

- Caution patient about possible dizziness, light-headedness, and fainting, especially when getting up from a lying or sitting position. Advise him to rise slowly, especially in the morning, and to sit with his feet dangling for 1 to 2 minutes before standing up.
- Instruct patient to sit or lie down immediately if he feels dizzy.
- To prevent fainting, advise patient to avoid alcohol, standing for long periods, pursuing excessive exercise, and being overly exposed to hot weather.
- Instruct patient to check with prescriber before taking OTC drugs during therapy.
- Advise patient to follow a low-sodium diet to help reduce blood pressure and prevent fluid retention.

guanethidine monosulfate

Apo-Guanethidine (CAN), Ismelin

Class and Category

Chemical class: Guanidine derivative

Therapeutic class: Antihypertensive

Pregnancy category: C

Indications and Dosages

↗ *To manage moderate to severe hypertension and renal hypertension*

TABLETS

Adults. *Initial:* 10 to 12.5 mg daily, increased as needed by 10 to 12.5 mg every wk.

Maintenance: 25 to 50 mg daily. Some patients may need up to 300 mg daily.

Children. 0.2 mg/kg daily, increased p.r.n. by 0.2 mg/kg every 7 to 10 days. *Maximum:* 3 mg/kg every 24 hr.

DOSAGE ADJUSTMENT Initial dosage increased to 25 to 50 mg daily for hospitalized adults because they can be monitored more closely. Then dosage increased by 25 to 50 mg every other day, p.r.n.

Route	Onset	Peak	Duration
P.O.	Unknown	8 hr	Unknown

Mechanism of Action

Exerts antihypertensive effect at peripheral

sympathetic nerve endings. Through an uptake mechanism, guanethidine is stored in adrenergic neurons, where it displaces norepinephrine from its storage sites. This action blocks normal release of norepinephrine in response to nerve impulses, which depletes norepinephrine stores in synapses and relaxes vessel walls, reducing peripheral resistance and blood pressure.

Contraindications

Heart failure not caused by hypertension, hypersensitivity to guanethidine or its components, MAO inhibitor use within 1 week of guanethidine use, pheochromocytoma

Interactions

DRUGS

alpha blockers, beta blockers, rauwolfia alkaloids: Possibly orthostatic hypotension or bradycardia

amphetamines, appetite suppressants, cyclobenzaprine, haloperidol, loxapine, maprotiline, methylphenidate, phenothiazines, thioxanthenes, tricyclic antidepressants: Decreased antihypertensive effect of guanethidine

anticholinergics: Possibly decreased inhibition of gastric acid secretion

barbiturates, opioids: Increased hypotensive effect

insulin, oral antidiabetic drugs: Possibly increased antidiabetic effect of these drugs
MAO inhibitors: Possibly severe blood pressure increase

NSAIDs: Possibly sodium and water retention and decreased antihypertensive effect of guanethidine

sympathomimetics: Possibly reduced antihypertensive effect of guanethidine, leading to hypertension; possibly potentiated effects of sympathomimetics

vasodilators: Increased orthostatic hypotension

ACTIVITIES

alcohol use: Increased hypotensive effect

Adverse Reactions

CNS: Depression, dizziness, fatigue, headache, lassitude, paresthesia, syncope

CV: Angina, bradycardia, orthostatic hypotension, palpitations, peripheral edema

EENT: Blurred vision, dry mouth, glossitis, nasal congestion, parotid gland tenderness, ptosis

GI: Anorexia, constipation, diarrhea (severe), indigestion, nausea, vomiting

GU: Ejaculation disorders, elevated BUN level, impotence, nocturia, priapism, urinary frequency

HEME: Anemia, leukopenia, thrombocytopenia

MS: Leg cramps, muscle twitching, myalgia

RESP: Asthma exacerbation, dyspnea

SKIN: Alopecia, dermatitis

Other: Weight gain

Nursing Considerations

- As prescribed, stop MAO inhibitor therapy at least 1 week before starting guanethidine.
- Because guanethidine has cumulative effects, give a small initial dose and increase gradually, as prescribed. When blood pressure is controlled, expect to reduce dosage to lowest effective level.
- Watch for orthostatic hypotension, which occurs most often when patient rises in the morning and is exacerbated by hot weather, exercise, and alcohol. Assess supine and standing blood pressures, especially after dosage adjustments.
- Measure daily weight to help detect fluid retention. Also observe for edema and other signs of heart failure. A thiazide diuretic may be prescribed to decrease sodium and fluid retention.
- Notify prescriber if severe diarrhea occurs. Drug may need to be discontinued.
- Monitor febrile patient for increased hypotension and adverse reactions because fever decreases drug requirements.
- As ordered, stop giving guanethidine 2 weeks before surgery to reduce risk of cardiac arrest during anesthesia.

PATIENT TEACHING

- Teach patient how to recognize orthostatic hypotension, and advise changing position slowly. Explain that symptoms are worse in the morning and worsened by exercise, hot weather, alcohol, and hot showers.
- Instruct patient to report fainting, frequent dizziness, and severe diarrhea.
- Caution patient to avoid alcohol because it may increase risk of orthostatic hypotension.
- Instruct patient to weigh himself daily at the same time, on the same scale, and wearing the same amount of clothing. Advise him to report signs of fluid retention, such as reduced urine volume, sud-

- den weight increase, and limb swelling.
- Urge patient to consult prescriber before taking OTC drugs during guanethidine therapy.
- If a diabetic patient takes insulin or a sulfonylurea, instruct him to monitor his blood glucose level more frequently to check for hypoglycemia.
- Advise patient to follow a low-sodium diet to help reduce blood pressure and prevent fluid retention.

guanfacine hydrochloride

Intuniv, Tenex

Class and Category

Chemical class: Dichlorobenzine derivative

Therapeutic class: Antihypertensive

Pregnancy category: B

Indications and Dosages

↗ *To manage hypertension, alone or with other antihypertensives*

TABLETS

Adults. 1 mg daily at bedtime, increased if needed to 2 mg after 3 to 4 wk. Increased to 3 mg if needed after another 3 to 4 wk.

Maintenance: 2 or 3 mg daily.

DOSE ADJUSTMENT Twice-daily administration used if blood pressure tends to rise at the end of 24-hr period.

↗ *To treat attention deficit hyperactivity disorder (ADHD)*

E.R. TABLETS

Adults and children age 6 and over. *Initial:* 1 mg once daily, increased, as needed, by 1 mg/wk. *Maintenance:* 1 to 4 mg once daily. *Maximum:* 4 mg once daily.

Route	Onset	Peak	Duration
P.O.	Unknown*	8–12 hr†	24 hr

Mechanism of Action

Decreases sympathetic nerve impulse outflow from the vasomotor center of the brain to the heart and blood vessels by

* For single dose; in 1 wk for multiple doses.

† For single dose; 1 to 3 mo for multiple doses.

stimulating central α_2 -adrenergic receptors. This action reduces peripheral vascular resistance, renovascular resistance, heart rate, and blood pressure. Prolonged guanfacine use may reduce total peripheral vascular resistance, slightly reducing heart rate. Guanfacine also stimulates growth hormone secretion, reduces circulating plasma catecholamine levels, and reduces left ventricular hypertrophy.

Contraindications

Hypersensitivity to guanfacine

Interactions

DRUGS

CNS depressants: Possibly increased CNS depression

ketoconazole and other strong CYP3A4/5

inhibitors: Increased plasma guanfacine level and increased risk of bradycardia, hypotension, and sedation

NSAIDs, sympathomimetics, tricyclic antidepressants: Possibly decreased antihypertensive effect of guanfacine

other antihypertensives: Possibly increased antihypertensive effect, resulting in hypotension

rifampin and other CYP3A4 inducers:

Decreased plasma guanfacine level and effectiveness

valproic acid: Increased plasma valproic acid level

ACTIVITIES

alcohol use: Possibly increased CNS depression

Adverse Reactions

CNS: Anxiety, asthenia, confusion, depression, dizziness, drowsiness, fatigue, headache, irritability, lethargy, nervousness, sedation, seizures, somnolence, syncope, weakness

CV: Atrioventricular block, bradycardia, chest pain, hypertension, orthostatic hypotension, sinus arrhythmia

EENT: Conjunctivitis, dry mouth

GI: Abdominal pain, constipation, dyspepsia, elevated liver enzyme levels, nausea, vomiting

GU: Decreased libido, enuresis, impotence, urinary frequency

RESP: Asthma

SKIN: Dermatitis, diaphoresis, pallor, pruritus, purpura, rash

Other: Increased weight

Nursing Considerations

- Use guanfacine cautiously in patients with cerebrovascular disease, chronic renal or hepatic failure, recent MI, or severe coronary insufficiency.
- Give drug at bedtime to minimize daytime sedation.

WARNING Expect to stop hypertension treatment by decreasing dosage gradually over 2 to 4 days. Typically, if patient hasn't taken drug for 2 or more days, he may have withdrawal symptoms, including abdominal cramps, anxiety, chest pain, diaphoresis, headache, increased salivation, insomnia, irregular heart rate and rhythm, nausea, nervousness, restlessness, tremor, and vomiting.

For patients being treated for ADHD, expect to taper dosage gradually over 3 to 7 days by no more than 1 mg every 3 to 7 days to prevent rebound hypertension.

- If you suspect that patient has drug-related depression, notify prescriber immediately and expect to discontinue drug.

PATIENT TEACHING

- Instruct patient to take guanfacine at bedtime to reduce daytime drowsiness.
- Tell patient not to break, crush, or chew extended-release tablets before swallowing.
- Caution patient about possible drowsiness, and advise him to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to avoid consuming alcohol and other CNS depressants while taking guanfacine.
- Advise patient to report rash.
- Inform male patient that guanfacine may cause impotence. Suggest that he discuss impotence with prescriber, if it occurs.
- Caution patient not to stop taking drug abruptly because doing so can cause a dangerous rise in blood pressure along with anxiety and nervousness.

halazepam

Paxipam

Class, Category, and Schedule

Chemical class: Benzodiazepine

Therapeutic class: Antianxiety

Pregnancy category: D

Controlled substance schedule: IV

Indications and Dosages

➤ *To manage anxiety*

TABLETS

Adults. 20 to 40 mg t.i.d. or q.i.d. *Optimal:* 80 to 160 mg daily.

DOSAGE ADJUSTMENT Dosage reduced to 20 mg once or twice daily if needed for debilitated patients.

Route	Onset	Peak	Duration
P.O.	Slow	Unknown	6–8 hr

Mechanism of Action

May potentiate the effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptor sites in limbic and cortical areas of the CNS. By binding to these receptor sites, halazepam increases inhibitory effects of GABA and blocks cortical and limbic arousal.

Contraindications

Acute angle-closure glaucoma, hypersensitivity to halazepam or its components, itraconazole or ketoconazole therapy, psychosis

Interactions

DRUGS

antacids: Possibly altered rate of halazepam absorption

barbiturates, CNS depressants, opioids:

Increased CNS depression, possibly sedation and impaired motor function

cimetidine, diltiazem, disulfiram, erythromycin, fluoxetine, fluvoxamine, isoniazid, itraconazole, ketoconazole, metoprolol, nefazodone, oral contraceptives, propoxyphene, propranolol, ranitidine, valproic acid, verapamil: Decreased halazepam clearance, increased blood level, and increased risk of adverse effects

clozapine: Possibly respiratory depression
digoxin: Increased blood digoxin level and risk of digitalis toxicity

levodopa: Decreased antidyskinetic effect

neuromuscular blockers: Increased or blocked neuromuscular blockade

theophyllines: Decreased sedative effect of halazepam

ACTIVITIES

alcohol use: Increased CNS depression, possibly sedation and impaired motor function
smoking: Decreased halazepam effectiveness

Adverse Reactions

CNS: Agitation, anxiety, ataxia, confusion, depression, dizziness, drowsiness, euphoria, headache, irritability, nervousness, slurred speech, tremor, weakness

CV: Angina, palpitations, sinus tachycardia

EENT: Diplopia, dry mouth, tinnitus

GI: Abdominal cramps or pain, constipation, diarrhea, increased salivation, nausea, vomiting

GU: Decreased libido, dysuria

MS: Arthralgia

SKIN: Pruritus, rash

Nursing Considerations

- Use haloperidol cautiously in patients with impaired hepatic or renal function, seizure disorders, or suicidal tendencies.
- Be aware that risk of haloperidol addiction and abuse is relatively high.
- Monitor renal and liver function test results, as appropriate, during long-term treatment.
- Expect to withdraw drug gradually over 2 weeks to avoid withdrawal symptoms, which include anxiety, confusion, insomnia, psychosis, and seizures.

PATIENT TEACHING

- Instruct patient to take haloperidol exactly as prescribed and not to stop abruptly because withdrawal symptoms may occur.
- Caution patient to avoid alcohol and other CNS depressants during therapy. Advise patient to avoid OTC drugs, such as cough and cold remedies, because they may contain CNS depressants.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to report depression, difficulty voiding, double vision, persistent drowsiness, and rash.
- Explain that drug's full effects may not occur for 6 weeks.

haloperidol

Apo-Haloperidol (CAN), Haldol, Novo-Peridol (CAN), Peridol (CAN)

haloperidol decanoate

Haldol Decanoate, Haldol LA (CAN)

haloperidol lactate

Haldol Concentrate

Class and Category

Chemical class: Butyrophenone derivative

Therapeutic class: Antidyskinetic, antipsychotic

Pregnancy category: C (haloperidol decanoate), not rated (haloperidol, haloperidol lactate)

Indications and Dosages

↗ *To treat psychotic disorders*

ORAL SOLUTION, TABLETS

Adults and adolescents. 0.5 to 5 mg b.i.d. or t.i.d. *Maximum:* Usually 100 mg daily.

Children ages 3 to 12. 0.05 mg/kg daily in divided doses b.i.d. or t.i.d. Increased by 0.5 mg every 5 to 7 days, if needed.

Maximum: 0.15 mg/kg daily.

↗ *To treat nonpsychotic behavior disorders and Tourette's syndrome*

ORAL SOLUTION, TABLETS

Adults and adolescents. 0.5 to 5 mg b.i.d. or t.i.d. *Maximum:* Usually 100 mg daily.

Children ages 3 to 12. 0.05 to 0.075 mg/kg daily in divided doses b.i.d. or t.i.d.

Increased by 0.5 mg every 5 to 7 days, if needed. *Maximum:* 0.075 mg/kg daily.

DOSAGE ADJUSTMENT Initial dosage reduced to 0.5 to 2 mg b.i.d. or t.i.d. if needed for elderly or debilitated patients.

↗ *To treat acute psychotic episodes*

I.M. INJECTION

Adults and adolescents. *Initial:* 2 to 5 mg, with subsequent doses up to every 60 min.

Or, if symptoms are controlled, dose may be repeated every 4 to 8 hr. *Maximum:* Usually 100 mg daily. First oral dose may be given 12 to 24 hr after last parenteral dose.

↗ *To provide long-term antipsychotic therapy for patients who require parenteral therapy*

LONG-ACTING I.M. (DECANOATE) INJECTION

Adults. *Initial:* 10 to 15 times the daily oral dose up to 100 mg. Repeated every 4 wk, if needed. *Maximum:* 300 mg/mo.

Mechanism of Action

May block postsynaptic dopamine receptors in the limbic system and increase brain turnover of dopamine, producing an antipsychotic effect.

Contraindications

Blood dyscrasias, bone marrow depression, cerebral arteriosclerosis, coma, concurrent use of large amounts of other CNS depressants, coronary artery disease, epilepsy, hepatic dysfunction, hypersensitivity to haloperidol or its components, Parkinson's disease, severe hypertension or hypotension, severe CNS depression, subcortical brain damage

Route	Onset	Peak	Duration
I.M.*	Unknown	3–4 days†	Unknown

Interactions

DRUGS

amphetamines: Possibly decreased stimulant effects of amphetamines and decreased antipsychotic effect of haloperidol

anticholinergics, antidyskinetics, antihistamines: Increased anticholinergic effect and risk of decreased antipsychotic effect of haloperidol

anticonvulsants: Possibly decreased effectiveness of anticonvulsants and decreased blood haloperidol level

bromocriptine: Possibly decreased effectiveness of bromocriptine

bupropion: Lowered seizure threshold, increased risk of major motor seizure

CNS depressants: Increased CNS depression and risk of respiratory depression and hypotension

diazoxide: Possibly hypoglycemia

dopamine (high-dose therapy): Possibly decreased vasoconstriction

ephedrine: Possibly decreased vasopressor effect of ephedrine

epinephrine: Possibly severe hypotension and tachycardia

fluoxetine: Increased risk of severe and frequent extrapyramidal effects

guanadrel, guanethidine: Decreased hypotensive effects of these drugs

levodopa, pergolide: Possibly decreased therapeutic effects of these drugs

lithium: Increased risk of neurotoxicity

MAO inhibitors, maprotiline, tricyclic antidepressants: Increased sedative and anticholinergic effects of these drugs

* For haloperidol decanoate and lactate.

† For haloperidol decanoate only; 30 to 45 min for haloperidol lactate.

metaraminol: Possibly decreased vasopressor effect of metaraminol

methoxamine: Decreased vasopressor effect, shortened duration of methoxamine action

methyl dopa: Possibly disorientation, slowed or difficult thought processes

phenylephrine: Decreased vasopressor response to phenylephrine

ACTIVITIES

alcohol use: Increased CNS depression and risk of respiratory depression and hypotension

Adverse Reactions

CNS: Agitation, anxiety, confusion, drowsiness, dystonia, euphoria, extrapyramidal reactions that may be irreversible (akathisia, pseudoparkinsonism, tardive dyskinesia), hallucinations, headache, insomnia, neuroleptic malignant syndrome, restlessness, slurred speech, tremor, vertigo

CV: Cardiac arrest, hypertension, orthostatic hypotension, QT-interval prolongation, ventricular arrhythmias, tachycardia, torsades de pointes

EENT: Blurred vision, dry mouth, increased salivation (all drug forms); stomatitis (oral solution)

ENDO: Breast engorgement, galactorrhea

GI: Constipation, nausea, vomiting

GU: Decreased libido, difficult ejaculation, impotence, menstrual irregularities, urine retention

HEME: Agranulocytosis, anemia, leukocytosis, leukopenia

SKIN: Diaphoresis, photosensitivity, rash

Other: Heatstroke, weight gain

Nursing Considerations

- Haloperidol shouldn't be used to treat dementia-related psychosis in the elderly because of an increased mortality risk.
- Use haloperidol cautiously in patients with a history of prolonged QT interval, patients with uncorrected electrolyte disturbances, and patients receiving Class IA or III antiarrhythmics because of an increased risk of prolonged QT interval. Monitor elderly patients closely because they may have an increased risk of prolonged QT interval.
- Dilute oral solution with a beverage, such as cola or orange, apple, or tomato juice.
- Give haloperidol decanoate (long-acting form prepared in sesame oil to produce

slow, sustained release) by deep I.M. injection into gluteal muscle using Z-track technique and 21G needle. Don't give more than 3 ml per site. Expect to reach stable plasma level after third or fourth dose.

- If injection solution has a slight yellow discoloration, be aware that this change doesn't affect potency.
- Watch for tardive dyskinesia (potentially irreversible involuntary movements) in patients receiving long-term therapy, especially elderly women who take large doses.
- Monitor CBC, especially if patient has a low WBC count or history of drug-induced leukopenia or neutropenia, often during the first few months of therapy. If WBC count drops, especially if neutrophil count drops below 1,000/mm³, expect haloperidol to be discontinued. If neutropenia is significant, also monitor patient for fever or other symptoms of infection and provide appropriate treatment, as prescribed.
- If extrapyramidal reactions occur during the first few days of treatment, reduce dosage, as prescribed. If symptoms persist, drug may be discontinued. Dystonia also may occur during first few days of treatment, especially in patients receiving higher doses and in males and younger age-groups. Notify prescriber.
- Avoid stopping haloperidol abruptly unless severe adverse reactions occur.
- Monitor for signs of neuroleptic malignant syndrome, a rare but possibly fatal disorder linked to antipsychotic drugs. Signs include altered mental status, arrhythmias, fever, and muscle rigidity.

WARNING Sudden death, QT-interval prolongation, and torsades de pointes, although uncommon, may occur in patients receiving haloperidol despite the lack of such predisposing factors as electrolyte imbalance, concurrent therapy with drugs known to prolong the QT interval, underlying cardiac abnormalities, hypothyroidism, and familial long-QT syndrome.

PATIENT TEACHING

- Advise patient to take haloperidol exactly as prescribed and not to stop abruptly because withdrawal symptoms may occur.
- To prevent oral mucosal irritation, instruct patient to dilute liquid form with juice or

cola before taking it.

- Caution patient to avoid skin contact with oral solution because it may cause a rash.
- Advise patient to take tablets with food or a full glass of milk or water to reduce GI distress.
- Instruct patient to consume adequate fluids and to take precautions against heat-stroke.
- Urge patient not to drink alcohol during therapy.
- If sedation occurs, caution patient to avoid driving and other hazardous activities.
- Instruct patient to report repetitive movements, tremor, and vision changes.

heparin calcium

Calcilean (CAN), Calciparine

heparin sodium

Hepalean (CAN), Heparin Leo (CAN), Heparin Lock Flush, Liquaemin

Class and Category

Chemical class: Glycosaminoglycan

Therapeutic class: Anticoagulant

Pregnancy category: C

Indications and Dosages

↗ *To prevent and treat deep vein thrombosis and pulmonary embolism, to treat peripheral arterial embolism, and to prevent thromboembolism before and after cardioversion of chronic atrial fibrillation*

I.V. INFUSION OR INJECTION

Adults. *Loading:* 35 to 70 units/kg or 5,000 units by injection. Then 20,000 to 40,000 units infused over 24 hr.

Children. *Loading:* 50 units/kg by injection. Then 100 units/kg infused every 4 hr or 20,000 units/m² infused over 24 hr.

I.V. INJECTION

Adults. *Initial:* 10,000 units. *Maintenance:* 5,000 to 10,000 units every 4 to 6 hr.

Children. *Initial:* 50 units/kg. *Maintenance:* 100 units/kg/dose every 4 hr.

I.V. OR SUBCUTANEOUS INJECTION

Adults. *Loading:* 5,000 units I.V. Then 10,000 to 20,000 units subcutaneously.

Maintenance: 8,000 to 10,000 units subcutaneously every 8 hr or 15,000 to 20,000 units subcutaneously every 12 hr.

➤ *To diagnose and treat disseminated intravascular coagulation (DIC)*

I.V. INFUSION OR INJECTION

Adults. 50 to 100 units/kg every 4 hr. Drug may be discontinued if no improvement occurs in 4 to 8 hr.

Children. 25 to 50 units/kg every 4 hr. Drug may be discontinued if no improvement occurs in 4 to 8 hr.

➤ *To prevent postoperative thromboembolism*

SUBCUTANEOUS INJECTION

Adults. 5,000 units 2 hr before surgery and then 5,000 units every 8 to 12 hr for 7 days or until patient is fully ambulatory.

➤ *To prevent clots in patients undergoing open-heart and vascular surgery*

I.V. INFUSION OR INJECTION

Adults. 300 units/kg for procedures that last less than 60 min; 400 units/kg for procedures that last longer than 60 min.

Minimum: 150 units/kg.

Children. 300 units/kg for procedures that last less than 60 min. Then dosage based on coagulation test results. *Minimum:* 150 units/kg.

➤ *To maintain heparin lock patency*

I.V. INJECTION

Adults. 10 to 100 units/ml heparin flush solution (enough to fill device) after each use of device.

DOSAGE ADJUSTMENT Increased dosage may be needed if patient needs aggressive anticoagulation to treat or prevent life-threatening thromboses, if heparin will be given I.V., and if heparin has been manufactured under the new standard implemented in October, 2009. (The letter “N” appears in the lot number or after the expiration date on heparin products made under the new standard. An exception is Hospira, which identifies its new-standard products using a lot number starting with “82” or higher.)

Route	Onset	Peak	Duration
I.V.	Immediate	Minutes	Unknown
SubQ	20–60 min	Unknown	Unknown

Mechanism of Action

Binds with antithrombin III, enhancing antithrombin III’s inactivation of the coagulation enzymes thrombin (factor IIa) and factors Xa and XIa. At low doses, heparin inhibits factor Xa and prevents conversion

of prothrombin to thrombin. Thrombin is needed for conversion of fibrinogen to fibrin; without fibrin, clots can’t form. At high doses, heparin inactivates thrombin, preventing fibrin formation and existing clot extension.

Incompatibilities

Don’t mix heparin with any other drug unless you have an order to do so and have checked with pharmacist. Heparin is incompatible with many drugs and solutions, especially ones that contain a phosphate buffer, sodium bicarbonate, or sodium oxalate.

Contraindications

Hypersensitivity to heparin or its components; neonates; severe thrombocytopenia; uncontrolled bleeding, except in DIC

Interactions

DRUGS

antihistamines, digoxin, nicotine, tetracyclines: Decreased anticoagulant effect of heparin
aspirin, NSAIDs, platelet aggregation inhibitors, sulfipyrazone: Increased platelet inhibition and risk of bleeding
cefamandole, cefoperazone, cefotetan, methimazole, plicamycin, propylthiouracil, valproic acid: Possibly hypoprothrombinemia and increased risk of bleeding
chloroquine, hydroxychloroquine: Possibly thrombocytopenia and increased risk of hemorrhage
ethacrynic acid, glucocorticoids, salicylates: Increased risk of bleeding and GI ulceration and hemorrhage
nitroglycerin (I.V.): Possibly decreased anticoagulant effect of heparin
probencid: Possibly increased anticoagulant effect of heparin
thrombolytics: Increased risk of hemorrhage

ACTIVITIES

smoking: Decreased anticoagulant effect

Adverse Reactions

CNS: Chills, dizziness, fever, headache, peripheral neuropathy

CV: Chest pain, thrombosis

EENT: Epistaxis, gingival bleeding, rhinitis

GI: Abdominal distention and pain, hematemesis, melena, nausea, vomiting

GU: Hematuria, hypermenorrhea

HEME: Easy bruising, excessive bleeding

from wounds, thrombocytopenia

MS: Back pain, myalgia, osteoporosis

RESP: Dyspnea, wheezing

SKIN: Alopecia, cyanosis, petechiae, pruritus, urticaria

Other: Anaphylaxis; injection site hematoma, irritation, pain, redness, and ulceration

Nursing Considerations

- Use heparin cautiously in alcoholics; menstruating women; patients over age 60, especially women; and patients with mild hepatic or renal disease or a history of allergies, asthma, or GI ulcer.

WARNING Be aware that the new standard for manufacturing heparin in the U.S. has decreased its I.V. potency by about 10%. When using this route, determine if the heparin has been manufactured under the new standard by looking for the letter “N” in the lot number or after the expiration date (or, if made by Hospira, the number “82” or higher at the start of the lot number). If giving such heparin, be aware that more drug may be required than in the past to achieve desired level of anticoagulation in some patients. The change in potency also may require more frequent or intensive APTT or ACT monitoring.

Change in potency doesn’t appear problematic using subcutaneous route.

WARNING Give heparin only by subcutaneous or I.V. route; I.M. use causes hematoma, irritation, and pain.

- Avoid injecting any drugs by I.M. route during heparin therapy, to decrease risk of bleeding and hematoma.

WARNING Don’t use heparin sodium injection as a catheter-lock flush because fatal errors have occurred in children when 1-ml heparin sodium injection vials were confused with 1-ml catheter-lock flush vials. Always examine vial labels closely to ensure correct product is being used.

- Administer subcutaneous heparin into anterior abdominal wall, above the iliac crest, and 5 cm (2”) or more away from the umbilicus. To minimize subcutaneous tissue trauma, lift adipose tissue away from deep tissues; don’t aspirate for blood before injecting drug; don’t move needle while injecting drug; and don’t massage injection site before or after injection. You

can apply gentle pressure to the site after withdrawing needle.

- Alternate injection sites, and watch for signs of bleeding and hematoma.
- To prepare heparin for continuous infusion, invert container at least six times to prevent drug from pooling. Anticipate slight discoloration of prepared solution; this doesn’t indicate a change in potency.
- During continuous I.V. therapy, expect to obtain APTT after 8 hours of therapy. Use the arm opposite the infusion site.
- For intermittent I.V. therapy, expect to adjust dose based on coagulation test results performed 30 minutes earlier. Therapeutic range is typically 1.5 to 2.5 times the control.
- Bleeding is major adverse effect of heparin therapy. Take safety precautions to prevent bleeding, such as having patient use a soft-bristled toothbrush and an electric razor. Bleeding may occur at any site and also may indicate an underlying problem, such as GI or urinary tract bleeding. Other sites of bleeding that could be fatal and require immediate attention includes adrenal, ovarian, and retroperitoneal hemorrhage.
- Monitor blood test results, and observe for signs of bleeding, such as ecchymosis, epistaxis, hematemesis, hematuria, melena, and petechiae. Thrombocytopenia of any degree should be monitored closely. If platelet count drops below 100,000/mm³ or recurrent thrombosis develops, notify prescriber and expect heparin to be discontinued.
- Make sure all health care providers know that patient is receiving heparin.
- Keep protamine sulfate on hand to use as an antidote for heparin. Be aware that each milligram of protamine sulfate neutralizes 100 units of heparin.
- Be aware that prescriber may order oral anticoagulants before discontinuing heparin to avoid increased coagulation caused by heparin withdrawal. Heparin may be discontinued when full therapeutic effect of oral anticoagulant is achieved.
- Know that women over age 60 have highest risk of hemorrhage during therapy.
- Watch closely if patient is receiving heparin therapy and nitroglycerin I.V. because PTT may decrease and then rebound after nitroglycerin is discontin-

ued. Monitor PTT closely, and be prepared to adjust heparin dose, as prescribed.

WARNING Delayed-onset, heparin-induced thrombocytopenia may occur several weeks after heparin is discontinued and may progress to heparin-induced thrombocytopenia thrombosis, causing venous and arterial thromboses.

- Various heparin products contain the preservative benzyl alcohol, which isn't recommended for children under age 1 month because it may cause gasping syndrome, which may be fatal.

PATIENT TEACHING

- Explain that heparin can't be taken orally.
- Inform patient about increased risk of bleeding; urge her to avoid injuries and to use a soft-bristled toothbrush and an electric razor.
- Urge patient to report any abnormal sign or symptom to prescriber, even weeks after heparin has been discontinued, because of the potential for delayed adverse reactions.
- Advise patient to avoid drugs that interact with heparin, such as aspirin and ibuprofen.
- Instruct patient and family to watch for and report abdominal or lower back pain, black stools, bleeding gums, bloody urine, excessive menstrual bleeding, nosebleeds, and severe headaches.
- Explain that temporary hair loss may occur.
- Advise patient to wear or carry appropriate medical identification.

hyaluronan (high-molecular-weight)

Euflexxa, Orthovisc

Class and Category

Chemical class: Natural complex glycosaminoglycan sugar

Therapeutic class: Analgesic

Pregnancy category: Not rated

Indications and Dosages

➤ *To relieve osteoarthritic knee pain in patients who respond inadequately to conservative nonpharmacologic therapy and to simple analgesics*

INTRA-ARTICULAR INJECTION (ORTHOVISC)

Adults. 30 mg/wk for 3 to 4 wk.

INTRA-ARTICULAR INJECTION (EUFLEXXA)

Adults. 20 mg/wk for 3 wk.

Mechanism of Action

Relieves pain associated with osteoarthritis by lubricating the joint and absorbing shock when the joint moves. Hyaluronan is a viscoelastic substance normally found in joint tissues and in the fluid that fills joints; it is instilled directly into the joint.

Contraindications

Hypersensitivity to hyaluronan avian, avian-derived products (such as eggs, feathers, or poultry) or any of their components; knee infections; skin diseases affecting the knee area

Adverse Reactions

CNS: Headache

MS: Acute arthritis, arthralgia, back pain, bursitis

Other: Injection site bruising, edema, erythema, pain, pruritus, or rash

Nursing Considerations

- Prepare patient for removal of joint effusion, if present, before hyaluronan injection.
- Assist the trained health care professional who gives intra-articular injections, as needed, making sure that strict aseptic technique is followed during procedure.
- Be aware that prefilled syringe is for single use and that contents of syringe should be used immediately after opening.

PATIENT TEACHING

- Inform patient that transient knee pain, swelling, or other localized reactions, such as itchiness or bruising, may occur after hyaluronan injection.
- Instruct patient to avoid strenuous or weight-bearing activities lasting longer than 1 hour for 48 hours after injection.
- Inform patient that she may feel achy after injection but that this discomfort is typically mild and brief.
- Advise patient that pain may not be relieved until after third injection.

hyalalazine hydrochloride

Apo-Hyalalazine (CAN), Apresoline (CAN), Novo-Hylazin (CAN)

Class and Category

Chemical class: Phthalazine derivative

Therapeutic class: Antihypertensive, vasodilator

Pregnancy category: C

Indications and Dosages

↗ *To manage essential hypertension, alone or with other antihypertensives*

TABLETS

Adults. *Initial:* 40 mg daily in divided doses b.i.d. or q.i.d. for first 2 to 4 days and then increased to 100 mg daily in divided doses b.i.d. or q.i.d. for remainder of first wk.

Maximum: Usually 200 mg daily, but sometimes 300 to 400 mg daily.

Children. 0.75 mg/kg daily in divided doses b.i.d. or q.i.d. Increased gradually over 3 to 4 wk. *Maximum:* 7.5 mg/kg or 200 mg daily.

↗ *To manage severe essential hypertension when drug can't be taken orally or when need to reduce blood pressure is urgent*

I.V. OR I.M. INJECTION

Adults. 5 to 40 mg, repeated as needed.

Children. 1.7 to 3.5 mg/kg daily in divided doses every 4 to 6 hr, as needed.

Route	Onset	Peak	Duration
P.O.	20–30 min	1–2 hr	2–4 hr
I.V.	5–20 min	10–80 min	2–6 hr
I.M.	10–30 min	1 hr	2–6 hr

Mechanism of Action

May act in a manner that resembles organic nitrates and sodium nitroprusside, except that hydralazine is selective for arteries. It:

- exerts a direct vasodilating effect on vascular smooth muscle
- interferes with calcium movement in vascular smooth muscle by altering cellular calcium metabolism
- dilates arteries, not veins, which minimizes orthostatic hypotension and increases cardiac output and cerebral blood flow
- causes reflex autonomic response that increases heart rate, cardiac output, and left ventricular ejection fraction
- has a positive inotropic effect on the heart.

Incompatibilities

Don't mix hydralazine in I.V. infusion solutions.

Contraindications

Coronary artery disease, hypersensitivity to

hydralazine or its components, mitral valve disease

Interactions**DRUGS**

beta blockers: Increased effects of both drugs

diazoxide, MAO inhibitors, other antihypertensives: Risk of severe hypotension

epinephrine: Possibly decreased vasopressor effect of epinephrine

NSAIDs: Decreased hydralazine effects

sympathomimetics: Possibly decreased antihypertensive effect of hydralazine

FOODS

all foods: Possibly increased bioavailability of hydralazine

Adverse Reactions

CNS: Chills, fever, headache, peripheral neuritis

CV: Angina, edema, orthostatic hypotension, palpitations, tachycardia

EENT: Lacrimation, nasal congestion

GI: Anorexia, constipation, diarrhea, nausea, vomiting

RESP: Dyspnea

SKIN: Blisters, flushing, pruritus, rash, urticaria

Other: Lupus-like symptoms, especially with high doses; lymphadenopathy

Nursing Considerations

- Monitor CBC, lupus erythematosus cell preparation, and ANA titer before therapy and periodically as appropriate during long-term treatment.
- Anticipate that drug may change color in solution. Consult pharmacist if color changes.
- Be aware that hydralazine may change color when exposed to a metal filter.
- Give tablets with food to increase bioavailability.
- Monitor blood pressure and pulse rate regularly and weigh patient daily during therapy.
- Check blood pressure with patient in lying, sitting, and standing positions, and watch for signs of orthostatic hypotension. Expect orthostatic hypotension to be most common in the morning, during hot weather, and with exercise.

WARNING Expect to discontinue drug immediately if patient has lupus-like

symptoms, such as arthralgia, fever, myalgia, pharyngitis, and splenomegaly.

- Expect prescriber to withdraw hydralazine gradually to avoid a rapid increase in blood pressure.
- Expect to treat peripheral neuritis with pyridoxine.

PATIENT TEACHING

- Instruct patient to take hydralazine tablets with food.
- Advise patient to change position slowly, especially in the morning. Caution that hot showers may increase hypotension.
- Instruct patient to immediately notify prescriber about fever, muscle and joint aches, and sore throat.
- Urge patient to report numbness and tingling in limbs, which may require treatment with another drug.
- Caution patient against stopping drug abruptly because doing so may cause severe hypertension.

hydrochlorothiazide

Esidrix, Hydro-chlor, Hydro-D, HydroDIURIL, Microzide, Neo-Codema (CAN), Novo-Hydraside (CAN), Oretic, Urozide (CAN)

Class and Category

Chemical class: Benzothiadiazide

Therapeutic class: Antihypertensive, diuretic

Pregnancy category: B

Indications and Dosages

↗ *To manage hypertension*

CAPSULES

Adults. 12.5 mg daily.

ORAL SOLUTION, TABLETS

Adults. 25 to 100 mg daily as a single dose or in divided doses b.i.d.

Children age 6 months and over. 1 to 2 mg/kg daily as a single dose or in divided doses b.i.d.

Infants under age 6 months. Up to 3 mg/kg daily.

↗ *As adjunct to treat edema caused by cirrhosis, corticosteroids, estrogen, heart failure, or renal disorders*

ORAL SOLUTION, TABLETS

Adults. 25 to 100 mg b.i.d., once daily, or every other day for 3 to 5 days/wk.

Children age 6 months and over. 1 to

2 mg/kg daily as a single dose or in divided doses b.i.d.

Infants under age 6 months. Up to 3 mg/kg daily.

Route	Onset	Peak	Duration
P.O.	2 hr	4 hr	6–12 hr

Contraindications

Anuria; hypersensitivity to hydrochlorothiazide, other thiazides, sulfonamide derivatives, or their components; renal failure

Interactions

DRUGS

ACTH, amphotericin B, corticosteroids:

Increased electrolyte depletion, especially potassium

amantadine: Possibly increased blood level and risk of toxicity of amantadine

amiodarone: Increased risk of arrhythmias from hypokalemia

antihypertensives: Increased antihypertensive effects

barbiturates, opioids: Possibly orthostatic hypotension

calcium: Possibly increased serum calcium level

cholestyramine, colestipol: Reduced GI absorption of hydrochlorothiazide

diazoxide: Increased antihypertensive and hyperglycemic effects of hydrochlorothiazide

diflunisal: Possibly increased blood hydrochlorothiazide level

digoxin: Increased risk of digitalis toxicity from hypokalemia

dopamine: Possibly increased diuretic effects of both drugs

insulin, oral antidiabetic drugs: Possibly increased blood glucose level

lithium: Decreased lithium clearance, increased risk of lithium toxicity

neuromuscular blockers: Possibly enhanced neuromuscular blockade from hypokalemia

nondepolarizing skeletal muscle relaxants:

Possibly increased response to muscle relaxants

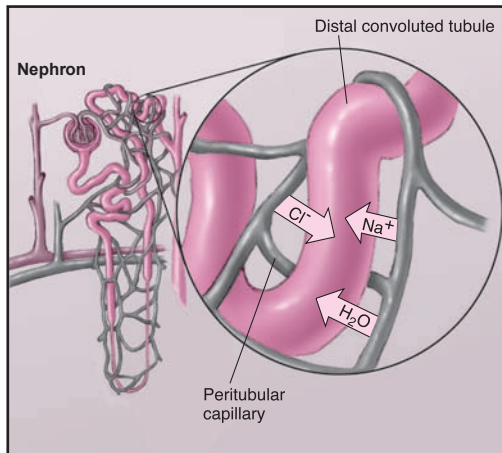

NSAIDs: Decreased diuretic effect of hydrochlorothiazide, increased risk of renal failure

oral anticoagulants: Possibly decreased anticoagulant effects

sympathomimetics: Possibly decreased antihypertensive effect of hydrochlorothiazide

Mechanism of Action

A thiazide diuretic, hydrochlorothiazide promotes movement of sodium (Na^+), chloride (Cl^-), and water (H_2O) from blood in peritubular capillaries into nephron's distal convoluted tubule, as shown. Initially, it may decrease extracellular fluid volume, plasma volume, and cardiac output, which helps explain blood pressure reduction. It also may reduce blood pressure by direct arterial dilation. After several weeks, extracellular fluid volume, plasma volume, and cardiac output return to normal, and peripheral vascular resistance remains decreased.

vitamin D: Increased risk of hypercalcemia

ACTIVITIES

alcohol use: Possibly orthostatic hypotension

Adverse Reactions

CNS: Dizziness, fever, headache, insomnia, paresthesia, vertigo, weakness

CV: Hypotension, orthostatic hypotension, vasculitis

EENT: Blurred vision, dry mouth

ENDO: Hyperglycemia

GI: Abdominal cramps, anorexia, constipation, diarrhea, indigestion, jaundice, nausea, pancreatitis, vomiting

GU: Decreased libido, impotence, interstitial nephritis, nocturia, polyuria, renal failure

HEME: Agranulocytosis, aplastic anemia, hemolytic anemia, leukopenia, neutropenia, thrombocytopenia

MS: Muscle spasms and weakness

SKIN: Alopecia, cutaneous vasculitis, erythema multiforme, exfoliative dermatitis, photosensitivity, purpura, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, dehydration, hypercalcemia, hyperuricemia, hypochloremia, hypokalemia, hyponatremia, hypovolemia, metabolic alkalosis, weight loss

Nursing Considerations

- Give hydrochlorothiazide in the morning

and early evening to avoid nocturia.

- Monitor fluid intake and output, daily weight, blood pressure, and serum levels of electrolytes, especially potassium.
- Assess for evidence of hypokalemia, such as muscle spasms and weakness.
- Monitor BUN and serum creatinine levels.
- Check blood glucose level often, as ordered, in diabetic patients, and expect to increase antidiabetic dosage, as needed.
- If patient has gouty arthritis, expect increased risk of gout attacks during therapy.

PATIENT TEACHING

- Advise patient to take hydrochlorothiazide morning and early evening to avoid awakening during the night to urinate.
- Instruct patient to take drug with food or milk if adverse GI reactions occur.
- Tell patient to weigh herself at the same time each day wearing the same amount of clothing and to notify prescriber if she gains more than 2 lb (0.9 kg) per day or 5 lb (2.3 kg) per week.
- Instruct patient to eat a diet high in potassium-rich food, including citrus fruits, bananas, tomatoes, and dates.
- Advise patient to change position slowly to minimize effects of orthostatic hypotension.
- Urge patient to report decreased urination, muscle cramps and weakness, and unusual bleeding or bruising.

hydrocortisone (cortisol)

Cortef, Cortenema, Hydrocortone

hydrocortisone acetate

Cortifoam, Hydrocortone Acetate

hydrocortisone cypionate

Cortef

hydrocortisone sodium phosphate

Hydrocortone Phosphate

hydrocortisone sodium succinate

A-hydroCort, Solu-Cortef

Class and Category

Chemical class: Glucocorticoid

Therapeutic class: Adrenocorticoid replacement, anti-inflammatory

Pregnancy category: Not rated; C (Cortifoam)

Indications and Dosages

↗ *To treat severe inflammation or acute adrenal insufficiency*

ORAL SUSPENSION, TABLETS (HYDROCORTISONE, HYDROCORTISONE CYPIONATE)

Adults. 20 to 240 mg daily as a single dose or in divided doses.

I.V. INFUSION OR I.V., I.M., OR SUBCUTANEOUS INJECTION (HYDROCORTISONE SODIUM PHOSPHATE); I.M. INJECTION (HYDROCORTISONE)

Adults. 15 to 240 mg daily as a single dose or in divided doses. *Usual:* One-half to one-third the oral dose.

DOSAGE ADJUSTMENT Dosage increased to more than 240 mg daily if needed to treat acute disease.

I.V. INFUSION; I.V. OR I.M. INJECTION (HYDROCORTISONE SODIUM SUCCINATE)

Adults. 100 to 500 mg every 2, 4, or 6 hr.

↗ *To treat joint and tissue inflammation*
INTRA-ARTICULAR INJECTION (HYDROCORTISONE ACETATE)

Adults. 25 to 37.5 mg injected into large joints or bursae as a single dose, or 10 to 25 mg into small joints as a single dose.

INTRALESIONAL INJECTION (HYDROCORTISONE ACETATE)

Adults. 5 to 12.5 mg injected into tendon sheaths as a single dose, or 12.5 to 25 mg injected into ganglia as a single dose.

SOFT-TISSUE INJECTION (HYDROCORTISONE ACETATE)

Adults. 25 to 50 mg as a single dose.

Sometimes a dose of up to 75 mg is needed.

↗ *As adjunct to treat ulcerative proctitis of the distal portion of the rectum in patients who can't retain hydrocortisone or other corticosteroid enemas*

RECTAL AEROSOL (HYDROCORTISONE ACETATE)

Adult men. Initial: 1 applicatorful once or twice daily for 2 to 3 wk; then every other day thereafter. *Maintenance:* Highly individualized.

↗ *To treat ulcerative colitis*

ENEMA (HYDROCORTISONE)

Adults. 100 mg every night for 2 to 3 wk or until condition improves.

Route	Onset	Peak	Duration
P.O.†	Unknown	1 hr	1.25–1.5 days
P.O.	Unknown	1–2 hr	Unknown
I.V. ‡§	Rapid	Unknown	Unknown
I.M.†	Unknown	4–8 hr	Unknown
I.M.‡	Rapid	1 hr	Unknown
I.M.§	Rapid	1 hr	Variable
Other*	Unknown	24–48 hr	3 days–4 wk

Mechanism of Action

Binds to intracellular glucocorticoid receptors and suppresses inflammatory and immune responses by:

- inhibiting neutrophil and monocyte accumulation at inflammation site and suppressing their phagocytic and bactericidal activity
- stabilizing lysosomal membranes

† Hydrocortisone

‡ Phosphate

§ Succinate

|| Cypionate

* Acetate; intra-articular, intralesional, and soft-tissue injection.

- suppressing antigen response of macrophages and helper T cells
- inhibiting synthesis of cellular mediators of inflammatory response, such as cytokines, interleukins, and prostaglandins.

Contraindications

Hypersensitivity to hydrocortisone or its components, idiopathic thrombocytopenic purpura (I.M.), intestinal conditions prohibiting intrarectal steroids (P.R.), recent live-virus vaccination, systemic fungal infection

Interactions

DRUGS

acetaminophen: Increased risk of hepatotoxicity

amphotericin B, carbonic anhydrase

inhibitors: Possibly severe hypokalemia

anabolic steroids, androgens: Increased risk of edema and severe acne

anticholinergics: Possibly increased intraocular pressure

anticoagulants, thrombolytics: Increased risk of GI ulceration and hemorrhage, possibly decreased therapeutic effects of these drugs

asparaginase: Increased risk of hyperglycemia and toxicity

aspirin, NSAIDs: Increased risk of GI distress and bleeding

cholestyramine: Possibly increased hydrocortisone clearance

cyclosporine: Possibly increased action of both drugs; increased risk of seizures

digoxin: Possibly hypokalemia-induced arrhythmias and digitalis toxicity

ephedrine, phenobarbital, phenytoin, rifampin: Decreased blood hydrocortisone level

estrogens, oral contraceptives: Increased therapeutic and toxic effects of hydrocortisone

insulin, oral antidiabetic drugs: Possibly increased blood glucose level

isoniazid: Possibly decreased therapeutic effects of isoniazid

macrolide antibiotics: Possibly decreased hydrocortisone clearance

mexiletine: Decreased blood mexiletine level

neuromuscular blockers: Possibly increased neuromuscular blockade, causing respiratory depression or apnea

potassium-depleting drugs, such as thiazide diuretics: Possibly severe hypokalemia

potassium supplements: Possibly decreased

effects of these supplements

somatrem, somatropin: Possibly decreased therapeutic effects of these drugs

streptozocin: Increased risk of hyperglycemia

vaccines: Decreased antibody response and increased risk of neurologic complications

ACTIVITIES

alcohol use: Increased risk of GI distress and bleeding

Adverse Reactions

CNS: Ataxia, behavioral changes, depression, dizziness, euphoria, fatigue, headache, increased intracranial pressure with papilledema, insomnia, malaise, mood changes, paresthesia, seizures, steroid psychosis, syncope, vertigo

CV: Arrhythmias (from hypokalemia), fat embolism, heart failure, hypertension, hypotension, thromboembolism, thrombophlebitis

EENT: Exophthalmos, glaucoma, increased intraocular pressure, nystagmus, posterior subcapsular cataracts

ENDO: Adrenal insufficiency during stress, cushingoid symptoms (buffalo hump, central obesity, moon face, supraclavicular fat pad enlargement), diabetes mellitus, growth suppression in children, hyperglycemia, negative nitrogen balance from protein catabolism

GI: Abdominal distention; hiccups; increased appetite; nausea; pancreatitis; peptic ulcer; rectal abnormalities, such as bleeding, blistering, burning, itching, or pain (rectal form); ulcerative esophagitis; vomiting

GU: Amenorrhea, glycosuria, menstrual irregularities, perineal burning or tingling

HEME: Easy bruising, leukocytosis

MS: Arthralgia; aseptic necrosis of femoral and humeral heads; compression fractures; muscle atrophy, twitching, or weakness;

myalgia; osteoporosis; spontaneous fractures; steroid myopathy; tendon rupture

SKIN: Acne; altered skin pigmentation; diaphoresis; erythema; hirsutism; necrotizing vasculitis; petechiae; purpura; rash; scarring; sterile abscess; striae; subcutaneous fat atrophy; thin, fragile skin; urticaria

Other: Anaphylaxis, hypocalcemia, hypokalemia, hypokalemic alkalosis, impaired wound healing, masking of signs of infection, metabolic alkalosis, suppressed skin test reaction, weight gain

Nursing Considerations

- Systemic hydrocortisone shouldn't be given to immunocompromised patients, such as those with fungal and other infections, including amebiasis, hepatitis B, tuberculosis, vaccinia, and varicella.
- Give daily dose of hydrocortisone in morning to mimic normal peak in adrenocortical secretion of corticosteroids.
- When possible, give oral dose with food or milk to avoid GI distress.
- Don't give acetate injectable suspension by I.V. route.
- Give hydrocortisone sodium succinate as a direct I.V. injection over 30 seconds to several minutes, or as an intermittent or a continuous infusion. For infusion, dilute to 1 mg/ml or less with D₅W, normal saline solution, or dextrose 5% in normal saline solution.
- Inject I.M. form deep into gluteal muscle, and rotate injection sites to prevent muscle atrophy. Subcutaneous injection may cause atrophy and sterile abscess.
- Shake foam container vigorously for 5 to 10 seconds before each use. Gently withdraw applicator plunger past the fill-line on the applicator barrel while container is upright on a level surface. Administer rectal foam only with provided applicator. After each use, wash applicator, container cap, and underlying tip with warm water.
- High-dose therapy shouldn't be given for longer than 48 hours. Be alert for depression and psychotic episodes.
- Monitor weight, blood pressure, and electrolyte levels regularly during therapy.
- Expect hydrocortisone to worsen infections or mask signs and symptoms.
- Monitor blood glucose level in diabetic patients, and increase insulin or oral antidiabetic drug dosage, as prescribed.
- Know that elderly patients are at high risk for osteoporosis during long-term therapy.
- Anticipate the possibility of acute adrenal insufficiency with stress, such as emotional upset, fever, surgery, or trauma. Increase hydrocortisone dosage, as prescribed.

WARNING Avoid withdrawing drug suddenly after long-term therapy because adrenal crisis can result. Expect to reduce dosage gradually and monitor response.

PATIENT TEACHING

- Advise patient to take daily dose of hydro-

cortisone at 9 a.m.

- Instruct patient to take tablets or oral suspension with milk or food.
- Teach patient how to use foam or enema form, if prescribed.
- Caution patient not to stop drug abruptly without first consulting prescriber.
- Instruct patient to report early evidence of adrenal insufficiency: anorexia, difficulty breathing, dizziness, fainting, fatigue, joint pain, muscle weakness, and nausea.
- Inform patient that he may bruise easily.
- Advise patient on long-term therapy to have periodic eye examinations.
- If patient receives long-term therapy, urge her to carry or wear medical identification.
- Caution patient to avoid people with infections because drug can suppress immune system, increasing risk of infection. If patient comes into contact with chickenpox or measles, instruct him to call prescriber because he may need prophylactic care.

hydromorphone hydrochloride (dihydromorphinone)

Dilaudid, Dilaudid-5, Dilaudid-HP, Hydrostat IR, Palladone, PMS-Hydromorphone (CAN), PMS-Hydromorphone Syrup (CAN)

Class, Category, and Schedule

Chemical class: Phenanthrene derivative, semisynthetic opioid derivative

Therapeutic class: Analgesic

Pregnancy category: C

Controlled substance schedule: II

Indications and Dosages

➤ *To relieve moderate to severe pain*

ORAL SOLUTION

Adults. 2.5 to 10 mg every 3 to 6 hr, p.r.n.

TABLETS

Adults. 2 mg every 3 to 6 hr, p.r.n.

Increased to 4 mg or more every 4 to 6 hr, if indicated.

E.R. CAPSULES

Adults. Highly individualized and dependent on patient's previous total daily 24-hour opioid use. Once dosage is determined,

drug is given daily.

I.V. INJECTION

Adults. 1 mg every 3 hr, p.r.n.

I.M. OR SUBCUTANEOUS INJECTION

Adults. 1 or 2 mg every 3 to 6 hr, p.r.n.
Increased to 3 or 4 mg every 4 to 6 hr, if needed for severe pain.

SUPPOSITORIES

Adults. 3 mg every 4 to 8 hr, p.r.n.

Route	Onset	Peak	Duration
P.O.	30 min	1.5–2 hr	4 hr
I.V.	10–15 min	15–30 min	2–3 hr
I.M.	15 min	30–60 min	4–5 hr
SubQ	15 min	30–90 min	4 hr
P.R.	30 min	Unknown	4 hr

Mechanism of Action

May bind with opioid receptors in the spinal cord and higher levels in the CNS. In this way, hydromorphone is believed to stimulate mu and kappa receptors, thus altering the perception of and emotional response to pain.

Contraindications

Acute asthma; hypersensitivity to hydromorphone, other narcotics, or their components; increased intracranial pressure; severe respiratory depression; upper respiratory tract obstruction

Interactions

DRUGS

anticholinergics: Increased risk of ileus, severe constipation, or urine retention
antihypertensives, diuretics, guanadrel, guanethidine, mecamlamine: Increased risk of orthostatic hypotension
barbiturate anesthetics: Increased sedative effect of hydromorphone
belladonna alkaloids, difenoxin and atropine, diphenoxylate and atropine, kaolin pectin, loperamide, paregoric: Increased risk of CNS depression and severe constipation
buprenorphine, butorphanol, dezocine, nalbuphine, pentazocine: Possibly potentiates or suppressed symptoms of spontaneous opioid withdrawal
CNS depressants, other opioid analgesics: Additive CNS depression and hypotension
hydroxyzine: Increased analgesia, CNS depression, and hypotension

metoclopramide: Decreased effect of metoclopramide on GI motility
naloxone: Possibly withdrawal symptoms in physically dependent patients
naltrexone: Possibly prolonged respiratory depression or cardiac arrest
neuromuscular blockers: Additive CNS depression

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Anxiety, confusion, dizziness, drowsiness, euphoria, hallucinations, headache, nervousness, restlessness, sedation, somnolence, tremor, weakness

CV: Hypertension, orthostatic hypotension, palpitations, tachycardia

EENT: Blurred vision, diplopia, dry mouth, laryngeal edema, laryngospasm, nystagmus, tinnitus

GI: Abdominal cramps, anorexia, biliary tract spasm, constipation, hepatotoxicity, nausea, vomiting

GU: Dysuria, urine retention

RESP: Dyspnea, respiratory depression, wheezing

SKIN: Diaphoresis, flushing

Other: Injection site pain, redness, and swelling; physical and psychological dependence

Nursing Considerations

- To improve analgesic action, give hydromorphone before pain becomes intense.
- Give I.V. form by direct injection over at least 2 minutes. For infusion, mix drug with D₅W, normal saline solution, or Ringer's solution.
- Monitor patient for respiratory depression when using I.V. route. Keep resuscitation equipment and naloxone nearby.
- Rotate I.M. and subcutaneous injection sites.
- Monitor effectiveness of hydromorphone in relieving pain; consult prescriber as needed.
- Assess patient for constipation.
- Monitor patient for evidence of physical dependence or abuse.
- Anticipate that drug may mask or worsen gallbladder pain.
- Be aware that all other around-the-clock opioid analgesics should be stopped when E.R. capsules are prescribed. Expect to give

immediate-release nonopioid analgesics for exacerbation of pain and for preventing pain during certain activities.

PATIENT TEACHING

- Instruct patient to take drug exactly as prescribed and before pain is severe.
- Advise patient to take drug with food to avoid GI distress.
- Tell patient not to break open or chew E.R. capsules but to swallow them whole.
- Instruct patient to refrigerate suppositories.
- Caution patient to avoid alcohol and OTC drugs during therapy, unless prescriber approves.
- Instruct patient to report constipation, difficulty breathing, severe nausea, or vomiting.
- Inform patient that drug may cause drowsiness and sedation. Advise her to avoid hazardous activities until drug's CNS effects are known.
- Tell patient to change position slowly to minimize orthostatic hypotension.
- To avoid withdrawal, instruct physically dependent patient not to stop taking hydromorphone abruptly.

hydroxychloroquine sulfate

Plaquenil

Class and Category

Chemical class: 4-aminoquinoline compound

Therapeutic class: Antiprotozoal, anti-rheumatic, lupus erythematosus suppressant

Pregnancy category: C

Indications and Dosages

➤ *To prevent malaria*

TABLETS

Adults. 400 mg the same day of each week starting 2 wk before entering endemic area and continuing until departure from endemic area. If this isn't possible, initially 800 mg in two divided doses 6 hr apart, followed 1 wk later with 400 mg and then 400 mg on same day of each week thereafter until departure from endemic area.

Infants and children. 5 mg/kg the same day

of each week, starting 2 wk before entering endemic area and continuing until departure from endemic area. If this isn't possible, initially 10 mg/kg in two divided doses 6 hr apart, followed 1 wk later with 5 mg/kg and then 5 mg/kg on same day of each week thereafter until departure from endemic area. *Maximum:* Adult dosage.

➤ *To treat acute attacks of malaria caused by Plasmodium vivax, P. malariae, P. ovale, and susceptible strains of P. falciparum*

TABLETS

Adults. *Initial:* 800 mg, followed by 400 mg in 6 to 8 hr and 400 mg on next 2 consecutive days. Or, 800 mg given as a single dose or an initial dose of 10 mg base/kg (maximum, 620 mg base [800 mg]), followed by 5 mg base/kg (maximum, 310 mg base [400 mg]) 6 hr after first dose, 5 mg base/kg 18 hr after second dose, and 5 mg base/kg 24 hr after third dose.

Infants and children. *Initial:* 10 mg base/kg (maximum, 620 mg base [800 mg]), followed by 5 mg base/kg (maximum, 310 mg base [400 mg]) 6 hr after first dose, 5 mg base/kg 18 hr after second dose, and 5 mg base/kg 24 hr after third dose.

➤ *To treat chronic discoid and systemic lupus erythematosus*

TABLETS

Adults. *Initial:* 400 mg once or twice daily for several weeks or months. *Maintenance:* 200 to 400 mg daily.

➤ *To treat acute or chronic rheumatoid arthritis*

TABLETS

Adults. *Initial:* 400 to 600 mg daily for 4 to 12 wk. *Maintenance:* 200 mg to 400 mg daily.

DOSAGE ADJUSTMENT For patients with rheumatoid arthritis who develop troublesome adverse reactions, initial dosage decreased for 5 to 10 days and then gradually increased to optimum response level.

Mechanism of Action

May mildly suppress the immune system, inhibiting production of rheumatoid factor and acute phase reactants. Hydroxychloroquine also accumulates in WBCs, stabilizing lysosomal membranes and inhibiting enzymes such as collagenase and proteases that cause cartilage breakdown. These actions may decrease symptoms of rheuma-

toid arthritis and lupus erythematosus.

Hydroxychloroquine also binds to and alters DNA of malaria parasite to prevent it from reproducing. It also may increase the pH of acid vesicles, which interferes with vesicle function and may inhibit parasitic phospholipid metabolism in erythrocytes, thereby halting plasmodial activity.

Contraindications

Hypersensitivity to 4-aminoquinoline compounds (including hydroxychloroquine), long-term therapy in children, retinal or visual changes related to 4-aminoquinoline compounds

Interactions

DRUGS

auriothioglucose: Increased risk of blood dyscrasias

digoxin: Increased digoxin concentrations

Adverse Reactions

CNS: Abnormal nerve conduction, ataxia, dizziness, emotional lability, headache, irritability, lassitude, nervousness, neuromuscular sensory abnormalities, nightmares, psychosis, seizures, vertigo

CV: Cardiomyopathy (prolonged high doses)

EENT: Abnormal pigmentation (bullseye appearance) or colored vision, blurred vision, central scotoma with decreased visual acuity, corneal deposits, decreased corneal sensitivity, diplopia, irreversible retinal damage (in lupus erythematosus or rheumatoid arthritis), halo vision, lassitude, macular edema or atrophy, nerve-related hearing loss, nystagmus, pericentral or paracentral scotoma, photophobia, retinal fundus changes, tinnitus, visual abnormalities

ENDO: Hypoglycemia

GI: Abdominal cramps, anorexia, diarrhea, elevated liver function test results, fulminant hepatic failure, nausea, vomiting

HEME: Agranulocytosis, aplastic anemia, hemolysis (in patients with glucose-6-phosphate dehydrogenase [G6PD] deficiency), leukopenia, thrombocytopenia

MS: Atrophy of proximal skeletal muscle groups, depressed tendon reflexes, muscle weakness

RESP: Bronchospasm

SKIN: Acute generalized exanthematous pustulosis, alopecia, altered mucosal and skin pigmentation, bleaching of hair, der-

matitis (including exfoliative dermatitis), non-light-sensitive psoriasis, pruritus, psoriasis exacerbation, rash, Stevens-Johnson syndrome, urticaria

Other: Angioedema, porphyria, weight loss

Nursing Considerations

- Use hydroxychloroquine cautiously in patients with G6PD deficiency, patients with hepatic disease or alcoholism, and patients taking hepatotoxic drugs.
- Monitor children closely for adverse reactions because they're especially sensitive to 4-aminoquinoline compounds.
- Observe patients with psoriasis closely because hydroxychloroquine may lead to severe psoriasis attack. Also monitor patients with porphyria closely because hydroxychloroquine may worsen it. Expect to use hydroxychloroquine in patients with psoriasis or porphyria only after risks and benefits have been considered.
- During prolonged therapy, obtain periodic blood cell counts, as ordered, to detect adverse hematologic effects. Expect to stop drug if severe adverse effects occur.
- Monitor patient's vision when giving hydroxychloroquine for lupus erythematosus or rheumatoid arthritis because irreversible retinal damage may occur in some patients during long-term or high-dose therapy. Ask regularly about vision abnormalities, such as light flashes or streaks, that may indicate retinopathy. Expect patient to have an initial ophthalmologic examination, followed by examinations every 3 months. Report changes to prescriber immediately, and expect drug to be stopped. Retinal changes may progress even after therapy stops.
- Monitor patient on long-term therapy for muscle weakness and abnormal knee and ankle reflexes. If present, notify prescriber and expect drug to be stopped.
- Expect drug to be stopped if patient with rheumatoid arthritis shows no improvement, such as reduced joint swelling or increased mobility, in 6 months.
- If serious adverse reactions occur, notify prescriber immediately. Expect drug to be stopped. Also expect to give ammonium chloride (8 g daily in divided doses for adults) 3 or 4 days weekly for several months because acidification of urine

increases renal excretion of drug.

PATIENT TEACHING

- Instruct patient to take drug with meals or milk to minimize stomach upset.
- Tell patient to take hydroxychloroquine exactly as prescribed because taking too much may cause serious adverse reactions and taking too little or skipping doses decreases effectiveness.
- Caution patient to notify prescriber about troublesome adverse reactions. Hydroxychloroquine dosage may need to be adjusted or drug stopped.
- Caution patient who takes drug for rheumatoid arthritis or lupus erythematosus about possible visual reactions and the need for periodic eye examinations. Tell patient to notify prescriber about abnormal visual changes, including blurred vision, halos around lights, and light flashes or streaks; explain that drug will need to be stopped.
- Tell patient receiving prolonged therapy about the need for periodic blood tests to detect adverse effects.
- Advise patient to notify prescriber if muscle weakness develops.

hydroxyzine hydrochloride

Apo-Hydroxyzine (CAN), Atarax, Multipax (CAN), Novo-Hydroxyzin (CAN)

hydroxyzine pamoate

Vistaril

Class and Category

Chemical class: Piperazine derivative

Therapeutic class: Antianxiety, antiemetic, antihistamine, sedative-hypnotic

Pregnancy category: C

Indications and Dosages

↗ *To relieve anxiety and induce sedation and hypnosis*

CAPSULES, ORAL SUSPENSION, SYRUP, TABLETS

Adults and adolescents. 50 to 100 mg as a single dose.

Children. 600 mcg/kg as a single dose.

I.M. INJECTION

Adults and adolescents. 50 to 100 mg every 4 to 6 hr, p.r.n. (antianxiety); 50 mg as a single dose (sedative-hypnotic).

↗ *To treat pruritus*

CAPSULES, ORAL SUSPENSION, SYRUP, TABLETS

Adults and adolescents. 25 to 100 mg t.i.d. or q.i.d., p.r.n.

Children. 500 mcg/kg every 6 hr, p.r.n.

↗ *To provide antiemetic effects*

CAPSULES, ORAL SUSPENSION, SYRUP, TABLETS

Adults and adolescents. 25 to 100 mg t.i.d. or q.i.d., p.r.n.

Children. 500 mcg/kg every 6 hr, p.r.n.

I.M. INJECTION

Adults and adolescents. 25 to 100 mg, p.r.n.

Children. 1.1 mg/kg as a single dose.

↗ *As adjunct to permit reduction in preoperative and postoperative opioid dosage*

I.M. INJECTION

Adults and adolescents. 25 to 100 mg given with prescribed opioid.

Children. 1.1 mg/kg given with prescribed opioid.

DOSAGE ADJUSTMENT For elderly patients, treatment is started at lowest possible dosage.

Route	Onset	Peak	Duration
P.O.	15–60 min	Unknown	4–6 hr
I.M.	20–30 min	Unknown	4–6 hr

Mechanism of Action

Competes with histamine for histamine₁ receptor sites on surfaces of effector cells. This suppresses results of histaminic activity, including edema, flare, and pruritus. Hydroxyzine's antiemetic effect may stem from central anticholinergic actions. Sedative actions occur at subcortical level of CNS and are dose-related.

Contraindications

Breast-feeding; early pregnancy; hypersensitivity to cetirizine, hydroxyzine, or their components

Interactions

DRUGS

CNS depressants: Increased CNS depression

ACTIVITIES

alcohol use: Increased CNS depression

Adverse Reactions

CNS: Drowsiness, hallucinations, headache,

involuntary motor activity, seizures, tremor

EENT: Dry mouth

SKIN: Pruritus, rash, urticaria

Other: Allergic reaction, injection site pain

Nursing Considerations

- Don't give hydroxyzine by subcutaneous or I.V. route because tissue necrosis may occur.
- Inject I.M. form deep into large muscle, using Z-track method.
- Observe for oversedation if patient takes another CNS depressant.

PATIENT TEACHING

- Urge patient to avoid alcohol.
- Caution patient about drowsiness; tell her to avoid hazardous activities until drug's CNS effects are known.
- Instruct woman to tell prescriber if she is or could be pregnant because drug is contraindicated in early pregnancy.

hyoscyamine sulfate

Anaspaz, A-Spas S/L, Cystospaz, Cystospaz-M, Donnamar, ED-SPAZ, Gastrosed, Levbid, Levsin, Levsin/SL, Levsinex Timecaps, Symax SL, Symax SR

Class and Category

Chemical class: Belladonna alkaloid, tertiary amine

Therapeutic class: Antimuscarinic, antispasmodic

Pregnancy category: C

Indications and Dosages

↗ *To treat peptic ulcers and GI tract disorders caused by spasm*

ELIXIR, ORAL SOLUTION

Adults and adolescents. 0.125 to 0.25 mg every 4 to 6 hr.

Children. Dosage individualized by weight.

E.R. CAPSULES

Adults and adolescents. 0.375 mg every 12 hr.

E.R. TABLETS

Adults and adolescents. 0.375 to 0.75 mg every 12 hr. *Maximum:* 1.5 mg daily.

TABLETS

Adults and adolescents. 0.125 to 0.5 mg t.i.d. or q.i.d.

Children. Dosage individualized by weight.

I.V., I.M., OR SUBCUTANEOUS INJECTION

Adults and adolescents. 0.25 to 0.5 mg every 4 to 6 hr.

Children. Dosage individualized by weight.

↗ *To control salivation and excessive secretions during surgical procedures*

I.V. INJECTION

Adults and adolescents. 0.5 mg 30 to 60 min before procedure.

Route	Onset	Peak	Duration
P.O.*	20–30 min	30–60 min	4 hr
P.O. (E.R.)†	20–30 min	40–90 min	12 hr
I.V., I.M., SubQ	2–3 min	15–30 min	4 hr

Mechanism of Action

Competitively inhibits acetylcholine at autonomic postganglionic cholinergic receptors. Because the most sensitive receptors are in salivary, bronchial, and sweat glands, hyoscyamine acts mainly to reduce salivary, bronchial, and sweat gland secretions. It also causes GI smooth muscle to contract and decreases gastric secretion and GI motility. It also causes bladder detrusor muscle to contract, reduces nasal and oropharyngeal secretions, and decreases airway resistance from relaxation of smooth muscle in the bronchi and bronchioles.

Contraindications

Acute hemorrhage and hemodynamic instability; angle-closure glaucoma; hepatic disease; hypersensitivity to hyoscyamine, other anticholinergics, or their components; ileus; intestinal atony; myasthenia gravis; myocardial ischemia; obstructive GI disease; obstructive uropathy; renal disease; severe ulcerative colitis; tachycardia; toxic megacolon

Interactions

DRUGS

anticholinergics: Possibly increased anti-

* For tablets only; for elixir and oral solution, onset is 5 to 20 min, and peak and duration are unknown.

† For E.R. tablets only; for E.R. capsules, onset and peak are unknown, and duration is 12 hr.

cholinergic effects

antidiarrheals (adsorbent): Possibly decreased hyoscyamine effects
calcium- and magnesium-containing antacids, carbonic anhydrase inhibitors, citrates, sodium bicarbonate, urinary alkalinizers:

Possibly potentiated therapeutic and adverse effects of hyoscyamine

haloperidol: Possibly decreased haloperidol effects

ketoconazole: Possibly reduced ketoconazole absorption

metoclopramide: Possibly antagonized therapeutic effects of metoclopramide

opioid analgesics: Increased risk of severe constipation and ileus

Adverse Reactions

CNS: Drowsiness, insomnia

EENT: Blurred vision; dry mouth, nose, and throat; photophobia

ENDO: Decreased lactation

GI: Constipation

GU: Impotence, urine retention

SKIN: Decreased sweating

Other: Heatstroke, injection site redness and urticaria

Nursing Considerations

- Use hyoscyamine cautiously in patients who have arrhythmias, autonomic neuropathy, coronary artery disease, heart failure, hiatal hernia with reflux esophagitis, hypertension, hyperthyroidism, renal failure, or tachycardia.
- Give drug 30 to 60 minutes before meals and at bedtime. Give bedtime dose at least 2 hours after last meal of day.
- Anticipate that tablets may not disintegrate and may appear in stool.

WARNING Anticipate an increased risk of drug-induced heatstroke in hot or humid weather because hyoscyamine decreases sweating.

WARNING Be aware that lower doses may paradoxically decrease heart rate.

Higher doses affect nicotinic receptors in autonomic ganglia, causing delirium, disorientation, hallucinations, and restlessness.

- Monitor urine output, and be alert for urine retention.

PATIENT TEACHING

- Instruct patient to void before taking each dose and to notify prescriber if she

has trouble urinating during therapy.

- Advise patient to take drug 30 to 60 minutes before meals and at bedtime. Bedtime dose should be taken at least 2 hours after last meal of the day.
- Explain that drug may cause drowsiness. Advise patient to avoid hazardous activities until drug's CNS effects are known.
- If patient reports dry mouth, suggest using sugarless hard candy or gum.
- Inform male patient that drug may cause impotence. If it occurs, suggest that he discuss it with prescriber.
- Advise patient to avoid exposure to high temperatures and to increase fluid intake, unless contraindicated.

ibuprofen

Actiprofen Caplets (CAN), Advil, Apo-Ibuprofen (CAN), Bayer Select Ibuprofen Pain Relief Formula Caplets, Caldolor, Children's Advil, Children's Motrin, Dolgesic, Excedrin IB, Genpril, Haltran, Ibifon 600 Caplets, Ibuprofen, Ibuprohm Caplets, Ibu-Tab, Medipren, Midol IB, Motrin, Motrin-IB, Novo-Profen (CAN), Nu-Ibuprofen (CAN), Nuprin, Pamprin-IB, Q-Profen, Rufen, Trendar

Class and Category

Chemical class: Propionic acid derivative

Therapeutic class: Analgesic, anti-inflammatory, antipyretic

Pregnancy category: C (before 30 weeks gestation); D (starting at 30 weeks gestation)

Indications and Dosages

➤ *To relieve pain in rheumatoid arthritis and osteoarthritis*

CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS

Adults. 300 mg q.i.d., or 400, 600, or 800 mg t.i.d. or q.i.d. Range: 1.2 to 3.2 g daily.

➤ *To relieve mild to moderate pain*

CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS

Adults. 400 mg every 4 to 6 hr, p.r.n.

I.V. INFUSION

Adults. 400 to 800 mg infused over at least 30 minutes, every 6 hours, as needed.

➤ *To relieve acute migraine pain*

CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS

Adults. 200 to 400 mg at onset of migraine pain. *Maximum:* 400 mg daily.

↗ *To relieve pain in primary dysmenorrhea*

CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS

Adults. 400 mg every 4 hr, p.r.n.

↗ *To relieve pain in juvenile arthritis*

CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS

Children. 30 to 70 mg/kg daily in divided doses t.i.d. or q.i.d.; 20 mg/kg daily for mild disease.

↗ *To relieve minor aches, pains, and dysmenorrhea and to reduce fever*

CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS

Adults. 200 to 400 mg every 4 to 6 hr.

Maximum: 1.2 g daily.

↗ *To relieve moderate to severe pain as an adjunct to opioid analgesics*

I.V. INFUSION

Adults. 400 mg to 800 mg infused over at least 30 minutes, every 6 hours, as needed.

↗ *To reduce fever*

CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS

Children ages 6 months to 12 years. 5 to 10 mg/kg every 4 to 6 hr. *Maximum:* 40 mg/kg daily.

I.V. INFUSION

Adults. 400 mg infused over at least 30 minutes, followed by 400 mg infused over at least 30 minutes, every 4 to 6 hours. Or, 100 to 200 mg infused over at least 30 minutes, every 4 hours, as needed.

Route	Onset	Peak	Duration
P.O.*	30 min	Unknown	4–6 hr
P.O.†	Up to 7 days	1–2 wk	Unknown
P.O.‡	In 1 hr	2–4 hr	6–8 hr

Mechanism of Action

Blocks activity of cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate inflammatory response and cause local vasodilation, swelling, and pain. By inhibiting prostaglandins, this

* For analgesic effects.

† For anti-inflammatory effects.

‡ For antipyretic effects.

NSAID reduces inflammatory symptoms and relieves pain. Ibuprofen's antipyretic action probably stems from its effect on the hypothalamus, which increases peripheral blood flow, causing vasodilation and encouraging heat dissipation.

Contraindications

Angioedema, asthma, bronchospasm, nasal polyps, rhinitis, or urticaria caused by hypersensitivity to aspirin, ibuprofen, iodides, or other NSAIDs; perioperative pain with coronary artery bypass graft surgery

Interactions**DRUGS**

acetaminophen: Possibly increased renal effects with long-term use of both drugs
antihypertensives: Decreased effectiveness of these drugs

aspirin: Possibly decreased cardioprotective and stroke-preventive effects of aspirin

aspirin, other NSAIDs: Increased risk of bleeding and adverse GI effects

bone marrow depressants: Possibly increased leukopenic and thrombocytopenic effects of bone marrow depressants

cefamandole, cefoperazone, cefotetan:

Increased risk of hypoprothrombinemia and bleeding

colchicine, platelet aggregation inhibitors:

Increased risk of GI bleeding, hemorrhage, and ulcers

corticosteroids, potassium supplements:

Increased risk of adverse GI effects

cyclosporine: Increased risk of nephrotoxicity from both drugs, increased blood cyclosporine level

digoxin: Increased blood digoxin level and risk of digitalis toxicity

diuretics (loop, potassium-sparing, and thiazide): Decreased diuretic and antihypertensive effects

gold compounds, nephrotoxic drugs:

Increased risk of adverse renal effects

heparin, oral anticoagulants, thrombolytics:

Increased anticoagulant effects, increased risk of hemorrhage

insulin, oral antidiabetics: Possibly increased hypoglycemic effects of these drugs

lithium: Increased blood lithium level

methotrexate: Decreased methotrexate

clearance and increased risk of toxicity

plicamycin, valproic acid: Increased risk of

hypoprothrombinemia and GI bleeding, hemorrhage, and ulcers
probenecid: Possibly increased blood level, effectiveness, and risk of toxicity of ibuprofen

ACTIVITIES

alcohol use: Increased risk of adverse GI effects

Adverse Reactions

CNS: Aseptic meningitis, dizziness, headache, nervousness, seizures, stroke

CV: Fluid retention, heart failure, hypertension, MI, peripheral edema, tachycardia

EENT: Amblyopia, epistaxis, stomatitis, tinnitus

GI: Abdominal cramps, distention, or pain; anorexia; constipation; diarrhea; diverticulitis; dyspepsia; dysphagia; elevated liver function test results; epigastric discomfort; esophagitis; flatulence; gastritis; gastroenteritis; gastroesophageal reflux disease; GI bleeding, hemorrhage, perforation, or ulceration; heartburn; hemorrhoids; hepatic failure; hepatitis; hiatal hernia; indigestion; melena; nausea; stomatitis; vomiting

GU: Cystitis, hematuria, renal failure

(acute)

HEME: Agranulocytosis, anemia, aplastic anemia, eosinophilia, hemolytic anemia, leukopenia, neutropenia, pancytopenia, prolonged bleeding time, thrombocytopenia
RESP: Bronchospasm, dyspnea, wheezing
SKIN: Blisters, erythema multiforme, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, flulike symptoms, hypokalemia, weight gain

Nursing Considerations

- Use ibuprofen with extreme caution in patients with a history of ulcer disease or GI bleeding because NSAIDs such as ibuprofen increase risk of GI bleeding and ulceration. Expect to use ibuprofen for shortest time possible in these patients.
- Risk of serious cardiovascular thrombotic events such as a MI or stroke increases the longer ibuprofen is used. Expect to give drug for shortest time possible.
- For I.V. use, dilute Caldolor brand of ibuprofen to final concentration of 4 mg/ml or less using 0.9% sodium chloride injection, 5% dextrose injection, or lactat-

ed Ringer's solution. For an 800-mg dose, dilute 8 ml Caldolor in at least 200 ml diluent; for a 400-mg dose, dilute 4 ml Caldolor in at least 100 ml diluent.

Diluted solutions may be kept at room temperature up to 24 hours. When infusing ibuprofen intravenously, infusion time must be at least 30 minutes.

- Serious GI tract ulceration, bleeding, and perforation may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give oral drug with food. If GI distress occurs, withhold drug and notify prescriber immediately.
- Use ibuprofen cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

WARNING Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

- Monitor patient—especially if he's elderly or receiving long-term oral ibuprofen therapy—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver function test results because, in rare cases, elevations may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure.
- Monitor BUN and serum creatinine levels in elderly patients, patients taking diuretics or ACE inhibitors, and patients with heart failure, impaired renal function, or hepatic dysfunction; drug may cause renal failure.
- Monitor CBC for decreased hemoglobin and hematocrit. Drug may worsen anemia.

WARNING If patient has bone marrow suppression or is receiving an antineoplastic drug, monitor laboratory results (including WBC count), and watch for evidence of infection. Ibuprofen's anti-inflammatory and antipyretic actions may mask signs and symptoms, such as fever and pain.

- Assess patient's skin regularly for signs of rash or other hypersensitivity reaction because ibuprofen is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID sensitivity. At first sign of reaction,

stop drug and notify prescriber.

- Although analgesic effect occurs at low doses, expect to give at least 400 mg four times daily for anti-inflammatory effect.
- Expect higher doses for rheumatoid arthritis than for osteoarthritis.
- Be aware that ibuprofen oral suspension may contain sucrose, which may affect blood glucose level in diabetic patients.

PATIENT TEACHING

- Instruct patient to take tablets with a full glass of water, and caution him not to lie down for 15 to 30 minutes to prevent esophageal irritation.
- Advise patient to take drug with food or after meals to reduce GI distress.
- Urge patient no more drug or for longer time than prescribed because stomach bleeding may occur and risk of MI or stroke may increase.
- Instruct patient to consult prescriber if he needs to take drug for more than 3 days for fever or 10 days for pain; if stomach problems (heartburn, upset, pain) recur; if he has a history of ulcers, bleeding problems, hypertension, or heart or renal disease; if he takes a diuretic; or if he's over age 65.
- Inform patient with phenylketonuria that Motrin chewable tablets contain aspartame.
- Inform patient that full therapeutic effect for arthritis may take 2 weeks or longer.
- Urge patient to avoid taking two different NSAIDs at the same time, unless directed, and to alert prescriber before taking ibuprofen if he has ever had an allergic reaction to any other analgesic or fever-reducing drug or has a history of asthma.
- Urge patient to avoid alcohol, aspirin, and corticosteroids while taking ibuprofen, unless prescribed. If patient takes aspirin as prevention of MI or stroke, explain that ibuprofen may interfere with this effect.
- Suggest that patient wear sunscreen and protective clothing when outdoors.
- Advise patient to report flulike symptoms, rash, signs of GI bleeding, swelling, vision changes, and weight gain.
- Urge parents to tell prescriber promptly if child receiving drug develops a severe or persistent sore throat, high fever, headache, persistent diarrhea, nausea, or vomiting or hasn't been drinking fluids.
- Advise parents to consult prescriber before

- giving OTC ibuprofen to a child if the child has asthma, ulcers, bleeding problems, high blood pressure, heart or kidney disease, a need for diuretic therapy, serious adverse effects from previous use of fever reducers or pain relievers, or persistent stomach problems, such as heartburn, upset stomach, or stomach pain.
- Caution pregnant patient not to take NSAIDs such as ibuprofen during last trimester because they may cause premature closure of the ductus arteriosus.
- Explain that ibuprofen may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, weakness, and slurring of speech.
- Explain that ibuprofen may increase risk of serious adverse GI reactions; stress importance of seeking immediate medical attention for such signs and symptoms as epigastric or abdominal pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions. Urge him to seek immediate medical attention for rash, blisters, itching, fever, or other indications of hypersensitivity.

ibutilide fumarate

Corvert

Class and Category

Chemical: Methanesulfonanilide derivative

Therapeutic: Class III antiarrhythmic

Pregnancy category: C

Indications and Dosages

↗ *To rapidly convert recent-onset atrial flutter or fibrillation to sinus rhythm*

I.V. INFUSION

Adults weighing 60 kg (132 lb) or more.

1 mg over 10 min. Dose repeated 10 min after first dose is finished if arrhythmia persists.

Adults weighing less than 60 kg. 0.01 mg/kg over 10 min. Dose is repeated 10 min after first dose is completed if arrhythmia persists.

DOSAGE ADJUSTMENT Infusion stopped if arrhythmia is terminated or if sustained or

nonsustained ventricular tachycardia or prolonged QT or QTc interval develops.

Mechanism of Action

May promote sodium movement through slow inward sodium channels in myocardial cell membranes. Ibutilide also may inhibit potassium channels in myocardial cell membranes involved in cardiac repolarization. These actions prolong cardiac action potential by delaying repolarization and increasing atrial and ventricular refractoriness. As a result, sinus rate slows and AV conduction is delayed.

Contraindications

Hypersensitivity to ibutilide or components

Interactions

DRUGS

amiodarone, astemizole, disopyramide, meprobitaline, phenothiazines, procainamide, quinidine, sotalol, tricyclic antidepressants: Possibly prolonged QT interval, leading to increased risk of proarrhythmias

Adverse Reactions

CNS: Headache, syncope

CV: AV block, bradycardia, bundle-branch block, heart failure, hypertension, hypotension, idioventricular rhythm, orthostatic hypotension, palpitations, prolonged QT interval, sinus and supraventricular tachycardia, supraventricular arrhythmias, ventricular arrhythmias, ventricular tachycardia (sustained and nonsustained)

GI: Nausea

GU: Renal failure

Nursing Considerations

- Before giving ibutilide, check serum electrolyte levels and expect to correct abnormalities, as prescribed. Be especially alert for hypokalemia and hypomagnesemia, which can lead to arrhythmias.
- Give drug undiluted or dilute in 50 ml normal saline solution or D₅W. Add contents of 10-ml vial (0.1 mg/ml) to 50 ml solution to obtain 0.017 mg/ml. Use polyvinyl chloride plastic bags or polyolefin bags for admixtures. Give drug within 24 hours (48 hours if refrigerated).
- Infuse drug slowly over 10 minutes.
- As ordered, monitor patient's cardiac rhythm continuously during infusion and for at least 4 hours afterward—longer if arrhythmias appear or if patient has

abnormal hepatic function. Observe patient for ventricular ectopy.

- Make sure defibrillator and drugs to treat sustained ventricular tachycardia are available during therapy and when monitoring patient after therapy.

PATIENT TEACHING

- Inform patient that ibutilide will be given by I.V. infusion and that his heart rhythm will be monitored continuously.
- Ask patient to report chest pain, faintness, numbness, tingling, palpitations, and shortness of breath.
- Advise patient to keep follow-up appointments to monitor heart rhythm.

iloperidone

Fanapt

Class and Category

Chemical class: Piperidinyl-benzisoxazole derivative

Therapeutic class: Second-generation antipsychotic; atypical antipsychotic

Pregnancy category: C

Indications and Dosages

↗ *To treat schizophrenia*

TABLETS

Adults. *Initial:* 1 mg twice daily, adjusted to target dosage range as follows: 2 mg twice daily on day 2, 4 mg twice daily on day 3, and 6 mg twice daily on day 4. Dosage may be further increased, if needed, as follows: 8 mg twice daily on day 5, 10 mg twice daily on day 6, and 12 mg twice daily on day 7. *Maximum:* 12 mg b.i.d. twice daily.

DOSAGE ADJUSTMENT For patients taking strong CYP2D6 or CYP3A4 inhibitors, dosage reduced by half.

Route	Onset	Peak	Duration
P.O.	1–2 wk	2–4 hr	Unknown

Mechanism of Action

Selectively blocks serotonin type 2 (5-HT₂) and dopamine type 2 (D₂) receptors in CNS, thereby suppressing psychotic symptoms.

Contraindications

Hypersensitivity to iloperidone or its components

Interactions

DRUGS

antibiotics such as fluoroquinolones or macrolides, class I A antiarrhythmics such as procainamide or quinidine, class III antiarrhythmics such as amiodarone or sotalol, other antipsychotic drugs such as chlorpromazine or thioridazine, or any other drug that affects the QT interval such as methadone or pentamidine: Possibly prolonged QT interval
antihypertensive drugs: Increased antihypertensive effects

CYP3A4 inhibitors such as ketoconazole, CYP2D6 inhibitors such as fluoxetine or paroxetine: Increased plasma iloperidone level

dextromethorphan: Increased blood dextromethorphan level

Adverse Reactions

CNS: Aggression, delusion, dizziness, extrapyramidal effects, fatigue, lethargy, seizures, somnolence, suicidal ideation, restlessness, tremor

CV: CHF, orthostatic hypotension, palpitations, QT-interval prolongation, tachycardia

EENT: Blurred vision, conjunctivitis, dry mouth, nasal congestion, nasopharyngitis, upper respiratory tract infection

ENDO: Diabetic ketoacidosis, elevated prolactin levels, hyperglycemia, hyperosmolar coma

GI: Abdominal discomfort, diarrhea, nausea

GU: Ejaculation failure, erectile dysfunction, priapism, urinary incontinence

HEME: Leukopenia

MS: Arthralgia, musculoskeletal stiffness, spasms, myalgia

RESP: Dyspnea

SKIN: Rash

Other: Weight gain

Nursing Considerations

- Iloperidone shouldn't be used in patients with a history of cardiovascular disease such as QT-interval prolongation, recent MI, uncompensated heart failure, or cardiac arrhythmias. It also shouldn't be used in patients taking other drugs known to prolong the QT interval and in patients with hepatic impairment.

WARNING Iloperidone shouldn't be used to treat patients with dementia-related psychosis, especially elderly patients, because of an increased risk of death.

- Use cautiously in patients who have a history of seizures or who have conditions that lower the seizure threshold, such as Alzheimer's dementia. Also use cautiously in patients at risk for aspiration pneumonia.
- Expect to start dosage adjustment schedule in patients who have been off iloperidone therapy for more than 3 days.
- Obtain baseline serum potassium and magnesium levels in patients at risk for electrolyte imbalances, and then monitor periodically throughout therapy, as ordered, because electrolyte imbalances increase risk of prolonged QT interval or arrhythmia. If patient reports dizziness, palpitations, or syncope, notify prescriber and expect further evaluation to be done.

WARNING Neuroleptic malignant syndrome has occurred in patients taking other antipsychotic drugs. Monitor patient for hyperpyrexia, muscle rigidity, altered mental status, and autonomic instability. If present, notify prescriber immediately, expect drug to be discontinued, and start intensive treatment, as prescribed. Watch for recurrence if patient resumes antipsychotic therapy.

- Monitor patient for tardive dyskinesia, which has occurred with other antipsychotic drugs. If patient develops involuntary, dyskinetic movements, notify prescriber and expect to discontinue drug.
- Monitor blood glucose level, especially in patients with diabetes mellitus, because iloperidone may alter blood glucose enough to induce life-threatening ketoacidosis or hyperosmolar coma.
- Monitor patient's CBC periodically, as ordered, especially during first few months of therapy, because iloperidone may cause neutropenia. Also, be aware that other antipsychotic drugs have caused sometimes fatal leukopenia and agranulocytosis. If patient's WBC count decreases, expect drug to be discontinued.
- Monitor patient closely for abnormal tendencies that may suggest suicidal thinking, especially when iloperidone therapy starts or dosage is changed.

PATIENT TEACHING

- Inform patient that when iloperidone therapy starts, dosage must be adjusted for up to a week to reach target level. Also

explain that adjustment process will need to be repeated if she skips drug for more than 3 days.

- Advise patient or caregiver to notify prescriber about unusual, severe, or persistent adverse reactions because drug may need to be discontinued.
- Urge patient or caregiver to report evidence of abnormal thinking, especially when therapy starts or dosage changes.
- Tell diabetic patient to monitor blood glucose levels closely and to report persistent elevations immediately to prescriber.
- Caution patient to avoid hazardous activities until CNS effects of drug are known. Patient should also avoid alcohol.
- Instruct patient to avoid activities that might raise body temperature, such as doing strenuous exercise, being exposed to extreme heat, taking other drugs with anticholinergic activity, or being subjected to dehydration.
- Stress the need to comply with follow-up appointments and laboratory tests.
- Tell patient to rise slowly from lying to sitting position and from sitting position to standing to avoid dizziness or lightheadedness during therapy.

iloprost

Ventavis

Class and Category

Chemical class: Synthetic analogue of prostacyclin PGI₂

Therapeutic class: Pulmonary arterial anti-hypertensive

Pregnancy category: C

Indications and Dosages

➤ *To improve symptoms and exercise tolerance and prevent further deterioration from pulmonary arterial hypertension in patients with New York Heart Association (NYHA) Class III or IV symptoms*

INHALATION SOLUTION

Adults. *Initial:* 2.5 mcg as one-time dose. If tolerated well for 2 hr, dosage increased to 5 mcg. *Maintenance:* 5 mcg six to nine times daily during waking hours with at least 2 hr between each dose. *Maximum:* 45 mcg daily.

Mechanism of Action

Dilates systemic and pulmonary arterial vascular beds, which lowers blood pressure in pulmonary arterial system.

Contraindications

Hypersensitivity to iloprost or its components

Interactions

DRUGS

anticoagulants: Increased risk of bleeding
antihypertensives, vasodilators: Increased hypotensive effect

Adverse Reactions

CNS: Apathy, dizziness, headache, insomnia, restlessness, syncope

CV: Chest pain, congestive heart failure, hypotension, palpitations, peripheral edema, supraventricular tachycardia, thrombosis, vasodilation

EENT: Epistaxis, gingival bleeding, tongue pain

ENDO: Hyperglycemia

GI: Abdominal cramps, diarrhea, nausea, vomiting

GU: Renal failure

MS: Back pain, muscle cramps or spasms

RESP: Bronchospasm, dyspnea, hemoptysis, increased cough, pneumonia, wheezing

SKIN: Flushing

Other: Flulike symptoms, increased alkaline phosphatase level

Nursing Considerations

- Use iloprost cautiously in patients with hepatic or renal impairment.
- Give iloprost only with the Prodose AAD System, a pulmonary drug delivery device. Avoid letting solution contact skin or eyes.
- **WARNING** Don't give drug if patient's systolic blood pressure is less than 85 mm Hg.
- Notify prescriber if patient develops exertional syncope because dosage may need to be adjusted.

WARNING Stop iloprost immediately if patient develops evidence of pulmonary edema, such as shortness of breath, anxiety, restlessness, and abnormal breath sounds. Notify prescriber, and provide supportive care, as prescribed.

- Monitor patient's vital signs while starting therapy because drug may cause syncope.
- Assess patient's compliance with treatment regimen. If patient has repeatedly length-

ened treatment times, resulting in incomplete dosing, notify prescriber. A different strength may be ordered that decreases inhalation time, which may help increase compliance.

PATIENT TEACHING

- Instruct patient to use iloprost inhalation therapy exactly as prescribed. Tell patient that at least 2 hours must elapse between doses but that benefits of iloprost may not last 2 hours, so he should adjust times of administration to cover planned activities.
- Teach patient how to administer iloprost using Prodose AAD System. Tell patient to have a backup system available in case of equipment malfunction.
- Advise patient to stand up slowly because drug may cause dizziness or faintness. If these symptoms persist or worsen, tell patient to notify prescriber because a dosage adjustment may be required.

imipramine hydrochloride

Apo-Imipramine (CAN), Impril (CAN), Norfranil, Novopramine (CAN), Tipramine, Tofranil

imipramine pamoate

Tofranil-PM

Class and Category

Chemical class: Dibenzazepine derivative

Therapeutic class: Antidepressant

Pregnancy category: Not rated

Indications and Dosages

↗ *To treat depression*

CAPSULES

Adults. *Initial:* 75 mg daily at bedtime, gradually increased as needed and tolerated.

Maximum: 300 mg daily (hospitalized patients), 200 mg/day (outpatients).

TABLETS

Adults. *Initial:* 25 to 50 mg t.i.d. or q.i.d., gradually increased as needed and tolerated.

Maximum: 300 mg daily (hospitalized patients), 200 mg daily (outpatients).

DOSAGE ADJUSTMENT Initial dosage reduced to 25 mg at bedtime for depressed elderly

patients; then adjusted as needed and tolerated up to 100 mg daily in divided doses.

Adolescents. *Initial:* 25 to 50 mg daily in divided doses, adjusted as needed and tolerated. *Maximum:* 100 mg daily.

Children ages 6 to 12. 10 to 30 mg daily in divided doses b.i.d.

↗ *As adjunct to treat childhood enuresis*

TABLETS

Children age 6 and over. 25 mg 1 hr before bedtime. Increased to 50 mg if no response occurs within 1 wk and child is under age 12; increased to 75 mg if child is age 12 or over. *Maximum:* 2.5 mg/kg daily.

Route	Onset	Peak	Duration
P.O.	2–3 wk*	Unknown	Unknown

Mechanism of Action

May interfere with reuptake of serotonin (and possibly other neurotransmitters) at presynaptic neurons, thus enhancing serotonin's effects at postsynaptic receptors. Mood elevation may result from restoration of normal levels of neurotransmitters at nerve synapses. This tricyclic antidepressant also blocks acetylcholine receptors, which may explain how it relieves enuresis.

Contraindications

Acute recovery period after MI; hypersensitivity to imipramine, other tricyclic antidepressants, or their components; use within 2 weeks of MAO inhibitor therapy

Interactions

DRUGS

amantadine, anticholinergics, antidyskinetics,

antihistamines: Risk of increased anticholinergic effects, including confusion, hallucinations, and nightmares

anticonvulsants: Increased risk of CNS depression, increased risk of seizures, decreased effectiveness of imipramine

antithyroid drugs: Possibly agranulocytosis
barbiturates, carbamazepine: Possibly decreased imipramine level and effects
cimetidine, fluoxetine: Possibly increased blood imipramine level

clonidine, guanadrel, guanethidine: Possibly decreased antihypertensive effects of these drugs, increased CNS depression (clonidine)

* For antidepressant effect.

CNS depressants: Increased CNS depression, respiratory depression, and hypotension
disulfiram, ethchlorvynol: Risk of delirium, increased CNS depression (ethchlorvynol)
estramustine, estrogen-containing oral contraceptives, estrogens: Risk of increased bioavailability of imipramine, increased depression

MAO inhibitors: Increased risk of hypertensive crisis, severe seizures, and death
oral anticoagulants: Possibly increased anti-coagulant activity

pimozide, probucol: Risk of arrhythmias
sympathomimetics (including ophthalmic epinephrine and vasoconstrictive local anesthetics): Increased risk of arrhythmias, hyperpyrexia, hypertension, tachycardia
thyroid hormones: Risk of increased therapeutic and adverse effects of both drugs

ACTIVITIES

alcohol use: Increased CNS depression, increased alcohol effects

sun exposure: Increased risk of photosensitivity

Adverse Reactions

CNS: Anxiety, ataxia, chills, confusion, delirium, dizziness, drowsiness, excitation, extrapyramidal reactions, fever, hallucinations, headache, insomnia, nervousness, nightmares, parkinsonism, seizures, stroke, suicidal ideation, tremor

CV: Arrhythmias, orthostatic hypotension, palpitations

EENT: Blurred vision, dry mouth, increased intraocular pressure, pharyngitis, taste perversion, tinnitus, tongue swelling

ENDO: Gynecomastia, syndrome of inappropriate ADH secretion

GI: Constipation, diarrhea, heartburn, ileus, increased appetite, nausea, vomiting

GU: Impotence, libido changes, testicular swelling, urine retention

HEME: Agranulocytosis, bone marrow depression

RESP: Wheezing

SKIN: Alopecia, diaphoresis, jaundice, photosensitivity, pruritus, rash, urticaria

Other: Allergic reaction, facial edema, weight gain

Nursing Considerations

- Use imipramine cautiously in patients with a history of urine retention or angle-closure glaucoma because drug's anti-

cholinergic effects may cause urine retention and increased intraocular pressure.

WARNING Don't give MAO inhibitors within 2 weeks of imipramine. Patient may experience hypertensive crisis, seizures, and death.

- Frequently assess for adverse reactions during first 2 hours of therapy.
- Check supine and standing blood pressure for orthostatic hypotension before and during imipramine therapy and before dosage increases.
- Anticipate increased risk of arrhythmias in patients with a history of cardiac disease.
- When drug is used for depression, expect mood elevation to take 2 to 3 weeks. Watch patient closely for suicidal tendencies, especially children and adolescents and especially when therapy starts or dosage changes, because depression may worsen temporarily at these times.
- Avoid abrupt withdrawal of drug in patients on long-term therapy. Such withdrawal may cause headache, malaise, nausea, sleep disturbance, and vomiting.
- Taper drug gradually, as ordered, a few days before surgery to avoid risk of hypertension during surgery.
- Obtain CBC, as ordered, if patient experiences signs and symptoms of infection, such as fever or pharyngitis.
- Limit amount of drug given to potentially suicidal patient.

PATIENT TEACHING

- Advise patient to take imipramine exactly as prescribed. Warn that stopping drug abruptly may cause headache, malaise, nausea, trouble sleeping, and vomiting.
- Caution parents to monitor child or adolescent closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Urge patient to report chills, trouble urinating, dizziness, excess sedation, fever, palpitations, signs of allergic reaction, and sore throat.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcohol during imipramine therapy because it increases CNS depression and alcohol effects.
- Suggest that patient eat small, frequent meals to help relieve nausea.
- Instruct patient to avoid prolonged expo-

sure to sunlight because of the risk of photosensitivity.

- Inform male patient about possible impotence and increased or decreased libido.
- If patient reports dry mouth, suggest sugarless candy or gum to relieve it. Tell him to check with prescriber if dry mouth persists after 2 weeks.

immune globulin intramuscular (human)

(gamma globulin, IG)

BayGam, WinRho SDF

immune globulin intravenous (human)

(IGIV, immune serum
globulin, ISG, IVIG)

Gamimune N 5% S/D, Gamimune N 10% S/D, Gammagard Liquid, Gammagard S/D, Gammagard S/D 0.5 g, Gammar-P IV, Gamunex 10%, Iveegam EN, Octagam 5%, Polygam S/D, Rhophylac, Sandoglobulin, Venoglobulin-I, Venoglobulin-S 5%, Venoglobulin-S 10%, WinRho SDF

Class and Category

Chemical class: Polyvalent antibody

Therapeutic class: Antibacterial, anti-Kawasaki disease agent, antipolyneuropathy agent, antiviral, immunizing agent, platelet count stimulator

Pregnancy category: C

Indications and Dosages

↗ *To treat primary immunodeficiency*

I.M. INJECTION (BAYGAM)

Adults. 0.66 ml/kg (at least 200 mg/kg) every 3 to 4 wk; initial dose may be doubled.

I.V. INFUSION (GAMIMUNE N 5% S/D OR 10% S/D)

Adults. 100 to 200 mg/kg every mo. If response is inadequate, dose may be increased to as much as 400 mg/kg or dosing frequency may be increased.

I.V. INFUSION (GAMMAGARD S/D, POLYGAM S/D)

Adults. 200 to 400 mg/kg initially, then at least 100 mg/kg every mo thereafter. If response is inadequate, dose or frequency may be adjusted.

I.V. INFUSION (GAMMAR-P IV)

Adults. 200 to 400 mg/kg every 3 to 4 wk.

Adolescents and children. 200 mg/kg every 3 to 4 wk.

I.V. INFUSION (GAMUNEX 10%)

Adults. 300 to 600 mg/kg every 3 or 4 wk.

I.V. INFUSION (IVEEGAM EN)

Adults. 200 mg/kg every mo.

I.V. INFUSION (OCTAGAM 5%)

Adults. *Initial:* 30 mg/kg/hr for first 30 minutes; increased, if tolerated, to 60 mg/kg/hr for second 30 minutes and, if tolerated, to 120 mg/kg/hr for another 30 minutes; followed by maintenance infusion of up to 200 mg/kg/hr.

I.V. INFUSION (SANDOGLOBULIN)

Adults and children. 200 mg/kg every mo.

If response is inadequate, dose may be increased to 300 mg/kg or dosing frequency may be increased.

I.V. INFUSION (VENOGLOBULIN-I)

Adults and children. 200 mg/kg every mo.

If response is inadequate, dose may be increased to 300 to 400 mg/kg every mo or dosing frequency may be increased.

I.V. INFUSION (VENOGLOBULIN-S 5% OR 10%)

Adults and children. 200 mg/kg every mo.

If response is inadequate, dose may be increased to as much as 400 mg/kg or dosing frequency may be increased.

↗ *To treat primary immunodeficiency disorders associated with defects in humoral immunity*

I.V. INFUSION (GAMMAGARD LIQUID)

Adults and children. 300 to 600 mg/kg daily every 3 to 4 wk.

↗ *To treat idiopathic thrombocytopenic purpura (ITP)*

I.V. INFUSION (GAMIMUNE N 5% S/D)

Adults and children. 400 mg/kg daily for 5 days. Or, 1,000 mg/kg for 1 or 2 days for patients not at risk for increased fluid volume.

I.V. INFUSION (GAMIMUNE N 10% S/D)

Adults and children. 1,000 mg/kg for 1 or 2 days for patients not at risk for increased fluid volume.

I.V. INFUSION (GAMUNEX 10%)

Adults. 1 g/kg daily for 2 consecutive days (second dose may be withheld if adequate

increase in platelet count occurs 24 hours after first dose). Or, 0.4 g/kg daily for 5 consecutive days.

DOSAGE ADJUSTMENT In acute ITP of childhood, I.V. Sandoglobulin therapy may be discontinued after second day of 5-day course if initial platelet count response is adequate (30,000 to 50,000/mm³). In chronic ITP, an additional I.V. infusion of 400 mg/kg (of either Sandoglobulin or Gamimune) may be prescribed if platelet count falls below 30,000/mm³ or if patient develops significant bleeding. If response remains inadequate, an additional I.V. infusion of 800 to 1,000 mg/kg may be given.

I.V. INFUSION (GAMMAGARD S/D)

Adults. 1 g/kg. If response is inadequate, up to three separate doses may be administered on alternate days.

I.V. INFUSION (RHOPHYLAC)

Adults. 50 mcg/kg at 2 ml/15 to 60 seconds.

I.V. INFUSION (SANDOGLOBULIN)

Adults and adolescents. 400 mg/kg daily for 2 to 5 consecutive days.

I.V. INFUSION (VENOGLOBULIN-I)

Adults and children. *Induction:* Cumulative dose up to 2 g/kg over 2 to 7 consecutive days. *Maintenance (adults):* 2 g/kg as a single dose every 2 wk as needed to maintain platelet count above 30,000/mm³ or prevent bleeding episodes. *Maintenance (children):* 1 g/kg as a single dose every 2 wk as needed to maintain platelet count above 30,000/mm³ or prevent bleeding episodes.

I.V. INFUSION (VENOGLOBULIN-S 5% OR 10%)

Adults and children. Cumulative dose up to 2,000 mg/kg over 5 consecutive days.

DOSAGE ADJUSTMENT An additional I.V. infusion of 1,000 mg/kg may be administered to maintain a platelet count of 30,000/mm³ in children or 20,000/mm³ in adults or to prevent bleeding episodes.

➤ *To treat acute or chronic pediatric ITP; to treat chronic adult-onset ITP; to treat pediatric- and adult-onset ITP secondary to HIV infection*

I.V. INJECTION (WINRHO SDF)

Adults and children. *Initial:* 250 international units/kg given as a single injection over 3 to 5 min. Or, 125 international units/kg given as a single injection over 3 to 5 min and repeated once on a separate day. *Maintenance:* Frequency and dosage highly individualized based on patient's hemoglo-

bin and platelet levels.

DOSAGE ADJUSTMENT For patients with hemoglobin level less than 10 g/dl, dose reduced to 125 to 200 international units/kg.

➤ *As adjunct to treat Kawasaki disease*

I.V. INFUSION (GAMMAGARD S/D)

Adults and adolescents. 1 g/kg as a single dose; or, 400 mg/kg daily for 4 consecutive days.

I.V. INFUSION (IVEEGAM EN, VENOGLOBULIN-S 5% OR 10%)

Adults and adolescents. 2 g/kg as a single dose; or, Iveegam EN may be given at 400 mg/kg daily for 4 days.

➤ *To decrease the risk of graft-versus-host disease, interstitial pneumonia, septicemia, and other infections during first 100 days after bone marrow transplantation*

I.V. INFUSION (GAMIMUNE N 5% S/D OR 10% S/D)

Adults over age 20. 500 mg/kg on 7th and 2nd days before transplant (or at time when conditioning therapy for transplantation begins), and then weekly through 90th day after transplant.

➤ *As adjunct to treat bacterial infections secondary to B-cell chronic lymphocytic leukemia*

I.V. INFUSION (GAMMAGARD S/D, POLY GAM S/D)

Adults and adolescents. 400 mg/kg every 3 to 4 wk.

➤ *To prevent bacterial infection in children with HIV who are immunosuppressed*

I.V. INFUSION (GAMIMUNE N 5% S/D OR 10% S/D)

Children. 400 mg/kg daily every 28 days.

➤ *To prevent hepatitis A*

I.M. INJECTION (BAYGAM)

Adults with household or institutional contacts. 0.02 ml/kg (0.01 ml/lb).

Adults traveling to areas where hepatitis A is common. 0.02 ml/kg if staying less than 3 mo, 0.06 ml/kg (repeated every 4 to 6 mo) if staying 3 mo or longer.

➤ *To prevent or lessen severity of measles (rubeola) in susceptible persons*

I.M. INJECTION (BAYGAM)

Adults. 0.2 ml/kg (0.11 ml/lb) for persons exposed fewer than 6 days previously.

➤ *To provide passive immunization against varicella in immunosuppressed patients*

I.M. INJECTION (BAYGAM)

Adults. 0.6 to 1.2 ml/kg if varicella-zoster immune globulin (human) is unavailable.

↗ *To reduce the risk of infection and fetal damage in women who have been exposed to rubella in early pregnancy*

I.M. INJECTION (BAYGAM)

Adults. 0.55 ml/kg.

↗ *To suppress Rh isoimmunization*

I.M. INJECTION, I.V. INFUSION (RHOPHYLAC)

Adult pregnant women. 1,500 international units as a single dose at 28 to 30 wk gestation followed by 1,500 international units within 72 hr after delivery of an Rh-positive newborn.

I.M. INJECTION (WINRHO SDF)

Adult pregnant women. 1,500 international units as a single dose at 28 wk gestation followed by 600 international units within 72 hr after delivery of an Rh-positive newborn.

I.V. INJECTION (WINRHO SDF)

Adult pregnant women. 1,500 international units as a single dose infused over 3 to 5 min at 28 wk gestation followed by 600 international units over 3 to 5 min within 72 hr after delivery of an Rh-positive newborn.

DOSE ADJUSTMENT For patients more than 34 wk gestation and having an abortion, amniocentesis, or other manipulative procedure, 600 international units given within 72 hr but preferably immediately after procedure. For patients 34 wk gestation or less and having amniocentesis or chorionic villus sampling, 1,500 international units given immediately after procedure and repeated every 12 wk for duration of pregnancy. For patients with threatened abortion at any stage of pregnancy, 1,500 international units given immediately.

↗ *To treat incompatible blood transfusions*

I.M. INJECTION, I.V. INFUSION (RHOPHYLAC)

Adults exposed to Rh-positive RBCs. 100 international units/2 ml transfused blood or 1 ml erythrocyte concentrate within 72 hr of exposure.

I.M. INJECTION (WINRHO SDF)

Adults exposed to Rh-positive whole blood. 6,000 international units every 12 hr until total dose (60 international units/ml of blood) is given.

Adults exposed to Rh-positive RBCs. 6,000 international units every 12 hr until total dose (120 international units/ml of cells) is given.

I.V. INJECTION (WINRHO SDF)

Adults exposed to Rh-positive whole blood. 3,000 international units infused over 3 to 5 min every 8 hr until total dose (45 international units/ml of blood) is given.

Adults exposed to Rh-positive RBCs.

3,000 international units infused over 3 to 5 min every 8 hr until total dose (90 international units/ml of cells) is given.

↗ *To treat massive fetomaternal hemorrhage*

I.M. INJECTION, I.V. INFUSION (RHOPHYLAC)

Adults exposed to Rh-positive RBCs.

1,500 international units plus 100 international units for every 1 ml of fetal RBCs exceeding 15 ml if transplacental bleeding is quantified or an additional 1,500 international units if transplacental bleeding can't be quantified within 72 hours of hemorrhage.

I.M. INJECTION (WINRHO SDF)

Adults exposed to Rh-positive whole blood.

6,000 international units every 12 hr until total dose (60 international units/ml of blood) is given.

Adults exposed to Rh-positive RBCs.

6,000 international units every 12 hr until total dose (120 international units/ml of cells) is given.

I.V. INJECTION (WINRHO SDF)

Adults exposed to Rh-positive whole blood.

3,000 international units infused over 3 to 5 min every 8 hr until total dose (45 international units/ml of blood) is given.

Adults exposed to Rh-positive RBCs.

3,000 international units infused over 3 to 5 min every 8 hr until total dose (90 international units/ml of cells) is given.

Route	Onset	Peak	Duration
I.V.	Unknown	Unknown	21–28 days

Mechanism of Action

Releases antibody-specific globulins to produce an antibody-antigen reaction that results in bacterial lysis and facilitates bacterial phagocytosis. In treatment of ITP, immune globulin blocks iron receptors on macrophages to increase immunoglobulin action. Immune globulin also increases cytokine production and improves B-cell immune function by regulating T-cell and macrophage activity. Newly formed antigen-

antibody complexes produce split complement components that cause bacterial lysis.

In Kawasaki disease and bacterial infections with B-cell chronic lymphocytic leukemia, immune globulin neutralizes bacterial and viral toxins that harm immune and inflammatory responses.

Incompatibilities

Don't mix immune globulin with any other drugs, including other immune globulins, or with any I.V. solutions other than D₅W or manufacturer's supplied diluent because effects of doing so are unknown.

Contraindications

Hypersensitivity to immune globulin (human) or its components, IgA deficiency in patients with known antibody to IgA

Interactions

DRUGS

live-virus vaccines: Possibly decreased response to vaccine

Adverse Reactions

CNS: Headache, malaise

CV: Tachycardia

GI: Nausea, vomiting

MS: Arthralgia, back pain, myalgia

RESP: Dyspnea

Nursing Considerations

- Before giving immune globulin, monitor patient's fluid volume and BUN and serum creatinine levels, as ordered, to determine risk for acute renal failure. Those at increased risk include patients with renal insufficiency, diabetes mellitus, volume depletion, sepsis, or paraproteinemia; those taking nephrotoxic drugs; and those over age 65. Expect drug to be discontinued if renal function deteriorates.
- When preparing immune globulin, verify that appropriate form is being used—either immune globulin intramuscular for I.M. injection or immune globulin intravenous for I.V. infusion.
- To reconstitute drug (except Gammagard Liquid, which doesn't need reconstitution), follow manufacturer's guidelines and use only diluent recommended by manufacturer. Don't shake solution; excessive shaking causes foaming. If drug or diluent is cold, drug may take up to 20 minutes to dissolve.

- If drug is reconstituted outside of sterile laminar airflow conditions, administer it immediately and discard unused portions.
- Consult manufacturer's guidelines to determine appropriate flow rate for starting infusion. Expect to increase flow rate after 15 to 30 minutes, as specified.
- When giving drug by I.M. injection, inject it only into deltoid muscle of upper arm or anterolateral aspect of upper thigh. If giving a dose larger than 5 ml, divide it and administer at separate sites.

WARNING Watch for an acute inflammatory reaction in patients who have never received immune globulin therapy before, in those whose last treatment was more than 8 weeks before, and in those whose initial infusion rate exceeded 1 ml/minute. Within 30 minutes to 1 hour after beginning of infusion, assess for chills, fever, facial flushing, feeling of tightness in chest, dizziness, nausea, vomiting, diaphoresis, and hypotension. Notify prescriber immediately if such symptoms occur, and be prepared to stop infusion until symptoms have subsided.

WARNING After immune globulin administration, monitor patient closely for aseptic meningitis. Notify prescriber if patient develops drowsiness, fever, nausea, vomiting, nuchal rigidity, photophobia, painful eye movements, or severe headache.

- Be aware that immune globulin intravenous is made from human plasma and therefore may contain infectious agents, such as viruses. Risk of transmitting a virus by infusion has been reduced by screening blood donors, testing donated blood, and inactivating or removing certain viruses from the product.
- For patient receiving WinRho SDF to treat ITP, assess clinical response by monitoring patient's platelet count, RBC count, hemoglobin level, and reticulocyte level.
- For patient receiving WinRho SDF for exposure to incompatible blood transfusions or massive fetal hemorrhage, give drug within 72 hours of incident.

PATIENT TEACHING

- Instruct patient to immediately report any symptoms he experiences after receiving immune globulin.
- Inform patient to postpone live-virus vaccinations for up to 11 months after receiving

ing immune globulin because drug may delay or inhibit response to vaccine.

inamrinone (amrinone)

Inocor

Class and Category

Chemical class: Bipyridine derivative

Therapeutic class: Cardiac inotrope

Pregnancy category: C

Indications and Dosages

➤ *To treat heart failure in patients who haven't responded sufficiently to digoxin, diuretics, or vasodilators*

I.V. INFUSION

Adults. *Initial:* 0.75 mg/kg by bolus over 2 to 3 min and repeated after 30 min, if needed. *Maintenance:* 5 to 10 mcg/kg/min by infusion. *Maximum:* 10 mg/kg daily.

Route	Onset	Peak	Duration
I.V.	2–5 min	In 10 min	30 min–2 hr

Mechanism of Action

Inhibits phosphodiesterase enzymes that normally degrade myocardial cAMP. This action increases intracellular levels of cAMP, which regulates intracellular and extracellular calcium balance. Increased intracellular cAMP level enhances influx of calcium into cell, thereby increasing force of myocardial contractions. Inamrinone also acts directly on peripheral vascular smooth-muscle cells, causing relaxation and dilation, which reduces preload and afterload.

Incompatibilities

Don't administer inamrinone through same I.V. line as furosemide because precipitate may form. Don't dilute inamrinone in solution that contains dextrose because a chemical interaction occurs over 24 hours.

Contraindications

Hypersensitivity to inamrinone, bisulfites, or their components; severe aortic or pulmonary valvular disease

Interactions

DRUGS

disopyramide: Possibly severe hypotension

Adverse Reactions

CNS: Fever

CV: Chest pain, hypotension, pericarditis, supraventricular tachycardia, ventricular arrhythmias

GI: Abdominal pain, anorexia, elevated liver function test results, hepatotoxicity, nausea, vomiting

HEME: Elevated erythrocyte sedimentation rate, thrombocytopenia (especially with high-dose or prolonged treatment)

MS: Myositis

RESP: Hypoxemia, pleuritis

SKIN: Jaundice

Other: Infusion site burning

Nursing Considerations

WARNING Be aware that inamrinone may increase risk of ventricular arrhythmias in patients with atrial flutter or fibrillation. To minimize risk, expect to pretreat such patients with digoxin.

- Give drug undiluted or diluted in normal or half-normal (0.45) saline solution to a concentration of 1 to 3 mg/ml, as prescribed. Use diluted solution within 24 hours.

WARNING Monitor vital signs regularly. If blood pressure falls significantly, slow or stop infusion and notify prescriber.

- Monitor weight, cardiac index, central venous pressure, pulmonary artery wedge pressure, and fluid intake and output as appropriate to assess drug's effectiveness.

WARNING Assess often for signs of thrombocytopenia, such as bruising or bleeding and altered platelet count. If signs appear, expect to decrease inamrinone dose or discontinue drug.

PATIENT TEACHING

- Instruct patient to notify you or another nurse if he becomes dizzy, which may indicate hypotension.

indapamide

Apo-Indapamide (CAN), Gen-Indapamide (CAN), Lozide (CAN), Lozol, Novo-Indapamide (CAN), Nu-Indapamide (CAN)

Class and Category

Chemical class: Sulfonamide

Therapeutic class: Antihypertensive, diuretic
Pregnancy category: B

Indications and Dosages

↗ *To treat edema caused by heart failure*

TABLETS

Adults. 2.5 mg daily in the morning, increased to 5 mg daily after 1 wk, if indicated.

↗ *To manage hypertension*

TABLETS

Adults. 2.5 mg daily, increased to 5 mg after 4 wk, if needed.

Route	Onset	Peak	Duration
P.O.*	1–2 hr	Unknown	36 hr
P.O.†	1–2 wk	8–12 wk	Up to 8 wk

Mechanism of Action

Acts mainly on distal convoluted tubules, where it enhances excretion of sodium, chloride, and water by inhibiting sodium ion movement across renal tubules. The resulting decrease in plasma and extracellular fluid volume decreases peripheral vascular resistance and reduces blood pressure. This thiazide diuretic also may cause arterial vasodilation by blocking calcium channels in smooth-muscle cells.

Contraindications

Anuria; hypersensitivity to thiazide or related diuretics or to sulfonamide-derived drugs

Interactions

DRUGS

amiodarone: Increased risk of arrhythmias if hypokalemia develops

cholestyramine, colestipol: Decreased indapamide absorption

diazoxide: Increased risk of hyperglycemia

digoxin: Increased risk of digitalis toxicity if hypokalemia develops

hypotension-producing drugs: Increased antihypertensive or diuretic effects

lithium: Increased risk of lithium toxicity

neuromuscular blockers: Possibly increased neuromuscular blockade, risk of respiratory depression

oral anticoagulants: Possibly decreased anticoagulant effects

* For edema.

† For hypertension (with multiple doses).

Adverse Reactions

CNS: Anxiety, dizziness, drowsiness, fatigue, fever, headache, mood changes, nervousness, sleep disturbance, vertigo, weakness

CV: Arrhythmias, hypercholesterolemia, orthostatic hypotension, palpitations

EENT: Dry mouth

ENDO: Hyperglycemia, hypoglycemia

GI: Anorexia, constipation, diarrhea, hepatitis, nausea, pancreatitis, thirst, vomiting

GU: Impotence, nocturia

MS: Gout, muscle spasms

SKIN: Jaundice, necrotizing vasculitis, photosensitivity, pruritus, rash, urticaria

Other: Dilutional hyponatremia and hyponatremia, hypokalemia, metabolic alkalosis, weight loss

Nursing Considerations

- Administer indapamide with food or milk to reduce adverse GI reactions.
- Give drug early in the day to avoid nocturia.
- Weigh patient daily, and monitor fluid intake and output, blood pressure, and serum electrolyte levels, especially in elderly women, because severe hyponatremia and hypokalemia may occur. Hypokalemia also commonly occurs in patients taking diuretics. Report electrolyte abnormalities, and expect to provide corrective measures, as prescribed.
- Monitor BUN and serum creatinine levels regularly, as appropriate.
- If muscle cramps and weakness develop from hypokalemia, expect prescriber to order potassium supplement or potassium-sparing diuretic.
- When managing hypertension, expect therapeutic response to indapamide to take several weeks.

PATIENT TEACHING

- Advise patient to take indapamide early in the day to avoid nighttime urination and to take it with food or milk to minimize GI distress.
- Encourage patient to eat high-potassium foods, such as oranges and bananas.
- Caution patient to change position slowly to minimize effects of orthostatic hypotension.
- Instruct patient to weigh himself daily at the same time and wearing similar clothing. Direct him to report a weight gain of more than 2 lb (0.9 kg) per day or 5 lb

(2.3 kg) per week.

- Inform patient about possible photosensitivity.
- If patient has a dry mouth, suggest sugarless gum or hard candy to relieve it.

indomethacin

Apo-Indomethacin (CAN), Indocid (CAN), Indocin, Indocin SR, Novo-Methacin (CAN), Nu-Indo (CAN)

indomethacin sodium trihydrate

Apo-Indomethacin (CAN), Indameth, Indocid (CAN), Indocid PDA (CAN), Indocin, Indocin I.V., Novomethacin (CAN)

Class and Category

Chemical class: Indoleacetic acid derivative

Therapeutic class: Antigout, anti-inflammatory, antirheumatic

Pregnancy category: Not rated

Indications and Dosages

↗ *To relieve symptoms of ankylosing spondylitis, osteoarthritis, and rheumatoid arthritis*

CAPSULES, ORAL SUSPENSION

Adults. 25 to 50 mg b.i.d. to q.i.d., increased by 25 or 50 mg daily every wk, if needed.

Maximum: 200 mg daily. After adequate response, dosage reduced as low as possible.

E.R. CAPSULES (ANTIRHEUMATIC)

Adults. 75 mg daily, increased to 75 mg b.i.d, if needed.

SUPPOSITORIES

Adults. 50 mg up to q.i.d.

↗ *To relieve symptoms of acute gouty arthritis*

CAPSULES, ORAL SUSPENSION

Adults. *Initial:* 100 mg. Increased up to 50 mg t.i.d. *Maximum:* 200 mg daily. After pain is relieved, dosage tapered until drug is discontinued.

SUPPOSITORIES

Adults. 50 mg up to q.i.d. *Maximum:* 200 mg daily.

↗ *To treat inflammation and relieve acute shoulder pain from bursitis or tendinitis*

CAPSULES, ORAL SUSPENSION

Adults. 75 to 150 mg daily in divided doses

t.i.d. or q.i.d. for 7 to 14 days.

SUPPOSITORIES

Adults. 50 mg up to q.i.d. *Maximum:* 200 mg daily.

DOSAGE ADJUSTMENT Dosage reduced for elderly patients.

↗ *To treat hemodynamically significant patent ductus arteriosus in premature infants weighing 500 to 1,750 g (1 to 3.9 lb)*

I.V. INJECTION

Infants over age 7 days. *Initial:* 200 mcg/kg (0.2 mg/kg) over 5 to 10 sec; 1 or 2 additional doses of 250 mcg/kg (0.25 mg/kg) given at 12- to 24-hr intervals, if needed.

Neonates ages 2 to 7 days. *Initial:* 200 mcg/kg (0.2 mg/kg) over 5 to 10 sec; 1 or 2 additional doses of 200 mcg/kg (0.2 mg/kg) given at 12- to 24-hr intervals, if needed.

Neonates under age 48 hours. *Initial:* 200 mcg/kg (0.2 mg/kg) over 5 to 10 sec; 1 or 2 additional doses of 100 mcg/kg (0.1 mg/kg) given at 12- to 24-hr intervals, if needed.

Route	Onset	Peak	Duration
P.O.*	2–4 hr	2–5 days	Unknown
P.O.†	30 min	Unknown	4–6 hr
P.O.‡	In 7 days	1–2 wk	Unknown

Mechanism of Action

Blocks activity of cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate inflammatory response and cause local vasodilation, swelling, and pain. By blocking cyclooxygenase and inhibiting prostaglandins, this NSAID reduces inflammatory symptoms and helps relieve pain.

Incompatibilities

Don't give indomethacin suspension with alkaline antacids or liquids. Don't mix reconstituted indomethacin sodium with I.V. infusion solutions.

Contraindications

Allergy or hypersensitivity to aspirin, indomethacin, iodides, other NSAIDs, or their components; history of proctitis or recent rectal bleeding (suppositories)

* For antigout effects.

† For anti-inflammatory effects.

‡ For antirheumatic effects.

Interactions

DRUGS

Note: All effects listed are for oral forms and suppositories unless indicated.

acetaminophen: Increased risk of adverse renal effects (long-term use of both drugs)

aluminum- and magnesium-containing antacids: Possibly decreased blood indomethacin level

aminoglycosides: Increased risk of aminoglycoside toxicity

antihypertensives: Decreased effectiveness of these drugs

aspirin, other NSAIDs: Increased risk of adverse GI effects and non-GI bleeding

bone marrow depressants: Possibly increased leukopenic or thrombocytopenic effects of these drugs

cefamandole, cefoperazone, cefotetan: Increased risk of hypoprothrombinemia and bleeding

colchicine, platelet aggregation inhibitors: Increased risk of GI bleeding, hemorrhage, and ulcers

corticosteroids, potassium supplements: Increased risk of adverse GI effects

cyclosporine: Increased risk of nephrotoxicity from both drugs, increased blood cyclosporine level

diflunisal: Increased blood indomethacin level and risk of GI bleeding

digoxin: Increased blood digoxin level and risk of digitalis toxicity (all forms)

diuretics (thiazide, loop, and potassium-sparing): Decreased diuretic and antihypertensive effects

gold compounds, nephrotoxic drugs: Increased risk of adverse renal effects

heparin, oral anticoagulants, thrombolytics: Possibly increased anticoagulant effects and risk of hemorrhage

lithium: Increased blood lithium level and risk of toxicity

methotrexate: Increased risk of methotrexate toxicity

plicamycin, valproic acid: Increased risk of hypoprothrombinemia and GI bleeding, hemorrhage, and ulcers

probenecid: Increased blood level and effectiveness of indomethacin, increased risk of indomethacin toxicity

zidovudine: Increased blood zidovudine level and risk of toxicity, increased risk of indomethacin toxicity

ACTIVITIES

alcohol use: Increased risk of adverse GI effects

Adverse Reactions

Note: All reactions are for oral forms and suppositories unless indicated.

CNS: Confusion, depression, dizziness, drowsiness, fatigue, hallucinations, headache, intraventricular hemorrhage (I.V.), peripheral neuropathy, seizures, stroke, syncope, vertigo

CV: Arrhythmias, chest pain, edema, fluid retention (all forms), heart failure, hypertension, MI, pulmonary hypertension (I.V.), tachycardia

EENT: Blurred vision, corneal and retinal damage, epistaxis, hearing loss, tinnitus

ENDO: Hypoglycemia (I.V.)

GI: Abdominal cramps or pain, abdominal distention (I.V.), anorexia, constipation, diarrhea, diverticulitis, dyspepsia, dysphagia, epigastric discomfort, esophagitis, gastric perforation, gastritis, gastroenteritis, gastroesophageal reflux disease, GI bleeding and ulceration (all forms), hemorrhoids, hepatic dysfunction (I.V.), hepatic failure, hiatal hernia, ileus (I.V.), indigestion, melena, nausea, necrotizing enterocolitis (I.V.), pancreatitis, peptic ulcer, perforation of stomach or intestine, stomatitis, vomiting (all forms)

GU: Acute renal failure, hematuria, interstitial nephritis, nephrotic syndrome, oliguria (I.V.), proteinuria, renal dysfunction (I.V.), vaginal bleeding

HEME: Agranulocytosis, anemia, aplastic anemia, bone marrow depression, disseminated intravascular coagulation, hemolytic anemia, iron deficiency anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia, unusual bleeding or bruising (all forms)

RESP: Asthma, respiratory depression

SKIN: Ecchymosis, erythema multiforme, erythema nodosum, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, hyperkalemia (I.V.), hyponatremia (I.V.), injection site irritation

Nursing Considerations

- Use indomethacin with extreme caution in patients with history of ulcer disease or GI

bleeding because NSAIDs such as indomethacin increase risk of GI bleeding and ulceration. Expect to use drug for shortest time possible in these patients.

- Be aware that serious GI tract ulceration, bleeding, and perforation may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give oral indomethacin with food, a full glass of water (not suspension), or an antacid to reduce GI distress.
- If GI distress occurs, withhold drug and notify prescriber immediately.
- Use indomethacin cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.
- Shake suspension well before giving it.
- For arthritis, give up to 100 mg of daily dose (not E.R. capsules) at bedtime to reduce nighttime pain and morning stiffness.
- Make sure suppository stays in rectum at least 1 hour to improve absorption.
- To reconstitute I.V. form, add 1 to 2 ml of preservative-free sodium chloride for injection or preservative-free sterile water to vial. Solution made with 1 ml diluent contains 100 mcg (0.1 mg) indomethacin/0.1 ml. Solution made with 2 ml diluent contains 50 mcg (0.05 mg) indomethacin/0.1 ml. Use solution immediately because it contains no preservatives. Discard unused portion.
- Be aware that scheduled I.V. doses may be withheld if infant or neonate has anuria or a significant decrease in urine output (less than 0.6 ml/kg/hr).
- When using I.V. form, avoid extravasation to protect surrounding tissue.
- Anticipate a second course (3 more doses) of I.V. indomethacin if patent ductus arteriosus fails to close or reopens. After two courses, surgery may be performed.

WARNING Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

- Monitor patient—especially if he's elderly or receiving long-term indomethacin therapy—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia,

melenia, stomatitis, and vomiting.

- Monitor liver function test results because, rarely, elevations may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure.
- Monitor BUN and serum creatinine levels in elderly patients, those taking diuretics or ACE inhibitors, and those with heart failure, impaired renal function, or hepatic dysfunction; drug may cause renal failure.
- Monitor CBC for decreased hemoglobin and hematocrit. Drug may worsen anemia.

WARNING If patient has bone marrow suppression or is receiving an antineoplastic drug, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of indomethacin may mask signs and symptoms, such as fever and pain.

- Assess patient's skin regularly for signs of rash or other hypersensitivity reaction because indomethacin is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID sensitivity. At first sign of reaction, stop drug and notify prescriber.
- Because indomethacin causes sodium retention, monitor weight and blood pressure, especially if patient has hypertension.
- When drug is used to treat gouty arthritis, expect its action to peak in 24 to 36 hours and significant swelling to gradually disappear over 3 to 5 days.
- Be aware that E.R. form shouldn't be used to treat gouty arthritis.
- Expect to use suppositories for patients who can't swallow oral form.
- To evaluate drug effectiveness, assess for reduced pain and inflammation and improved joint mobility.
- Expect patient to have intermittent check-ups during long-term therapy and an ophthalmologic examination if vision changes.

PATIENT TEACHING

- Urge patient to take indomethacin capsules with full glass of water and to avoid lying down for 15 to 30 minutes afterward. This helps prevent drug from lodging in esophagus and causing irritation. Caution patient not to open or crush capsules.
- Instruct patient to take drug with food or an antacid to reduce GI distress.
- Instruct patient to make sure suppository

stays in rectum at least 1 hour.

- Urge patient to avoid alcohol during indomethacin therapy.
- Remind patient that improvement may not occur for 2 to 4 weeks after starting indomethacin and that he should continue taking drug, as prescribed.
- Inform breast-feeding patient that indomethacin appears in breast milk and may cause seizures in infants. Urge her to use another feeding method during therapy.
- Caution against prolonged sun exposure during therapy.
- Urge patient to notify prescriber immediately about changes in vision or hearing, fever, itching, rash, sore throat, swelling in arms or legs, and weight gain.
- Stress importance of having ordered laboratory tests and eye examinations during long-term therapy.
- Caution pregnant patient not to take NSAIDs such as indomethacin during last trimester because they may cause premature closure of the ductus arteriosus.
- Explain that indomethacin may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, weakness, and slurring of speech.
- Explain that indomethacin may increase risk of serious adverse GI reactions; stress need to seek immediate medical attention for such signs and symptoms as epigastric or abdominal pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions. Urge him to seek immediate medical attention for rash, blisters, itching, fever, or other indications of hypersensitivity.

infliximab

Remicade

Class and Category

Chemical class: Monoclonal antibody

Therapeutic class: Anti-inflammatory

Pregnancy category: C

Indications and Dosages

↗ *To control moderate to severe Crohn's disease long-term*

I.V. INFUSION

Adults and children. *Induction:* 5 mg/kg over 2 hr, repeated 2 and 6 wk after first infusion. *Maintenance:* 5 mg/kg over 2 hr every 8 wk.

DOSAGE ADJUSTMENT For adults who respond and then lose response, dosage may be increased to 10 mg/kg.

↗ *To reduce number of draining enterocutaneous and rectovaginal fistulas and to maintain fistula closure in fistulizing Crohn's disease*

I.V. INFUSION

Adults. *Induction:* 5 mg/kg over 2 hr, repeated 2 and 6 wk after first infusion. *Maintenance:* 5 mg/kg over 2 hr every 8 wk.

DOSAGE ADJUSTMENT For patients who respond and then lose response, dosage may be increased to 10 mg/kg.

↗ *To reduce signs and symptoms, to induce and maintain remission and mucosal healing, and to eliminate corticosteroid use in patients with moderately to severely active ulcerative colitis who have had an inadequate response to conventional therapy*

I.V. INFUSION

Adults. 5 mg/kg over 2 hr, repeated 2 and 6 wk after infusion. *Maintenance:* 5 mg/kg over 2 hr every 8 wk.

↗ *As adjunct to reduce signs and symptoms, inhibit progression of structural damage, and improve physical function in patients with moderate to severe active rheumatoid arthritis*

I.V. INFUSION

Adults. 3 mg/kg, with methotrexate, repeated 2 and 6 wk after first infusion and then every 8 wk thereafter.

↗ *To treat active ankylosing spondylitis*

I.V. INFUSION

Adults. 5 mg/kg, repeated 2 and 6 wk after first infusion and then every 6 wk thereafter.

↗ *To reduce signs and symptoms, inhibit progression of structural damage, and improve physical function in patients with psoriatic arthritis*

I.V. INFUSION

Adults. 5 mg/kg, with or without methotrexate, repeated 2 and 6 wk after first infusion and then every 8 wk thereafter.

↗ *To treat chronic severe plaque psoriasis in patients who are candidates for sys-*

temic therapy but those therapies are medically less appropriate

I.V. INFUSION

Adults. 5 mg/kg, repeated 2 and 6 wk after first infusion and every 8 wk thereafter.

Mechanism of Action

Binds with cytokine tumor necrosis factor-alpha (TNF-alpha), preventing it from binding with its receptors. As a result, TNF-alpha can't produce proinflammatory cytokines and endothelial permeability. Infiltration of inflammatory cells into inflamed intestine and joints declines.

Incompatibilities

Don't infuse infliximab in same I.V. line with other drugs or through plasticized polyvinyl chloride infusion equipment or devices.

Contraindications

Breastfeeding; hypersensitivity to infliximab, murine proteins, or their components; moderate or severe New York Heart Association (NYHA) Class III or IV heart failure

Interactions

DRUGS

anakinra, etanercept: Increased risk of neutropenia and serious infections

Adverse Reactions

CNS: Chills, dizziness, fatigue, fever, Guillain-Barré syndrome, headache, meningitis, neuritis, numbness, paresthesia, stroke, syncope, tingling

CV: Arrhythmias, chest pain, hypertension, hypotension, MI, myelitis, neuropathies, pericardial effusion, systemic and cutaneous vasculitis, thrombophlebitis

EENT: Oral candidiasis, pharyngitis, rhinitis, sinusitis, visual changes

GI: Abdominal hernia; abdominal pain; acute hepatic failure; cholecystitis; cholestasis; diarrhea; dyspepsia; elevated aminotransferases; GI hemorrhage; hepatitis; hepatotoxicity; ileus; intestinal obstruction, perforation, or stenosis; melena; pancreatitis; nausea; splenic infarction; splenomegaly; vomiting

GU: Kidney infection, renal failure, ureteral obstruction, UTI, vaginal candidiasis, vaginitis

HEME: Anemia, leukopenia, neutropenia,

pancytopenia, thrombocytopenia

MS: Ankylosing spondylitis, arthralgia, back pain, limb weakness, myalgia, psoriatic arthritis

RESP: Adult respiratory distress syndrome, bronchitis, cough, dyspnea, interstitial lung disease, pneumonia, tuberculosis, respiratory tract infection, wheezing

SKIN: Facial flushing, jaundice, pruritus, psoriasis, rash, urticaria

Other: Antibody formation to infliximab; bacterial, fungal, or viral infection; infusion reaction; lupuslike symptoms; lymphadenopathy; malignancies, such as leukemia and lymphomas, including hepatosplenic T-cell lymphoma; sepsis

Nursing Considerations

- Infliximab therapy shouldn't be started in a patient with an active infection, including serious localized infection.
- Use with extreme caution if patient has a history of chronic or recurrent infection, known exposure to tuberculosis, an underlying condition that predisposes to infection, or residence or travel to areas of endemic tuberculosis or mycoses, such as histoplasmosis, coccidioidomycosis, or blastomycosis.
- Use cautiously in elderly patients because they have a higher risk of infection.
- Use cautiously in patients with previous or ongoing hematologic abnormalities because infliximab may cause serious or even life-threatening adverse hematologic effects. Monitor patient's CBC regularly, as ordered. If adverse effects occur, expect drug to be discontinued.

WARNING Because drug increases risk of developing tuberculosis or reactivating latent tuberculosis, expect prescriber to evaluate patient's risk and start tuberculosis treatment, as needed, before starting infliximab.

WARNING Infliximab increases risk of serious or fatal opportunistic infections, including invasive fungal infections as well as bacterial and viral infections. The most common ones include aspergillosis, candidiasis, coccidioidomycosis, histoplasmosis, listeriosis, and pneumocytosis.

WARNING Watch for infection, especially if patient receives immunosuppressant therapy or has a chronic infection. Upper res-

piratory tract infections and UTI are most common, but sepsis and fatal infections have occurred.

- To reconstitute infliximab, use 21G (or smaller) needle to add 10 ml sterile water for injection to each vial of drug. Swirl to mix; don't shake. Solution may foam and be clear or light yellow.
 - Withdraw volume equal to amount of reconstituted drug from a 250-ml glass bottle or polypropylene or polyolefin infusion bag of normal saline solution. Then add reconstituted infliximab to bottle to dilute to 250 ml. Use within 3 hours.
 - Infuse over at least 2 hours using polyethylene-lined infusion set and in-line, sterile, nonpyrogenic, low-protein-binding filter with pores 1.2 microns or less. Don't reuse.
 - Be prepared to stop infusion if hypersensitivity or CNS reaction occurs. Keep acetaminophen, antihistamines, corticosteroids, and epinephrine on hand. A reaction may occur 2 hours to 12 days after infusion.
- WARNING** Avoid giving drug to patients with New York Heart Association Class III or IV congestive heart failure (CHF) because it may worsen the condition or cause death. If patient does receive infliximab, expect to stop it if CHF worsens.
- Because severe hepatic reactions may occur, monitor liver function. Expect to stop drug if jaundice develops or liver enzymes are 5 times or more the upper limit of normal.
 - Be aware that infliximab is a tumor necrosis factor (TNF) blocker. Malignancies, especially leukemia and such rare lymphomas as hepatosplenic T-cell lymphoma have been reported in patients, particularly children and adolescents, receiving TNF blockers. Patients at increased risk of leukemia are those with rheumatoid arthritis. Patients at increased risk of lymphomas are those with rheumatoid arthritis, Crohn's disease, ankylosing spondylitis, psoriatic arthritis, and plaque psoriasis, especially those with long-term or very active disease. Monitor them closely.

PATIENT TEACHING

- Inform patient that infliximab should take effect within 1 to 2 weeks.
- Urge patient to report evidence of infection, such as painful urination, cough, and sore throat. Infusion reaction (chest pain,

chills, dyspnea, facial flushing, fever, itching, headache, rash) may occur for up to 12 days.

- Explain that infliximab increases the risk of lymphoma; urge prompt medical attention for suspicious signs or symptoms.

ipecac syrup

Ipecac Syrup

Class and Category

Chemical class: *Cephaelis acuminata* or *Cephaelis ipecacuanha* derivative
Therapeutic class: Emetic
Pregnancy category: C

Indications and Dosages

➤ *To induce vomiting after drug overdose and certain types of poisoning*

SYRUP

Adults and children over age 12. 15 to 30 ml followed by 240 ml water. Dose repeated if vomiting doesn't begin within 20 to 30 min.

Children ages 1 to 12. 15 ml preceded or followed by 120 to 240 ml water. Dose repeated if vomiting doesn't begin within 20 to 30 min.

Infants ages 6 months to 1 year. 5 to 10 ml preceded or followed by 120 to 240 ml water.

Route	Onset	Peak	Duration
P.O.	20–30 min	Unknown	20–25 min

Mechanism of Action

Induces vomiting by irritating gastric mucosa and stimulating medullary chemoreceptor trigger zone in CNS.

Contraindications

Loss of gag reflex, poisoning with strychnine or corrosives (such as alkaloid substances, petroleum distillates, and strong acids), seizures, semiconsciousness or unconsciousness, severe inebriation, shock

Interactions

DRUGS

activated charcoal: Lack of emetic effect

Adverse Reactions

CNS: Depression, drowsiness

EENT: Aspiration of vomitus, coughing

GI: Diarrhea, indigestion

G
H
I

Nursing Considerations

- Give ipecac syrup only to conscious patients, and follow with adequate water. Give young or frightened children water before or after ipecac.
- Expect vomiting to start in 20 to 30 minutes.
- If vomiting doesn't start within 30 minutes of second dose, prepare for gastric lavage.
- Don't give ipecac after ingestion of petroleum distillates, such as gasoline, or caustic substances, to avoid further injury to esophagus.
- If activated charcoal will be given, expect to do so after patient vomits or 30 minutes after second ipecac dose because activated charcoal adsorbs and inhibits ipecac.
- Arrhythmias, atrial fibrillation, bradycardia, fatal myocarditis, hypotension, myalgia, or muscle stiffness or weakness may develop if patient takes too much ipecac or doesn't vomit.

PATIENT TEACHING

- Inform patient of ipecac's effects.
- Tell adult patient to drink 8 oz (240 ml) of water after taking drug and child to drink 4 to 8 oz (120 to 240 ml) before or after taking drug.
- Inform patient or parents of child that diarrhea may occur after taking drug.
- Urge parents to keep ipecac syrup and phone number of a poison control center.

WARNING Advise parents to replace their ipecac extract or tincture with ipecac syrup. Explain that ipecac fluid extract is 14 times more concentrated than ipecac syrup and can cause serious, possibly toxic, effects if given incorrectly.

ipratropium bromide

Apo-Ipravent (CAN), Atrovent, Kendral-Ipratropium (CAN)

Class and Category

Chemical class: Quaternary N-methyl isopropyl derivative of noratropine
Therapeutic class: Anticholinergic, bronchodilator
Pregnancy category: B

Indications and Dosages

↗ *To treat bronchitis and COPD*

INHALATION AEROSOL

Adults and adolescents. 2 to 4 inhalations (36 to 72 mcg) t.i.d. or q.i.d. *Maximum:* Up to 12 inhalations (216 mcg)/24 hr.

INHALATION SOLUTION FOR NEBULIZER

Adults and adolescents. 250 to 500 mcg dissolved in preservative-free sterile normal saline solution every 6 to 8 hr. For severe COPD exacerbations, 500 mcg every 4 to 8 hr.

↗ *To treat perennial and allergic rhinitis*

NASAL SPRAY

Adults and children age 6 and over. 2 sprays of 0.03% (21 mcg/spray) per nostril b.i.d. or t.i.d. *Maximum:* 12 sprays (252 mcg)/24 hr.

↗ *To treat rhinorrhea caused by the common cold*

NASAL SPRAY

Adults and children age 5 and over. 2 sprays of 0.06% (42 mcg/spray) per nostril t.i.d. or q.i.d. for up to 4 days. *Maximum:* 16 sprays (672 mcg)/24 hr.

Route	Onset	Peak	Duration
Inhalation	5–15 min	1–2 hr	3–8 hr
Nasal	5 min	1–4 hr	4–8 hr

Contraindications

Hypersensitivity to atropine, ipratropium bromide, or their components; hypersensitivity to peanuts, soya lecithin, soybeans, or related products (with aerosol inhaler)

Interactions

DRUGS

anticholinergics: Increased anticholinergic effects

tacrine: Decreased effects of both drugs

Adverse Reactions

CNS: Dizziness, insomnia

CV: Atrial fibrillation (oral inhalation), bradycardia (nasal spray), edema, hypertension, palpitations, supraventricular tachycardia (oral inhalation), tachycardia

EENT: Acute eye pain, dry mouth or pharyngeal area, laryngospasm, taste perversion (all drug forms); blurred vision, eye irritation and pain, glaucoma or worsening of existing glaucoma (if nasal spray comes in contact with eyes); epistaxis, mydriasis, nasal dryness and irritation, pharyngitis,

Mechanism of Action

After acetylcholine is released from cholinergic fibers, ipratropium prevents it from attaching to muscarinic receptors on membranes of smooth-muscle cells, as shown at right. By blocking acetylcholine's effects in bronchi and bronchioles, ipratropium relaxes smooth muscles and causes bronchodilation.

rhinitis, sinusitis, tinnitus (with nasal spray)

GI: Bowel obstruction, constipation, diarrhea, ileus, nausea, vomiting

GU: Prostatitis, urine retention

MS: Arthritis

RESP: Bronchitis, bronchospasm, cough, dyspnea, increased sputum production, wheezing

SKIN: Dermatitis, pruritus, rash, urticaria

Other: Anaphylaxis, angioedema, flulike symptoms

Nursing Considerations

- Use ipratropium cautiously in patients with angle-closure glaucoma, benign prostatic hyperplasia, or bladder neck obstruction and in patients with hepatic or renal dysfunction.
- As prescribed, mix ipratropium inhalation solution with preservative-free albuterol, and preservative-free ipratropium inhalation solution with cromolyn inhalation solution. Use within 1 hour.
- When using a nebulizer, apply a mouthpiece to prevent drug from leaking out around mask and causing blurred vision or eye pain.

PATIENT TEACHING

- Caution patient not to use ipratropium to treat acute bronchospasm.
- Inform patient that although some people feel relief within 24 hours of drug use, maximum effect may take up to 2 weeks.
- Teach patient to use inhaler or nasal spray.

Tell him to shake inhaler well at each use.

- Advise patient to keep spray out of his eyes because it may irritate them or blur his vision. If spray comes in contact with eyes, instruct patient to flush them with cool tap water for several minutes and to contact prescriber.
- Instruct patient to rinse mouth after each nebulizer or inhaler treatment to help minimize throat dryness and irritation.
- If patient is using 0.06% nasal spray for a common cold, advise against use for longer than 4 days.
- Teach patient to track canister contents by counting and recording number of doses.
- Advise patient to report decreased response to ipratropium as well as difficulty voiding, eye pain, nasal dryness, nose bleeds, palpitations, and vision changes.

irbesartan

Avapro

Class and Category

Chemical class: Nonpeptide angiotensin II antagonist

Therapeutic class: Antihypertensive

Pregnancy category: D

Indications and Dosages

➤ *To manage hypertension, alone or with other antihypertensives*

TABLETS

Adults and adolescents. *Initial:* 150 mg daily. *Maximum:* 300 mg daily.

DOSAGE ADJUSTMENT Initial dosage reduced to 75 mg daily for patients with hypovolemia or hyponatremia from such causes as hemodialysis or vigorous diuretic therapy. **Children ages 6 to 12.** *Initial:* 75 mg daily. *Maximum:* 150 mg daily.

➤ *To treat nephropathy in type 2 diabetes mellitus*

TABLETS

Adults. 300 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	In 4–6 wk	Unknown

Mechanism of Action

Selectively blocks binding of the potent vasoconstrictor angiotensin (AT) II to AT₁ receptor sites in many tissues, including vascular smooth muscle and adrenal glands. This inhibits the vasoconstrictive and aldosterone-secreting effects of AT II, which reduces blood pressure.

Contraindications

Hypersensitivity to irbesartan or its components

Interactions**DRUGS**

diuretics: Possibly additive hypotensive effects

Adverse Reactions

CNS: Anxiety, dizziness, fatigue, headache, nervousness

CV: Chest pain, hypotension, peripheral edema, tachycardia

EENT: Pharyngitis, rhinitis

GI: Abdominal pain, diarrhea, heartburn, hepatitis, indigestion, nausea, vomiting

GU: UTI

MS: Musculoskeletal pain

RESP: Upper respiratory tract infection

SKIN: Rash

Nursing Considerations

- If patient has known or suspected hypovolemia, provide treatment, such as I.V. normal saline solution, as prescribed, to correct this condition before beginning irbesartan therapy. Or expect to begin therapy with a lower dosage.
- Check blood pressure often to evaluate

drug's effectiveness.

- If blood pressure isn't controlled with irbesartan alone, expect to also give a diuretic, such as hydrochlorothiazide, as prescribed.

WARNING If patient receives a diuretic or another antihypertensive during irbesartan therapy, frequently monitor blood pressure because he's at risk for hypotension.

- If patient experiences symptomatic hypotension, expect to stop drug temporarily. Immediately place him in supine position and prepare to give I.V. normal saline solution, as prescribed. Expect to resume drug therapy after blood pressure stabilizes.
- If patient receives a diuretic, provide adequate hydration, as appropriate, to help prevent hypovolemia. Also monitor patient for signs and symptoms of hypovolemia, such as hypotension, dizziness, and fainting.

WARNING Monitor patient for increased BUN and serum creatinine levels if he has heart failure or impaired renal function because drug may cause acute renal failure. If increases are significant or persistent, notify prescriber immediately.

PATIENT TEACHING

- Advise patient to take drug at the same time each day to maintain its therapeutic effect.
- Explain importance of regular exercise, proper diet, and other lifestyle changes in controlling hypertension.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to consult prescriber before taking any new drug.
- To reduce risk of dehydration and hypotension, advise patient to drink adequate fluids during hot weather and exercise.
- Instruct patient to contact prescriber if severe nausea, vomiting, or diarrhea occurs and continues because of the risk of dehydration and hypotension.
- Advise female patient to notify prescriber immediately about known or suspected pregnancy. Explain that if she becomes pregnant, prescriber may replace irbesartan with another antihypertensive that's safe to use during pregnancy.
- Urge patient to keep follow-up appointments with prescriber to monitor progress.

iron dextran

(contains 50 mg of elemental iron per milliliter)

DexFerrum, DexIron (CAN), InFeD

Class and Category

Chemical class: Iron salt, mineral

Therapeutic class: Antianemic

Pregnancy category: C

Indications and Dosages

↗ *To treat iron deficiency anemia*

I.V. INFUSION

Adults and children weighing more than 15 kg (33 lb). Dose (ml) = 0.0442 (desired hemoglobin – observed hemoglobin) × lean body weight (kg) + (0.26 × lean body weight). Or, consult dosage table in package insert. *Maximum:* 2 ml (100 mg) daily.

Children over age 4 months weighing 5 to 15 kg (11 to 33 lb). Dose (ml) = 0.0442

(desired hemoglobin – observed hemoglobin) × weight (kg) + (0.26 × weight). Or, consult dosage table in package insert.

Maximum: 1 ml (50 mg) daily.

↗ *To replace iron lost in blood loss*

I.V. INFUSION

Adults. Replacement iron (mg) = ml of blood loss × hematocrit.

Mechanism of Action

Restores hemoglobin and replenishes iron stores. Iron, an essential component of hemoglobin, myoglobin, and several enzymes (including cytochromes, catalase, and peroxidase), is needed for catecholamine metabolism and normal neutrophil function.

In iron dextran therapy, iron binds to available protein parts after the drug has been split into iron and dextran by cells of the reticuloendothelial system. The bound iron forms hemosiderin or ferritin, physiologic forms of iron, and transferrin, which replenish hemoglobin and depleted iron stores. Dextran is metabolized or excreted.

Incompatibilities

Don't mix iron dextran with blood for transfusion, other drugs, or parenteral nutrition solutions for I.V. infusion.

Contraindications

Anemia other than iron deficiency, hyper-

sensitivity to iron dextran or its components

Adverse Reactions

CNS: Chills, disorientation, dizziness, fever, headache, malaise, paresthesia, seizures, syncope, unconsciousness, weakness

CV: Arrhythmias, bradycardia, chest pain, hypertension, hypotension, shock, tachycardia

EENT: Altered taste

GI: Abdominal pain, diarrhea, nausea, vomiting

GU: Hematuria

HEME: Leukocytosis

MS: Arthralgia, arthritis, backache, myalgia, rhabdomyolysis

RESP: Bronchospasm, dyspnea, respiratory arrest, wheezing

SKIN: Cyanosis, diaphoresis, rash, pruritus, purpura, urticaria

Other: Anaphylaxis, infusion site phlebitis

Nursing Considerations

- Expect oral iron therapy to stop before iron dextran therapy starts. Iron dextran is given only when oral therapy isn't feasible; it also may be given by I.M. injection.
- Expect to monitor hemoglobin level, hematocrit, serum ferritin level, and transferrin saturation, as ordered, before, during, and after iron dextran therapy.

WARNING Before starting iron dextran therapy, give a test dose of 0.5 ml iron dextran gradually over 30 seconds, as prescribed, and monitor patient closely for anaphylactic reaction.

- Wait 1 to 2 hours before giving remainder of dose. Infuse undiluted iron dextran slowly, at no more than 1 ml/minute (50 mg/minute).

WARNING Monitor patient closely for signs and symptoms of anaphylaxis (such as severe hypotension, loss of consciousness, collapse, dyspnea, and seizures) during and after infusion. Patients with a history of asthma or allergies are at increased risk for anaphylaxis, possibly death. Institute emergency resuscitation measures as needed, including epinephrine administration, as prescribed.

WARNING Assess blood pressure often after iron dextran administration because hypotension is a common adverse effect that may be related to infusion rate; avoid rapid infusion.

- Be aware that patient may have adverse reactions, including arthralgia, backache, chills, and vomiting, 1 to 2 days after drug therapy. Symptoms should resolve within 3 to 4 days.
- Assess patients with a history of rheumatoid arthritis for exacerbation of joint pain and swelling.
- If patient has cardiovascular disease, watch for worsening from drug's adverse effects.
- Assess patient for iron overload, characterized by sedation, decreased activity, pale eyes, and bleeding in GI tract and lungs.
- Store iron dextran at 59° to 86° F (15° to 30° C).

PATIENT TEACHING

- Instruct patient to immediately report signs of adverse reaction, such as shortness of breath, wheezing, or rash, during iron dextran therapy.
- Advise patient not to take any oral iron without first consulting prescriber.
- Inform patient that symptoms of iron deficiency may include decreased stamina, learning problems, shortness of breath, and fatigue. Urge patient to plan periods of activity and rest to avoid excessive fatigue.
- Stress need to follow dosage regimen and keep follow-up medical and laboratory appointments.

iron sucrose

(contains 100 mg of elemental iron per 5 ml)

Venofer

Class and Category

Chemical class: Iron salt, mineral

Therapeutic class: Antianemic

Pregnancy category: B

Indications and Dosages

➤ *To treat iron deficiency anemia in hemodialysis patients receiving erythropoietin*

I.V. INJECTION

Adults. *Initial:* 100 mg elemental iron injected undiluted over 2 to 5 min during dialysis. *Usual:* 100 mg elemental iron every wk to 3 times/wk to total dose of 1,000 mg. Dosage repeated as needed to maintain tar-

get levels of hemoglobin and hematocrit and acceptable blood iron level. *Maximum:* 100 mg/dose.

I.V. INFUSION

Adults. *Initial:* 100 mg elemental iron infused diluted over 15 min during dialysis. *Usual:* 100 mg elemental iron every wk to 3 times/wk to a total dose of 1,000 mg. Dosage repeated as needed to maintain target levels of hemoglobin and hematocrit and acceptable blood iron level. *Maximum:* 100 mg/dose.

➤ *To treat iron deficiency anemia in peritoneal dialysis patients receiving erythropoietin*

I.V. INFUSION

Adults. *Initial:* 300 mg elemental iron infused diluted over 1.5 hr on days 1 and 14, followed by 400 mg elemental iron infused over 2.5 hr on day 28. Dosage repeated as needed to maintain target levels of hemoglobin and hematocrit and acceptable blood iron level. *Maximum:* 1,000 mg/28 days.

➤ *To treat iron deficiency anemia in non-dialysis patients with chronic renal disease regardless of whether they're receiving erythropoietin*

I.V. INJECTION

Adults. *Initial:* 200 mg elemental iron injected undiluted over 2 to 5 min and repeated 4 more times over a 14-day period for a total dose of 1,000 mg. Dosage repeated as needed to maintain target levels of hemoglobin and hematocrit and acceptable blood iron level. *Maximum:* 1,000 mg/14 days.

I.V. INFUSION

Adults. 500 mg elemental iron infused diluted over 3.5 to 5 hr on days 1 and 14. Dosage repeated as needed to maintain target levels of hemoglobin and hematocrit and acceptable blood iron level. *Maximum:* 1,000 mg/14 days.

Mechanism of Action

Acts to replenish iron stores lost during dialysis because of increased erythropoiesis and insufficient absorption of iron from GI tract. Iron is an essential component of hemoglobin, myoglobin, and several enzymes, including cytochromes, catalase, and peroxidase, and is needed for catecholamine metabolism and normal neu-

trophil function. Iron sucrose injection also normalizes RBC production by binding with hemoglobin or being stored as ferritin in reticuloendothelial cells of the liver, spleen, and bone marrow.

Incompatibilities

Don't mix with other drugs or parenteral nutrition solutions for I.V. infusion.

Contraindications

Anemia other than iron deficiency, hypersensitivity to iron salts or their components, iron overload

Interactions

DRUGS

chloramphenicol: Possibly decreased effectiveness of iron sucrose

oral iron preparations: Possibly reduced absorption of oral iron supplements

Adverse Reactions

CNS: Asthenia, dizziness, fatigue, fever, headache, hypoesthesia, malaise

CV: Chest pain, heart failure, hypertension, hypotension, peripheral edema

EENT: Conjunctivitis, ear pain, nasal congestion, nasopharyngitis, rhinitis, sinusitis, taste perversion

ENDO: Hyperglycemia, hypoglycemia

GI: Abdominal pain, constipation, diarrhea, elevated liver function test results, nausea, occult-positive feces, peritoneal infection, vomiting

GU: UTI

MS: Arthralgia, arthritis, back pain, leg cramps, muscle pain or weakness, myalgia

RESP: Cough, dyspnea, pneumonia, upper respiratory tract infection

SKIN: Pruritus, rash

Other: Anaphylaxis; fluid overload; gout; hypervolemia; infusion or injection site burning, pain, or redness; sepsis

Nursing Considerations

- To reconstitute iron sucrose injection for infusion, dilute 100 mg elemental iron in maximum of 100 ml normal saline solution (for hemodialysis patients) or 250 ml (for peritoneal dialysis and nondialysis patients) immediately before infusion. Discard any unused diluted solution.
- Give drug directly into dialysis line by slow I.V. injection or by infusion.

WARNING Monitor patient closely for evi-

dence of anaphylaxis, such as severe hypotension, loss of consciousness, collapse, dyspnea, or seizures, during and after therapy. Institute emergency resuscitation measures as needed.

WARNING Assess blood pressure often after drug administration because hypotension is a common adverse reaction that may be related to infusion rate (avoid rapid infusion) or total cumulative dose.

- Monitor hemoglobin, hematocrit, serum ferritin, and transferrin saturation, as ordered, before, during, and after iron sucrose therapy. Test serum iron level 48 hours after last dose. Notify prescriber and expect to stop therapy if blood iron levels are normal or elevated, to prevent iron toxicity.
- Watch for evidence of iron overload, such as sedation, decreased activity, pale eyes, and bleeding in GI tract and lungs.

PATIENT TEACHING

- Advise patient not to take any oral iron preparations during iron sucrose therapy without first consulting prescriber.
- Inform patient that symptoms of iron deficiency may include decreased stamina, learning problems, shortness of breath, and fatigue.

isocarboxazid

Marplan

Class and Category

Chemical class: Hydrazine derivative

Therapeutic class: Antidepressant

Pregnancy category: C

Indications and Dosages

➤ To treat major depression

TABLETS

Adults and adolescents over age 16. Initial: 10 mg b.i.d., increased by 10 mg daily every 2 to 4 days, as needed and tolerated.

Maximum: 60 mg daily.

Route	Onset	Peak	Duration
P.O.	7–10 days	Unknown	10 days

Mechanism of Action

Irreversibly binds to MAO, reducing its activity and increasing levels of neurotrans-

mitters, including serotonin and the catecholamine neurotransmitters dopamine, epinephrine, and norepinephrine. This regulation of CNS neurotransmitters helps to ease depression. With long-term use, drug results in down-regulation (desensitization) of α_2 - or beta-adrenergic and serotonin receptors after 2 to 4 weeks, which also produces an antidepressant effect.

Contraindications

Cardiovascular disease; cerebrovascular disease; heart failure; hepatic disease; history of headaches; hypersensitivity to isocarboxazid or its components; hypertension; pheochromocytoma; severe renal impairment; use of anesthetics, antihypertensives, bupropion, buspirone, carbamazepine, CNS depressants, cyclobenzaprine, dextromethorphan, meperidine, selective serotonin reuptake inhibitors, sympathomimetics, or tricyclic antidepressants; use within 14 days of another MAO inhibitor

Interactions

DRUGS

anticholinergics, antidyskinetics, antihistamines: Increased anticholinergic effect, prolonged CNS depression (with antihistamines)

anticonvulsants: Increased CNS depression, possibly altered seizure pattern

antihypertensives, diuretics: Increased hypotensive effect

bromocriptine: Possibly interference with bromocriptine effects

bupropion: Increased risk of bupropion toxicity

buspirone, guanadrel, guanethidine:

Increased risk of hypertension

caffeine-containing drugs: Increased risk of dangerous arrhythmias and severe hypertension

carbamazepine, cyclobenzaprine, maprotiline, other MAO inhibitors: Increased risk of hyperpyretic crisis, hypertensive crisis, severe seizures, and death; altered pattern of seizures (with carbamazepine)

CNS depressants: Increased CNS depression

dextromethorphan: Increased risk of excitation, hypertension, and hyperpyrexia

doxapram: Increased vasopressor effects of either drug

fluoxetine, paroxetine, sertraline, trazodone, tricyclic antidepressants: Increased risk of

life-threatening serotonin syndrome
haloperidol, loxapine, molindone, phenothiazines, pimozone, thioxanthenes: Prolonged and intensified anticholinergic, hypotensive, and sedative effects

insulin, oral antidiabetic drugs: Increased hypoglycemic effects

levodopa: Increased risk of sudden, moderate to severe hypertension

local anesthetics (with epinephrine or levonordefrin): Possibly severe hypertension

meperidine, other opioid analgesics: Increased risk of coma, hyperpyrexia, hypotension, immediate excitation, rigidity, seizures, severe hypertension, severe respiratory depression, shock, sweating, and death

methyl dopa: Increased risk of hallucinations, headache, hyperexcitability, and severe hypertension

methylphenidate: Increased CNS stimulation

metrizamide: Decreased seizure threshold and increased risk of seizures

oral anticoagulants: Increased anticoagulant activity

phenylephrine (nasal or ophthalmic):

Potentiated vasopressor effect of phenylephrine

rauwolfia alkaloids: Increased risk of moderate to severe hypertension, CNS depression (when isocarboxazid is added to rauwolfia alkaloid therapy), CNS excitation and hypertension (when rauwolfia alkaloid is added to isocarboxazid therapy)

spinal anesthetics: Increased risk of hypotension

sympathomimetics: Prolonged and intensified cardiac stimulant and vasopressor effects

tryptophan: Increased risk of confusion, disorientation, hyperreflexia, hyperthermia, hyperventilation, mania or hypomania, and shivering

FOODS

aged cheese; avocados; bananas; fava or broad beans; cured meat or sausage; overripe fruit; pickled or smoked fish, meats or poultry; protein extract; soy sauce; yeast extract; and other foods high in tyramine or other pressor amines: Increased risk of dangerous arrhythmias and severe hypertensive crisis

ACTIVITIES

alcohol-containing products that also may contain tyramine, such as beer (including

reduced-alcohol and alcohol-free beer), *hard liquor, liqueurs, sherry, and wines (red and white)*: Increased risk of developing hypertensive crisis

Adverse Reactions

CNS: Agitation, dizziness, drowsiness, fever, headache, insomnia, intracranial bleeding, overstimulation, restlessness, sedation, suicidal ideation, tremor, weakness

CV: Bradycardia, chest pain, edema, hypertensive crisis, orthostatic hypotension, palpitations, tachycardia

EENT: Blurred vision, dry mouth, mydriasis, photophobia, yellowing of sclera

GI: Abdominal pain, anorexia, constipation, diarrhea, elevated liver function test results, increased appetite, nausea

GU: Dark urine, oliguria, sexual dysfunction

HEME: Leukopenia

MS: Muscle spasms, myoclonus, neck stiffness

SKIN: Clammy skin, diaphoresis, jaundice, rash

Other: Unusual weight gain

Nursing Considerations

- Monitor patient's blood pressure during isocarboxazid therapy to detect hypertensive crisis and decrease risk of orthostatic hypotension.

WARNING Notify prescriber immediately if patient has evidence of hypertensive crisis (drug's most serious adverse effect), such as chest pain, headache, neck stiffness, and palpitations. Expect to stop drug immediately if these occur.

- Keep phentolamine readily available to treat hypertensive crisis. Give 5 mg by slow I.V. infusion, as prescribed, to reduce blood pressure without causing excessive hypotension. Use external cooling measures, as prescribed, to manage fever.
- To avoid hypertensive crisis, expect to wait 10 to 14 days when switching patient from one MAO inhibitor to another or when switching from a dibenzazepine-related drug, such as amitriptyline or perphenazine.
- Monitor patient with a history of epilepsy for seizures because isocarboxazid may alter seizure threshold. Institute seizure precautions according to facility protocol.
- Monitor liver function test results, and assess patient for abdominal pain, dark

urine, and jaundice because isocarboxazid may cause hepatic dysfunction.

- Expect to observe some therapeutic effect in 7 to 10 days, but keep in mind that full effect may not occur for 4 to 8 weeks.
- Be aware that, for maintenance therapy, the smallest possible dose should be used. Once clinical effect has been achieved, expect to decrease the dosage slowly over several weeks.
- Keep dietary restrictions in place for at least 2 weeks after stopping isocarboxazid because of slow recovery from drug's enzyme-inhibiting effects.
- Ideally, expect to stop drug 10 days before elective surgery, as prescribed, to avoid hypotension.
- Anticipate that coadministration with a selective serotonin reuptake inhibitor may cause confusion, diaphoresis, diarrhea, seizures, and other less severe symptoms.
- Monitor depressed patient for suicidal tendencies, especially when therapy starts or dosage changes, because depression may worsen temporarily. If suicidal tendencies arise, institute suicide precautions, as appropriate and according to facility policy, and notify prescriber immediately.
- Monitor patient for sudden insomnia. If it develops, notify prescriber and be prepared to give drug early in the day.

PATIENT TEACHING

- Inform patient and family members that therapeutic effects of isocarboxazid may take several weeks to appear and that he should continue taking drug as prescribed.
- Caution parents to monitor pediatric patients, including adolescents, closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Caution patient to rise slowly from a lying or sitting position to minimize effects of orthostatic hypotension.

WARNING Instruct patient to avoid the following foods, beverages, and drugs during isocarboxazid therapy and for 2 weeks afterward: alcohol-free and reduced-alcohol beer and wine; appetite suppressants; beer; broad beans; cheese (except cottage and cream cheese); chocolate and caffeine in large quantities; dry sausage (including Genoa salami, hard salami, Lebanon bologna, and pepperoni); hay fever drugs; inhaled asthma drugs; liver;

meat extract; OTC cold and cough medicines (including those containing dextromethorphan); nasal decongestants (tablets, drops, or spray); pickled herring; products that contain tyramine; protein-rich foods that may have undergone protein changes by aging, fermenting, pickling, or smoking; sauerkraut; sinus drugs; weight-loss products; yeast extracts (including brewer's yeast in large quantities); yogurt; and wine.

- Advise patient to notify prescriber immediately about chest pain, dizziness, headache, nausea, neck stiffness, palpitations, rapid heart rate, sweating, and vomiting.
- Advise patient to inform all health care providers (including dentists) that he takes an MAO inhibitor because certain drugs are contraindicated within 2 weeks of it.
- Urge patient to avoid hazardous activities until drug's adverse effects are known.
- Urge patient with diabetes mellitus who's taking insulin or an oral antidiabetic to check blood glucose level often during therapy because isocarboxazid may affect glucose control.
- Caution patient not to stop taking drug abruptly to avoid recurrence of original symptoms.

isoetharine hydrochloride

Arm-a-Med Isoetharine (0.062%, 0.125%, 0.167%, 0.2%, 0.25%), Beta-2 (1%), Bronkosol (1%), Dey-Lute Isoetharine (0.08%, 0.1%, 0.17%, 0.25%)

isoetharine mesylate

Bronkometer (0.61%)

Class and Category

Chemical class: Catecholamine

Therapeutic class: Bronchodilator

Pregnancy category: Not rated

Indications and Dosages

↗ *To prevent and treat reversible bronchospasm from chronic bronchitis or emphysema*

INHALATION AEROSOL

Adults and adolescents. 1 or 2 inhalations (340 or 680 mcg) every 4 hr.

INHALATION SOLUTION FOR HAND-BULB NEBULIZER

Adults. 3 to 7 inhalations of undiluted 0.5% or 1% solution every 4 hr.

INHALATION SOLUTION FOR NEBULIZER

Adults. 2.5 to 10 mg over 15 to 20 min. Repeated every 4 hr, p.r.n.

Route	Onset	Peak	Duration
Inhalation	5 min	5–15 min	2–3 hr

Mechanism of Action

Attaches to beta₂ receptors on bronchial cell membranes, which stimulates the intracellular enzyme adenylate cyclase to convert adenosine triphosphate to cyclic adenosine monophosphate (cAMP). Increased intracellular levels of cAMP help relax bronchial smooth-muscle cells, stabilize mast cells, and inhibit histamine release.

Contraindications

Hypersensitivity to isoetharine, sympathomimetic amines, or their components

Interactions

DRUGS

beta blockers: Decreased effects of both drugs

cyclopropane, halothane: Increased risk of arrhythmias

ephedrine: Increased cardiac stimulation

epinephrine: Increased epinephrine effects

guanethidine: Decreased hypotensive effects

isoproterenol: Excessive cardiac stimulation

MAO inhibitors: Increased risk of hypertensive crisis, increased vascular effects of isoetharine

methyl dopa: Increased vasopressor response

nitrates: Possibly decreased effects of both drugs

oxytocic drugs: Increased risk of hypotension

rauwolfia alkaloids: Increased risk of hypertension

tricyclic antidepressants: Increased risk of arrhythmias

Adverse Reactions

CNS: Anxiety, dizziness, headache, insomnia, tremor, vertigo, weakness

CV: Angina, arrhythmias, hypertension, palpitations, tachycardia

EENT: Choking sensation, eyelid or lip swelling, laryngospasm, taste perversion

GI: Nausea, vomiting

RESP: Bronchospasm, cough, paradoxical increased airway resistance (with excessive use), wheezing

SKIN: Dermatitis, flushing, pruritus, urticaria

Other: Angioedema, facial edema

Nursing Considerations

- Dilute 1% isoetharine inhalation solution with 1 to 4 ml sterile normal saline solution; 0.062% to 0.25% solutions don't need to be diluted before use.
- Don't use a solution that's pink or darker than light yellow or one that contains precipitate.
- Wait 1 minute after initial inhaler dose to assess whether patient needs a second dose.
- Monitor blood pressure and pulse, and observe for arrhythmias during therapy.

PATIENT TEACHING

- Teach patient how to use isoetharine inhaler or nebulizer.
- Instruct patient to take drug exactly as directed and not to exceed dosage.
- Instruct patient not to take other drugs, even OTC drugs, unless prescribed.
- Teach patient how to determine when canister needs to be replaced by counting and recording number of doses.
- Instruct patient to report chest pain, difficulty breathing, failure to respond to usual isoetharine dose, irregular heartbeat, productive cough, or tremor.

isoniazid

(isonicotinic acid hydrazide, INH)

Isotamine (CAN), Laniazid, Nydrazid, PMS-Isoniazid (CAN)

Class and Category

Chemical class: Isonicotinic acid derivative

Therapeutic class: Antibiotic, antitubercular

Pregnancy category: C

Indications and Dosages

↗ *To prevent tuberculosis*

SYRUP, TABLETS, I.M. INJECTION

Adults and adolescents. 300 mg daily.

Children. 10 mg/kg daily (up to 300 mg).

↗ *As adjunct to treat active tuberculosis*

SYRUP, TABLETS

Adults and adolescents. 300 mg daily or 15 mg/kg (up to 900 mg) 2 or 3 times/wk, based on treatment regimen.

Children. 10 to 20 mg/kg (up to 300 mg) daily or 20 to 40 mg/kg (up to 900 mg) 2 or 3 times/wk, based on treatment regimen.

I.M. INJECTION

Adults and adolescents. 5 mg/kg (up to 300 mg) daily or 15 mg/kg (up to 900 mg) 2 or 3 times/wk, based on treatment regimen.

Children. 10 to 20 mg/kg (up to 300 mg) daily or 20 to 40 mg/kg (up to 900 mg) 2 or 3 times/wk, based on treatment regimen.

Mechanism of Action

Interferes with lipid and nucleic acid synthesis in actively growing tubercule bacilli cells. Isoniazid also disrupts bacterial cell wall synthesis and may interfere with mycolic acid synthesis in mycobacterial cells.

Contraindications

History of serious adverse reactions (such as hepatic injury) from isoniazid, hypersensitivity to isoniazid or its components

Interactions

DRUGS

acetaminophen: Increased risk of hepatotoxicity and possibly nephrotoxicity

alfentanil: Decreased alfentanil clearance and increased duration of effects

aluminum-containing antacids: Decreased isoniazid absorption

benzodiazepines: Decreased benzodiazepine clearance

carbamazepine: Increased blood carbamazepine level and toxicity, increased risk of isoniazid toxicity

corticosteroids: Decreased isoniazid effects

cycloserine: Increased risk of adverse CNS effects and CNS toxicity

disulfiram: Changes in behavior and coordination

enflurane: Increased risk of high-output renal failure

halothane: Increased risk of hepatotoxicity and hepatic encephalopathy

hepatotoxic drugs, rifampin: Increased risk

of hepatotoxicity

ketoconazole: Possibly decreased blood ketoconazole level and resistance to antifungal treatment

meperidine: Risk of hypotensive episodes or CNS depression

nephrotoxic drugs: Increased risk of nephrotoxicity

oral anticoagulants: Increased anticoagulation

phenytoin: Increased blood phenytoin level, increased risk of phenytoin toxicity

theophylline: Increased theophylline level

FOODS

histamine-containing foods, such as tuna, skipjack, and other tropical fish: Inhibited action of the enzyme diamine oxidase in foods, possibly resulting in headache, sweating, palpitations, flushing, and hypotension.

tyramine-containing foods, such as cheese and fish: Increased response to tyramine in foods, possibly resulting in chills; diaphoresis; headache; light-headedness; and red, itchy, clammy skin

ACTIVITIES

alcohol use: Increased risk of hepatotoxicity and increased isoniazid metabolism

Adverse Reactions

CNS: Clumsiness, confusion, dizziness, encephalopathy, fatigue, fever, hallucinations, neurotoxicity, paresthesia, peripheral neuritis, psychosis, seizures, weakness

CV: Vasculitis

EENT: Optic neuritis

ENDO: Gynecomastia, hyperglycemia

GI: Abdominal pain, anorexia, elevated liver function test results, epigastric distress, hepatitis, nausea, vomiting

GU: Glycosuria

HEME: Agranulocytosis, aplastic anemia, eosinophilia, hemolytic anemia, sideroblastic anemia, thrombocytopenia

MS: Arthralgia, joint stiffness

SKIN: Jaundice, pruritus, rash

Other: Hypocalcemia, hypophosphatemia, injection site irritation, lupus-like symptoms, lymphadenopathy

Nursing Considerations

- Administer isoniazid cautiously to diabetic, alcoholic, or malnourished patients and those at risk for peripheral neuritis.
- Give drug 1 hour before or 2 hours after

meals to promote absorption. If GI distress occurs, give drug with a small amount of food or an antacid that doesn't contain aluminum 1 hour before or 2 hours after meal.

- Monitor liver enzyme studies, which may be ordered monthly, because isoniazid can cause severe (possibly fatal) hepatitis.
- About 50% of patients metabolize isoniazid slowly, which may lead to increased toxic effects. Watch for adverse reactions, such as peripheral neuritis; if they occur, expect to decrease dosage.
- Give isoniazid with other antituberculous drugs, as prescribed, to prevent development of resistant organisms.
- Be aware that patients with advanced HIV infection may experience more severe adverse reactions in greater numbers.

PATIENT TEACHING

- Instruct patient to take isoniazid exactly as prescribed and not to stop without first consulting prescriber. Explain that treatment may take months or years.
- Direct patient to take drug on an empty stomach 1 hour before or 2 hours after meals. If GI distress occurs, instruct him to take drug with food or an antacid that doesn't contain aluminum.
- Advise patient to report signs of hepatic dysfunction, including dark urine, decreased appetite, fatigue, and jaundice.
- Caution patient not to drink alcohol while taking isoniazid because alcohol increases the risk of hepatotoxicity.
- Give patient a list of tyramine-containing foods to avoid when taking isoniazid, such as cheese, fish, salami, red wine, and yeast extracts. Explain that consuming these foods during isoniazid therapy may cause unpleasant adverse reactions, such as chills, pounding heartbeat, and sweating.
- Tell patient to avoid histamine-containing foods such as tuna, skipjack, and other tropical fish during therapy to avoid such adverse reactions as headache, sweating, rapid heartbeat, flushing, and low blood pressure.
- Tell patient that he'll need periodic laboratory tests and physical examinations.
- Urge patient to report fever, nausea, numbness and tingling in arms and legs, rash, vision changes, vomiting, and yellowing skin.

isoproterenol (isoprenaline)

Isuprel

isoproterenol hydrochloride

Isuprel, Isuprel Mistometer

isoproterenol sulfate

Medihaler-Iso

Class and Category

Chemical class: Catecholamine

Therapeutic class: Antiarrhythmic, bronchodilator

Pregnancy category: B (inhalation), C (I.V. infusion)

Indications and Dosages

↗ *To treat bronchospasm in asthma and to prevent and treat bronchospasm in COPD*

INHALATION AEROSOL (ISOPROTERENOL HYDROCHLORIDE)

Adults and adolescents. 1 oral inhalation (120 to 131 mcg), repeated in 2 to 5 min. Inhalations repeated every 3 to 4 hr, p.r.n.

INHALATION AEROSOL (ISOPROTERENOL SULFATE)

Adults and adolescents. 1 oral inhalation (80 mcg), repeated in 2 to 5 min. Inhalations repeated every 4 to 6 hr, p.r.n.

INHALATION SOLUTION FOR NEBULIZER (ISOPROTERENOL)

Adults and adolescents. 2.5 mg diluted and administered over 10 to 20 min. Repeated every 4 hr, p.r.n.

Children. 0.05 to 0.1 mg/kg (up to 1.25 mg) diluted and administered over 10 to 20 min. Repeated every 4 hr, p.r.n.

↗ *To manage bronchospasm during anesthesia*

I.V. INJECTION (ISOPROTERENOL HYDROCHLORIDE)

Adults. 0.01 to 0.02 mg, repeated p.r.n.

↗ *To treat bradycardia with significant hemodynamic change, such as third-degree heart block or prolonged QT intervals*

I.V. INFUSION (ISOPROTERENOL HYDROCHLORIDE)

Adults. *Initial:* 2 mcg/min. Titrated accord-

ing to heart rate, as ordered. *Maximum:* 10 mcg/min.

Route	Onset	Peak	Duration
I.V.*	Unknown	Unknown	1–2 hr
I.V.†	In 5 min	Unknown	10 min
Inhalation	In 5 min	5–15 min	In 3 hr

Mechanism of Action

Stimulates beta₁ receptors in the myocardium and cardiac conduction system, resulting in positive inotropic and chronotropic effects. Isoproterenol also shortens AV conduction time and refractory period in patients with AV block. This action increases ventricular rate and halts bradycardia and associated syncope.

In addition, isoproterenol attaches to beta₂ receptors on bronchial cell membranes. This action stimulates the intracellular enzyme adenylate cyclase to convert adenosine triphosphate to cyclic adenosine monophosphate (cAMP). An increased intracellular cAMP level relaxes bronchial smooth-muscle cells, stabilizes mast cells, and inhibits histamine release.

Contraindications

Angina pectoris, heart block or tachycardia from digitalis toxicity, ventricular arrhythmias that require inotropic therapy (I.V. form); hypersensitivity to isoproterenol or its components, such as sulfite in some preparations (inhalation form); tachyarrhythmias (I.V. and inhalation forms)

Interactions

DRUGS

Note: All interactions listed are for I.V. form unless indicated.

alpha blockers, other drugs with this action: Possibly decreased peripheral vasoconstricting and hypertensive effects of isoproterenol

anesthetics (hydrocarbon inhalation): Increased risk of atrial and ventricular arrhythmias

astemizole, cisapride, drugs that prolong QTc interval, terfenadine: Possibly prolonged QTc interval

beta blockers (ophthalmic): Decreased effects

*For treatment of bronchospasm.

†For treatment of bradycardia.

of isoproterenol, increased risk of bronchospasm, wheezing, decreased pulmonary function, and respiratory failure

beta blockers (systemic): Increased risk of bronchospasm, decreased effects of both drugs (including inhaled isoproterenol)

digoxin: Increased risk of arrhythmias, hypokalemia, and digitalis toxicity

diuretics, other antihypertensives: Possibly decreased antihypertensive effects

ergot alkaloids: Increased vasoconstriction and vasopressor effects

MAO inhibitors: Intensified and extended cardiac stimulation and vasopressor effects

quinidine, other drugs that affect myocardial reaction to sympathomimetics: Increased risk of arrhythmias

theophylline: Increased risk of cardiotoxicity, decreased blood theophylline level

thyroid hormones: Increased effects of both drugs, increased risk of coronary insufficiency in patients with coronary artery disease

tricyclic antidepressants: Increased vasopressor response, increased risk of prolonged QTc interval and arrhythmias

Adverse Reactions

CNS: Dizziness, headache, insomnia, nervousness, syncope, tremor, weakness

CV: Angina, arrhythmias, bradycardia, hypertension, hypotension, palpitations, tachycardia, ventricular arrhythmias

EENT: Dry mouth, oropharyngeal edema, taste perversion

ENDO: Hyperglycemia

GI: Heartburn, nausea, vomiting

MS: Muscle spasms and twitching

RESP: Bronchitis, bronchospasm, cough, dyspnea, increased sputum production, pulmonary edema, wheezing

SKIN: Dermatitis, diaphoresis, erythema multiforme, flushing, pallor, pruritus, rash, Stevens-Johnson syndrome, urticaria

Other: Angioedema, hypokalemia

Nursing Considerations

- Expect to give lowest possible dose of isoproterenol for shortest possible time to minimize tolerance.
- Don't administer I.V. isoproterenol if solution is pink or brown or contains precipitate.
- Administer isoproterenol infusion through a large vein, and monitor patient for signs

of extravasation.

- Monitor blood pressure, cardiac rhythm, central venous pressure, and urine output when giving I.V. drug. Adjust infusion rate to response, as ordered.
- Notify prescriber immediately if heart rate increases significantly or exceeds 110 beats/minute during I.V. infusion.
- Know that drug may increase pulse pressure and cause hypotension. Expect to reduce I.V. infusion slowly to decrease risk of hypotension.

WARNING Be aware that drug markedly increases risk of arrhythmias. If an arrhythmia develops, expect to give a cardioselective beta blocker, such as atenolol.

- Isoproterenol isn't used regularly to treat asthma, decreased cardiac output, hypotension, or shock because it increases the risk of arrhythmias, hypotension, and ischemia.

WARNING If drug aggravates a ventilation-perfusion problem, expect blood oxygen level to fall even as breathing seems to improve.

PATIENT TEACHING

- Instruct patient not to use isoproterenol inhaler more often than prescribed because it may cause cardiac and respiratory problems.
- Teach patient to use the inhaler. Provide a spacer, as needed.
- Instruct patient to wait 2 to 5 minutes before taking second inhalation.
- Advise patient to rinse his mouth after inhalation to remove drug residue and minimize mouth dryness.
- Inform patient that saliva may appear pink after inhalation.
- If patient uses a corticosteroid inhaler, tell him to take isoproterenol first and wait at least 2 minutes before taking corticosteroid.
- Instruct patient to notify prescriber about chest pain, dizziness, hyperglycemic symptoms (such as abdominal cramps, lethargy, nausea, and vomiting), insomnia, irregular heartbeat, palpitations, tremor, and weakness.
- Advise patient to also report reduced effectiveness of isoproterenol, increased use of inhaler, and increased symptoms after taking drug.

isosorbide dinitrate

Apo-ISDN (CAN), Cedocard-SR (CAN), Coradur (CAN), Coronex (CAN), Dilatrate-SR, Isordil Tembids, Isordil Titradoso, Sorbitrate

isosorbide mononitrate

IMDUR, ISMO, Monoket

Class and Category

Chemical class: Organic nitrate

Therapeutic class: Antianginal, vasodilator

Pregnancy category: C

Indications and Dosages

↗ *To treat or prevent angina*

CHEWABLE TABLETS

Adults. 5 mg every 2 to 3 hr, p.r.n. (dinitrate).

E.R. CAPSULES

Adults. 40 to 80 mg every 8 to 12 hr (dinitrate).

E.R. TABLETS

Adults. 20 to 80 mg every 8 to 12 hr (dinitrate); 30 to 60 mg daily, increased gradually as tolerated to 120 mg daily (mononitrate).

S.L. TABLETS

Adults. 2.5 to 5 mg every 2 to 3 hr, p.r.n. (dinitrate).

TABLETS

Adults. 5 to 40 mg every 6 hr, adjusted as needed (dinitrate); 20 mg in 2 doses given 7 hr apart (mononitrate).

Route	Onset	Peak	Duration
P.O.*	1 hr [†]	Unknown	5–6 hr
P.O. (chewable)*	In 3 min	Unknown	30 min–2 hr
P.O. (E.R.)*	30 min	Unknown	6–8 hr
P.O. (S.L.)*	In 3 min	Unknown	2 hr

Contraindications

Angle-closure glaucoma; cerebral hemorrhage; concurrent use of sildenafil; head trauma; hypersensitivity to isosorbide, other nitrates, or their components; orthostatic hypotension; severe anemia

Interactions

DRUGS

acetylcholine, norepinephrine: Possibly decreased effectiveness of these drugs
antihypertensives, calcium channel blockers, opioid analgesics, other vasodilators: Increased risk of orthostatic hypotension
aspirin: Increased blood level and pharma-

*For dinitrate.

†For mononitrate, onset also is 1 hr; peak and duration are unknown.

Mechanism of Action

Isosorbide may interact with nitrate receptors in vascular smooth-muscle cell membranes. By interacting with receptors' sulfhydryl groups, drug is reduced to nitric oxide. Nitric oxide activates the enzyme guanylate cyclase, increasing intracellular formation of cyclic guanosine monophosphate (cGMP). An increased cGMP level may relax vascular smooth muscle by forcing calcium out of muscle cells, causing vasodilation. This improves cardiac output by reducing mainly preload but also afterload.

colonic action of isosorbide
sildenafil, tadalafil, vardenafil: Increased risk of hypotension and death
sympathomimetics: Increased risk of hypotension, possibly decreased therapeutic effects of isosorbide

ACTIVITIES

alcohol use: Increased risk of orthostatic hypotension

Adverse Reactions

CNS: Agitation, confusion, dizziness, headache, insomnia, restlessness, syncope, vertigo, weakness

CV: Arrhythmias, orthostatic hypotension, palpitations, peripheral edema, tachycardia

EENT: Blurred vision, diplopia (all forms); sublingual burning (S.L. form)

GI: Abdominal pain, diarrhea, indigestion, nausea, vomiting

GU: Dysuria, impotence, urinary frequency

HEME: Hemolytic anemia

MS: Arthralgia, muscle twitching

RESP: Bronchitis, pneumonia, upper respiratory tract infection

SKIN: Diaphoresis, flushing, rash

Nursing Considerations

- Use isosorbide cautiously in patients with hypovolemia or mild hypotension. Monitor patient for increased hypotension and reduced cardiac output.
- Give drug 1 hour before or 2 hours after meals. Give with meals if patient experiences severe headaches or adverse GI reactions.
- Know that patient may experience daily headaches from isosorbide's vasodilating effects. Give acetaminophen, as prescribed, to relieve pain.

WARNING Be aware that stopping drug abruptly may cause angina and increase the risk of MI.

- Monitor blood pressure often during isosorbide therapy, especially in elderly patients; drug may cause severe hypotension.
- Keep isosorbide protected from heat and light.

PATIENT TEACHING

- Teach patient and family to recognize signs and symptoms of angina, including chest pain, fullness, or pressure, which commonly is accompanied by sweating

and nausea. Pain may radiate down the left arm or into the neck or jaw. Inform female patients and those with diabetes mellitus or hypertension that they may experience only fatigue and shortness of breath.

- Caution patient not to crush or chew isosorbide E.R. capsules or tablets or S.L. tablets unless specifically ordered to do so by prescriber.
- Instruct patient to place S.L. tablet under tongue and not to swallow it, but to let it dissolve. Explain that moisture in mouth promotes drug absorption and that tingling or burning in the mouth indicates drug effectiveness.
- Advise patient to chew chewable tablets well and to keep them in his mouth for 1 to 2 minutes before swallowing to enhance drug absorption.
- Instruct patient to take drug before any situation or activity that might precipitate angina.
- Advise patient to carry isosorbide with him at all times.
- Caution patient that abrupt drug discontinuation may cause angina and increase the risk of MI.
- Instruct patient to notify prescriber about blurred vision, fainting, increased angina attacks, rash, and severe or persistent headaches.
- Teach patient to reduce the effects of orthostatic hypotension by changing position slowly. Advise him to lie down if he becomes dizzy.
- Inform patient that drug commonly causes headache, which typically resolves after a few days of continuous therapy. Suggest that patient take acetaminophen as needed and as prescribed.
- Advise patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcohol consumption.
- Instruct patient to store drug in a tightly closed container and protect from light and heat.
- Advise male patient with erectile dysfunction to alert prescriber that he is taking isosorbide because sildenafil, tadalafil, and vardenafil can cause fatal reactions when taken with isosorbide.

isotretinoin

Accutane, Claravis

Class and Category

Chemical class: Retinoid

Therapeutic class: Acne inhibitor

Pregnancy category: X

Indications and Dosages

↗ *To treat severe recalcitrant nodular acne unresponsive to conventional therapy*

CAPSULES

Adults. *Initial:* 0.5 mg to 1 mg/kg daily in 2 divided doses, increased as needed up to 2 mg/kg daily given in 2 divided doses.

Maximum: 2 mg/kg daily. Course of therapy given for 15 to 20 wk with second course given, as needed, after a period of 2 mo or more off therapy.

Mechanism of Action

Inhibits sebaceous gland function and keratinization, which results in diminished nodular formation associated with recalcitrant nodular acne.

Contraindications

Hypersensitivity to isotretinoin or any of its components, hypersensitivity to parabens, pregnancy

Interactions

DRUGS

corticosteroids (systemic): Possibly increased risk of osteoporosis

hormonal contraceptives including microdosed progesterone preparations, medroxyprogesterone injection, levonorgestrel implants: Possibly decreased effectiveness of contraceptive

phenytoin: Possibly increased risk of osteomalacia

tetracyclines: Increased risk of benign intracranial hypertension

vitamin A supplements: Increased risk of additive toxic effects

Adverse Reactions

CNS: Aggressive or violent behavior, depression, dizziness, drowsiness, emotional instability, fatigue, headache, insomnia, lethargy, malaise, nervousness, paresthesias, pseudotumor cerebri, psychosis, seizures, stroke, suicidal ideation, syncope, weakness
CV: Chest pain, decreased high-density

lipoprotein level, edema, elevated creatinine phosphokinase level, hypercholesteremia, hypertriglyceridemia, palpitation, stroke, tachycardia, vascular thrombotic disease, vasculitis

ENDO: Abnormal menses, alterations in blood glucose levels

EENT: Bleeding and inflammation of gums, cataracts, color vision disorder, conjunctivitis, corneal opacities, decreased night vision, dry mouth or nose, dry eyes, epistaxis, eyelid inflammation, hearing impairment, keratitis, optic neuritis, photophobia, tinnitus, visual disturbances, voice alteration

GI: Colitis, hepatitis, ileitis, inflammatory bowel disease, liver enzyme elevation, nausea, pancreatitis

GU: Glomerulonephritis, hematuria, proteinuria, WBCs in urine

HEME: Anemia, agranulocytosis, neutropenia, platelet count elevation, sedimentation rate elevation, thrombocytopenia

MS: Arthralgia, arthritis, back pain (children), bone abnormalities, calcification of tendons and ligaments, premature epiphyseal closure, tendonitis

RESP: Bronchospasms, respiratory infection

SKIN: Alopecia, bruising, disseminated herpes simplex, dry lips or skin, eczema, eruptive xanthomas, facial erythema, flushing, fulminant acne, hair abnormalities, hirsutism, hyperpigmentation, hypopigmentation, increased sunburn susceptibility, infections, nail dystrophy, paronychia, peeling of palms and soles, photoallergic or photosensitizing reactions, pruritus, pyogenic granuloma, rash, seborrhea, skin fragility, sweating, urticaria

Other: Abnormal wound healing, alkaline phosphatase increase, allergic reactions, hyperuricemia, lymphadenopathy, weight loss

Nursing Considerations

- Ensure that women of childbearing age have had two negative urine or serum pregnancy tests with a sensitivity of at least 50 mIU/ml, joined the Accutane Survey, signed the consent form, and watched the videotape provided by manufacturer prior to beginning isotretinoin therapy.

WARNING Notify prescriber if elevated serum triglyceride levels can't be controlled or if symptoms of pancreatitis occur (abdominal pain, nausea, vomiting). Drug may need to be discontinued because fatal hemorrhagic pancreatitis has occurred with drug use.

- Obtain serum lipid level before therapy and periodically thereafter, as ordered, to detect elevated lipid levels that result from isotretinoin therapy.
- Monitor liver enzyme levels periodically, as ordered, because drug can cause hepatitis.
- Assess patient frequently for adverse reactions and report to prescriber any that occur; drug may have serious adverse effects that require discontinuation.

PATIENT TEACHING

- Instruct patient to take isotretinoin with food or milk.
- Advise women of childbearing age that two forms of contraceptives must be used simultaneously (unless absolute abstinence is the chosen method) 1 month before therapy and for 1 month after therapy has stopped because of potential for fetal harm. Inform women who use oral contraceptives that drug may lessen effectiveness of oral contraceptives. Urge patient to notify prescriber immediately if pregnancy occurs.
- Stress importance of picking up isotretinoin prescription within 7 days of a pregnancy test or, for male patients or women not of childbearing potential, within 30 days of prescription.
- Urge patient to report headache, nausea, vomiting and visual disturbances immediately to prescriber because drug will need to be discontinued immediately and patient referred to a neurologist.
- Caution patient and family that isotretinoin may cause aggressive or violent behavior, depression, psychosis, and suicidal ideation. Instruct patient to notify prescriber immediately if changes in mood occur.
- Tell patient to report hearing changes or tinnitus, visual difficulties, abdominal pain, rectal bleeding, or severe diarrhea to prescriber because drug may need to be discontinued.
- Advise patient to avoid hazardous activi-

ties until drug's CNS effects are known. Caution that changes in night vision may occur suddenly.

- Caution patient not to donate blood during therapy and for 1 month after therapy has stopped because blood might be given to a pregnant woman.
- Warn patient that transient exacerbation of acne may occur, especially during initial therapy and to notify prescriber if this occurs.
- Instruct patient to avoid wax epilation and skin resurfacing procedures during therapy and for at least 6 months thereafter because of scarring potential.
- Caution patient to avoid exposure to direct sunlight or UV light and to wear sunscreen when outdoors.
- Inform patient that contact lens tolerance may decrease during and after isotretinoin therapy.
- Alert patient to the potential for mild musculoskeletal adverse reactions, which usually clear rapidly after drug is discontinued. Urge patient to notify prescriber if symptoms become bothersome or serious because drug may need to be discontinued.
- Advise patient not to take vitamin A supplements while on isotretinoin therapy because of potentially additive toxic effects.
- Instruct patient to notify all prescribers of isotretinoin use because of the risk of interactions.
- Inform patient of need for frequent laboratory tests and importance of complying with scheduled appointments.

isradipine

DynaCirc

Class and Category

Chemical class: Dihydropyridine derivative

Therapeutic class: Antihypertensive

Pregnancy category: C

Indications and Dosages

↗ *To manage essential hypertension*

CAPSULES

Adults. *Initial:* 2.5 mg b.i.d., increased by 5 mg every 2 to 4 wk, if needed. *Maximum:* 20 mg daily.

Mechanism of Action

Inhibits calcium movement into coronary vascular smooth-muscle cells by blocking the slow calcium channels in their membranes. By decreasing intracellular calcium level, isradipine inhibits smooth-muscle cell contractions. The result is relaxation of coronary and vascular smooth muscle, decreased peripheral vascular resistance, and reduced systolic and diastolic blood pressure, all of which decrease myocardial oxygen demand.

Route	Onset	Peak	Duration
P.O.	2–3 hr	2–4 wk	Unknown

Contraindications

Hypersensitivity to isradipine or its components

Interactions

DRUGS

anesthetics (hydrocarbon inhalation), antihypertensives, hydrochlorothiazide, prazosin:

Increased risk of hypotension

beta blockers: Increased adverse effects of beta blockers

cimetidine: Increased blood level and bioavailability of isradipine

digoxin: Transiently increased blood digoxin level and risk of digitalis toxicity

estrogens: Possibly increased fluid retention and decreased isradipine effects

lithium: Increased risk of neurotoxicity

NSAIDs, sympathomimetics: Possibly decreased therapeutic effects of isradipine

procainamide, quinidine: Increased risk of prolonged QT interval

FOODS

grapefruit juice: Doubled isradipine bioavailability

other foods: Prolonged time to achieve peak blood level

Adverse Reactions

CNS: Asthenia, dizziness, fatigue, headache, paresthesia, somnolence, stroke, syncope, transient ischemic attack, weakness

CV: Angina, atrial fibrillation, heart failure, hypotension, MI, orthostatic hypotension, palpitations, peripheral edema, tachycardia, ventricular fibrillation

EENT: Gingival hyperplasia, pharyngitis, rhinitis

GI: Abdominal cramps, constipation, diarrhea, elevated liver function test results, indigestion, nausea, vomiting

HEME: Leukopenia

MS: Back pain

RESP: Cough

SKIN: Flushing, photosensitivity, rash, urticaria

Other: Angioedema

Nursing Considerations

- Monitor blood pressure and heart rate often during isradipine therapy.
- Monitor patient with impaired hepatic or renal function for an increased blood isradipine level.
- Avoid giving isradipine with food because doing so increases time to peak effect by about 1 hour.
- Observe for mild peripheral edema caused by vasodilation of small blood vessels. Know that this type of edema doesn't result from fluid retention or heart failure.

PATIENT TEACHING

- Inform patient that isradipine therapy will be long-term and will require laboratory tests and follow-up visits to monitor drug effects.
- Instruct patient to take drug exactly as prescribed and to swallow capsules whole, not crushing or chewing them.
- Advise patient to take drug on an empty stomach 1 hour before or 2 hours after meals.
- Instruct patient to take a missed dose as soon as he remembers it unless it's nearly time for the next dose. In that case, advise him to wait and take next scheduled dose, but not to double the dose. If more than one dose is missed, tell him to contact prescriber.

WARNING Urge patient not to stop taking drug suddenly. Doing so may lead to life-threatening problems.

- Inform patient that fragments of capsules may be visible in stool.
- Caution patient not to drink grapefruit juice during isradipine therapy.
- Urge patient to avoid potentially hazardous activities until isradipine's CNS effects are known.
- Caution patient to change position slowly to minimize orthostatic hypotension.
- Urge patient to contact prescriber if he

experiences chest pain, fainting, irregular heartbeat, rash, or swollen ankles while taking isradipine.

- Instruct patient to maintain good oral hygiene, perform gum massage, and see a dentist every 6 months to prevent gum bleeding and gum disorders.
- To help prevent photosensitivity reactions, caution patient to avoid direct sunlight and to wear protective clothing and apply sunscreen when outdoors.
- Instruct patient to store drug at room temperature in a dry place.

itraconazole

Sporanox

Class and Category

Chemical class: Triazole derivative

Therapeutic class: Antifungal

Pregnancy category: C

Indications and Dosages

↗ *To treat blastomycosis caused by Blastomyces dermatitidis and histoplasmosis caused by Histoplasma capsulatum*

CAPSULES

Adults and adolescents. *Initial:* 200 mg daily, increased by 100 mg daily, if needed. *Maximum:* 400 mg daily, with dosage greater than 200 mg given in divided doses b.i.d.

↗ *To treat aspergillosis unresponsive to amphotericin B*

CAPSULES

Adults and adolescents. 200 to 400 mg daily, with dosage greater than 200 mg daily given in divided doses b.i.d.

↗ *To treat oropharyngeal candidiasis*

ORAL SOLUTION

Adults and adolescents. 100 mg b.i.d. for 7 to 14 days.

↗ *To treat esophageal candidiasis*

ORAL SOLUTION

Adults and adolescents. 100 mg daily for at least 3 wk and continued for 2 wk after symptoms resolve.

↗ *To treat onychomycosis of toenails only or of toenails and fingernails*

CAPSULES

Adults and adolescents. 200 mg daily for 12 wk.

↗ *To treat onychomycosis of fingernails only*

CAPSULES

Adults and adolescents. 200 mg b.i.d. for 7 days; then repeated after 3 wk.

Mechanism of Action

Inhibits the synthesis of ergosterol, an essential component of fungal cell membranes, by binding with a cytochrome P-450 enzyme needed to convert lanosterol to ergosterol. Lack of ergosterol results in increased cellular permeability and leakage of cell contents. Itraconazole also may lead to fungal cell death by inhibiting fungal respiration under aerobic conditions.

Contraindications

Concurrent therapy with cisapride, dofetilide, ergot alkaloids, HMG-CoA inhibitors (lovastatin and simvastatin), levomethadyl, nisoldipine, oral midazolam, pimozide, quinidine, or triazolam; evidence of ventricular dysfunction, as in congestive heart failure (CHF) or a history of it (onychomycosis treatment); hypersensitivity to itraconazole or its components; planning for pregnancy during onychomycosis treatment

Interactions

DRUGS

alfentanil, buspirone, busulfan, carbamazepine, cyclosporine, digoxin, docetaxel, indinavir, methylprednisolone, phenytoin, pimozide, rifabutin, ritonavir, saquinavir, sirolimus, tacrolimus, trimetrexate, vinca alkaloids: Possibly increased blood levels of these drugs and serious adverse effects
alprazolam, diazepam, oral midazolam, triazolam: Elevated blood levels and possibly prolonged sedative effects of these drugs
antacids, anticholinergics, H₂-receptor antagonists, omeprazole, sucralfate: Possibly decreased itraconazole absorption
atorvastatin, lovastatin, simvastatin: Increased blood levels of these drugs; possibly rhabdomyolysis
calcium channel blockers: Possibly edema and increased blood levels of these drugs
carbamazepine, isoniazid, nevirapine, phenobarbital, phenytoin, rifabutin, rifampin: Possibly decreased blood itraconazole level
cilostazol, eletriptan; glucocorticosteroids such as budesonide, dexamethasone, fluticasone, and methylprednisolone; trimetrexate:

Possibly inhibited metabolism of these drugs

cisapride, dofetilide, disopyramide, halofantrine, levomethadyl, pimozide, quinidine:

Possibly increased plasma levels of these drugs leading to potentially life-threatening cardiovascular complications such as cardiac arrest, prolonged QT interval, torsades de pointes, ventricular tachycardia, and sudden death

clarithromycin, erythromycin, indinavir, ritonavir: Possibly increased blood itraconazole level

didanosine: Possibly decreased therapeutic effects of itraconazole

ergot alkaloids: Possibly increased plasma ergot alkaloid elevation leading to cerebral ischemia and ischemia of the extremities

fentanyl: Possibly increased plasma fentanyl level causing potentially fatal respiratory depression

nisoldipine: Increased plasma nisoldipine levels that do not decrease after drug dosage is reduced

oral antidiabetic drugs: Possibly increased blood levels of these drugs and risk of hypoglycemia

warfarin: Increased anticoagulant effect of warfarin

Adverse Reactions

CNS: Dizziness, drowsiness, fatigue, fever, headache, paresthesia, peripheral neuropathy, vertigo

CV: CHF, hypertriglyceridemia, hypertension, peripheral edema

EENT: Blurred vision, diplopia, transient or permanent hearing loss, tinnitus

GI: Abdominal pain, anorexia, constipation, diarrhea, elevated liver function test results, flatulence, hepatic failure, hepatitis, hepatotoxicity, hyperbilirubinemia, indigestion, nausea, vomiting

GU: Erectile dysfunction, menstrual irregularities, urinary incontinence

HEME: Leukopenia, neutropenia, thrombocytopenia

MS: Arthralgia, myalgia

RESP: Cough, dyspnea, pulmonary edema

SKIN: Alopecia, diaphoresis, erythema multiforme, exfoliative dermatitis, leukocytoclastic vasculitis, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, hypokalemia, serum sickness

Nursing Considerations

- Use itraconazole with extreme caution in patients with risk factors for CHF, such as ischemic or valvular heart disease, significant COPD, and renal failure and other edematous disorders because of increased risk of developing CHF during itraconazole treatment.
- Use itraconazole cautiously in patients with hypersensitivity to other azole antifungals (because cross-hypersensitivity is unknown) and in patients with renal or hepatic impairment.
- Because itraconazole has been linked to serious adverse cardiac and hepatic effects, expect to send appropriate nail specimens for laboratory testing to confirm onychomycosis before beginning therapy.

WARNING Keep in mind that itraconazole is a potent inhibitor of the cytochrome P-450 3A4 (CYP3A4) isoenzyme system, which may increase blood levels of drugs metabolized by this system. Patients taking such drugs as cisapride with itraconazole or other CYP3A4 inhibitors have experienced life-threatening cardiovascular complications, such as prolonged QT interval, torsades de pointes, and ventricular tachycardia, as well as sudden death.

- Administer itraconazole capsules (not oral solution) with a meal to ensure maximal absorption.
- Keep in mind that a patient with AIDS may have hypochlorhydria, which reduces drug absorption. For such a patient, expect to administer higher doses of itraconazole.
- Monitor liver function test results in patients with impaired hepatic function and those who have experienced hepatotoxicity with other drugs.
- If patient develops signs and symptoms of peripheral neuropathy or CHF, such as fatigue, dyspnea, and peripheral edema, expect to discontinue drug.
- Assess patient for rash every 8 hours during therapy; notify prescriber if rash occurs.
- If patient also receives warfarin, monitor PT and assess patient for signs and symptoms of bleeding.

- If patient also receives digoxin, monitor blood digoxin level as appropriate to detect toxic level, and assess patient for signs and symptoms of digitalis toxicity, such as nausea and yellow vision.

PATIENT TEACHING

- Instruct patient to take itraconazole capsules with a meal, but oral solution without food.
- If patient also takes an oral antidiabetic drug, instruct him to check his blood glucose level often because of the increased risk of hypoglycemia.
- Advise patient to avoid taking antacids with oral itraconazole.
- Advise patient to notify prescriber immediately of changes in other drugs, such as new drugs and dosage changes.
- Advise patient to notify prescriber immediately about abdominal pain, diarrhea, headache, hearing loss, nausea, peripheral neuropathy, rash, or vomiting.
- Instruct patient to notify prescriber if he experiences signs of liver problems, such as abdominal pain, dark urine, fatigue, loss of appetite, pale stools, weakness, or yellow eyes or skin.
- Caution breast-feeding patient to consult prescriber about continuation of breast-feeding during itraconazole therapy.

J K L

kanamycin sulfate

Kantrex

Class and Category

Chemical class: Aminoglycoside

Therapeutic class: Antibiotic

Pregnancy category: D

Indications and Dosages

↗ *To treat infections caused by gram-negative organisms (including Acinetobacter species, Enterobacter aerogenes, Escherichia coli, Haemophilus influenzae, Klebsiella pneumoniae, Neisseria species, Proteus species, Providencia species, Salmonella species, Serratia marcescens, Shigella species, and Yersinia species) and gram-positive organisms (including Staphylococcus aureus and Staphylococcus epidermidis)*

I.M. INJECTION

Adults and children. 3.75 mg/kg every 6 hr, 5 mg/kg every 8 hr, or 7.5 mg/kg every 12 hr for 7 to 10 days. *Maximum:* 1.5 g daily.

I.V. INFUSION

Adults and children. 5 mg/kg every 8 hr or 7.5 mg/kg every 12 hr for 7 to 10 days. *Maximum:* 1.5 g daily.

↗ *As adjunct to suppress intestinal bacterial growth*

CAPSULES

Adults. 1 g/hr for 4 hr and then 1 g every 6 hr for 36 to 72 hr.

↗ *To treat hepatic coma*

CAPSULES

Adults. 8 to 12 g daily in divided doses.

↗ *To treat respiratory tract infection*

INHALATION NEBULIZER

Adults. 250 mg b.i.d. to q.i.d. *Maximum:* 1.5 g daily.

DOSAGE ADJUSTMENT For elderly patients and those with renal failure, dosage reduced and blood kanamycin level and renal function test results monitored.

Mechanism of Action

Binds to negatively charged sites on bacterial outer cell membranes, which disrupts cell membrane integrity. Kanamycin also binds

to bacterial ribosomal subunits and inhibits protein synthesis; these actions lead to cell death.

Route	Onset	Peak	Duration
P.O.	Slow	Unknown	Unknown
I.V.	Rapid	Unknown	Unknown
I.M.	Unknown	1–2 hr	Unknown

Incompatibilities

Don't mix kanamycin in same syringe or administer through same I.V. line as other antibiotics.

Contraindications

Hypersensitivity to kanamycin, other aminoglycosides, or their components; intestinal obstruction (oral form)

Interactions

DRUGS

cephalosporins, vancomycin: Increased risk of nephrotoxicity

digoxin, loop diuretics: Increased ototoxic and nephrotoxic effects of kanamycin
general anesthetics, neuromuscular blockers: Increased risk of neuromuscular blockade
penicillins: Inactivation of kanamycin or synergistic effects

Adverse Reactions

CNS: Ataxia, dizziness, headache

EENT: Hearing loss

GI: Diarrhea

GU: Elevated BUN and serum creatinine levels, oliguria, proteinuria

MS: Muscle paralysis

RESP: Apnea

SKIN: Injection site irritation or pain

Nursing Considerations

- Obtain body fluid or tissue specimen for culture and sensitivity testing before kanamycin therapy begins, as indicated. Therapy may begin before test results are available.
- Administer I.M. injection deep into upper outer quadrant of gluteus maximus. Rotate injection sites.
- Be aware that oral kanamycin is minimally absorbed from intact GI mucosa but may be more absorbed from mechanically irrigated areas of the GI tract.
- For I.V. use, dilute 500-mg vial with 100 to 200 ml normal saline solution or D₅W, or 1-g vial with 200 to 400 ml normal saline

solution or D₅W, and infuse over 30 to 60 min. Vial contents may darken during storage but potency isn't affected.

- Keep patient well hydrated before and during therapy.
- Monitor blood kanamycin level periodically during therapy, as appropriate.
- Prolonged treatment increases risk of ototoxicity and nephrotoxicity. Monitor hearing and renal function if therapy lasts longer than 10 days.

PATIENT TEACHING

- Explain need to take kanamycin at prescribed intervals around the clock until patient completes full course of therapy.
- Advise patient to report dizziness, hearing loss, and severe diarrhea or headache.

ketoprofen

Actron, Apo-Keto (CAN), Orudis, Orudis KT, Orudis-SR (CAN), Oruvail, Rhodis

Class and Category

Chemical class: Propionic acid derivative

Therapeutic class: Analgesic, anti-inflammatory

Pregnancy category: B

Indications and Dosages

↗ *To treat symptoms of rheumatoid arthritis*

CAPSULES, TABLETS

Adults. *Initial:* 75 mg t.i.d. or 50 mg q.i.d. *Maximum:* 300 mg daily.

E.R. CAPSULES

Adults. *Maintenance:* 150 to 200 mg daily. *Maximum:* 300 mg daily.

↗ *To relieve pain in dysmenorrhea*

TABLETS

Adults. *Initial:* 25 to 50 mg every 6 to 8 hr p.r.n. *Maximum:* 300 mg daily.

DOSAGE ADJUSTMENT Dosage reduced by 33% to 50% for patients with renal impairment.

Mechanism of Action

Blocks activity of cyclooxygenase, the enzyme needed for prostaglandin synthesis. Prostaglandins, important mediators of inflammatory response, cause local vasodilation with swelling and pain. By blocking cyclooxygenase and inhibiting

prostaglandins, this NSAID reduces inflammatory symptoms and relieves pain.

Contraindications

Angioedema; aspirin-, iodide-, or NSAID-induced asthma, bronchospasm, nasal polyps, rhinitis, or urticaria; hypersensitivity to ketoprofen or its components

Interactions

DRUGS

ACE inhibitors: Possibly decreased hypotensive effect of ACE inhibitors

acetaminophen: Possibly increased adverse renal effects with long-term acetaminophen use

aspirin, other NSAIDs: Increased risk of bleeding and adverse GI effects, increased and prolonged blood ketoprofen levels

cefamandole, cefoperazone, cefotetan: Increased risk of hypoprothrombinemia and bleeding

colchicine, platelet aggregation inhibitors: Increased risk of GI bleeding, hemorrhage, and ulcers

corticosteroids, potassium supplements: Increased risk of adverse GI effects

cyclosporine: Increased risk of nephrotoxicity from both drugs, increased blood cyclosporine level

diuretics (loop, potassium-sparing, and thiazide): Decreased diuretic and antihypertensive effects

gold compounds, nephrotoxic drugs: Increased risk of adverse renal effects

heparin, oral anticoagulants, thrombolytics: Increased anticoagulant effects, increased risk of hemorrhage

insulin, oral antidiabetic drugs: Possibly increased hypoglycemic effects of these drugs

lithium: Increased blood lithium level and possibly toxicity

methotrexate: Decreased methotrexate clearance, increased risk of methotrexate toxicity

plicamycin, valproic acid: Increased risk of hypoprothrombinemia and GI bleeding, hemorrhage, and ulcers

probenecid: Possibly increased blood level, effectiveness, and risk of toxicity of ketoprofen

ACTIVITIES

alcohol use: Increased risk of adverse GI effects

Adverse Reactions

CNS: Headache, irritability, nervousness, seizures, stroke

CV: Edema, fluid retention, hypertension, MI, tachycardia

EENT: Tinnitus, vision changes

GI: Abdominal pain, anorexia, constipation, diarrhea, diverticulitis, dyspepsia, dysphagia, flatulence, gastritis, gastroenteritis, gastroesophageal reflux disease, GI bleeding and ulceration, hepatic failure, hiatal hernia, indigestion, melena, nausea, perforation of stomach or intestine, stomatitis, vomiting

GU: Acute renal failure, decreased urine output

HEME: Agranulocytosis, anemia, easy bruising, hemolytic anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia

RESP: Asthma, respiratory depression

SKIN: Erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis, rash

Other: Anaphylaxis, angioedema, rapid weight gain

Nursing Considerations

- Use ketoprofen with extreme caution in patients with history of ulcer disease or GI bleeding because NSAIDs such as ketoprofen increase risk of GI bleeding and ulceration. Expect to use ketoprofen for shortest time possible in these patients.
- Be aware that serious GI tract ulceration, bleeding, and perforation may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, withhold drug and notify prescriber immediately.
- Use ketoprofen cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

WARNING Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

- Monitor patient—especially if he's elderly or receiving long-term ketoprofen therapy—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal

reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.

- Monitor liver function test results because, rarely, elevations may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure.
- Monitor BUN and serum creatinine levels in elderly patients, patients taking diuretics or ACE inhibitors, and patients with heart failure, impaired renal function, or hepatic dysfunction; drug may cause renal failure.
- Monitor CBC for decreased hemoglobin level and hematocrit because drug may worsen anemia.

WARNING If patient has bone marrow suppression or is receiving an antineoplastic drug, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of ketoprofen may mask signs and symptoms, such as fever and pain.

- Assess patient's skin regularly for signs of rash or other hypersensitivity reaction because ketoprofen is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID sensitivity. At first sign of reaction, stop drug and notify prescriber.
- If patient takes acetaminophen, monitor fluid intake and output, BUN level, and serum creatinine level for evidence of adverse renal effects.

PATIENT TEACHING

- Instruct patient to take ketoprofen with food or after meals to prevent GI upset. Advise him to take drug with a full glass of water and to avoid lying down for 15 to 30 minutes afterward to prevent drug from lodging in esophagus and causing irritation.
- Advise patient to swallow drug whole and not to crush, break, chew, or open capsules.
- Instruct patient to avoid aspirin, aspirin-containing products, and alcohol while taking ketoprofen to decrease risk of adverse GI effects.
- Tell patient not to take more drug than prescribed because stomach bleeding may occur.
- If patient takes an anticoagulant, tell him to watch for and immediately report

bleeding problems, such as bloody or tarry stools and bloody vomitus.

- If patient takes insulin or an oral anti-diabetic, advise him to monitor blood glucose level closely. Urge him to carry candy or other simple sugars to treat mild hypoglycemia. If he has frequent or severe episodes, instruct him to consult prescriber.
- Inform patient that he may be nervous and irritable while taking ketoprofen.
- Instruct patient to notify prescriber immediately if he develops a rash, decreased urine output, dark yellow or brown urine, or signs of fluid retention, including swelling of extremities and unexplained rapid weight gain.
- Caution pregnant patient not to take NSAIDs such as ketoprofen during last trimester because they may cause premature closure of the ductus arteriosus.
- Explain that ketoprofen may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, weakness, and slurring of speech.
- Explain that ketoprofen may increase risk of serious adverse GI reactions; stress importance of seeking immediate medical attention for such signs and symptoms as epigastric or abdominal pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions. Urge him to seek immediate medical attention for rash, blisters, itching, fever, or other indications of hypersensitivity.

ketorolac tromethamine

Toradol

Class and Category

Chemical class: Acetic acid derivative

Therapeutic class: Analgesic, anti-inflammatory

Pregnancy category: C

Indications and Dosages

↗ *To treat moderate to severe pain*

TABLETS

Adults ages 16 to 64. *Initial:* 20 mg as single

dose, followed by 10 mg every 4 to 6 hr p.r.n., up to 4 times a day. *Maximum:* 40 mg daily for no more than 5 days.

DOSAGE ADJUSTMENT For patients weighing less than 50 kg, elderly patients, and patients with impaired renal function, initial dose reduced to 10 mg.

I.M. INJECTION

Adults ages 16 to 64. *Initial:* 60 mg as single dose, followed by oral ketorolac if needed; or 30 mg every 6 hr p.r.n. *Maximum:* 120 mg daily for no more than 5 days.

DOSAGE ADJUSTMENT For patients weighing less than 50 kg, elderly patients, and patients with impaired renal function, initial dose reduced to 30 mg, followed by oral ketorolac if needed; or 15 mg every 6 hr p.r.n., up to maximum of 60 mg daily for no more than 5 days.

I.V. INJECTION

Adults ages 16 to 64. *Initial:* 30 mg as single dose, followed by oral ketorolac if needed; or 30 mg every 6 hr p.r.n. *Maximum:* 120 mg daily for no more than 5 days.

DOSAGE ADJUSTMENT For patients weighing less than 50 kg, elderly patients, and patients with impaired renal function, initial dose reduced to 15 mg, followed by oral ketorolac if needed; or 15 mg every 6 hr p.r.n., up to maximum of 60 mg daily for no more than 5 days.

Route	Onset	Peak	Duration
P.O.	30–60 min	2–3 hr	5–6 hr
I.M., I.V.	30–60 min	1–2 hr	4–6 hr

Mechanism of Action

Blocks cyclooxygenase, an enzyme needed to synthesize prostaglandins. Prostaglandins mediate inflammatory response and cause local vasodilation, swelling, and pain. They also promote pain transmission from periphery to spinal cord. By blocking cyclooxygenase and inhibiting prostaglandins, this NSAID reduces inflammation and relieves pain.

Contraindications

Advanced renal impairment or risk of renal impairment due to volume depletion; before or during surgery if hemostasis is critical; breast-feeding; cerebrovascular bleeding; concurrent use of aspirin or other salicylates, other NSAIDs, or probenecid;

hemorrhagic diathesis; history of GI bleeding, GI perforation, or peptic ulcer disease; hemophilia or other bleeding problems, including coagulation or platelet function disorders; hypersensitivity to ketorolac tromethamine, aspirin, other NSAIDs, or their components; incomplete hemostasis; labor and delivery; treatment of perioperative pain during coronary artery bypass graft surgery

Interactions

DRUGS

ACE inhibitors, angiotensin II receptor

antagonists: Increased risk of renal impairment; decreased effectiveness of these drugs
acetaminophen, gold compounds: Increased risk of adverse renal effects

amphotericin, penicillamine, and other

nephrotoxic drugs: Increased risk or severity of adverse renal reactions

antihypertensives, diuretics: Possibly reduced effects of these drugs

aspirin and other salicylates, other NSAIDs: Additive toxicity

cefamandole, cefoperazone, cefotetan:

Possibly hypoprothrombinemia

corticosteroids, potassium supplements:

Increased risk of gastric ulcers or hemorrhage

furosemide: Decreased effects of furosemide

heparin, oral anticoagulants, platelet aggregation inhibitors, thrombolytics: Increased risk of GI bleeding and I.M. hematoma formation

lithium: Possibly increased blood lithium

level and increased risk of lithium toxicity
methotrexate: Possibly methotrexate toxicity

nondepolarizing muscle relaxants: Increased risk of apnea

pentoxifylline, selective serotonin reuptake

inhibitors: Increased risk of bleeding

plicamycin, valproic acid: Possibly hypoprothrombinemia and increased risk of bleeding

probenecid: Decreased elimination of ketorolac, increased risk of adverse effects

ACTIVITIES

alcohol use: Increased risk of adverse GI effects

Adverse Reactions

CNS: Aseptic meningitis, cerebral hemorrhage, coma, dizziness, drowsiness, headache, psychosis, seizures, stroke

CV: Edema, fluid retention, hypertension

EENT: Laryngeal edema, stomatitis

ENDO: Hyperglycemia

GI: Abdominal pain; acute pancreatitis; bloating; constipation; diarrhea; diverticulitis; flatulence; GI bleeding, perforation, or ulceration; hepatitis; hepatic failure; jaundice; indigestion; nausea; perforation of stomach or intestines; vomiting; worsening of inflammatory bowel disease

GU: Interstitial nephritis, renal failure, urine retention

HEME: Agranulocytosis, anemia, aplastic or hemolytic anemia, eosinophilia, leukopenia, lymphadenopathy, pancytopenia, thrombocytopenia

RESP: Bronchospasm, pneumonia, respiratory depression

SKIN: Diaphoresis, erythema multiforme, exfoliative dermatitis, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Other: Anaphylaxis, angioedema, hyperkalemia, hyponatremia, injection site pain, sepsis, unusual weight gain

Nursing Considerations

- Read ketorolac label carefully. Don't use I.M. form for I.V. route. Know that ketorolac isn't for intrathecal or epidural use.
- Inject I.M. ketorolac slowly, deep into a large muscle mass. Monitor site for bleeding, bruising, or hematoma.
- Give I.V. injection over at least 15 seconds.
- Notify prescriber if pain relief is inadequate or if breakthrough pain occurs between doses because supplemental doses of an opioid analgesic may be required.

WARNING Monitor liver function test results. If elevated levels persist or worsen, notify prescriber and expect to stop drug, as ordered, to prevent hepatic impairment.

WARNING Monitor patients with a history of peripheral edema, heart failure, or hypertension for adequate fluid balance because drug can promote fluid retention and worsen these conditions. Assess patient for dyspnea, edema, unexplained rapid weight gain, and decreased activity tolerance. Notify prescriber if such symptoms develop.

- Use ketorolac with extreme caution in patients with history of ulcer disease or GI bleeding because NSAIDs like ketorolac

increase risk of GI bleeding and ulceration. Use ketorolac in these patients for shortest length of time possible.

- Serious GI tract ulceration and bleeding and perforation of stomach or intestine can occur without warning or symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, withhold drug and notify prescriber immediately.
- Monitor patient with history of inflammatory bowel disease, such as ulcerative colitis or Crohn's disease, because ketorolac may worsen these conditions.
- Use ketorolac cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy because drug can lead to onset of hypertension or worsen existing hypertension.

WARNING Monitor patient closely for thrombotic events including MI and stroke because NSAIDs such as ketorolac increase risk.

- Monitor patient—especially if elderly—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver function test results because rarely, elevations may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure.
- Monitor BUN and serum creatinine levels in patients with heart failure, impaired renal function, or hepatic dysfunction; those who are taking diuretics or ACE inhibitors; and the elderly because drug may cause renal failure.
- Monitor CBC for decreased hemoglobin and hematocrit because drug may worsen anemia.

WARNING In patient who has bone marrow suppression or is receiving antineoplastic drug therapy, monitor laboratory results (including WBC) and assess for evidence of infection because ketorolac has anti-inflammatory and antipyretic actions that may mask signs and symptoms, such as fever and pain.

- Assess patient's skin routinely for rash or other evidence of hypersensitivity reactions because ketorolac is an NSAID and

may cause serious skin reactions without warning, even in patients with no history of NSAID hypersensitivity. Stop drug at first sign of reaction, and notify prescriber.

PATIENT TEACHING

- Instruct patient to take ketorolac tablets with a meal, a snack, or an antacid to prevent stomach upset. Advise him to take drug with a full glass of water and to stay upright for at least 15 minutes afterward.
- Advise patient not to take aspirin, other salicylates, or other NSAIDs while taking ketorolac without consulting prescriber. Urge patient to limit use of acetaminophen to only a few days during ketorolac therapy and to notify prescriber of use.
- Instruct him to immediately report blood in urine, easy bruising, itching, rash, swelling, or yellow eyes or skin.
- Caution pregnant patient that NSAIDs like ketorolac shouldn't be taken during last trimester because drug may cause premature closure of the ductus arteriosus.
- Explain that ketorolac may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, weakness, and slurring of speech.
- Tell patient that ketorolac also may increase risk of serious adverse GI reactions; stress importance of seeking immediate medical attention if signs or symptoms occur, such as epigastric or abdominal pain, indigestion, black tarry stools, and vomiting blood or coffee ground material.
- Alert patient to the possibility of serious skin reactions, although rare, occurring with ketorolac therapy. Urge patient to seek immediate medical attention if signs or symptoms occur, such as a rash, blisters, fever, or other signs of hypersensitivity, such as itching.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcohol while taking ketorolac.
- Encourage patient to have dental procedures performed before starting drug therapy because of increased risk of bleeding.
- Teach patient proper oral hygiene measures, and encourage him to use a soft-bristled toothbrush while taking ketorolac.

labetalol hydrochloride

Normodyne, Trandate

Class and Category

Chemical class: Benzamine derivative

Therapeutic class: Antihypertensive

Pregnancy category: C

Indications and Dosages

↗ *To manage hypertension*

TABLETS

Adults. *Initial:* 100 mg b.i.d., increased by 100 mg b.i.d. as needed and tolerated every 2 to 3 days. *Maintenance:* 200 to 400 mg b.i.d. For severe hypertension, 1.2 to 2.4 g daily in divided doses b.i.d. or t.i.d.

↗ *To manage severe hypertension and treat hypertensive emergencies*

I.V. INFUSION

Adults. 200 mg diluted in 160 ml of D₅W and infused at 2 mg/min until desired response occurs.

I.V. INJECTION

Adults. 20 mg given over 2 min; additional doses given in increments of 40 to 80 mg every 10 min as indicated until desired response occurs. *Maximum:* 300 mg.

Route	Onset	Peak	Duration
P.O.	20 min– 2 hr	1–4 hr	8–24 hr
I.V.	2–5 min	5–15 min	2–4 hr

Mechanism of Action

Selectively blocks α_1 and β_2 receptors in vascular smooth muscle and β_1 receptors in heart to reduce peripheral vascular resistance and blood pressure. Potent beta blockade prevents reflex tachycardia, which commonly occurs when alpha blockers reduce resting heart rate, cardiac output, or stroke volume.

Incompatibilities

Don't dilute labetalol in sodium bicarbonate solution or give through same I.V. line as alkaline drugs, such as furosemide; doing so may cause white precipitate to form.

Contraindications

Asthma, cardiogenic shock, heart failure,

hypersensitivity to labetalol or its components, second- or third-degree heart block, severe bradycardia

Interactions

DRUGS

allergen immunotherapy, allergenic extracts for skin testing: Increased risk of serious systemic reaction or anaphylaxis

beta blockers, digoxin: Increased risk of bradycardia

calcium channel blockers, clonidine, diazoxide, guanabenz, reserpine: Possibly hypotension

cimetidine: Possibly increased labetalol effects

estrogens, NSAIDs: Possibly reduced antihypertensive effect of labetalol

general anesthetics: Increased risk of hypotension and myocardial depression

insulin, oral antidiabetic drugs: Increased risk of hyperglycemia

nitroglycerin: Possibly hypertension

phenoxybenzamine, phentolamine: Possibly additive α_1 -blocking effects

sympathomimetics with alpha- and beta-adrenergic effects (such as pseudoephedrine):

Possibly hypertension, excessive bradycardia, or heart block
